The primary receptacle(s) shall be leakproof and shall not contain more than 500 ml. There shall be absorbent material placed between the primary receptacle and the secondary packaging; if several fragile primary receptacles are placed in a single secondary packaging, they shall be either individually wrapped or separated so as to prevent contact between them. The absorbent material shall be in sufficient quantity to absorb the entire contents of the primary receptacles and there shall be a secondary packaging that shall be leakproof. The primary receptacle or the secondary packaging shall be capable of withstanding without leakage an internal pressure producing a pressure differential of not less than 95 kPa (0.95 bar). The outer packaging shall not contain more than 4 litres.

For solids

The primary receptacle(s) shall be sift-proof and shall not contain more than 500 g. If several fragile primary receptacles are placed in a single secondary packaging, they shall be either individually wrapped or separated so as to prevent contact between them and there shall be a secondary packaging which shall be

**Management of a suspected case of Avian Influenza**

leak proof. The outer packaging shall not contain more than 4 kg. For air transport, the smallest overall external dimension of a completed package must be at least 10 cm.

General considerations

Existing infection control measures include the application of standard precautions to all patients receiving care in hospitals. If the diagnosis of influenza A(H5N1) infection is being considered on the basis of clinical features, additional precautions should be implemented until the diagnosis can be ruled out. Transmission of human influenza is by droplets and fine droplet nuclei (airborne).

Transmission by direct and indirect contact is also recognized. Because of the high mortality of the disease and the possibility of the virus mutating to cause efficient human-to-human transmission, WHO is currently recommending the use of high-efficiency masks in addition to droplet and contact precautions

Precautions while handling patients

The following precautions must be observed while handling admitted patients suspected to be suffering from H5N1 influenza.

- Isolate the patient to a single room. If a single room is not available, cohort patients separately in designated multi-bed rooms or wards; beds should be placed more than 1 metre apart and preferably be separated by a physical barrier (e.g. curtain, partition).
- Reinforce standard precautions with droplet and contact precautions. Appropriate personal protective equipment (PPE) for all those entering patients' rooms consists of mask (highefficiency mask if available or surgical mask), gown, face shield or goggles, and gloves.
- Limit the number of HCWs who have direct contact with the patient(s); these HCWs should not look after other patients. The number of other hospital employees (e.g. cleaners, laboratory personnel) with access to the environment of these patients should also be limited. Designated HCWs should all be properly trained in infection control precautions.
- Restrict the number of visitors and provide them with appropriate PPE and instruct them in its use.
- Ask HCWs with direct patient contact to monitor their own temperature twice daily and report to hospital authorities any febrile event. An HCW who has a fever (>38 ºC) and who has had direct patient contact should be treated immediately
- HCWs who are unwell should not be involved in direct patient care since they are more vulnerable and may be more likely to develop severe illness when exposed to influenza A(H5N1)

viruses.

- Dispose of waste properly by placing it in sealed, impermeable bags which should be clearly labelled "Biohazard" and incinerated. Linen and reusable materials that have been in contact with patients should be handled separately and disinfected.

Case management

The following steps may be followed for managing suspected cases:

- Take respiratory and blood specimens for laboratory testing for influenza and other infections as clinically indicated
- Treat with a neuraminidase inhibitor such as oseltamivir (75 mg orally, twice daily for 5 days) as early in the clinical course as possible. Refer to product information sheets for dosage and current limitations on paediatric use.
- Provide supportive care. Monitor oxygen saturation & treat desaturation with supplemental oxygen as required. As nebulizers and high-air-flow oxygen masks have been potentially implicated in the nosocomial spread of severe acute respiratory syndrome, use these measures only if clinically justified and apply them under strict infection control, including airborne transmission precautions.
- Take respiratory and blood specimens serially to check for possible bacterial infection.
- Consider intravenous antibiotic therapy to control secondary bacterial infections as required.
- Do not use amantadine or rimantadine because of the risk of increasing the selective pressure for development of a resistant influenza virus with pandemic potential. Preliminary results from WHO collaborating centres suggest that influenza A(H5N1) viruses recently isolated from humans are resistant to amantadine and rimantadine
- Avoid administration of salicylates (such as aspirin) in children under 18 years of age because of the risk of Reye syndrome. Use paracetamol or ibuprofen, either orally or by suppository, for management of fever as clinically indicated.
- Immunomodulators such as corticosteroids should be used only in the context of clinical trials. The immune response of humans with influenza A(H5N1) infection requires further study.
- Do not use ribavirin. There is no evidence to support its effectiveness against influenza viruses; moreover, adverse reactions such as anaemia are frequent and may further compromise the patient.

Discharge policy

Studies are required to provide better understanding of viral excretion patterns in humans infected with the influenza A(H5N1) viruses associated with the current outbreaks in Thailand and Viet Nam. Until further evidence is available, WHO recommends that infection control precautions for adult patients remain in place for 7 days after resolution of fever. Previous human influenza studies have indicated that children younger than 12 years can shed virus for 21 days after onset of illness. Therefore, infection control measures for children should ideally remain in place for this period. Where this is not feasible (because of a lack of local resources), the family should be educated on personal hygiene and infection control measures (e.g. hand-washing and use of a paper or surgical mask by a child who is still coughing). Children should not attend school during this period.

Public health measures

Report to the local public health authority all patients for whom the diagnosis of influenza A(H5N1) virus infection is being considered. Identify contacts as well as those persons who may have been exposed to the common source of infection. These persons should be monitored for 7 days after their last exposure to the

## Appendix 'F'

### Management of a suspected case of Avian Influenza

Case defintions for h5n1 influenza

**Patient under investigation**

- Any individual presenting with fever (temperature >38˚C)
- AND one or more of the following symptoms:
  - Cough;
  - Sore throat;
  - Shortness of breath;
- Who is under clinical observation and laboratory investigations are under way.

**Suspect influenza A/H5 case**

Any individual presenting with fever (temperature >38˚C)

- AND one or more of the following symptoms:
  - Cough;
  - Sore throat;
  - Shortness of breath;
- AND one or more of the following:
  - Laboratory evidence for influenza A by a test that does not sub-type the virus;
  - Having been in contact during the 7 days prior to the onset of symptoms with a confirmed case of Influenza A/H5 while this case was infectious.
  - Having been in contact during the 7 days prior to the onset of symptoms with birds, including chickens, that have died of an illness;
  - Having worked in a laboratory during the 7 days prior to the onset of symptoms where there is processing of samples from persons or animals that are suspected of having highly pathogenic avian influenza (HPAI) infection.

  OR
- Death from an unexplained acute respiratory illness
- AND one or more of the following
  - Residing in area where HPAI is suspected or confirmed;

- Having been in contact during the 7 days prior to the onset of symptoms with a confirmed case of Influenza A/H5 while this case was infectious.

**Probable influenza A/H5 case**

Any individual presenting with fever (temperature >38˚C)

- AND one or more of the following symptoms:
- Cough;
- Sore throat;
- Shortness of breath;
- AND limited laboratory evidence for Influenza A/H5 (H5 specific antibodies detected in a single serum specimen).

**Confirmed influenza A/H5 case**

- An individual§ for whom laboratory testing demonstrates one or more of the following
- Positive viral culture for Influenza A/H5;
- Positive PCR for Influenza A/H5;
- Imunofluorescence antibody (IFA) test positive using Influenza A/H5 monoclonal antibodies;
- 4-fold rise in Influenza A/H5 specific antibody titre in paired serum samples.
- Individuals infected with Influenza A/H5 virus are considered to be infectious starting from one day before the onset of symptoms up to 7 days after onset of symptoms.

## Appendix 'G'

**Advice for health education of all people**

The spread of bird flu in affected areas can normally be prevented.

- People should avoid contact with chickens, ducks or other poultry unless absolutely necessary. This is the best way to prevent infection with the bird flu virus.
- Children are at high risk because they may play where poultry are found. Teach your children the following basic guidelines:
- Avoid contact with any birds, their feathers, faeces and other waste.
- Do not keep birds as pets.
- Wash hands with soap and water after any contact.
- Not to sleep near poultry.
- Do not transport live or dead chickens, ducks or other poultry from one place to another even if you think your birds are healthy.
- If you unintentionally come into contact with poultry in an affected area, such as touching the bird's body, touching its faeces or other animal dirt, or walking on soil contaminated with poultry faeces:
- wash your hands well with soap and water after each contact;
- remove your shoes outside the house and clean them of all dirt; and
- check your temperature for 7 days at least once daily. If you develop a high temperature (>37.5˚C), visit a doctor or the nearest health care facility immediately.
- If you encounter sick and dead poultry for the first time and are unsure of the situation, inform the authorities immediately and leave the handling of the poultry to experienced personnel (cullers, clean-up personnel, etc.)

Take all precautionary measures to ensure that poultry and poultry products are properly prepared and safe to eat.

- Chicken prepared hygienically and cooked thoroughly, i.e. no pink juices should be observed, can be considered safe to eat. However, remember, if the bird has a transmittable disease, such as bird flu, the person preparing the food is at risk of becoming infected and the environment may become contaminated.
- Eggs, too, may carry pathogens, such as the bird-flu virus inside or on their shells. Care must be taken in handling raw eggs and shells. Wash shells in soapy water and wash hands afterwards. Eggs, cooked thoroughly (hard boiled, 5 minutes, 70°C) will not infect the consumer with bird flu.
- In general, all food should be thoroughly cooked to an internal temperature of 70˚C or above.

General Biosafety Measures for Poultry Farm Workers

- Proper clothing and equipment to protect workers involved in the culling of poultry flocks. These workers should wear protective clothing, preferably coverall, apron or surgical gowns and gumboots.
- Use N-95 respirator masks are preferred. In the absence of N 95 masks, standard well-fitted surgical masks should be used.
- A person exposed to infected chickens or poultry farms should be closely monitored.
- All the clinically suspected human cases should be treated in isolation with universal precautions to prevent spread of infection.

Wg Cdr Rajesh Vaidya

# Severe Acute Respiratory Syndrome (SARS)

## Introduction

Severe Acute Respiratory Syndrome (SARS) is a new disease which came into notice when a patient was admitted in Hanoi (Vietnam) on 26th Feb. 2003 with respiratory illness. Seven health workers who cared for this patient also became ill on 5th March 2003. Since then, the cases have been reported from 29 countries. International travel has facilitated its spread rapidly among six continents. Later on, it was found that the disease initially emerged in China (Guangdong province) in November 2002 from where it spread to other countries. (1- 4)

## Epidemiology

The evidence suggests that a newly discovered variant of Corona virus (SARS corona virus) is accountable for this syndrome. Most SARS cases till date have occurred in previously healthy young adults. A few suspected cases have been reported among children. WHO estimates that case fatality ratio ranges from 0% to 50% depending on the age group affected, with an overall estimate of about 15%. (1-4)

## Incidence

### World

As on 15th May 2003, a cumulative total of 7548 probable cases and 573 deaths due to SARS have been reported from 29 countries. The affected areas were: the People's Republic of China (PRC), particularly the Hong Kong Special Administrative Region and the Beijing Municipality, Guangdong, Inner Mongolia, Shanxi, Tianjin, Taiwan Province (China), Toronto (Canada), Singapore (Singapore), India and Manila (Philippines). As of now, China has reported more cases than the rest of the world combined. (1-7)

### India

As on 14th May, 2003, three probable cases of SARS have been reported from India, one each in West Bengal, Karnataka and Gujarat. (1-2)

### Armed Forces

There has been no case of SARS in the Indian Armed Forces.

### Current SARS Situation

Currently, there is no known SARS transmission anywhere in the world. The most recent human cases of SARS-CoV infection were reported in China in April 2004 in an outbreak resulting from laboratory-acquired infections. CDC and its partners, including the World Health Organization, continue to monitor the SARS situation globally. (1-4)

## Agent

SARS corona virus is an enveloped RNA virus. The SARS virus has fulfilled the Koch's postulates, and it has been successfully cultivated in vitro (In VERO cell line) as well as in vivo (Experimental infection has been established in monkeys). The genome of the SARS corona virus is 29,727 nucleotides in length and the genome organization is somewhat similar to that of other corona viruses, however the detailed sequence data confirm that this SARS corona virus is a previously unrecognized corona virus. The recent studies carried out in the WHO network laboratories have shown that the SARS virus can survive after drying on plastic surfaces for upto 48 hours. The studies conducted in Hong Kong have shown that virus can survive in faeces for at least 2 days and in urine for up to 24 hours. (1, 2, 5-9)

## Incubation period

The incubation period is usually 2-7 days but may extend upto 10 days. (1, 2)

## Transmission

SARS virus appears to spread most commonly by close person-to-person contact involving exposure to infectious droplets, and possibly by direct contact with infected body fluids. It is also possible that SARS is transmitting through other unidentified routes. Persons having close contact with the cases, especially the health care workers and family members are at higher risk.

## Clinical features

The illness begins with sudden onset of fever, sometimes associated with chills and rigors and sometimes accompanied by other symptoms e.g. headache, malaise and myalgia. Some people also experience mild respiratory symptoms at the onset. Typically, rash and neurologic findings are absent. Many patients have reported diarrhoea, especially in Hong Kong. After 3 -7 days a lower respiratory phase begins with the onset of a dry, non-productive cough or dyspnea that may be accompanied by or progress to hypoxemia. In 10% to 20% of cases, disease may become severe enough to require intubation and mechanical ventilation. The main symptoms of SARS are high fever (more than 38°C or 100.4°F), dry cough, or difficulty in breathing. Changes in X-ray indicative of pneumonia also occur. (1, 2, 8-10)

## Diagnosis

As SARS is currently a diagnosis of exclusion, the status of a reported case may change over time. (11-14)

(a) A case should be excluded if an alternative diagnosis can fully explain the illness after considering the possibility of co-infection.

(b) Cases that meet the surveillance case definition for SARS should not be discarded on the basis of a negative laboratory test.

(c) A patient should always be managed as clinically appropriate, regardless of their case status.

## Role of laboratory for defining a case

A variety of laboratory tests have been developed and are being validated for diagnosis of SARS as given below:

(a) Virus Detection Test

(b) Molecular Test (PCR) : PCR can detect very minute quantities of the genetic material of the SARS virus in various clinical specimens in the early phase of the disease.

(c) Cell culture : Virus in clinical specimens from SARS patients can also be detected by infecting certain cell lines (VERO cell lines). Once isolated, the virus must be identified as SARS virus with further tests. Cell culture is the only test to indicate the infectivity of a SARS case.

(d) Antibody Detection Test

(i) ELISA test detects antibodies in the serum of SARS patients reliably as from day 21 after the onset of clinical symptoms and signs.

(ii) Immunoflourescence assays (IFA) detect antibodies in serum of SARS patients 10 days after the onset of illness.

(iii) Neutralization test (NT): This test assesses and quantifies, by means of titration, the ability of patients' sera to neutralize the infectivity of SARS-Co V on cell culture.

The test which has been most widely used so far is PCR test which is supposed to have a high specificity but low sensitivity. The clinical samples from suspect/ probable SARS cases should only be subjected to laboratory tests. Testing of samples from asymptomatic contacts is not recommended.

The following laboratories are equipped for analysis of the samples:

(a) National Institute of Virology (NIV), 20-A, Dr. Ambedkar Road, Pune-411001; Tel: 020-6127301, 6126302, 6127303, 6126304, Fax: 020-6122669,

E-mail: icmrniv@icmrniv.ren.nic.in

(b) National Institute of Communicable Diseases (NICD), 22 Sham Nath Marg, Delhi-110054; Tel: 011-23928700, 23971326, 23913148, 23971272, 23912836, Fax: 011-23922677

E-mail: dirnicd@bol.net.in.

(c) Tuberculosis Research Centre, (TRC), Mayor V. R. Ramanathan Road, Chetput, Chennai-600031. Tel: 044-28265403.

(d) National Institute of Cholera and Enteric Diseases (NICED), P-33, CIT Road, Scheme XM, Beliaghata, Kolkata-700010; Tel: 033-23500448, 23537469, 23537470; Fax: 033-23505066; E-Mail: )

(e) National AIDS Research Institute (NARI), Plot No. 73, G-Block, MIDC, Bhosari, Pune - 411026. Tel: 020-7121072, 7121343 Fax: 020-7121071

Collection, storage and transportation of clinical samples

**The following specimens should be collected from suspected/probable cases of SARS:**

(a) Acute & convalescent blood/serum for serology (at 21 days interval)

(b) Throat swab in viral transport medium.

(c) Nasopharyngeal swab or aspirate in viral transport medium (2 ml).

(d) Stool for virology: fresh or in viral transport medium.

(e) Whole blood (5-10 ml) with anticoagulant (EDTA).

**If available, the following samples may also be sent to the laboratory**

(a) Urine sample (50 cc) in a sterile container.

(b) Bronchoalveolar lavage fluid or tracheal aspirate in a sterile container.

(c) CSF, if additional symptoms of meningitis are present.

(d) All tissues from biopsy or autopsy, fresh & fixed

All the samples should be collected in sterile leak proof containers taking all biosafety precautions. While throat swab, nasopharyngeal swab or bronchoalveolar lavage and frozen tissues should be stored at -70˚C, serum may be stored at 4-8˚C for 1-2 days and at -20˚C for a long period. All specimens should be sent under cold chain condition (2-8˚C) within 24 hours. If a urine sample cannot be sent to the laboratory within 2 hours, it should be centrifuged and the deposit resuspended in a viral transport medium and should be sent to the laboratory under strict aseptic conditions. All samples should have three-layer packaging and be properly labelled. Always notify the receiving laboratory in advance. The clinical samples should be accompanied by proper clinical information of the case as per the "Case Information Proforma".

General bio-safety measures for clinical samples

(a) Clinical samples should be collected by hospital staff working for care of SARS cases and not by the laboratory staff.

(b) All clinical samples have to be collected with standard precautions.

(c) Always use N95 (0.3 mm pore size) masks while taking samples. In case of non-availability of N95 mask, triple layered surgical mask may be used.

(d) Use latex disposable gloves.

(e) Wear laboratory coat/disposable apron.

(f) Always cover your hair with head cover.

(g) Use protective eyewear/face shields, if the procedure is likely to generate aerosols or splashes of secretions.

(h) All waste while collecting specimen has to be handled with standard precautions. The waste should be placed in an appropriate leak proof and autoclavable biohazard bag and autoclaved before disposal. Contaminated non-disposables should be treated properly.

(j) The Clinical samples should be processed only in the designated laboratory having the appropriate containment facilities.

**Guidelines for personal protective equipments (regarding face mask)**

WHO has revised guidelines regarding the use of Personal Protective Equipment. In the light of this, a Technical sub group on management of SARS has given the following recommendations regarding facemask:

(a) Surveillance settings: In surveillance settings such as at airports / sea ports triple layered surgical mask should be used by the surveillance teams.

(b) Casualty / Triage Area / Inpatients settings: Patients and health care workers should wear P100 or P99 filter level or equivalent comparable masks. N95 or equivalent comparable masks can be worn when higher protection alternatives are not available.

(c) Critical care setting: During intubations, artificial ventilation and endotracheal suctioning, special mask developed by DRDO India should be used.

One should avoid the use of masks made of woven materials such as cotton or gauze as viral particles can pass through them.

**How to use the N95 mask**

Press the mask firmly against your face with the nosepiece on the bridge of the nose. Stretch and position the top band high on the back of the head, stretch the bottom band over the head and below the ears. Use both hands to mould the metal nose piece to the shape of the nose. The masks can be discarded appropriately after 4 hours of continuous use or once it comes into contact with any fluids. The mask should be discarded in autoclavable biosafety bags which should be autoclaved before the final disposal.

**Treatment and prognosis**

As of now, there is no vaccine or specific treatment available for SARS. However, good supportive treatment has been found effective in many cases. (1, 2, 9-12)

(a) Ribavarin and steroids have shown to be useful in treating critically ill patients. Ribavarin may be given 8mg/kg every 8 hours intravenously or 1.2g every 12 hours orally, with an oral loading dose of 4g for those with normal renal functions. Administer for 7-14 days depending upon the response.

(b) Give hydrocortisone 2mg/kg every six hours or 4 mg/kg every 8 hours intravenously. Tail off over one week when there is clinical improvement.

(c) For severe and rapidly deteriorating cases give methyl prednisolone 10mg / kg every 24 hours intravenously for two days, and then continue with hydrocortisone as above.

(d) Antibiotics treatment (coverage for typical and atypical agents for 7-14 days using drugs such as levofloxacin and macrolides) is advocated to prevent superadded infection.

Investigation to exclude other causes of pneumonia should be carried out. Patients who require mechanical ventilation generally fulfill the diagnostic criteria for ARDS with diffuse infiltrates on chest radiography and hypoxaemia without evidence of left ventricular failure. All suspect or probable cases of SARS must be treated in isolation with barrier nursing and universal precautions should be taken by the health care workers to prevent the further spread of disease. All the States/UTs have identified the hospitals where cases of SARS should be referred for treatment. List of such hospitals may be obtained from the respective State Health Authorities. Nebulization should not be done. If patient is on a ventilator, close system suctioning catheter and bacterial filter on expiratory and inspiratory limbs of ventilator circuit should be used.

**A patient may be considered for discharge when the followings are present:**

(a) Afebrile for 48 hours and resolving cough

(b) White cell and platelet count, creatine phosphokinase, liver function tests, plasma sodium and C reactive protein are returning to normal, if previously abnormal

(c) Improving chest X-ray changes.

Following discharge from the hospital, convalescent cases should remain at home for 10 days and keep minimum contact with others. Further confinement may be recommended after clinical assessment. Nevertheless, cases must contact their hospitals from where they were discharged if their condition deteriorates and symptoms reappear at any time.

**Prevention and control**

Isolation of suspect and probable cases of SARS and universal precautions taken by the healthcare workers and others who are likely to come in contact with SARS cases would prevent the further spread of disease. WHO recommends that international travellers departing from the places on the affected areas list should be screened for possible SARS at the point of departure. Travellers with one or more symptoms of SARS and having a history of exposure or who appear acutely ill should be assessed by a clinician and may be advised to postpone their trip until they feel better. Under the International Health Regulations all aircraft pilots and masters of ships are required to provide a General Declaration on Health to the Airport/Port authorities and APHOs/PHOs wherein any sickness on board is declared. This needs to be further strengthened by sensitizing all concerned to remain vigilant. Unless absolutely necessary, people should not visit hospitals where the SARS cases have been isolated to avoid any contact with them. Similarly avoid going to the crowded areas, otherwise keep your stay as short as possible.

All persons who come in contact with the suspect and probable cases of SARS should contact the local health authorities if they develop symptoms of SARS within 10 days of exposure. Temperature should be recorded daily as this is the first symptom which is likely to appear. Contact cases should restrict their movement and remain voluntarily confined to their homes.

All persons disembarking in India are required to fill up a proforma. Any person meeting the criteria of suspect/ probable SARS should be referred to the hospitals identified by Central/State Governments for further investigations and treatment in isolation. The cases should also be reported to Director, NICD, Delhi, respective State Health Authorities and Director, EMR. Healthy passengers are advised to contact local health authorities if they develop symptoms of SARS in the next 10 days.

WHO guidelines/documents on case definition, preliminary clinical description, case management, hospital discharge and follow-up policy, and hospital infection control have been circulated to all the States/UTs, Central Government Hospitals, Ministry of Home Affairs, Ministry of Civil Aviation/Airport Authority of India, and APHOs/PHOs.

Infection Control Guidance at the Hospitals

(a) All persons requiring assessment for SARS at the hospital should be assessed at a separate area to minimize transmission to others.

(b) Wherever possible, cases under investigations for SARS should be separated from the probable cases.

(c) All suspect/probable cases to wear N95 mask or three layered surgical facemask or any mask of 0.3 µm filter size as recommended.

(d) Healthcare staff involved in the treatment, or cleaning should wear personal protective equipments (disposable masks, gloves, gown, goggles, shoes, etc).

(e) Hand washing is very important and should be practised before and after contact with any patient, after activities likely to cause contamination, and after removing gloves.

(f) Alcohol based skin disinfectants can be used.

(g) Cases should be isolated or cohort placement should be done with independent air supply, exhaust system, and bathroom facilities.

(h) Turn off the air-conditioning and open window, if independent air supply is not possible.

(j) Strict barrier nursing using precautions for airborne, droplet and contact transmission.

(k) Movement of patients outside the isolation unit should be avoided; otherwise they should wear a N-95 or triple layer surgical or a 0.3 µm filter size mask.

(l) Non-essential staff and visitors should not be allowed in the ward.

(m) Disposable equipments should be used wherever possible and disposed of appropriately. All devices to be reused should be sterilized in accordance with manufacturers' instructions. Surfaces should be cleaned with broad-spectrum disinfectants of proven antiviral activity.

(n) All sharps should be dealt with promptly and safely.

**Cleaning and Disinfection of the SARS Patient Environment**

In-patient rooms housing SARS patients should be cleaned and disinfected daily and at the time of patient transfer or discharge. Daily cleaning and disinfection should include horizontal surfaces (e.g., over-bed table, night stand), surfaces that are frequently touched by patients and healthcare personnel (e.g., bed rails, phone), and lavatory facilities. Terminal cleaning and disinfection following transfer or discharge should include the type of surfaces described above plus obviously soiled vertical surfaces, frequently touched surfaces (e.g., light cords and switches, door knobs), and durable patient equipment (e.g., bed, night stand, over-bed table, wheel chair, commode etc). Curtain dividers should also be changed and laundered as appropriate for the curtain fabric. Patient care equipments such as mechanical ventilators, pulse oximeters, blood pressure cuff, should be cleaned and disinfected in accordance with current recommendations and manufacturer's instructions.

Cubicles or rooms in OPD areas where patients with suspected SARS are evaluated should be cleaned and disinfected before another patient is seen or cared for in that environment. Areas that should be specifically targeted for cleaning include the examination table and horizontal surfaces that may have been touched by the patient or healthcare providers. Solutions used for cleaning and disinfection should be discarded after use. Thoroughly rinse and clean housekeeping equipment after use in a SARS room or area and allow the equipment to dry. Launder reusable mop heads and cleaning clothes according to current practice.

Screening of International Travellers

(a) All International passengers and crew coming to the international airports and ports must be screened for SARS by a medical officer through the specially designed proforma available at all International Airports/Ports.

(b) The suspected case should be provided mask by the airport authorities/Port Organizations and isolated in an identified room at Airports/Ports till transported to the hospitals identified by the State Government.

(c) The identified hospital should be informed by Airport authorities/ Port Organization about the arrival of a suspected case and then transported to the identified hospital in ambulance.

(d) The details of the case should be provided to the identified nodal officers of the States, Ministry of Civil Aviation, National Institute of Communicable Diseases, Delhi and Directorate General of Health Services, Nirman Bhavan, New Delhi-110011 by Airport authority/ Port Organizations.

(e) All identified hospitals in Centre/ States should treat the cases in isolation with nursing barriers and observe universal precautions.

(f) The standard management protocols evolved by WHO and circulated to the Central and State Govts. should be followed. The same has also been mentioned in the text.

(g) The hospital authorities may take the help of the Regional Centres situated in Chennai (Tuberculosis Research Centre-ICMR), Mumbai (Enterovirus Research Centre-ICMR), Kolkata (NICED-ICMR), Delhi (NICD) and Pune (NIV, NARI-ICMR) to collect the samples.

(h) The case discharge protocol issued by WHO and already circulated should be followed.

(j) The hospital infection control guidelines already circulated should be followed to prevent the spread of infection in the hospital.

(k) All Indian Nationals disembarking by the same flight/ ship from which the SARS patient came should be followed up by the concerned State Governments to which they belong to for further 10 days. Ministry of Civil Aviation and Ministry of Shipping would provide the list of passengers to the State Governments for follow-up. (9, 14-16)

## Introduction

Diseases spread from one person or organism to another by direct or indirect contact are usually called 'contagious' diseases' or 'Contact diseases' (1). By an unopposed convention the use of the word 'Contagious' and contact-transmission is reserved in medical literature for those diseases which are transmitted only through direct or indirect personal contact (2) and not through the other routes of transmission. Such infections cause mainly the skin and sexually transmitted infections (STI) and also diseases like trachoma, conjunctivitis and so on. Direct contact is necessary for transmitting skin infections like scabies and STIs. Indirect contact can transmit infections like fungal or pyogenic infections, trachoma and so on. Indirect infections can take place mainly through clothing and use of common soaps, towels, combs, razors, cosmetics like surma and so on. Some common infective and non-infective skin diseases, STIs and trachoma are briefly discussed in this chapter. Standard text books should be referred to for a detailed study. (3-5)

# Contact Diseases Other than Sexually Transmitted Infections (STI)

## Skin Diseases

### Introduction

Structure and Functions of Skin

The skin is the outermost protective structure of the body which intervenes between the internal structure of an organism and his environment. With the surface area of 2 $m^2$ and accounting for 16-20% of the total body weight, the skin is the largest organ of the body. The main functions of the skin are :

(a) Protection of the organism from noxious environmental, physical, chemical, mechanical, biological agents and radiations.

(b) Perception of sensory stimuli through cutaneous nerve endings

(c) Prevent fluid loss and regulate body temperature.

(d) Plays a role in social and sexual communication.

(e) Psychosomatic disorders may cause purely skin manifestations and the skin conditions may produce psychological disturbances (6).

Although the mortality due to skin diseases are negligible, but they contribute immensely in morbidity affecting the performance of a soldier besides causing great amount of stress and depression. The skin diseases results in ;-

(a) Considerable loss of effective manpower as 10 percent of all admissions to hospitals are due to skin diseases.

(b) A large number of personnel suffering from skin diseases may not be admitted to hospitals or invalided out, but they always suffer from partial incapacity.

(c) Diseases in this group have always shown a rapid increase under conditions of military expansion and actual warfare.

(d) A large number of ambulatory patients are in skin diseases than in diseases of any other organs. Therefore, the number of persons who report to the medical officer is far less than the actual incidence. On a survey carried out in a certain theatre of war the ratio of hospitalised to non-hospitalised skin cases was roughly 3:5.

However, much of the manpower wastage due to skin diseases is avoidable. The RMO is in a key position to help and cut down the morbidity and man-day wastage by advising the unit commander and subunit-commanders regarding the preventive and control measures. He should continuously educate all ranks in personal hygiene, early detection of cases and deal with them more effectively.

How to take Care of the Skin?

Where a good healthy skin improves the personality and confidence of an individual, a dull and unhealthy skin may cause psychosocial problems. As it is said 'skin is the mirror of oneself', the stress and happiness is reflected in the skin. Some tips to take care of the skin are :

(a) The skin and its appendages should be kept clean by regular washing with soap and clean water. In temperate climate one bath daily with warm water and soft toilet soap is adequate. If the work involves excessive sweating, either due to environmental or working conditions or after games, a second bath may be necessary.

(b) During bathing, give particular attention to body folds viz. webs of the fingers and toes, antecubital areas, armpits, groins, gluteal folds, perineum and popliteal areas.

(c) The scalp must be washed with good toilet soap or conditioning shampoo for removing dirt, debris or any excess of oil. Hair should always be kept short.

(d) Shaving should be always done with clean razors and preferably by oneself then unit barber. Blades should be kept clean, sharp and should be replaced frequently.

(e) It is a common practice with men to massage the body with oil before or after the bath. Vigorous

massaging with unclean hands causes inapparent injury and infection of the hair roots. However, a very thin layer of oil applied on the skin immediately after bathing keeps it elastic.

(f) Clothes should always be clean, specially the undergarments. They should be changed and washed daily.

(g) Early recognition and prompt treatment of skin diseases reduces the manpower wastage. Troops should be educated about self examination and common skin ailments and they should be encouraged to report to the unit RMO for further treatment.

How can we take care of the hands and feet?

Disorders of the skin of the feet, cause significant morbidity in soldiers. This is due to the increased usage of boots and socks over prolonged periods in uncongenial climate. The general measures to keep the skin of the feet healthy are:-

(a) Proper washing and cleaning of feet with soap should be done and well dried before wearing socks and shoes. Shoes should be well fitting, neither loose nor too tight, smooth, pliable, comfortable and of a permeable material.

(b) Rubber and canvas shoes in hot-humid environments cause sweat retention and sodden skin; hard leather causes callosities; projections like nails inside the shoes predispose to corns.

(c) Every person must use only his own pair of shoes and socks. Socks should be changed and washed daily. After daily work, personnel should take off their shoes and socks and use footwear which is of the open, chappal type to dry and aerate interdigital areas.

Care of the Hands

Adequate hand washing facilities should be provided at dining hall, bathrooms, work place etc. Occupations involving handling of strong chemicals and infectious materials should be done with proper work gloves. Harsh scrubbing with strong chemicals and detergents, too frequent washing of the hands with soap and water and prolonged immersion of hands in water should be avoided.

Table - 1 : Morphology of Skin diseases

| Primary lesions | Secondary lesions | Special lesions |
|---|---|---|
| Macule | Crust | Burrow |
| Papule | Erosion | Comedo |
| Plaque | Excoriation | Milium |
| Nodule | Ulcer | Telangiectasis |
| Wheal | Scar | Target lesion |
| Vesicle | | |
| Bulla | | |
| Pustule | | |
| Cyst | | |

Skin lesions are classified as primary or secondary and besides this there are some special lesions given in Table - 1 that are diagnostic of a particular disease (7).

**Classification of Skin Diseases**

(a) Bacterial Infections
  (i) Acute Pyodermal Infections
    - Furunculosis
    - Impetigo
    - Ecthyma
    - Folliculitis
    - Sycosis Barbae
  (ii) Chronic Infectious Sores
    - Tropical Ulcers
    - Desert Sore

(b) Fungal Infections
  (i) Dermatophytosis (TIneas)

(c) Parasitic Infestation
  (i) Scabies

(d) Leprosy

(e) Others

Important service related skin infections are briefly mentioned in coming paragraphs.

## Bacterial Infections

**Introduction**

A healthy person and healthy skin resists physical, chemical, mechanical and biological trauma. Infection develops when the right combination of agent, host and environmental factors exists. The usual bacteria involved are pyococci, fusiform bacilli, diptheroid bacilli, spirochetes and M. leprae.

**(a) Acute Pyodermal Infections**

Pyodermas are the skin infections caused by Staphylococci and Streptococci. The chief organisms which are responsible to initiate the infection are coagulase positive staphylococcus aureus, the haemolytic streptococci usually are secondary invaders.

Reservoir and Source of Infection

The reservoir of infection is the human carriers with the nasal, oropharyngeal and gastro-intestinal commensal organisms. The foci of overt infection in these sites, infected sores or wounds, discharging sinuses, draining furuncles in the ears and so on, also act as sources of infection to self or others.

Mode of Transmission

The organisms are transferred to the site by autoinfection or from one person to another by contact. However, the infectivity of the lesions of pyoderma is not very high except for the vulnerable individual under adverse conditions, and in children. Contaminated clothing and dressings are also a means of transfer of organisms from

one person to another.

Predisposing Conditions

Children are more susceptible to these conditions. Scaly, dry and hairy skins are more vulnerable. Maceration increased sweating, friction between surfaces or from clothing are the most important factors increasing vulnerability. Cuts, wounds, abrasions, burns, skin conditions like eczema, fungal infections, viral exanthemata or itchy dermatoses like insect bites, urticaria, mite and louse infestation (which on scratching cause excoriation), obesity, diabetes mellitus, malnutrition, blood dyscrasias, hypogammaglobulinaemia, unhygienic habits, infrequent baths and overcrowding, all increase the liability to develop pyodermas.

Clinical Entities

The clinical classification of common pyodermas is mainly based on the site of skin affected and severity of the disease. The following common conditions are recognized:-

(i) Furunculosis

A boil is an inflammation of a pilosebaceous follicle or a ceruminous gland commonly caused by Staphylcoccus aureus. Often the boils are multiple and cause considerable disability. Aggregations of boils (carbuncles) occur in conditions like diabetes mellitus. The common sites for furunculosis are hairy, sweaty parts liable to friction and maceration, such as the buttocks, neck, face, axillae and the area underlying the belt. Favoured sites for carbuncles are the back of the neck, the upper back, and the lateral thighs (8). Bad personal hygiene is an important factor causing recurring furunculosis. The infection is quite common in athletes. Although boils may occur in otherwise healthy individuals, they are commonly seen in persons suffering from some pre-existing disease. The important conditions predisposing to furunculosis are prickly heat, acne, pediculosis, scabies, septic foci in the tonsils, throat, discharging ear, diabetes, nephritis, malaria and other debilitating diseases or obesity. Many individuals suffering from recurrent boils are carriers of staphylococci in their anterior nares or the perineum. However, furunculosis may occur in the absence of any apparent predisposing cause.

(ii) Impetigo

A common contagious superficial inflammatory disease generally caused by streptococcus pyogenes, staphylococcus aureus or a combination of both. The lesions consist of fragile vesicles which quickly rupture and the serum which exudes forms typical honey-coloured crusts on the skin. As a primary condition it affects the face, particularly the chin and beard area, but may complicate other skin conditions like scabies, pediculosis, prickly heat and so on. The condition is very infectious spreading rapidly within 48 hours of direct contact, or contact with contaminated toilet articles or through insanitary barbers.

Fig - 1 : Impetigo

(iii) Ecthyma

This is essentially a deep type of impetigo caused by haemolytic streptococci. It ordinarily begins with a blister which erodes through the epidermis to produce a shallow ulcer. Oozing occurs with formation of a hard, adherent, thick crust which may conceal the underlying ulcer completely. The most common sites are on the legs. Lesions may occur repeatedly after minor trauma. Poor hygiene and neglect of a primary skin condition are predisposing factors. The lesions may follow insect bites, minor scratches, chickenpox, vaccinia and herpes zoster.

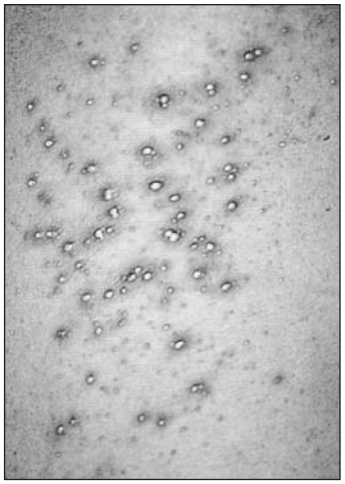
(iv) Folliculitis

This is of two types

**Follicular impetigo (superficial form)**

Folliculitis means an inflammation of the hair follicle. This is also a form of impetigo characterized by small dome shaped pustules at the mouth of the follicles, generally on the legs and thighs, caused by coagulase- positive staphylococci aureus. The process is superficial; therefore, there is no scarring. This type of infection is quite common among the troops and causes considerable disability. Massaging the extremities with dirty hands causing trauma and infection of the hair follicles is one of the predisposing factors. It occurs commonly in persons with a tendency to seborrhoeic dermatitis. It may develop as a complication of shaving. It may become extremely chronic and persist in the absence of any bacterial infection. Cutting oils and tar products are occupational causative agents of folliculitis.

Fig - 2 : Folliculitis



### Sycosis Barbae (Barber's rash)

It is a staphylococcal pustular folliculitis affecting male beard area and upper lip. The disease may be contracted from infected razors, shaving brushes or towels; often it is preceded by chronic blepharitis. Seborrhoeic men are somewhat more prone to sycosis barbae. In many cases there is gross sepsis in the gums, nasal sinuses or antra. The disease usually commences in a localized area and spreads rapidly. The primary lesion is a papulopustule from each of which a hair protrudes. These rupture and crusts are formed. Adjacent follicles are infected and as resistance of the skin weakens, the lesions become nodular. Suppuration occurs in the nodules, and the hair may come off even by a gentle pull.

Prevention and Control

Prophylaxis against these pyococcal conditions is achieved by:

(a) A high standard of personal cleanliness, a daily bath and avoidance of using each others' toilet articles such as shaving kit and towels.

(b) The unit barber's shop should be regularly inspected to ensure that razors, scissors, brushes, combs and linen are kept clean and disinfected. Blades should be thrown after every single use and proper disposal of such blades to be implemented preferably by deep burial. Self-shaving is in fashion today.

(c) Certain common personal hygiene measures like washing of hands after ablution, avoiding nose picking or thumb sucking, keeping the nails short, avoiding the massage of hairy areas especially legs and forearm with irritant oils like mustard oil, need emphasis.

(d) Early treatment curbs transmission by destroying the source of organisms. Strict aseptic measures in self-handling infected lesions, soiled clothing and dressings prevent spread of the disease among other personnel.

Treatment

(a) Squeezing or early incising is harmful. Hot compresses and permitting the infection to follow its normal course without much interference is enough for solitary boils. When the lesion 'points', it may be gently nicked aseptically, drainage established and an aseptic dressing applied. The pus should be wiped, collected on dressings and removed without allowing it to drain over the surrounding skin.

(b) The cleanliness of the surrounding area of skin is of paramount importance, otherwise satellite furuncles occur.

(c) Adherent crusts can be removed by intermittent hot compresses with normal saline. Thereafter, anti-bacterial creams like 1% silver sulfadiazine should be applied and penicillin or sulphonamide creams should be avoided.

(d) Warm magnesium sulph-glycerine dressing done daily for a few days causes pointing of the furuncles. Ordinary impetigo should show distinct evidence of clearing within 48 hours and will be healed within a week.

(e) Systemic antibiotics may become necessary if the disease becomes widespread and or severe. In such cases or if the condition becomes resistant or recurrent, hospitalization and or treatment by a dermatologist is necessary.

Table - 2 : Key points : staphylococcal skin infections

- Staphylococcus aureus is the most common cause of skin infection.
- Staphylococcus aureus has replaced streptococcus pyogenes as the most common cause of impetigo.
- Bullous impetigo is always caused by S aureus strains, usually phage II, type 71, that produce exfoliative toxins.
- Approximately 20% of the population is colonized by S. aureus.
- The anterior nares is the most common site of S.

### (b) Chronic Infectious Sores

Any trauma causing break in the continuity of the skin surface can get infected by specific organisms such as B. anthracis, M. tuberculosis or common pyococci and cause ulceration and formation of chronic, intractable sores covered with slough or crust and discharging pus or sero-sanguinous discharge when the crust is disturbed. The lymph nodes draining the area get inflamed and systemic symptoms may occur. Some sores manifest a specific natural course and appearance. Tropical ulcers and desert sores are typical examples of such specific sores.

(i) Tropical Ulcers (Ulcer Tropicum)

These are confined to the hot and humid tropical regions and thus the name Tropical Ulcers. In moist foothill areas of the northeastern regions of India they commonly occur amongst road labourers and others who, from the nature of their work, are liable to receive minute injuries on exposed parts such as the legs. The ulcers are often named after the region in which they are specially prevalent e.g. Naga sore, Annam ulcer. The starting point is a cut, abrasion, insect bite or other minor injury often trivial in nature and hence neglected. A small, tender, papule or bleb develops on the infected abrasion. This soon breaks down and after a short period of inflammatory reaction the ulcer becomes sub-acute or chronic, indolent and spreading. It rapidly deepens and becomes covered with a yellow, thick, purulent, foul smelling slough. The margins are indurated and raised; edges are undermined, and the depth is often difficult to determine on account of the presence of the tenacious slough. These sores are extremely painful, but in the absence of secondary infection there is little constitutional disturbance and generally there is no fever.

Healing is very slow and leaves a whitish scar. Regional lymph nodes are not involved.

(ii) Desert Sore

It occurs in deserts and arid areas and usually in men associated with horses, camels and mules. The sores occur at the site of abrasion or insect bite, on the exposed parts of arms and legs, covered by hair such as dorsum of the hands and forearm, elbows and knee joints. The lesion starts with a painful vesicle full of straw-coloured fluid. When the vesicle bursts a shallow, tender ulcer covered with a thin grey slough is left. The chronic ulcer has a characteristic circular punched out appearance with undermined edges, thickened margins and the base covered with grey coloured thin debris beneath which an adherent membrane is present. There is little or no discharge.

Prevention and Control

Prophylactic measures are as follows :

(a) Protection from injuries, abrasions, insect bites and brushing against bush and vegetation or scrub by use of long trousers and shirt sleeves rolled down.

(b) A high standard of personal hygiene is very important.

(c) Early efficient treatment of even the trivial injuries.

(d) In an endemic area of tropical ulcers i.e. North-Eastern India, all labourers, who are prone to receive minor injuries should immerse their legs in a solution of bleaching powder (one teaspoon to 5 l) at the end of the day's work.

(e) Management involves rest, limb elevation and treatment. Penicilin and /or metronidazole are the drugs of choice along with local dressings. Cases not responding to this regime early should be referred to the dermatologist. 2000 units of antidiphtheritic serum injected locally clears the desert ulcers which show C. diphtheriae and a course of PAM injections clears the soft sores showing spirochaetae.

## Fungal Infections

### Dermatophytosis (Tinea, Ringworm, Dermatomycosis, Epidermophytosis, Trichophytosis, Microsporosis )

Definition

Dermatophytosis and tinea are general terms, essentially synonymous, applied to mycotic disease of keratinized areas of the body i.e. skin, nails and hair without giving rise to the disease of the internal organs caused by a group of fungi called dermatophytes. Out of a large number of fungi present in nature only a few are pathogenic to human beings. The dematophytoses are subdivided according to the site of infection. (Table - 3)(9).

Tinea Barbae

Fungal disease that begins as a small papule and spreads peripherally, leaving scaly patches of temporary baldness. Infected hairs become brittle and breaks off easily. Occasionally boggy, raised and suppurative lesions develop called Kerions.

Table - 3 : Clinical presentations of dermatophyte infections

| Infection | Location |
|---|---|
| Tinea Barbae | beard |
| Tinea Capitis | Scalp |
| Tinea faciei | face |
| Tinea Cruris | groin |
| Tinea Corporis | Trunk, extremities |
| Tinea Unguium | Nails |
| Tinea manuum (manus) | hands |
| Tinea Pedis | feet |

Tinea Cruris

Fungal disease of the groin characteristically appears as a flat, spreading, ring shaped lesions. The periphery is usually reddish, vesicular or pustular and may be dry and scaly or moist and crusted. As the lesion progresses peripherally, the central area often clears, leaving apparently normal skin.

Tinea Pedis

Fungal disease of foot with characteristic scaling or cracking of the skin, especially between the toes, or blisters containing a thin watery fluid; commonly called Athelete's foot. Adults are more often affected than children, males more than females. Infections are more frequent and more severe in hot humid weather.

Agent

The pathogenic fungi belong to the three principal genera. Microspora infect hair and skin; Trichophyton infects hair, skin or nails; and Epidermophyton infects skin or nails. The different species can only be distinguished by a study of the morphological characteristics of their conidia (spores) and other accessory structures after culturing them. Microspora may be identified by a direct microscopic examination of infected hair. However, the cutaneous lesions are in most cases indistinguishable.

Reservoir and Source

The reservoir and source of infection in the community is a person suffering from an infection. Another important source of infection is the animal reservoir. This causes highly inflammatory, resistant lesions (10).

Mode of Transmission

Direct skin to skin or indirect contact especially from toilet seats, barber clippers, combs, hairbrushes, bath boards, neck rests, towels and hats contaminated with hair of infected people or animals. Undergarments may play some part but this has not been authentically proved. However, in cases of T. pedis the shoes of the affected individual, in cases of T. capitis the combs, barber's scissors and clippers are factors in transmission.

Susceptibility

Local skin peculiarities and intertriginous areas which are subject to friction, maceration, perspiration and increased temperature predispose to development of the disease after acquiring the infection. All ages are susceptible. Viable fungus may persist on contaminated materials for long periods.

Incubation Period

| | |
|---|---|
| Tinea barbae and capitis | Usually 10-14 days |
| Tinea cruris | Usually 4-10 days |
| Tinea Pedis and unguium | Unknown |

Predisposing Conditions

Fungal infections are extremely common in hot-damp areas. Persons who habitually perspire more, suffer more. Mild cases easily become severe by friction and sweating, rendering the sufferer unfit for duty. The commonest sites are therefore the sweaty areas of the body liable to be exposed to friction like the armpits, groins and feet, especially in between the toes. The superimposing secondary pyococcal infections increase the disability.

Clinical Varieties

The commonest manifestation of this fungal infection of the skin is a ring (annular) lesion; hence, the lay term 'ringworm' (Tinea and dermatophytosis are other names). The manifestations vary with the anatomical site involved and the species of fungus affecting. The commonest clinical types are the T. pedis and T. cruris, T. barbae comes next, followed by T. corporis. Infection of the armpits, scalp and nails are less important among troops. In children any part of the body may be affected but they are more susceptible to T. capitis which subsides as they grow. In women T. pedis is uncommon but skin under the breast and around the waist is commonly affected. In adult men, the feet are usually the first to be infected to produce what is commonly known as 'Athlete's foot'. Intertriginous, vesiculo-bullous or dry squamous lesions may occur.

Intertriginous Ringworm ("Athletes foot")

It is the commonest type affecting the skin, between and underneath the toes and producing maceration, sogginess, peeling and fissuring, accompanied by foul odour and pruritis. The initial lesion is a group of small vesicles occurring most commonly in the 4th and 5th interspaces; but extension to all interdigital spaces occur in severe cases, and subsequent extension to the under surface of the toes and adjacent part of the soles is frequent (Fig - 3).

Fig - 3 : Athelet's Foot

Vesiculo-bullous Ringworm

It most commonly affects the insteps of the soles and balls of the foot. In severe cases, the whole sole may be involved. Deep- seated vesicles of variable size and number develop and often fuse to form bullae or multilocular blisters which contain yellowish gelatinous fluid. Pruritis is severe.

Squamous Ringworm

Scaling, relative lack of inflammation and extreme chronicity usually affects the entire plantar surface extending over the sides of the foot These may be associated with intertriginous involvement of the toes.

Tinea Cruris (Jock Itch)

It is another common type occurring in males. It is essentially an intertriginous type of infection starting in the crural or perineal folds with extension posteriorly, anteriorly and on to the upper-inner surfaces of the thigh. The disease is not seriously disabling by itself, but it frequently becomes so by inappropriate and irritating treatment. In patients who are fat and sweat easily, the affected areas may become severely macerated and ooze; secondary infection with pyogenic organisms then readily occurs and increases suffering and disability (Fig - 4).

Prevention and control of fungal infections.

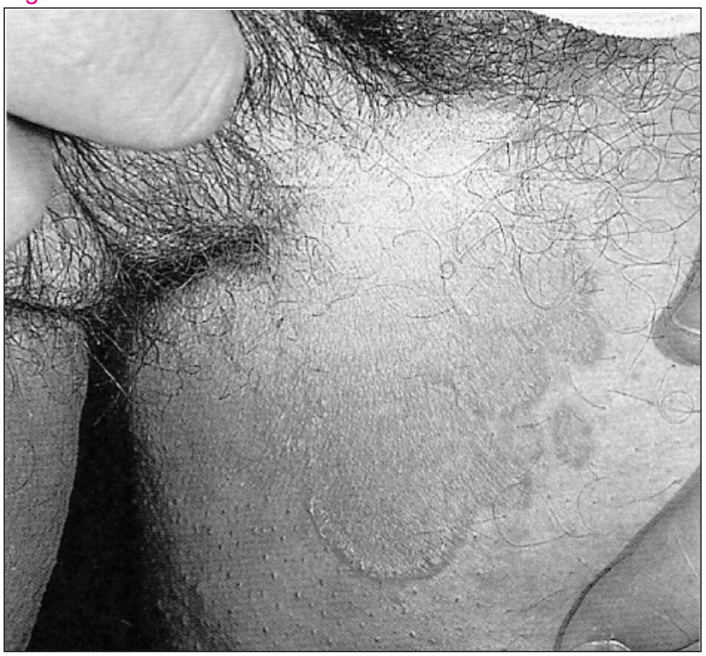
Prophylaxis is achieved by the following general measures:-

(a) Maintenance of strict personal hygiene with special care in drying the area. Areas between the toes, and armpits and in crotches should be more carefully dried after a bath, especially among athletes or in persons who excessively sweat due to any cause.

(b) Use foot powder or dusting powder before wearing socks and boots /shoes and undergarments, this helps in maintaining the skin dry in these places.

(c) Education of all ranks concerning the nature of the

Fig - 4 : Tinea Cruris



infection and its mode of spread is necessary.

(d) The towel which is used for drying the vulnerable parts of the body should be washed frequently and dried.

(e) Men should not exchange each others' towels, footwear and items of underclothing.

(f) Clothing should be of cotton, loose and non-irritating.

(g) Whether infection spreads through fomites or not is doubtful but general cleanliness in the ablution rooms and swimming baths have proved helpful. Floors and duckboards should be scrubbed and washed with cresol or bleaching powder solution. Shallow footbath containing a solution of bleach (1 scoop to 10 lit of water) may be provided at the swimming baths and showers, for use of all persons entering the bath. Coconut coir matting should not be used as it always remains wet.

The control of spread of ringworm infection in a unit is intimately related to early detection and effective treatment of all cases suffering from ringworm. A routine foot inspection should be conducted by RMOs and those infected should be given prompt active treatment by the RMO or specialist in the hospital.

Treatment

(a) The prescription of Griseofulvin is the specific treatment of all fungal infections. Average adult dose is 0.5 g a day for 3 to 4 weeks.

(b) Regular use of 5 to 10 percent acid salicylic ointment for several months is an alternative treatment in the absence of the facilities or pending specialist advice and in mild cases. Moderate tinea cruris can be relieved with the application of Whitfield's ointment every night and Castellani's paint during the day.

(c) Acute flare-ups can be relieved with soaks of 1:8000 potassium permanganate lotion (colour should be light pink) for 20 min twice a day and dressed with calamine lotion.

## Parasitic Infections

Table - 4 : Antifungal Drugs (7)

| | |
|---|---|
| **Systemic Antifungals** | |
| Griseofulvin | |
| Amphotericin B | |
| Allylamines | |
| Azole compounds | |
| Imidazoles : miconazole, clotrimazole, ketoconazole | |
| Triazoles : Fluconazole, terconazole | |
| **Topical Antifungals** | |
| Tolnaftate | Potassium Iodide |
| Whitfields ointment | Natamycin |
| Nystatin | Selenium sulphide |
| Gentian Violet | Sodium Thiosulphate |
| Castellani's paint | Zinc pyrithione |

### Scabies

Definition

Scabies or 'the itch' is a specific contagious disease caused by the presence of Sarcoptes scabiei var hominis in the stratum corneum of the human skin. Historically, scabies is the most likely cause of 'the seventh year itch'. It is characterized by the formation of burrows and intense itching which is most troublesome when the infested person is in bed or in a warm room. Prolonged loss of sleep or the disturbed sleep produced by almost intolerable itching adversely affects the efficiency of the person. Besides itching, suffering in a case of scabies is mainly due to a secondary pyogenic infection of the scabies lesions, such as follicular pustules, boils, impetigo and even abscesses. It is uncommon for scabies to present in just one member of a family.

Agent

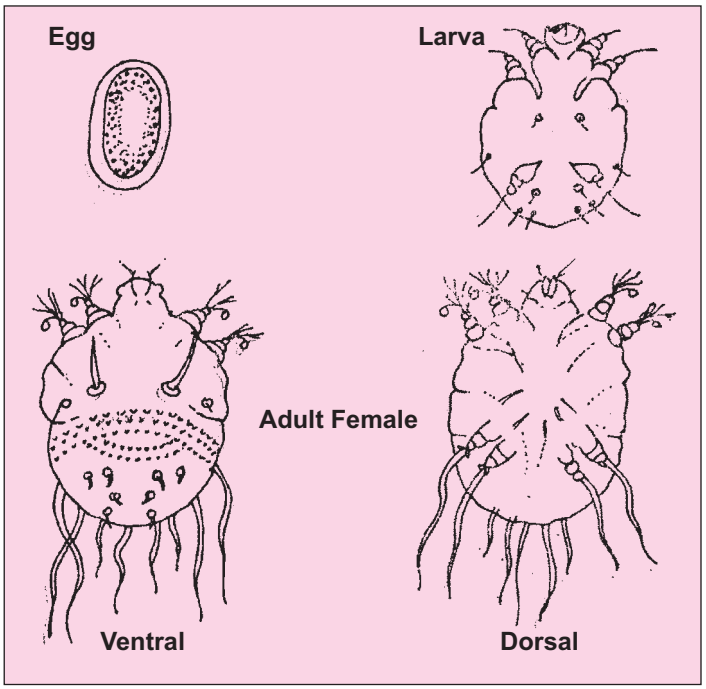
Sarcoptes scabiei is a very small mite just visible to a person with good eyesight. The female measures 0.4 mm. It is oval in shape and dirty white in colour (11). The male, which is rarely found, is about 2/3 the size of the female (Fig - 5).

Sarcoptes Scabiei (Itch Mite)

**Life Cycle**

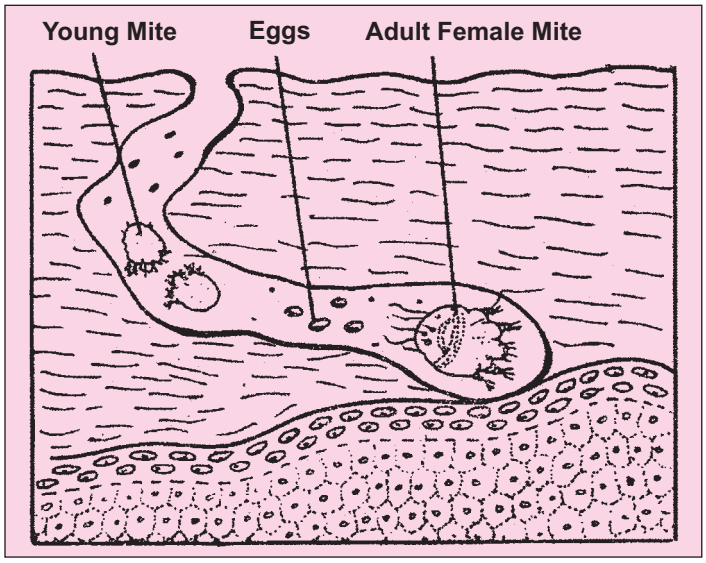
The female of the species is responsible for the symptoms. She burrows within the stratum corneum, and lays 2 to 3 eggs a day for 2 months. The eggs hatch out in 3 to 4 days. The larvae leave the burrow and take a temporary residence in the neighboring hair follicles. Here they moult into nymphs and then into immature adults in 6 to 8 days. The life cycle from egg to adult may take 10 -15 days. Adult mite lives for 1-2 months. The life cycle is passed solely in the skin. Successive generations

Fig - 5 : Sarcoptes Scabiei



cause further infestation (Fig - 6).

Fig - 6 : Itch mite in a burrow made in the skin



### Reservoir and Source

The itching is due to sensitization of the skin produced by absorbed products of the acarus metabolism and occurs after a month after infestation. Therefore, a person infested with scabies is unlikely to report sick and get treated up to a month. Thus he has ample opportunity and time to infect other individuals in the house, barrack or community, before the symptoms start.

### Mode of Transmission

Scabies spreads rapidly from one person to another through intimate contact, especially at night when the family sleeps huddled together in a one-room tenement. It is primarily a family disease. The older child brings it home from school or from the neighborhood and gives it to the younger ones and also to the parents. This is also one of the important infestations of residential schools. The infestation is brought in by children returning from home after vacation.

In Armed Forces barracks, it spreads from one person to another when there is overcrowding and poor personal hygiene. The infestation is generally brought in by new recruits and personnel returning from leave. The communal use of sports shirts and shorts and perhaps also towels used immediately after removal from an infested person may, although very rarely, cause transmission. It is not transmitted through blankets or if clothes are left aside for some time after removal by the infested person, since the female S scabei can survive only for 2 to 3 days away from the warm skin (12). When living on a person, an adult female mite can live up to a month. Pets do not transmit scabies as they become infested with a different kind of scabies mite.

### Diagnosis

The diagnosis is made by finding a mite in the burrow. The typical burrow is 5 to 10 mm long. In a fair skinned individual it may appear grey to black, due to dirt and the faeces of the mite within it, and is therefore easily mapped out. To extract the mite, a burrow should be selected in which it can be seen as a wax- like speck near the blind end of the burrow. A sterile needle is driven in the horny layer below the mite, keeping it almost parallel with the skin surface. The tip of the needle is then raised so that the burrow is opened out. The mite will be found clinging to the needle tip or on the under surface of the skin flap.

The sites of predilection for the burrow are : the sides and webs of the fingers, the front of the wrist, the points of the elbows, the anterior folds of the axillae, but not their hollows, the umbilical region, the prepuce, glans penis, scrotum and lower gluteal regions, in fact all areas of the skin which are soft and folded. There is almost always a large number of red, scratched patches on the sites of predilection. In troops, burrows may be rare on the fingers and, when short sleeves are worn, not so common on the wrists. When secondary infection occurs burrows often become obscure. If the diagnosis is not immediately apparent the man should be stripped and examined in good light when lesions in the other covered sites may be seen. In the lax tissues of the penis and scrotum a small papule is often seen, across the top of which, (unless it has been scratched or ulcerated) a typical burrow can often be detected. These lesions at times are mistaken for, and are occasionally complicated by, venereal sores. Similar but distinctly elongated papules are often found around the umbilicus and in axillary folds. The lesions on the gluteal folds and the elbows are often accompanied by secondary impetigo and such a condition should arouse suspicion of underlying scabies. On the presence of a rash with typical distribution, but without any typical burrows, one should not hesitate to diagnose scabies, particularly if there is a history of itching.

### Prevention and Control Measures

All ranks should be educated regarding the nature, mode of spread and precautions, especially, before going home on leave. Infestation rapidly spreads in overcrowded barracks unless relieved by proper spacing of beds. Interchange of clothing and sleeping huddled together should be forbidden. Personal hygiene among men in barracks should be maintained at a very high level. Bathing and laundering facilities in barracks should be adequate. Men usually report sick only when they suffer from intolerable itching, which usually takes place in a later stage after the infestation. Early detection followed by prompt and thorough treatment of the infested area is the most important control measures. All men returning from leave should be inspected from this point of view.

### Radical Treatment

The radical treatment of every case is one of the most important control measures. Mass treatment may be necessary in the case of widespread infestation especially in training and recruiting centers/ depots and other large units. The treatment of scabies is as follows:

(a) Apply a mite-killer cream like Permethrin (brand

Fig - 7 : Scabies

name: Elimite). These creams are applied from the neck down, left on overnight, then washed off. This application is usually repeated in seven days. An alternative treatment is application of an emulsion containing 25 percent benzyl benzoate to the entire body, except the head and face. In the case of babies, the head must also be treated. If it is thoroughly carried out, one application is usually adequate; 2nd application after an interval of 10 days may sometimes be needed. Applications on two consecutive days without washing may be occasionally required for individual cases of severe infestation. A bath is given after 24 h of the treatment. Cases showing complications of secondary bacterial infection and secondary eczematous changes should be admitted to hospital. The whole family or company or unit should be treated at the same time as a 'drill'.

(b) A single dose of oral Ivermectin is also safe and effective for most patients. The CDC recommends taking this drug at a dosage of 200 micrograms per kilogram body weight as a single dose, followed by a repeat dose two weeks later. It should be used with caution in elderly. Ivermectin and topical treatment provide a higher cure rate (8).

(c) Antihistamines, such as diphenhydramine can be useful in helping provide relief from itching.

(d) Because mites don't live long away from the body, it is not necessary to dry-clean the whole wardrobe, spray furniture and rugs, and so forth. No sterilisation of clothing is necessary; ordinary laundering in hot water is sufficient.

(e) Treat sexual contacts or relevant family members (who either have symptoms or have the kind of relationship that makes transmission likely).

Just as the itch of scabies takes a while to reach a crescendo, it takes a few days to subside after treatment. After a week or two, relief is dramatic. If that doesn't happen, the diagnosis of scabies must be questioned.

## Leprosy (Hansen's Disease)

### Definition

Leprosy is a chronic granulomatous immunological disorder caused by M. leprae primarily affecting the peripheral nerves and secondarily involving skin and mucosal membrane etc. It also affects eye, certain internal organs such as the kidney, liver, adrenal glands and in the male, testicles (4). The disease is clinically characterized by one or more of hypopigmented patches or partial/ total loss of sensation in the affected area or presence of thickened nerves or presence of acid fast bacilli in the skin smears.

### Importance of Leprosy

The seriousness of endemic leprosy in relation to other diseases cannot be evaluated solely by the number of patients or by the prevalence rates. The duration of the disease, the disabilities it causes, and the human and social consequences to the leprosy patients and their families, must also be taken into account. It is not only the long duration of the disease for lepromatous cases that is discouraging, but also the uncertainty of ultimate freedom from infection even after long periods of treatment. The anxiety may follow leprosy patients and their relatives throughout their lives and cast a permanent shadow over their families and their professional and social activities.

### Leprosy problem in World

The overall target for the global elimination of leprosy as a public health problem has been attained (13). The fall in prevalence rate is mainly due to an improvement in management of cases, very low rates of relapse, high cure rates, absence of drug resistance and shorter duration of treatment with MDT (14). The WHO estimates for 1994 were 2.4 million cases, a reduction of more than three fourths as compared to the estimated 10.6 million cases in 1976 (15). As of now, there is continued decline and in beginning of 2006, the number of leprosy cases in the world was around 0.2 million and global prevalence rate of leprosy was below 1 per 10,000 population. About 2.9 lakh cases are newly detected in 2005 which is 27% fall as compared to 2004. No drug resistance to MDT was reported (16). At present the highest burden is concentrated in 6 countries (India, Brazil, Indonesia, DRC, Bangladesh and Nepal ).

### Leprosy Problem in India

In last few years there is marked reduction in cases of Leprosy. As on 31$^{st}$ Mar 2006 the number of reported cases came down to 95150 giving prevalence rate of 0.84 cases per 10,000 population. India achieved elimination level of less than one case per 10,000 population by 31$^{st}$ Dec 2005. The disease shows high prevalence in 7 states (1-2 per 10000 population) viz. UP, Chattisgarh, Gujarat, Jharkand, Orissa, West Bengal and Delhi. These states contribute 67% of the total case load (17). Now the focus

of attention under national Leprosy Control Programme has shifted from endemic states to high priority districts and blocks. A Focused Leprosy Elimination Plan (FLEP) was carried out in 2005 targeting high endemic distts and blocks which included Block Leprosy Awareness campaign (BLAC). The hospital admission rate in Armed Forces is about 0.3 per 1000 (18).

### Agent

In 1873, Gerhard Armauer Hansen, a Norwegian scientist demonstrated these bacilli in leprosy lesions. Later they are called Mycobacterium leprae. The bacilli are acid fast and with ZN stain appear pink/red; and resemble the tubercle bacilli morphologically. The bacilli may be arranged in small or large clumps or bundles (called Globi) or may occur singly. They are less toxic and less pathogenic than many other organisms and their generation time is around 13-14 days. Thus the incubation period of the disease is much longer than that of most other infectious diseases. Other than man, it has multiplied in the footpads of mice, in tissues of immunosuppressed rodents and in the nine banded armadillo.

Reservoir

Man is the only known reservoir. Though natural infection has been reported in Armadillo and certain primates but it is not epidemiologically important. "Active or Open" cases who are shedding the organisms mainly through nasal discharges more so in Lepromatous cases are the chief source of infection.

Mode of Transmission

The exact mechanism of transmission is still unclear (19).

**Exit of M. leprae**

The major exit points of M. Leprae from untreated lepromatous patients are the nose, mouth, and in some cases abraded skin lesions.

**Entry of M. leprae**

Most likely sites of entry are skin and nasal mucosa. The bacilli from nasal discharges of infectious patients gain entrance through the skin or respiratory tract. House hold contact is important. Untreated lepromatous patients act as 'source case' or 'pool of infection' in the community.

The different modes of transmission are

(a) Droplet infection
  (i) Respiratory tract
  (ii) Aerosols containing bacilli
(b) Contact transmission
  (i) Direct (skin-to-skin)
  (ii) Indirect (soil and fomites)
(c) Other routes
  (i) Breast milk
  (ii) Tattooing needles

### Host

Infection can take place at any age to any sex depending upon the opportunities for exposure in endemic areas. In areas where leprosy is rare, the first contact may not take place early in life and thus the disease may appear late. However, a high incidence of infection among children means the disease is active and spreading. Incidence rates are highest in 10 to 20 yrs of age gp and then fall. In general, leprosy is more commonly seen in men then women due to their greater mobility and increased opportunity to contact the infection. Only a few people exposed to infection develop clinical signs of leprosy, although immunological conversion takes place in large proportions of contacts. It is now recognized that the effective immune response in leprosy is a cell-mediated one. In lepromatous leprosy there is a complete breakdown in the cell mediated immune response.

Incubation Period

(a) Long incubation period
(b) Average :3-5 years
(c) Tuberculoid type has shorter incubation period

Communicability

A patient is infective, if morphologically solid-staining (viable) bacilli are demonstrable.

### Classification of Leprosy

Leprosy is a disease of numerous classifications. This is probably a reflection of great variation in individual host resistance to the disease. These classifications are based on clinical, bacteriological, immunological and histological status of patients. The various classification in use are:

(a) Indian Classification
(b) Madrid classification
(c) Ridley and Jopling classification.
(d) WHO operational classification

The Indian classification is the official classification of the Indian Leprosy Association and most widely used in India. It is clinico-bacterial classification and described as under:-

Indian Classification (20) is as follows :

**(a) Indeterminate type**

Early cases with one or two vague hypopigmented macules and with and without sensory impairment. Lesions are bacteriologically negative.

**(b) Tuberculoid type:**

Cases with one or two well defined lesions which may be flat or raised, hypopigmented or erythematous and are anaesthetic.

**(c) Borderline type:**

Cases with four or more lesions which may be flat or raised, well or ill defined, hypopigmented or erythematous and shows sensory impairment or loss. Bacteriological positivity is variable and if left untreated can progress to lepromatous type.

**(d) Lepromatous type:**

Cases with diffuse infiltration or numerous flat or raised lesions, symmetrical without any sensory loss.

**(e) Pure neuritic type**

Cases show nerve involvement but do not have any lesion in skin. Cases are bacteriologically negative.

In 1987, WHO study group endorsed that all the patients showing smears positivity should be classified as having multibacillary leprosy for the purpose of MDT treatment. Same study group in 1993 gave clinical classification into two groups

(a) Paucibacillary leprosy (1-5 skin lesions).

(b) Multibacillary leprosy (more than 5 skin lesions)

**Diagnosis**

The following features assist in the diagnosis of the disease:-

(a) Clinical features.

(i) Skin lesions. (Infiltration, macules, papules, tubercles and nodules)

(ii) Paraesthesia. History of numbness and loss of hot and cold sensations in the extremities.

(iii) Thickening of nerve trunks

(iv) Anhidrosis.

(b) Histamine test

0.1 ml of 1/1000 solution of histamine chlorhydrate or phosphate is injected intradermally into the hypopigmented patches. In normal persons it gives rise to wheal surrounded by an erythematous flare (Lewis triple response) within a few minutes. In cases of leprosy where nerve supply is destroyed this response is lost.

(c) Skin smears

The skin smears, nasal smears and nasal scrapings are collected, fixed and stained with ZN method. This is used to distinguish between paucibacillary and multibacillary leprosy. A negative result, which is usual in indeterminate and tuberculoid cases, does not eliminate the diagnosis of leprosy. In certain cases histopathological examination may be necessary.

(d) Immunological Tests.

Lepromin Test

The lepromin test, also called Mitsuda reaction, was first described by the Japanese worker, K Mitsuda in 1916. It is an intradermal immunological test employed to detect CMI and classify the type of disease and to find out the prognosis in a given case. Lepromin is a suspension of lepromatous tissue rich in M.leprae in an isotonic solution of sodium chlorides sterilized by heating. The test is performed by injecting intradermally 0.1 ml of lepromin or lepra antigen in the forearm of a patient and the reaction is examined at the end of 48 hours and 21 days. The test results in 2 types of reaction.

**(a) Early reaction (Fernandez reaction)**

If there is erythema and induration measuring more than 10 mm in diameter at the end of 48 hours at the site of injection it is considered positive.

**(b) Delayed reaction**

At the end of 21 days, if there is a nodule more than 5 mm in diameter at the site of inoculation, it is said to be positive. This delayed reaction is also known as the classical or Mitsuda reaction. In strongly positive individuals there may be ulceration.

The early positive reaction shows that person has been previously sensitized by exposure to leprosy bacilli. The test is often positive in healthy persons and in those suffering from tuberculoid form of leprosy, and positivity gets weaker as we pass to lepromatous form of disease indicating a failure of CMI. The lepromin test is not a diagnostic test, its value lies in estimating prognosis, positive test indicating good prognosis.

(e) Other tests are :

(a) Lymphocyte Transformation Test (LTT)

(b) Leucocyte Migration Inhibition Test (LMIT)

(c) Fluorescent Leprosy Antibody Absorption Test (FLA-ABS test)

(d) ELISA

**Reactions in Leprosy**

Reactions are acute exacerbations of disease either due to alteration in CMI status (type 1 reaction) or immune complexes (type II or ENL reaction). Clinically there is increase in number and infiltration of lesions, neuritis, associated with constitutional symptoms and involvement of various organs like eyes, bones, testis and viscera. Reactions are best managed in hospital, whereby along with specific antileprosy treatment, anti-inflammatory drugs, steroids or antireactional drugs (Clofazimine, thalidomide,) may be administered (21).

**Prevention and Control**

(a) Problem estimation and early diagnosis

A quick random sample survey is done to collect base line data in the community. Contact surveillance of households with a lepromatous case is recommended for a minimum period of 10 years after case is declared bacteriologically negative, and for 5 years in households with a non-lepromatous case from the time of diagnosis of the index case. Mass surveys are expensive but repeated annual examinations of school children yield better results at relatively low cost (22, 23).

(b) Chemotherapy

WHO study group has recommended multi-drug therapy for both multi- bacillary and pauci bacillary leprosy (24). However, all cases in Armed Forces should be referred to Dermatologist immediately on suspicion. Any case of Leprosy is unfit for recruitment.

**Objectives of treatment**

(a) To interrupt transmission of infection in the

Table - 5 : Principles of Leprosy Treatment (25)

- Stop the infection with chemotherapy.
- Treat infections
- Educate the patient about leprosy.
- Prevent disability.
- Support the patient socially and psychologically.

community by sterilizing infectious patients as rapidly as possible with bactericidal drugs.

(b) To ensure early detection and treatment of cases, to prevent deformities

(c) To prevent drug resistance

(d) Curtailing the duration of treatment

**Recommended Regimens**

**(a) Multibacillary leprosy**

As per the recent recommendations, following groups of patients are to be given MDT :-

(a) All smear positive cases

(b) Skin lesions more than five in number

(c) More than one nerve trunk thickening

(d) All cases of relapse/reactivation

(e) All cases who have been treated with Dapsone monotherapy earlier.

**(b) Paucibacillary leprosy:**

MDT is not contraindicated in patients with HIV infection.

| | | |
|---|---|---|
| Rifampicin | : | 600mg once monthly, supervised |
| Dapsone | : | 100mg daily, self administered |
| Clofazimine | : | 300mg once monthly, supervised and 50mg daily, self administered. |

**Duration of treatment**

| | | |
|---|---|---|
| Rifampicin | : | 600mg once a month for 6 months supervised |
| Dapsone | : | 100mg daily for 6 months self |

**Multibacillary leprosy :** for 12 months, can be extended to 18 months and continued where possible upto smear negativity. Highly bacilliferous LL/BL patients may need 2-3 years or more of MDT for achieving bacteriological negativity.

**Paucibacillary leprosy :** for 6 months.

Follow-up of cases

Follow up of patients after completion of treatment is an important part of MDT. For paucibacillary cases follow up for at least once a year for 2 yrs after completion of treatment and for multibacillary cases at least once a year for 5 yrs.

BCG vaccination

Mycobacterium W vaccine has been released for human use for immuno modulation therapy.

Rehabilitation

It is an important aspect of leprosy control. It means the medical, surgical, social, educational, and vocational restoration as far as possible of treated patients to normal activity so that they resume their place in the home, in society and industry. Early treatment helps in disability limitation.

Health education

The education should be directed towards general public and to patients helping them develop attitudes and behavior by their own actions and efforts and seeking professional help whenever required. Early recognition of symptoms, prompt diagnosis, health seeking behavior, personal care, treatment adherence and rehabilitation are important aspects of health education.

In the Armed Forces, all suspected cases of leprosy are transferred to the nearest leprosy centres which are Command Hospital (Southern Command) Pune, MH Agra, Base Hospital Barrackpore, Delhi, Lucknow and MH Ramgarh. All cases are given institutional treatment. Family members of personnel suffering from leprosy are authorized only out-door treatment. Medical Officers are also advised to refer to Army Orders 150 of 1975 and 36 of 1987.

Table - 6 : Key Points - Hansen's Disease (Leprosy)

- Leprosy is a chronic granulomatous infection caused by Mycobacterium leprae, affecting primarily skin and peripheral nerves.
- Mode of transmission of leprosy is still not proven, but current evidence favors respiratory transmission.
- The diagnosis of leprosy is usually made based on skin lesions, cutaneous anesthesia, and enlarged superficial nerves and by demonstrating leprosy bacilli in the skin.
- Patients with tuberculoid leprosy have a high degree of immunity against M. leprae and have few skin lesions and few organisms in their skin.
- Patients with lepromatous leprosy have low immunity against M. leprae and have many skin

## Physical agents

### Prickly Heat (Miliaria)

This is an erythematous eruption resulting from blocking of the sweat pores by horny plugs of the excoriated cutaneous debris and a dried decomposition product of sweat, leading to a rupture of the occluded sweat ducts with subsequent extravasation of sweat into the epidermis or less commonly into the dermis. This occurs by excessive sweating in a hot humid climate aided by the removal of the natural cutaneous lipoid covering by frequent washing with soap and a maceration of the epidermis due to friction by rough clothing. Men from the hills are specially liable and acclimatized individuals suffer less. Prickly heat is not a grave matter but is sufficiently distressing so as to interfere with efficient occupational pursuits because of the incessant burning itch. On the other hand, it may be so extensive as to lead to a relative anhidrosis and precipitate heat stroke (26, 27).

**It is of following types** (28)

**(a) Miliaria Crystallina**

The blockage of sweat pores leads to either accumulation of fluid under the stratum corneum in clear colored vesicles.

**(b) Miliaria Rubra**

Leakage of sweat within the epidermis and resultant superficial papulovesicular eruption.

**(c) Miliaria Pustulosa**

Leakage of sweat within the epidermis and resultant papulopustular eruption.

**(d) Miliaria Profunda**

The blockage of pores lead to bursting of duct in upper dermis and resultant dermal inflammation seen as persistent deep seated papules.

Clinical Features

Clinically prickly heat appears as erythematous vesicles mostly on the sides of the trunk, abdomen, anticubital and popliteal fossae and sites such as the belt line and the areas where clothing rubs. The face, palms and soles escape. The lesions are usually bilateral. The eruption waxes and wanes in close correlation with the heat load. Vigorous exercise may also cause the rash. Secondary infection may give rise to furunculosis and bullous impetigo.

Prophylaxis

It is achieved by rapid evaporation of sweat and avoidance of friction by clothing. Any unnecessary exercise or work which promotes sweating should be avoided. Too much starch on clothing promotes sweating and friction, and should be avoided. A bare body suffers less from prickly heat. Ointments are occlusive and should be avoided. Excessive bathing with use of harsh, irritant agents, too much soap and friction by a rough towel are all contributory factors which should be avoided. However after activity leading to increased sweating, bathing without use of soap is helpful.

The treatment in the MI Room focuses on measures which inhibit sweating. At present the prickly heat powder containing 1 part each of sulphur precipitatum, camphor and pulverised boric acid, 2 parts of zinc oxide and 3 parts of starch powder is useful.

## Contact Dermatoses

Contact dermatitis refers to cutaneous inflammation resulting from the interaction of an external agent and the skin. These reactions occur through one of two mechanisms: a nonimmunologic irritant contact dermatitis (ICD) or an immunologic allergic contact dermatitis (ACD). ICD accounts for 80% and ACD is responsible for 20% of contact dermatitis. While over 2800 substances have been identified as contact allergens, almost any substance can act as an irritant (29). A serviceman may come in contact with potentially dangerous substances or he may be particularly sensitive to some substances which are used in the modern weaponry and equipment. The contact dermatoses are recognized by the following points:-

(a) Eruption is localized to the point of contact.

(b) Remission on removal from the source and exacerbation on re-exposure occurs.

(c) Distribution and correlation exist with the nature of duties.

(d) Similarity of results of patch testing with a suspected agent is diagnostic (this should not be attempted when the dermatoses is in an acute stage).

### Precipitating factors

Some materials in their natural state or in the form of dust, fume, gas or radiation are particularly harmful owing to the following properties:-

(a) Physical properties

Physical properties causing friction as by abrasives, foreign body reaction by piercing minute slivers or particles and local effects by heat, cold, moisture or radiation.

(b) Chemical properties

Chemical properties cause contact dermatitis by a primary irritant or by sensitization. The primary irritant reaction is due to interaction between the acidic or alkaline substances and skin proteins causing desiccation, keratolysis, protein precipitation or oxidation.

(c) Biological agents

Biological agents like anthrax, fungus and lice may be associated with the occupation of servicemen.

Table - 7 : Key points - Contact Dermatitis (8)

- Eighty percent of contact dermatitis reactions are due to irritation and 20% are due to allergic causes.
- Location of the dermatitis can help identify the causative agent.
- Patch testing is the only way to distinguish between allergic and irritant contact dermatitis.
- ACD is frequently patchy and can spread beyond the site of maximal contact.
- Allergen and irritant avoidance, moisturisation, and topical therapy are the keys to therapy.

## Psychocutaneous Disorders

Psychocutaneous diseases can be classified into three major categories:

(a) Primary psychiatric disorders with dermatologic manifestations

(b) Primary dermatologic disorders that result in secondary psychiatric problems

(c) Primary dermatologic disorders exacerbated by stress

### Mechanism

The mechanisms by which psychocutaneous disorders are brought about are :

(a) Increased physiological vasomotor responses.
(b) Hyperhidrosis and increased sebaceous activity changing the metabolism of the skin.
(c) Certain skin disorders termed as 'reaction-pattern disorders' are precipitated while certain disorders are aggravated by psychic stresses. Self infliction and malingering to obtain physical well-being and monetary gains may also be contributory factors.

**Common Psychocutaneous Disorders**

(a) Hyperhidrosis of palms and soles
(b) Trichotillomania
(c) Alopecia
(d) Vitiligo
(e) Neurodermatitis or lichen simplex, atopic dermatitis
(f) Pruritis
(g) Urticaria
(h) Nail dystrophies
(j) Aggravated by psychic factors :
  (i) Lichen planus
  (ii) Psoriasis
  (iii) Seborrhoeic dermatitis
  (iv) Acne vulgaris

**Diagnosis**

Although a skin disorder may be a manifestation of anxiety the patient may be completely unaware of the tensions unless deeply probed. A casual question, "Do you have any worries?" will be answered in the negative and any amateurish, attempt to unravel anxieties will be unsuccessful and harmful. Psychocutaneous disorders present a clinical picture showing a bizarre pattern, the diagnosis of which is not obvious. A disturbing experience before the onset, multiplicity of complaints, personal and family history of mental abnormality and a history of childhood experiences will aid in the diagnosis.

**Prevention**

It is by elimination of emotionally unstable individuals or those with a familial background of psychic disorders at the time of recruitment. The life in the Armed Forces presents far too many occasions for stressful situations with its resulting psychosomatic disorders. Man management which reduces strains and stresses, mental anxiety, oppressed emotions, boredom and monotony and promotes relaxation, is necessary to minimize such conditions.

## Trachoma

**Definition**

It is a chronic communicable kerato-conjunctivitis of insidious or abrupt onset. It is characterized by conjunctival inflammation with lymphoid follicles and papillary hyperplasia associated with vascular invasion of the cornea (pannus) and in its later stages by conjunctival cicatrization which may lead to gross deformity of the eyelids, progressive visual disability and blindness (30).

Table - 8 : Key points - Psychocutaneous Disorders (8)

- Forty percent of all dermatologic patients have associated psychologic morbidity
- Patients with delusions of parasitosis have monosymptomatic hypochondrial psychosis; the remainder of their mental functions are typically normal.
- Pimozide is the treatment of choice for delusions of parasitosis.
- Trichotillomania is most common in young girls and, in most cases, has an excellent prognosis.
- Adults who develop trichotillomania are more likely

This condition may be associated with bacterial infection.

**Epidemiology**

Geographical Distribution

Trachoma is a major preventable cause of blindness in developing countries. About 6 million people currently suffer from blindness due to trachoma in Africa and Asia. The incidence and prevalence of trachoma has shown a significant decrease in many endemic countries of SEAR during the past few decades. The decrease is due to improved sanitation, water, housing and implementation of control measures but it still remains a problem in parts of Myanmar, western region of Nepal and in few rural areas in India (31).

Incidence

Mild and quiescent trachoma is no longer a health problem in the Armed Forces. It is no longer a common cause of rejection during recruitment.

Agent

The infectious agent is chlamydia (Bedsonia) trachomatis which includes several antigenic types.

**Reservoir**

Man is the only reservoir. The eyes of infected individuals (especially children from 1 to 15 years of age) are the sources of infection.

**Mode of Transmission**

Transmission occurs by close contacts, hands, towels, handkerchief, pillow cases, flies and dust. A dry and hot climate with dust, dirt squalor and crowding in houses, dormitories, hostels, barracks, swimming pools and general unhygienic conditions leading to fly breeding and midget breeding favour the spread of disease. The use of common family vial of eye cosmetics, such as 'surma' and 'kajal' or towels and wipe clothes is a potent cause of spread in families and close institutions such as schools, hostels and so on. One can, thus, summarize the main environmental risk factors which are involved in the transmission of trachoma as six Ds (dry, dusty, dirty, dung, discharge and density (over- crowding) or five Fs (flies, faeces, face (eyes) fingers and fomites) (32).

Host

No person is immune. In endemic areas children have

active disease more frequently than adults. The severity of the disease often is related to environmental conditions. Lack of water and exposure to dry winds, dust and fine sand may contribute to the severity of the disease.

**Incubation Period**

It is 5 to 12 days.

**Communicability Period**

This is very prolonged and starts before the appearance of the follicles and continues until cicatrization has occurred.

**Clinical features**

Trachoma is classified as Blinding and non blinding. Trachoma inflammation may undergo spontaneous resolution or may progress to conjunctival scarring which can cause inward deviation of eyelashes (trichiasis) or of the lid margin (entropion). The abrasion of the cornea by eyelashes frequently results in corneal ulceration, followed by scarring and visual loss.

**Prevention and Control**

(a) Chemotherapy

Mass treatment done when prevalence is more than 5% of severe or moderate trachoma cases in children under 10 years is seen. With prevalence less than this, selective treatment is done. Trachoma usually responds to modern drugs (sulphacetamide, aureomycin, 1% tetracycline, chloromycetin, erythromycin). Field trials on trachoma control have shown that the "intermittent schedule" of treatment i.e. local application of one of the broad spectrum antibiotics twice a day for 5 days in a month at monthly intervals for a period of at least 6 months, is satisfactory.

(b) Surgical correction

Individuals with lid deformities (trichiasis, entropion) will require surgical correction to avoid complications like blindness.

(c) Health Education

Long term antibiotic treatment must be carried out by the affected population itself. This is important to get co-operation of people in maintaining personal and community hygiene. It has been shown that once a member of family is infected others are invariably affected. Therefore, health education is of paramount importance and will require permanent change in the behaviour patterns and in environmental factors.

(d) Hygiene and Sanitation

Ultimately, only environmental improvements can reduce transmission and reinfection. These measures comprise control of flies, safe water supply and improvement in personal and general hygiene.

Lt Col Sunil Agarwal

# Sexually Transmitted Infections (STI)

## Introduction

STI are a group of contagious diseases transmitted predominantly by sexual contact and caused by wide range of bacterial/viral, protozoal, fungal and ectoparasites. During the past two decades, STD's have undergone a dramatic transformation like.

(a) Greatly reduced rates of the STIs due to effective public health programs and changing sexual behaviour.

(b) Changing patterns of STI rates due to HIV/AIDS calling for intensified AIDS-STI control efforts.

(c) The growing evidence that certain STI's function as risk factor for transmission of HIV infection.

Attention is now given not only to specific diseases but also to clinical syndromes associated with STI's. Most of the recently recognised STI's are now referred to as second generation STI's. AIDS is the most recently recognized (33).

## Epidemiological Pattern of STD (34)

Global

True incidence of STI's is not known because of stigma involved but the trend in gonorrhoea and primary syphilis is on the increase. The matter of concern is emergence of antimicrobial resistance agents of STI. Second generation STIs are tending to replace the classical bacterial diseases (syphilis, gonorrhoea, chancroid). Minimal estimates of new cases for major STDs are

| | | |
|---|---|---|
| Gonorrhoea | : | 62 million/yr |
| Genital chlamydial infection | : | 92 million/yr |
| Syphilis | : | 12 million/yr |
| Chancroid | : | 07 million/yr |
| Genital herpes | : | 20 million/yr |
| Genital human papilloma infection | : | 30 million/yr |

On an average 900,000 people are believed to be infected each day.

India

In India the yearly incidence of STI's is 4-5% which accounts for 40 million cases per year.

(a) Syphilis: Prevalence of 1.4 2.4% in serological surveys.

(b) Gonorrhoea: More widely prevalent than syphilis, 80% of the infected women are asymptomatic carrier.

(c) Chancroid: widely prevalent in India.

(d) LGV: Its more prevalent in southern states of Tamil Nadu, AP, Maharashtra and Karnataka than in northern states. Greater prevalence in coastal areas is found. Information on other STI's are not available because of poor reporting system.

## Importance of STDs in the Armed Forces

The incidence of sexually transmitted disease in the Indian Army has always been low and has now dropped so low that it cannot be considered as of any real medical significance. However, the underlying factors which cause increased incidence in a unit, points directly or indirectly to bad discipline low moral and lack of man-management. These factors also have considerable importance in determining the efficiency of unit administration and fighting reliability (36).

The rates increased progressively during war years and remained high till 1948. From 1949 onwards the incidence of STDs declined and from 1962 to 1972 when the Armed Forces expanded and were actively deployed during the national emergency the rates marginally increased. Thereafter it has shown decline and is stabilized. Even the WHO has felt that members of Armed Forces form a high risk group for STDs.

**Classification of sexually transmitted agents**

| Bacterial | Ectoparasites |
|---|---|
| Neisseria gonorrhoea | Sarcoptes scabiei |
| Chlamydia trachomatis | Phthirus pubis |
| Treponema pallidum | Viral agents |
| Haemophilus ducreyi | Human(alpha) herpes virus1 and 2 |
| Mycoplasma hominis | Human(beta)herpes virus 5 |
| Ureaplasma urealyticum | Hepatitis virus B |
| Calymmatobacterium | Human papilloma virus |
| Granulomatis | Molluscum contagiosum |
| Shigella | HIV |
| Campylobacter | Protozoal agents |
| Group B Streptococcus | Entamoeba histolytica |
| Bacterial vaginosis related Organism | Giardia lamblia |
| Fungal agents | Trichomonas vaginalis |
| Candida albicans | |

## Syndromic Management of STI/RTI

Many STIs/RTIs can be identified and treated on the basis of characteristic symptoms and signs. Symptoms and signs can be grouped together into Syndromes, upper respiratory infection, gastroenteritis and vaginal discharge are examples of common syndromes. It is often difficult to know exactly what organism is causing the syndrome, and treatment may need to cover several possible infections. Syndromic management refers to the approach of treating STI/RTI symptoms and signs based on the organisms most commonly responsible for each syndrome. Laboratory tests require resources, add to the

cost of treatment, may require clients to make extra visits to the clinic and almost always result in delays in treatment. For these reasons, syndromic management guidelines are widely used for syndromes such as lower abdominal pain, urethral discharge and genital ulcer, even in developed countries with advanced laboratory facilities.(37)

WHO has developed simple flowcharts (also called algorithms) to guide health care providers in using the syndromic approach to manage syndromes.

Syndromic Approach

Most STD patients consult a doctor or health care provider with complaints related to one of the following syndromes:

(a) Urethral discharge
(b) Vaginal discharge
(c) Genital ulcer
(d) Inguinal swelling

Table - 1 : Using the Syndromic Approach (38)

| | Syndrome | Possible STI/RTI |
|---|---|---|
| Men | Urethral discharge | Chlamydia, gonorrhea |
| Women | Lower abdominal pain | Chlamydia, gonorrhea |
| | Vaginal discharge | Chlamydia, other bacteria, bacterial vaginosis, candidiasis, trichomonas |

(e) Lower abdominal pain

Table - 2 : How to avoid Sexually Transmitted Diseases

| Avoid high-risk behaviors and practice safe sex |
|---|
| ✎ Though not necessarily practical or desirable, abstinence is the only way to completely prevent STDs. |
| ✎ Avoid sex with many different partners. The less sexual partners a person has, the lower the risk of infection. |
| ✎ Sexually transmitted diseases can be avoided to a large extent by practicing safe sex (eg using |

These syndromes apply to possible STIs/RTIs as in Table - 1

## Syphilis

### Agent

The causal organism is *Treponema pallidum*. In vivo replication time, relative to most bacteria is about 30 hrs. The organism is 6 to 15 microns in length to 0.15 micron wide.

Mode of Transmission

Syphillis is usually acquired by sexual contact. Infants acquire congenital infection by transplacental transmission of *T. pallidum*.

### Stages of Syphillis

Both congenital and acquired syphilis are divided into early and late stages. Early acquired syphilis is further subdivided into an incubation period, primary, secondary and early latent stages. The following types and stages are recognized :-

Acquired Syphilis (7)

**(a) Early Syphilis (diagnosed in first two years of infection)**
(i) Primary stage
(ii) Secondary stage
(iii) Recurrent stage
(iv) Early latent stage

**(b) Late Syphilis (diagnosed after the second year of infection)**
(i) Late latent stage
(ii) Late Benign stage (gumma)
(iii) Cardiovascular Syphilis
(iv) Central Nervous System Syphilis

Congenital Syphilis

(Since *T. pallidum* is introduced directly into the fetal circulation, there is no primary stage as seen in acquired syphilis)

**(a) Early Phase (within the first two years of life)**

Analogous to the secondary stage of acquired syphilis

**(b) Late Phase (after two yrs of age)**

Analogous to the tertiary stage of acquired syphilis

**(c) Stigmata-scars and deformities resulting from early or late lesions which have healed.**

### Pathogenesis

*T. pallidum* enters the body through a break in squamous or columnar epithelium during sexual contact. The incubation period has a mean of 21 days with extremes of 10 to 90 days. Variation in expression of disease reflect differences in the immune status of the hosts.

### Clinical Features

Primary Syphillis

The first clinical manifestation is usually a local lesion at the site of entry. The lesion starts as dull red macule, which rapidly becomes papular and then ulcerate. A small, clean, painless, hard ulcer (Hunterian chancre) appears on the site. The early chancre has a clear red base, but later covers with a gray slough. Untreated, a chancre will persist for 3 to 6 wks and then heal. Regional lymphadenopathy develops within a week and the nodes are painless, nontender, small to moderate in size, rubbery and nonsuppurative.

Secondry Syphillis

*T. pallidum* disseminate widely throughout the body. After 3-6 weeks, the disease is seen to be systemic. The more common symptoms include sore throat, malaise,

headache, weight loss, fever, musculoskeletol pains. A rash of early secondary stage appears on the back, chest, abdomen, arms and thighs, and also on the mucous patches in the mouth. Rash characteristically includes the palms and the soles. Rashes can be of follicular, annular or papular type. Papular rashes may become large and raised and may resemble viral warts, but they are characteristically broad and flat so called Condylomata lata. Generalised lympadenopathy is common with moderately enlarged nodes rubbery, discrete and nontender. Even the rash may subside with a little treatment but infective relapses occur with varying intervals of latent periods.

Tertiary Syphilis

Involvement of other systems occurs in 10 percent of cases or less. After3 to 4 years, the benign manifestations as gumma in bones, deeper parts of the skin, muscles or liver make their appearance. After about 5-10 years or upto even 20 years the vital organs like the brain, heart, nerves and big arteries are affected and the severe signs of cardiovascular and neuro-syphilis may appear. The predominant features of cardiac syphilis are aortic regurgitation, aortic aneurysm, arrhythmias and angina. The neurosyphilis can present in a variety of ways meningovascular syphilis, tabes dorsalis and general paresis.

**The classification of Neurosyphillis is (39) :**

(a) Asyptomatic neurosyphillis
(b) Meningeal neurosyphillis
(c) Meningovascular neurosyphillis
(d) Parenchymatous neurosyphillis
(e) Gummatous neurosyphillis

**HIV infection and Neurosyphillis**

Conventional syphilis treatment often fails in HIV infected patients. Moreover HIV patients demonstrate accelerated progression to early neurosyphilis. As a result of AIDS epidemic neurosyphilis is becoming more common in young adults.

Spontaneous cure may occur at any time after the late secondary manifestations subside or this latent phase may prolong throughout life. The disease is almost completely curable in the early stages but becomes progressively resistant as it advances. Infected man infects other women perhaps including his own wife during infective relapses. The disease is transmitted by the infected mother to the foetus after the 4$^{th}$ intrauterine month. Some of them are still born; others die soon after birth. Those who survive may become crippled, blind, deaf and mentally subnormal called congenital syphilis.

**Diagnosis**

The diagnosis of the primary hard chancre is confirmed by finding of *T. pallidum* on the dark-ground examination of the discharge from the ulcer. In the late primary or further stages and in congenital infection it is confirmed by the WR, Kahn or VDRL reaction. Skin biopsy may be quiet helpful. Other tests are FTA-ABS (Fluorescent antibody absorption test, MHA-TP (Microhemagglutination assay for antibodies to *T.pallidum*) and HATTS (Hemagglutination treponemal test for syphilis).

**Treatment**

(a) Early Syphilis

**(i) In HIV Negative patients**

- Procaine Penicillin 8 lac IU IM OD after test dose for 10 days or Bezathine Penicillin 2.4 MU IM after test dose divided half in each buttock.

**(ii) In HIV Positive patients**

- Procaine Penicillin 24 lac IU IM OD after test dose for 14 days or Crystalline Penicillin 30 lac QID IV for 10 days after test dose or Crystalline Penicillin 30 lac QID IV for 10 days after test dose.

(b) Late Syphilis

**(i) In HIV Negative patients**

- Procaine Penicillin 8 lac IU IM OD after test dose for 14-21days or crystalline Penicillin 10 lac IU IV QID for 14 days.

**(ii) In HIV Positive patients**

Table - 3 : Key points - Syphilis

- Syphilis is sexually transmitted disease that can also be transmitted from the mother to the fetus.
- Syphilis is produced by the spirochete Treponema pallidum, ssp. Pallidum
- Acquired syphilis is sexually transmitted and if untreated passes through primary, secondry and may into tertiary stages.
- The first two years of infection are termed early syphilis (infectious) and the later part called late syphilis (non infectious)
- Secondry syphilis is protean in its clinical appearance and can be difficult to recognise.
- Patients with syphilis have an increased incidence of other sexually transmitted infections such as gonorrhea, HIV infection, and veneral warts.

- Procaine Penicillin 24 lac IU IM OD after test dose for 14 days or Crystalline Penicillin 20-40 lac IU 4 hrly IV for 14 days after test dose.

## Gonorrhoea

This is the commonest cause of urethritis in India. Gonorrhoea is caused by Neisseria gonorrhoeae, Gram-negative intracellular diplococcus, a bacteria that grows and multiplies quickly in moist, warm areas of the body such as the cervix, urethra, mouth, or rectum. In women, the cervix is the most common site of infection. However, the disease can also spread to the uterus (womb) and fallopian tubes, causing pelvic inflammatory disease leading to infertility. Gonorrhoea is most commonly

spread during genital contact, but can also be passed from the genitals of one partner to the throat of the other during oral sex. Gonorrhoea of the rectum can occur in people who practice anal intercourse. In pregnant women, gonorrhoea can be passed from an infected woman to her newborn infant during delivery if left untreated.

Although transmission from males to females is easier, in females the infection is often mild, and many women who are infected have no visible symptoms of the disease. Most patients are males only. If symptoms of gonorrhoea develop, they usually appear within 2 to 10 days after

| Symptoms in women (40) |
|---|
| Painful, burning sensation when urinating |
| Yellowish or bloody discharge from the vagina |
| Bleeding between periods |

sexual contact with an infected partner, although a small percentage of patients may be infected for several months

| Symptoms in men |
|---|
| Burning sensation during urination |
| Yellowish-white discharge from the penis that usually stains the undergarments. |

without showing symptoms.

Men are more likely to show symptoms than women. The symptoms in men include:

A diagnosis is made through detection of bacteria in samples taken from the urethra, cervix, throat or rectum. The condition is treated with antibiotics, and treatment should also be given to the patient's partner. As with Chlamydia, further testing is recommended once treatment has ended to check whether the infection has cleared. The complications of Gonorrhoea are posterior urethritis, urethral stricture, cystitis, prostatitis, seminal vesiculitis, epididymo-orchitis and urethral fistulae (watercan Perineum).

It is generally more cost effective to treat presumptive chlamydial infection also in all persons with gonorrhoea. The treatment includes single dose Ceftriaxone 125 mg IM or Cefixime 400 mg orally or Ciprofloxacin 500 mg orally or Ofloxacin 400 mg orally along with Doxycycline 100 mg orally twice a day for 7 days.

## Chlamydia

Chlamydia is the most common and fastest spreading sexually transmitted disease. It stems from a bacterium, Chlamydia trachomatis. One of the three species within the genus Chlamydia, is an important cause of blindness and STD in humans.

Women diagnosed with Chlamydia can also infect their newborn infant during delivery. Symptoms usually appear approximately 7 to 21 days after infection and differ for men, women and children.

| **Chlamydia infections : Clinical features** |
|---|
| Symptoms in men (40) |
| Inflammation of the urethra (the bladder duct within the penis) |
| Stinging feeling when passing water |
| Clear discharge from penis and possible itchiness around the opening |
| Pain or tenderness in the testicles. |
| Symptoms in women |
| Stinging feeling when passing water |
| Unusual vaginal discharge |
| Pain caused by pelvic inflammation (PID) |
| Pain during intercourse |
| In some cases, bleeding between periods |
| Symptoms in infants |
| Inflammation of the eye (conjunctivitis) at birth |
| Breathing Problems |
| Premature birth |

One of the most common ways of testing for Chlamydia is for the MO to collect a cell sample from the infected area (cervix or penis) with a cotton swab. This is then sent to a laboratory for evaluation. Treatment consists of antibiotics, and should also be given to the patient's partner. A further swab is recommended once treatment has ended to check whether the infection has cleared. The recommended regimens are: Doxycycline 100 mg orally 2 times a day for 7 days or Azithromycin 1 gm orally, once.

## Herpes Genitalis (genital herpes)

Gential herpes is a highly contagious viral condition caused by the herpes simplex virus (HSV). It principally infects the skin and mucous membranes of the genitals and rectum, but can also appear in areas such as the mouth. It is transmitted primarily through physical and sexual contact. During birth, the presence of herpes simplex virus on the genitalia or in the birth canal is a threat to the infant. Infection in the newborn infant can lead to herpetic meningitis, herpetic viremia (herpes virus particles present in the blood) and chronic skin infection.

The symptoms of herpes simplex virus usually occur a week after infection, but sometimes take longer to appear. Initially, the skin becomes reddened and multiple small blisters filled with a clear, straw-coloured fluid appear. Prior to the presence of blisters, the infected individual may also experience increased skin sensitivity, tingling, burning or pain at the site where blisters will appear. Later, the blisters burst leaving shallow, painful ulcers which eventually scab and heal over a period of 7 to 14 days.

There is no cure for the herpes simplex virus; once infected, patients will remain a carrier for the rest of their

lives. Some remedies, however, can reduce the duration of the eruption. In addition, by being more aware of the initial symptoms of recurrence (skin sensitivity and tingling), timely treatment with medication such as Acyclovir will often abort the outbreak of blisters.

Although the symptoms of genital herpes may not be present, it is important for those infected to inform their partner that they have the disease. This will encourage both parties to use barrier protection (condoms) to prevent the spread of the illness. Using condoms and not sharing towels are good ways of reducing the chance of infection in the first place.

### Genital Warts

Warts, or condylomata acuminata, are caused by the human papilloma virus (HPV). Up to nine months can pass from the time of infection to the actual development of warts. In women, human papilloma virus can lead to changes in the cervix and to the development of cervical cancer. Therefore, it is important that this condition is diagnosed and treated.

The common symptoms are raised, rough, wart-like growths that may occur singly or in clusters. In men, they are usually found around the head of the penis. In women, they appear most often around the vaginal opening and may spread to the rectal area. It is also possible for the virus to appear on or near the cervix as whitish, flat-like lesions, usually only detectable through close visual examination of the cervix (colposcopy). In both men and women, lesions may also be present in the mouth and throat. In general, symptoms can intensify if the immune system is weakened, or during pregnancy or if the person has diabetes. The warts are very contagious, so safe sex is advisable.

A diagnosis is made when a characteristic lesion is visible. By swabbing the skin with 5 per cent acetic acid, 'invisible' warts will emerge as white-coloured patches.

### Chancroid

Chancroid is a sexually transmitted ulcerative disease often associated with an inguinal bubo. The causal organism of chancroid is Haemophilus ducreyi. The incubation period ranges between 3 to 10 days. Men usually present with ulcerative lesion or inguinal tenderness. The chancre begins with tender papule surrounded by erythema and within 2 to 3 days after the infection sloughing ulcer appears on the penis and goes on increasing until it affects a large portion of the penis. Women often present with less obvious symptoms including pain in voiding, pain on defecation, rectal bleeding, dyspareunia or vaginal discharge. Most lesions in males are on either the external or internal surface of the prepuce, on the frenulum, or in the coronal sulcus. In females, most lesions are at the entrance to the vagina and include lesions on the fourchette, labia, vestibule and clitoris. Diagnosis of chancroid depends on the isolation of H.ducreyi from a genital ulcer or bubo. Direct examination by a gram stain reveals gm ve organisms in a 'school of fish' pattern. It is best to confirm the diagnosis by culture.

The patients of chancroid who are HIV positive are more likely to have treatment failure. If both pathogens are present they act synergistically with increased infectivity, susceptibility and failure to respond to treatment. Chancroid is one of the major reason for the rapid heterosexual spread of HIV -1 in eastern and southern Africa.

### Control of STDs in the general population

Male promiscuity is due to immature sexual interest, the result of internal emotional disharmony with situation in life and maladjustment with intrinsic or extrinsic conflicts. Professional, commercialized and, to some extent, amateur female prostitution provides this opportunity for male promiscuity. Various chains and combinations of complex social, economic behavioural, environmental, and other intrinsic and extrinsic factors are at the root of this social evil. Economic distress, lack of security in childhood and adolescence, disharmony in married life, social persecution of or an apathy for abandoned, abducted, waylaid, 'fallen' or forlorn women and failure to rescue and rehabilitate them are some of the important causes which lead women to take refuge in prostitution. Adolescent delinquency is the next important cause.

### Treatment of partners

Breaking the cycle of infection is a critical part of STI prevention, and so the client should be encouraged to refer his or her partner(s) for treatment, even when no clinical signs of infection are evident. Providers should advise clients to notify their partners (including those without symptoms) of their exposure and encourage them to seek treatment.

### Policy regarding STDs in the Armed Forces

Detailed methods of prevention and control of STDs in Armed Forces are given in recent instructions, and Medical Officers are advised to refer to them (41, 42).

The following facts should be recognized and brought home to the Commanders by Medical Officers in order to evolve a correct policy regarding STD in the Armed Forces:-

(a) All responsibilities for control of STD should devolve on the regimental officers, JCOs and NCOs under the advice of Medical Officers. All STD control work should start from the unit officers.

(b) Promiscuity among men should not be recognized and condoned as a necessary evil associated with life in the Armed Forces.

(c) While concealment of STDs is a military offence in accordance with DSR 351 and 352, its contraction is not an offence. No punishment or discrimination should be made against a STD case during or after treatment.

(d) Full information of the perils of promiscuity should be conveyed to the Armed Forces personnel. Education in this respect deters the person from indulging freely in promiscuity.

(e) At the same time, facilities to protect oneself from results of promiscuity should be made available.

Experience has proved that this is not likely to increase promiscuity while it definitely reduces the incidence of STD.

(f) Incorrigible addicts of sexual promiscuity may be discharged from service as 'not likely to be efficient soldiers'. (DSR para 352 (f) and Army rule 13).

Preventive measures include the primary preventive measures, the secondary preventive (or control) measures and the administrative measures which support them. Prevention is achieved by inhibiting promiscuous tendencies amongst Armed Forces personnel. The extent of promiscuity depends upon the following factors:-

(a) The availability to brothels/prostitutes in the locality.

(b) Manner in which the energies of Armed Forces personnel are used during their leisure period.

(c) The higher the education the greater the possibility of diverting energies to creative healthy pursuits; education also disuades them from promiscuity or persuades them to use prophylactics.

**Primary Prevention**

(a) Provide alternative healthy diversions, incentives and facilities for education and betterment in careers and providing a healthy psychological atmosphere for a tranquil regimental life. Excellent facilities should be provided for indoor and outdoor recreation, organized games, educational and recreational outings, amateur dramas and concerts.

(b) Man-management should be of a high standard. Grant of full entitled leave should be ensured and regular letters are some remedies.

(c) Develop good Officer-men relationship in the units.

(d) The officers and JCOs should themselves set an example by always maintaining a high moral and ethical standard. The education officer, the welfare officer and the religious teacher should keep the social, religious, ethical and the moral virtues before the service personnel.

(e) Health education should be carried out through lectures, multimedia, flip charts, gp or indl discussions and articles in the periodicals read by service personnel. These lectures should follow the general patterns as under :

(i) Lectures should bring out all the scientifically accurate facts clearly, briefly, with simplicity and without ambiguity.

(ii) Salient features and the possible after effects on self, wife and children on the transmission of infection to them in respect of these important diseases should first be brought out in simple language without exaggeration.

(iii) The necessity for self control from promiscuous habits should be emphasized;

(iv) Use of prophylactic means to avoid STD if an exposure does occur should be explained;

(v) Treatment from the Armed Forces Medical Services, and faithful observance of surveillance should be emphasized.

**Secondary Prevention**

As a practical consideration, main objectives should be to reduce opportunities for promiscuity by administrative measures and acquaint them with hazards of STD and methods of avoiding contraction by use of prophylactics. Use of condoms during coitus is the simplest prophylactic method. It should be made easily available in MI Room/ RAP.

**Administrative Measures**

Following administrative measures must be adopted to augment the measures described above:-

(a) All known and suspected areas in the cantonment habited by prostitutes should be placed 'out of bounds' to all ranks and watched by the military police.

(b) Personnel should be warned on roll calls and through unit part I order repeatedly against promiscuity, concealment of STD and about the places and areas placed 'out of bounds'. Contravention of these orders then becomes a military offence in accordance with paras 351 and 352 of the DSR.

(c) A thorough epidemiological investigation of cases enables location of infective foci in the towns or locality.

(d) Regular six monthly medical examinations and special inspection before proceeding on and after reporting from leave, temporary duty and courses of instructions and for permanent duty should be carried out. Regular periodical anti-STD lectures and supply of condoms should be arranged.

(e) One who has contracted STD should be immediately admitted to hospital.

**Surveillance**

Post hospital surveillance must be carried out to ensure radical cure. All units should maintain a STD register compiled from the particular given in AFMSF-6. The unit should ensure that the person reports on due dates to RMO who should carry out the treatment or send him to hospital whichever is indicated. The examination and treatment of his wife and, if necessary, of the children should also be arranged.

Lt Col Sunil Agarwal

# Acquired Immuno Deficiency Syndrome (AIDS)

## Introduction

AIDS is a potentially lethal sexually transmitted disease and is caused by the HIV virus. Acquired Immuno Deficiency Syndrome (AIDS) is a severe life threatening clinical condition first recognized as a clinical syndrome in 1981. This syndrome represents the late clinical stage of infection with the human immunodeficiency virus (HIV), which most often results in progressive damage to the immune and other organ systems, including the CNS (43). This means that a person who carries the HIV virus is prone to many different illnesses and may die from diseases that are harmless to healthy people.

AIDS is still most widespread sub Saharan Africa, Asia, and the Caribbean islands, and is more common among homosexual and bisexual men. However, in more developed countries the disease is becoming more frequent among heterosexuals, especially young people. In the UK, new cases of HIV are now more prevalent among heterosexuals. Intravenous drug users and people with many different partners are particularly at risk from HIV.

## Global Occurrence

Promising development has been made in prevention and control of HIV/AIDS in recent years. Global efforts to address the AIDS epidemic, including increased access to effective treatment and prevention programmes have been commendable. However, the number of people living with HIV continues to grow, as does the number of deaths due to AIDS. According to estimates, 34.1 to 47.1 million people are living with HIV/AIDS globally. There were 4.3 million new infections and 2.8 million deaths during 2006. Sub-Saharan Africa continues to bear the brunt of the global epidemic. Two thirds of all adults and children with HIV globally live in the region, and almost 72% of all adult and child deaths due to AIDS in 2006 were in the region. More adult women are now getting infected with HIV, for every 10 adult men there are 14 adult women who are living with HIV. The interaction of HIV/AIDS with other infectious diseases is an increasing public health concern (44, 45).

As of Dec 2006, an estimated 7.2 Million people are living with HIV in the South East Asia region. On 01st Dec 2003, WHO and UNAIDS announced a detailed plan to reach the "3 by 5 target" of providing antiretroviral treatment (ART) to three million people living with HIV in the developing countries by the end of 2005.

## National Occurrence

The changing trend in the country indicate that HIV infection is spreading in two ways; from urban to rural areas and from individuals practicing high risk behaviour to the general population called type 4 pattern, first described in Thailand. Estimates at the National level are 5.2 million people were suffering from HIV infection at the end of 2005. The cumulative number of AIDS cases in the country has risen to 124995 by 2006. Majority of the HIV infections (88.5%) are in the age group of 15-49 years, out of which 31.8 % are in the 15-29 years age group. Amongst injecting drug users the infection has spread very rapidly in Manipur with HIV prevalence of more than 70% (17).

## Clinical Features

For the purpose of AIDS surveillance an adult or adolescent (>12 years of age) is considered to have AIDS if at least 2 of the following major signs are present in combination with at least 1 of the minor signs listed below, and if these signs are not known to be due to a condition unrelated to HIV infection.(17)

| Major signs |
|---|
| Weight loss > or = 10% of body weight |
| Chronic diarrhoea for more than 1 month |
| Prolonged fever for more than 1 month (intermittent or constant) |

| Minor signs |
|---|
| Persistent cough for more than 1 month |
| Generalized pruritic dermatitis |
| History of herpes zoster |
| Oropharyngeal candidiasis |
| Chronic progressive or disseminated herpes simplex infection |
| Generalized lymphadenopathy |

A more recent version of a case definition for AIDS that adds HIV serology and tuberculosis has been proposed by WHO as follows :

AIDS in an adult is defined by a positive HIV test and one of the following (in the absence of a condition unrelated to HIV infection that may cause the sign/diagnosis):

(a) Weight loss > 10% or cachexia, with diarrhoea or both, intermittent or constant, for > 1 month.

(b) Tuberculosis with weight loss > 10%, or disseminated, miliary, or extrapulmonary tuberculosis.

(c) Kaposi's sarcoma.

(d) Neurologic impairment preventing independent daily activities.

(e) Oesophageal candidiasis.

Cohort studies of HIV infected adults indicate that about 15%-20% develop AIDS within 5 years, about 50% within 7-10 years and close to 70% within 15 years. The case fatality of AIDS is very high and most patients (80-90%) die within 3-5 years after the diagnosis of AIDS is made (46).

## Screening tests (HIV Testing)

Fig - 1 : Kaposi's Sarcoma

Fig - 2 : Oral Candidiasis

Once HIV enters the body, the body starts to produce antibodies. Most HIV tests look for these antibodies rather than the virus itself. There are many different kinds of HIV tests, including rapid tests and home test kits. At first a highly sensitive test is used called ELISA, while a second confirmatory test is used to weed out any false positive or to confirm indeterminate results. The confirmatory test, Western Blot is a highly specific test. Alternatively, for confirmation 3 ELISA / rapid / simple tests based on different biological systems may be performed. The "Window Period" is the interval between entry of HIV into the body and appearance of antibodies to it. This period may range between 1- 6 months and during this period the individual may test negative for HIV by conventional tests.

Western Blot Test

This is highly specialized and expensive test which detects antibodies to different antigens of HIV I and II. Patients serum is made to react against these different antigens blotted on a paper and the bands of the various reacting antibodies are noted. Presence of at least 2 envelope antigens and one core antigen is necessary for establishing the diagnosis of HIV infection. The test, when combined with a screening ELISA, is highly specific (99%) but not so sensitive (95%) and hence is used only for confirming a positive ELISA test result (28).

**Other tests for HIV infection**

Other tests that are relatively expensive but are done for research purposes or in selected cases, include p24 antigen levels in blood, viral culture and its ability to form syncitium in culture, and qualitative or quantitative tests for detection of the viral RNA viz. PCR (polymerase chain reaction) method and the bDNA method (branched chain DNA). The last two tests can detect the number of viral particles (virions) in blood and are being increasingly used to predict prognosis and monitor efficacy of antiviral therapy.

Several laboratory markers are available to provide prognostic information and guide therapy decisions. The most widely used marker is the absolute CD4 lymphocyte count. As the count decreases, the risk of opportunistic infections increases. People with healthy immune system usually have counts above 950 CD4 cells per cu mm of blood. The number falls over the course of HIV infection. People with AIDS usually have CD4 cell count below 200 per cu mm. The trend of the count is more important than a single reading (47). Any HIV testing should be accompanied by proper counselling (Tabel - 1)

Table - 1 : Post Test Counselling

| |
|---|
| **Test Result Negative** |
| ✎ Discuss transmission and need for behaviour modification |
| ✎ Safer sex |
| ✎ Advice second test 3 months after last exposure |
| **Test Result Positive** |
| ✎ Explain significance and implications |
| ✎ Organize urgent medical follow up |
| ✎ Assess coping strategy |
| ✎ Provide verbal and written information |
| ✎ Discuss confidentiality issues |
| ✎ Organize emotional and practical support |

**Infectious agent**

HIV is a Retrovirus

HIV belongs to a class of viruses called retroviruses. Two types have been identified type 1 (HIV-1) and type 2 (HIV-2). Retroviruses are RNA (ribonucleic acid) viruses, and in order to replicate (duplicate) they must make a DNA (deoxyribonucleic acid) copy of their RNA. It is the DNA genes that allow the virus to replicate. Like all viruses, HIV can replicate only inside cells, commandering the cell's machinery to reproduce. Only HIV and other retroviruses, however, once inside a cell, use an enzyme called **reverse transcriptase** to convert their RNA into DNA, which can be incorporated into the host cell's genes.

**Slow viruses**

HIV belongs to a subgroup of retroviruses known as **lentiviruses**, or "slow" viruses. The course of infection with these viruses is characterized by a long interval between initial infection and the onset of serious symptoms.

**Structure of HIV (48)**

**The viral envelope**

HIV has a diameter of 1/10,000 of a millimeter and is spherical in shape. The outer coat of the virus, known as the viral envelope, is composed of two layers of fatty molecules called lipids, taken from the membrane of a human cell when a newly formed virus particle buds from the cell. Embedded in the viral envelope are proteins from the host cell, as well as 72 copies (on average) of a complex HIV protein (frequently called "spikes") that protrudes through the surface of the virus particle (virion). This protein, known as Env, consists of a cap made of three molecules called glycoprotein (gp) 120, and a stem consisting of three gp41 molecules that anchor the structure in the viral envelope.

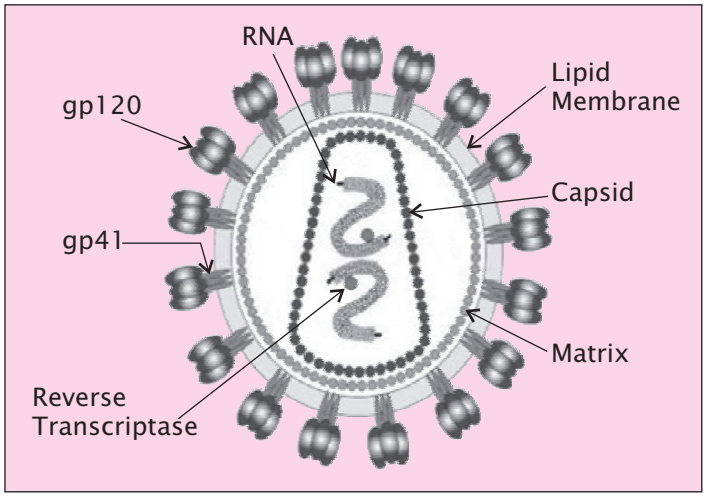
**The viral core**

Within the envelope of a mature HIV particle is a bullet-shaped core or capsid, made of 2,000 copies of another viral protein, p24. The capsid surrounds two single strands of HIV RNA, each of which has a copy of the virus's

nine genes. Three of these genes, gag, pol, and env, contain information needed to make structural proteins for new virus particles. Six regulatory genes, tat, rev, nef, vif, vpr, and vpu, contain information necessary to produce proteins that control the ability of HIV to infect a cell, produce new copies of virus, or cause disease.

Three enzymes carry out steps in the virus's life cycle:

Fig - 3 : Organisation of the HIV-1 Virion



reverse transcriptase, integrase and protease.

**Replication cycle of HIV**

Entry of HIV into cells (48)

Infection typically begins when an HIV particle, which contains two copies of the HIV RNA, encounters a cell with a surface molecule called Cluster Designation 4 (CD4). Cells carrying this molecule are known as CD4+ cells.

One or more of the virus's **gp120** molecules binds tightly to CD4 molecule(s) and co-receptor molecules on cell surface which lead to entry of the virus into the cell. The **gp41** of the envelope is critical to the fusion process.

Although CD4+ T cells appear to be the main targets of HIV, other immune system cells with and without CD4 molecules on their surfaces are infected as well. Among these are long-lived cells called **monocytes** and **macrophages** , which apparently can harbor large quantities of the virus without being killed, thus acting as reservoirs of HIV.

Reverse transcription

In the cytoplasm of the cell, HIV reverse transcriptase converts viral RNA into DNA, the nucleic acid form in which the cell carries its genes.

Integration

The newly made HIV DNA moves to the cell's nucleus, where it is spliced into the host's DNA with the help of HIV integrase. HIV DNA that enters the DNA of the cell is called a provirus.

Transcription

For a provirus to produce new viruses, RNA copies must be made that can be read by the host cell's protein-making machinery. These copies are called messenger RNA (mRNA), and production of mRNA is called transcription, a process that involves the host cell's own enzymes.

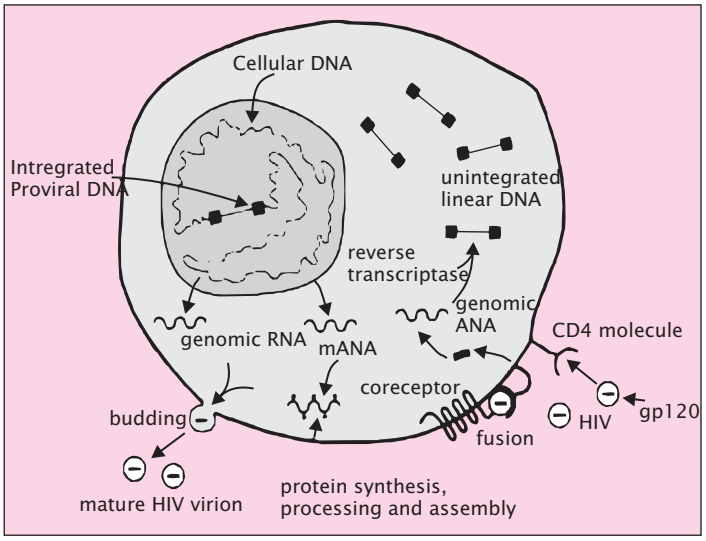
Translation

After HIV mRNA is processed in the cell's nucleus, it is transported to the cytoplasm. In the cytoplasm, the virus co-opts the cell's protein-making machinery-including structures called ribosomes-to make long chains of viral proteins and enzymes, using HIV mRNA as a template. This process is called translation.

Assembly and budding

Newly made HIV core proteins, enzymes, and genomic RNA gather inside the cell and an immature viral particle forms and buds off from the cell, acquiring an envelope that includes both cellular and HIV proteins from the cell membrane. During this part of the viral life cycle, the core of the virus is immature and the virus is not yet infectious. The long chains of proteins and enzymes that make up the immature viral core are now cut into smaller pieces by a

Fig - 4 : Replication Cycle of HIV



viral enzyme called protease.

**Reservoir : Humans**

**How HIV Is and Is Not Transmitted**

HIV is a fragile virus. It cannot live for very long outside the body. As a result, the virus is not transmitted through day-to-day activities such as shaking hands, hugging, or a casual kiss. You cannot become infected from a toilet seat, drinking fountain, doorknob, dishes, drinking glasses, food, or pets. You also cannot get HIV from mosquitoes.

**Mode of transmission**

HIV can be transmitted from person to person through:

(a) Sexual contact

(b) Sharing of HIV contaminated needles and syringes,

(c) Transfusion of infected blood or its components.

(d) Vertical transmission (i.e. from infected mother to

foetus)

(From 15% to 30% infants born to HIV-infected mothers are infected before, during, or shortly after birth; treatment of pregnant women results in marked reduction in infant infections) (43, 46).

Transmission of HIV

Among adults, HIV is spread most commonly during sexual intercourse with an infected partner. During intercourse, the virus can enter the body through the mucosal linings of the vagina, vulva, penis, or rectum or, rarely, via the mouth and possibly the upper gastrointestinal tract after oral sex. The likelihood of transmission is increased by factors that may damage these linings, especially other sexually transmitted infections that cause ulcers or inflammation (Table - 2).

Research suggests that immune system cells of the dendritic cell type, which live in the mucosa, may begin the infection process after sexual exposure by binding to and carrying the virus from the site of infection to the lymph nodes where other immune system cells become infected. A molecule on the surface of dendritic cells, DC-SIGN, may be critical for this transmission process.

**Theories of immunes system cell loss in HIV infection**

How HIV destroys or disables CD4+ T cells, and that a number of mechanisms may occur simultaneously in an HIV-infected person. Data suggest that billions of CD4+ T cells may be destroyed every day, eventually overwhelming the immune system's capacity to regenerate.

**(a) Direct cell killing**

Infected CD4+ T cells may be killed directly when large amounts of virus are produced and bud out from the cell surface, disrupting the cell membrane, or when viral proteins and nucleic acids collect inside the cell, interfering with cellular machinery.

**(b) Apoptosis**

Infected CD4+ T cells may be killed when the regulation of cell function is distorted by HIV proteins, probably leading to cell suicide by a process known as programmed cell death or apoptosis.

**(c) Innocent bystanders**

Uninfected cells may die in an innocent bystander scenario: HIV particles may bind to the cell surface, giving them the appearance of an infected cell and marking them for destruction by killer T cells after antibody attaches to the viral particle on the cell. This process is called antibody-dependent cellular cytotoxicity.

**(d) Anergy**

Researchers have shown in cell cultures that CD4+ T cells can be turned off by activation signals from HIV that leaves them unable to respond to further immune stimulation. This inactivated state is known as anergy.

**(e) Damage to precursor cells**

Studies suggest that HIV also destroys precursor cells that mature to have special immune functions, as well as the microenvironment of the bone marrow and the thymus needed for developing such cells. These organs probably lose the ability to regenerate, further compounding the suppression of the immune system.

**(f) Incubation period**

It is widely variable although the time from infection to the development of detectable antibodies is generally 1-3 months, the time from HIV infection to diagnosis of AIDS has an observed range of less than 1 year to 10 years or more.

**Course of HIV infection**

Among people enrolled in large epidemiologic studies in Western countries, the median time from infection with HIV to the development of AIDS-related symptoms has been approximately 10 to 12 years in the absence of antiretroviral therapy. However, there is a wide variation in disease progression. Approximately 10 percent of HIV-infected people in these studies have progressed to AIDS within the first 2 to 3 years following infection, while up to 5 percent of individuals in the studies have stable CD4+ T cell counts and no symptoms even after 12 or more years.

Factors such as age or genetic differences among individuals, the level of virulence of an individual strain of virus, and co-infection with other **microbes** may influence the rate and severity of disease progression.

Early events in HIV infection

Once it enters the body, HIV infects a large number of CD4+ cells and replicates rapidly. During this acute or primary phase of infection, the blood contains many viral particles that spread throughout the body, seeding various organs, particularly the lymphoid organs.

Two to 4 weeks after exposure to the virus, up to 70 percent of HIV-infected people suffer flu-like symptoms related to the acute infection. Their immune system fights back with killer T cells (CD8+ T cells) and B-cell-produced antibodies , which dramatically reduce HIV levels. A person's CD4+ T cell count may rebound somewhat and even approach its original level. A person may then remain free of HIV-related symptoms for years despite continuous replication of HIV in the lymphoid organs that had been seeded during the acute phase of infection.

One reason that HIV is unique is the fact that despite the body's aggressive immune responses, which are sufficient to clear most viral infections, some HIV invariably escapes. This is due in large part to the high rate of mutations that occur during the process of HIV replication.

Finally, the virus may hide within the chromosomes of an infected cell and be shielded from surveillance by the immune system. Such cells can be considered as a latent reservoir of the virus. Because the antiviral agents currently in our therapeutic arsenal attack actively replicating virus, they are not effective against hidden, inactive viral DNA (so-called provirus).

**Period of Communicability**

Presumed to begin early after onset of HIV infection and extend throughout life. Infectiousness increases with increasing immune deficiency; clinical symptoms and other STDs. Recent studies indicate that it may be high

Table - 2 : Factors increasing the risk of acquisition of HIV

| | |
|---|---|
| **Common to all transmission categories** | STI's especially genital ulcers |
| High Viral Load | Male to male vs heterosexual sex |
| Lower CD4 cell count | Cervical ectopy |
| AIDS | Non circumcised |
| Seroconversion | Receptive vs insertive anal sex |
| **Vertical transmission** | Increased no of partners |
| Older gestational age | Rectal or vaginal trauma |
| Vaginal vs elective caesarean | Mensturation |
| Prolonged rupture of membranes | **IV drug use** |
| No peripartum prophylaxis | Sharing equipment |
| Chorioamnionitis | Intravenous use |
| First born twin | Frequency of use |
| Lower birth weight | Cocaine use |
| **Breast Feeding** | Linked commercial sex |
| Longer duration feeding | Incarceration |
| Younger age | Lower income |
| Lower parity | **Occupational transmission** |
| Mastitis | Deep injury |
| | Previous arterial or venous siting |
| | Visible blood on device |
| **Sexual transmission** | |

during initial period after HIV infection. However patients on ART are less likely to transmit HIV infection to others (49)

**Prevention and Control**

Medical officers may note that the various details regarding epidemiology, transmission, prevention, control and various policy / medical administrative matters are given in the compilation 'Handbook on HIV/AIDS for Medical, Dental and Nursing Officers (51). These handbooks have been distributed by Armed Forces AIDS Control Organisation (ACO) to all the IEC nodes.

The various strategies of HIV/AIDS prevention includes

**(a) Information, Education and Communication (IEC)**

IEC should promote :

(i) Delay in first sexual encounter (targeting adolescents and young adults),

(ii) Reduction in number of sexual partners (ideally mutually monogamous relationship)

(iii) Increase in use of condoms.

In the Armed Forces, research, training, planning and development of IEC materials are carried out at the AIDS Control Organization (ACO) located at the Dept of PSM, AFMC Pune-40. IEC materials are produced in bulk by ACO for dissemination to the IEC nodes (located at Station Health Organizations) in the form of:

(i) Books

(ii) Posters

(iii) CD-ROMs

(iv) Video cassettes

(v) Flip charts

Station Health Organizations (SHO's) with additional inputs from ACO are carrying out IEC activities in their respective stations. The activities include:

(i) Advocacy at level of Commanders,

(ii) Health education of all ranks/families,

(iii) Peer group training to influence safe peer behaviour, etc.

(iv) Monitoring and evaluation of these activities are carried out by periodic review of relevant indicators besides repeated behavioural surveys particularly on three core areas i.e. age of first sexual encounter, number of sexual partners and prevalence of condom use.

**(b) Prevention of blood-borne HIV transmission**

All blood should be screened for HIV before transfusion. Strict sterilization practices should be ensured in hospitals and clinics. Autoclaved syringes and needles and other instruments should be used. Sharing of needles among drug addicts should be eliminated by health education.

**(c) Antiretroviral treatment and specific prophylaxis**

The prohibitive cost precludes the use of antiretroviral drugs on a mass scale in management of HIV infection in developing countries. Its use at present is limited to prevent perinatal transmission and for post exposure prophylaxis in cases of occupational exposure of Health Care Worker (HCW).

Primary prophylaxis against P. carinii pneumonia is indicated when CD4 count falls below 200 cells per cu mm. The regimens available are trimethoprim sulphamethoxazole, aerosolized pentamidine and dapsone.

**(d) Blood Safety, licensing of blood banks and exemption from licensing under certain condition-**

All blood banks in Armed Forces will transfuse blood only after it has been tested and found negative for HIV I & 2, HBsAG, Malaria, Syphilis, and other tests as specified in the current edition of Indian Pharmacopeia as well as consistent with the national Blood policy (52). All blood banks of Armed forces should therefore obtain the necessary license. An exemption has been given by Govt of India in respect of centres of Armed Forces Medical Service in border areas, small mid zonal hospitals including peripheral hospitals, Field Ambulances, Mobile Medical units and other field medical units including blood supply units in border / sensitive / field areas. The exemption from license in respect of above

establishments is, however, subject to the condition that these centers shall collect, process and transfuse blood only in life saving emergency situations; they will be under the supervision of a qualified Medical Officer as per specifications, and that they will undertake all the tests (HIV-1 and 2 / HBsAg / Malaria / Syphilis / others as specified). Concerned Medical Officers are advised to acquaint themselves with the provisions of afore-mentioned Govt of India Gazette (53).

## Policy and procedures on testing, notification and surveillance of HIV infection in the Armed Forces

The policy and procedures are contained in Office of the DGAFMS letters No 5496/HIV Policy/DGAFMS/DG-3A dt 23 May 2003, and 5496/DAFMS/DG-3A/PPTCT dt 07 May 2003 and their detail is given in separate chapter (54).

### Categories of persons to be screened for HIV

The following categories of individual are required to be screened for HIV infection in the armed forces:

(a) All blood donors
(b) All STD cases and those giving history of sexual promiscuity
(c) All antenatal cases and the husbands/children of the HIV positive cases
(d) Spouses and dependant children of HIV infected persons
(e) All personnel from foreign countries undergoing training/long courses in mil establishments.
(f) All Intravenous drug users
(g) All recipients of blood and blood products
(h) Patients on dialysis
(j) Suspected ARC/AIDS cases
(k) All cases of pulmonary & extra-pulmonary tuberculosis.
(l) Personnel proceeding to and returning from foreign missions/tenures abroad
(m) Other high risk cases e.g. those who test positive for HbsAg/ HCV/ VDRL etc
(n) Any other case which the treating physician deems necessary
(o) Cases undergoing invasive procedures/investigations where risk of transmission is high.
(p) Duty/travel overseas.

### Administration of Antiretroviral Therapy

Initiation

The Clinical Immunologist/Medical specialist/treating specialist at one of the Immunodeficiency centers shall initiate Anti retroviral therapy (ART). The personnel put on ART will be adequately monitored as indoor patients during the initial phase of ART. The basis of starting Anti retroviral therapy will be as under (any one of the following):

(a) WHO stage IV & advanced stage III disease irrespective of the CD4 count
(b) WHO stage I/II/III disease with CD4 count <200/microlitre
(c) HIV viral load >50,000 copies /ml (if done)

However there are studies which shows that, among patients with <50, 50-200, 200-350, 350-500, and >= 500 CD4 cells/$mm^3$ at baseline, respectively, 20%, 26%, 46%, 73% and 87% reached >= 800 CD4 cells/$mm^3$ within 7 yrs of starting ART. Keeping in view the long term complications of HAART and its resistance, the thresholds have been derived from prospectively monitored cohorts of HIV infected individuals which shows clear survival advantage when ART is initiated with CD4 cell counts between 200 to 350 cells/$mm^3$. (55)

Note

When facilities for CD4 count are not available, WHO Stage II & III disease besides Stage IV, with Total Lymphocyte Count below 1200 cells/$mm^3$ can be considered for initiating ART.

The following personnel are authorized treatment

(a) All service personnel with HIV infection meeting the above criteria
(b) Families and dependants of service personnel
(c) Serving personnel being boarded out and on ART, will be provided with Anti retroviral therapy for a period of two months on discharge and will be advised to continue ART thereafter.

### Blood donors' testing and reporting

The peripheral hospitals have been supplied with rapid testing kits. If the blood sample tests positive for HIV, the blood is disposed off by incineration. The individual is admitted to the nearest hospital for further investigation with the diagnosis "Immune-Surveillance for Investigation"

The hospital to which this blood donor is admitted will transfer the individual to one of the 08 'referral cum treatment hospitals' with Immunodeficiency as under: -

(a) CH(SC) Pune.
(b) BH, Delhi Cantt.
(c) CH(EC) , Calcutta.
(d) CH(CC), Lucknow
(e) CH(WC), Chandimandir
(f) CH(NC), Udhampur
(g) CH(AF), Bangalore
(h) INHS, Asvini.

### Disposal of HIV positive personnel

Medical officers are advised to acquaint themselves with the recent policy guidelines issued by office of the DGAFMS (54, 56) which have also been incorporated in the Handbook for Medical Officers as also refer to the DGAFMS Medical Memorandum on the subject (57). The detailed description is given in separate chapter.

The HIV positives will be classified as follows

(a) Not on ART

(i) Asymptomatic HIV positive individuals, not on antiretroviral drugs, will be placed in low Medical classification S1H1A1P2 (Temp) E1 for a maximum of 48 weeks.

(ii) Asymptomatic/Symptomatic HIV positive individuals, advised ART, but unwilling to take antiretroviral drugs, will be placed in S1H1A1P3E1 or an appropriate lower med classification.

(b) On ART

(i) These patients will be placed in low Medical classification S1H1A1P3 (T) E1 with appropriate employability restrictions and be observed maximum for a period of 01 year.

**Invalidment**

The guiding factor will be the functional ability of the individual. However, disabling manifestations of disease corresponding to WHO Stage IV who have shown unsatisfactory response to therapy will be considered for invalidment. These conditions include:

(a) HIV wasting syndrome

(b) Disabling neurological/psychiatric illness

(c) Disseminated Tuberculosis.

(d) HIV related malignancies.

(e) Any other AIDS defining criteria/disabling illness, including a CD4 count below 200 cells / mm3 despite having been exhibited adequate trial with ART.

Note

Cadets and recruits found to be HIV positive will not be eligible for commission/enrolment.

Asymptomatic HIV positive personnel (including cadets and recruits), on confirmation of diagnosis, will be labelled as 'Immune Surveillance' (ICD 043). They will be placed in medical category P2 (Perm) (or their equivalent in Navy and Air Force) by medical board. All restrictions applicable to med cat P2 (Perm) will be applicable. In addition, the following restrictions will be imposed: -

(a) Will not be posted to high altitude.

(b) Will not be put on flying duties.

(c) Will not be put on submarine/diving duties

(d) Will not be detailed on foreign assignments

**Attributability/Aggravation**

Attributability/Aggravation in respect of HIV/AIDS cases pertaining to invalidment and release will be guided by the policy guidelines prevailing in "Guide to Medical Officers' (Military Pensions) 2002" and as may be amended from time to time. It is imperative that utmost confidentiality and respect for human dignity be maintained while dealing with HIV positive individuals. Only the Commanding Officer and the Authorised Medical Attendant (AMA) need be aware of the individual's HIV status.

**Follow up**

The HIV positive cases will undergo a monthly evaluation by their AMA. If required, they will be referred to the Medical Specialist at the nearest service hospital. They would be required to report every year or earlier if required at the Immunodeficiency centers for evaluation, including Total lymphocyte count / CD4 counts (once a year) at these centers.

On posting of an individual from the unit /proceeding on course the previous unit will inform the receiving unit under intimation to Records office. On discharge /release/ invalidment/death of the HIV positive person /cases of AIDS the concerned unit will inform full details to ACO, AFMC, Pune for follow up action.

Note

Follow up of Family Members. Monthly and yearly follow up of HIV positive family members of a service personnel whenever living with the family, will also be carried out by the AMA and the local service hospital and all records maintained & notified to ACO.

**Information for health care workers for protection against HIV/AIDS**

Guidelines for prevention of HIV in Armed Forces have been issued vide DGAFMS DGAFMS letter No 5496/HIV Policy/DGAFMS/DG-3A dt 23 May 2003. In general the precautions required for attending patients with HIV/AIDS are identical with those for hepatitis - B.

**Post - Exposure Prophylaxis (PEP)**

An occupational exposure to risk of HIV infection is a percutaneous injury, contact of mucous membrane or contact of skin (when skin is chapped, abraded or afflicted with dermatitis or the contact is prolonged or involving extensive area) with blood, tissue or other body fluids to which universal precautions apply.

Action to be taken on occurrence of occupational exposure to HIV

The HCW are a special category of people who come in contact with patients (or their products) suffering from HIV/AIDS frequently and may contact infection in spite of all possible precautions. This becomes an occupational hazard for the HCW.

(a) Guidelines highlighted in "Guide to Medical Officers' (Military Pensions) 2002" will be taken into consideration while deciding attributability.

(b) On occurrence of Occupational exposure, in addition to taking necessary action of PEP, **"Reports of occupational exposure to HIV"** will be initiated as per **Annx 1 to Appx 'G'** of DGAFMS letter No 5496/HIV Policy/DGAFMS/DG-3A dt 23 May 2003.

(c) If a HIV positive HCW does not have a documented occupational exposure in the past, the Commanding Officer of the individual will submit a certificate as in **Annx 2 to Appx 'G'.** However, in case the Commanding Officer feels the exposure needs to be further established he may convene a Court of inquiry to determine attributability.

On exposure to a needle stick injury, blood and body

fluids from a known HIV positive, the individual will report to MO i/c MI Room/Duty Medical Officer who will send him for HIV testing and administer Tab Zidovudine (300 mg) and Lamivudine (150 mg) at the earliest (preferably within 24 hours) and continue this twice daily for four weeks.

(d) The MO i/c MI Room will take appropriate actions as mentioned in the concerned DGAFMS letter.

(e) **PEP Register :** SEMO / SMO shall be personally responsible to maintain the PEP register.

When to give PEP?

**(a) No drugs required**

(i) Small volume exposure (few drops) over intact skin /mucous membrane from a low risk individual (Asymptomatic HIV or viral load<1,500 c/mL)

**(b) 2 drug regimen**

(i) Small volume exposure (few drops) over non intact skin /mucous membrane from a high risk individual (Symptomatic HIV, AIDS, acute seroconversion, and high viral load) or from a Low risk individual (Asymptomatic HIV or viral load <1,500 c/mL)

(ii) Large volume exposure (major blood splash) over non intact skin /mucous membrane from a low risk individual (Asymptomatic HIV or viral load <1,500 c/mL)

(iii) Solid needle, superficial (Not severe), exposure from a low risk individual (Asymptomatic HIV or viral load <1,500 c/mL)

**(c) 3 drug regimen**

(i) Large volume exposure (major blood splash) over non intact skin /mucous membrane from a high risk individual (Symptomatic HIV, AIDS, acute seroconversion, and high viral load)

(ii) Severe injury (Large bore, deep injury, visible blood in device, needle in patient artery/vein) from either a low risk or high risk individual.

(iii) Solid needle, superficial (Not severe), exposure from a high risk individual (Symptomatic HIV, AIDS, acute seroconversion, and high viral load)

Monitoring

**Testing source**

If there is no recent positive or negative serology, a rapid test is preferred, since results should be available in <10 minutes. Standard serologic tests may take 3 to 7 days, but a negative EIA screening assay is usually available in 24 to 48 hours and is adequate for the decision to discontinue PEP. If the source has had an illness compatible with acute HIV syndrome, testing should include plasma HIV RNA levels.

**Testing health care worker**

HIV serology should be performed at the time of injury, and repeated at 6 weeks, 3 months, and 6 months. There have been three health care workers who seroconverted at >6 months post exposure. This represents about 4% of confirmed seroconversions in health care workers. Most health care workers who seroconverted had symptomatic acute HIV syndrome, usually 2 to 6 weeks post exposure.

**Caution**

The health care worker should be advised to practice safe sex or abstain until serology is negative at 6 months post exposure. The greatest risk is the first 6 to 12 weeks.

**Time**

PEP should be initiated as quickly as possible, preferably within 1 to 2 hours of exposure and up to 36 hours post exposure. The median time from exposure to treatment in health care workers with HIV exposure in the USA from October 1996 to September 1998 was estimated as1.8 hours .

**Side effects**

For health care workers who receive PEP, about 74% experience side effects, primarily nausea (58%), fatigue (37%), headache (16%), vomiting (16%), or diarrhea (14%). About 53% discontinue treatment before completion of the 4-week course due to multiple factors including side effects of drugs. The HCWs should therefore be properly briefed on these aspects to ensure compliance.

**Follow up of the HIV positive Mothers their Spouses & Children**

The Mothers who have tested positive will be followed up every 6 months after their delivery along with their children and spouses. The proforma to evaluate their health as well as the health of their spouse and siblings at the time they test positive and thereafter after every six months as per **Appces 'B' & 'C' to DGAFMS** office letter No 5496/DGAFMS/DG-3A/PPTCT dated 07 May 2003 will be filled in quintuplicate and distributed.

**Autopsies on HIV-positive cadavers**

An autopsy on confirmed HIV-positive cadavers is not mandatory. The details of procedure are as per Appx 'H' and DGAFMS Memorandum on the subject. No embalming will normally be undertaken in confirmed HIV cases.

Lt Col Sunil Agarwal

# Parenterally Transmitted Viral Hepatitis

## Introduction

Hepatitis means inflammation of the liver, which may be caused by viral or other infections, certain toxins and other conditions. This section deals with hepatitis B virus (HBV), hepatitis C virus (HCV), and hepatitis delta virus (HDV), which causes hepatitis as their primary clinical syndrome and are transmitted by blood or through sexual or perinatal contact. Hepatitis B is sometimes also referred as 'Serum Hepatitis'. HBV is a partially double stranded DNA of hepadnaviridae family and associated with both acute and chronic forms of hepatitis as well as hepatocellular carcinoma. This virus along with other hepatitis C and D are transmitted usually by parenteral route. Other hepatitis viruses like HAV and HEV are dealt in the chapter of Excremental diseases.

## Definition

An acute or sub acute febrile infectious disease characterized by sudden onset, nausea, anorexia & abdominal discomfort followed by dark coloured urine, light coloured stools and appearance of jaundice in sclera or skin caused by various viruses like viral hepatitis B,C and D viruses (58). A few patients develop a serum sickness like illness with urticarial rash, arthralgia, arthritis, or glomerulonephritis and vasculitis caused by immune complexes. There will be rise in the blood levels of liver enzymes especially alanine aminotransferase (ALT) and aspartate aminotransferase (AST). The blood bilirubin level also rises. Rarely patients may develop complications of acute fulminating hepatic necrosis and liver failure. This is less common with HCV than other viruses (59). Patients who are coinfected with HBV and HDV from same source may have more severe acute hepatitis, severe chronic disease and primary liver cancer.

## Prevalence

### Hepatitis B

The prevalence of HBV infection varies greatly worldwide. It is a serious global health problem, with more than 2 billion people infected worldwide, and 350 million suffering from chronic HBV infection. HBV infections result in 500, 000 to 1.2 million deaths per year caused by chronic hepatitis, cirrhosis, and hepatocellular carcinoma(60, 61). HBV virus causes 60-80 per cent of all primary liver cancer, which is one of the three common causes of cancer related death in East and SEAR, the Pacific Basin and Sub-Saharan Africa. More than one-third of the population has been infected with HBV, and it is estimated that there are 80 million HBV carriers (about 6% of the total population). Many are life long carriers, although not all are infectious, and some will clear the virus after intervals varying from many months to years. Transmission of HBV infection by blood transfusion and in other medical interventions in both modern and traditional health practices is also common in the Region(62).

In India, the carrier rate of HbsAg in hospital staff has been found to be higher (10. 87 per cent) than in voluntary blood donors (6 per cent) and in the general population (5 per cent). Sero-epidemiologic studies from Armed Forces also suggest that hepatitis carrier state is an important issue (63). In India the incidence of post transfusion hepatitis in multiple transfused patients is as high as 18 to 30 percent.

### Hepatitis C

Since HCV has been identified in the year 1989, it has been shown to be the major cause of parenterally transmitted non-A, non-B (PT-NANB) hepatitis. The incidence is world wide and estimated that 3 percent of the world's population is infected with HCB and 170 million individuals are chronic carriers at risk of developing liver cirrhosis or liver cancer.

### Hepatitis D or Delta hepatitis

Hepatitis D or Delta hepatitis is also widespread and the infection always occurs in association with Hepatitis B. HDV is believed to infect approximately 5% of the world's 300 million HBsAg carriers. The sharing of contaminated needles in intravenous drug use is thought to be the most common means of transmitting HDV. Persons who use intravenous drugs and are also positive for HBsAg, have been found to have HDV prevalence rates ranging from 17-90%. Sexual and perinatal transmissions are also

Human Blood Borne Hepatitis Viruses

| | Hepatitis B | Hepatitis C | Hepatitis D |
|---|---|---|---|
| **Virus type** | Hepadnaviridae | Unclassified | Unclassified |
| **Agent** | Partially double stranded DNA virus | Single stranded RNA virus | single-stranded RNA virus |
| **Host** | 15-29 yrs | Adults | 15-29 yrs |

described. Hepatitis G virus has recently been discovered in 1996. HGV can be transmitted by blood transfusion. HGV co-infection is observed in 6% of chronic HBV infections and in 10% of chronic HCV infections. However, whether HGV is actually pathogenic in humans remains unclear.

**Agent factors**

Hepatitis B

The studies of Krugman et al at the Willowbrook State School in New York confirmed the presence of at least two different epidemiologic types of hepatitis virus. The viruses he labeled were MS-1, transmitted orally causing 'Infectious hepatitis' and MS-2, transmitted parenterally causing 'Serum Hepatitis'. Hepatitis B virus is present in human blood of patients and carriers. Antigenically it is very complex. It has at least 3 separate antigens : surface antigen (HBsAg), core antigen (HBcAg) and antigen (HBeAg). HBsAg is a glycosylated lipoprotein that contains the major site for binding of neutralizing antibody. Four subtypes of HBsAg have been identified as adw, ayw, adr, and ayr which helps in epidemiologic studies to establish patterns of transmission. HBeAg is a marker for current active viral replication. HBcAg is detected in liver rather than serum and the cellular immune response to HBcAg in liver is responsible for hepatic necrosis. The virus has not yet been grown in the organ culture system. It is killed by heat at 60ºC for 10 hours or 90ºC for 1 hr in plasma.

**Hepatitis B Genotypes**

There are eight genotypes of hepatitis B Virus (A to H). Genotypes have different geographic distributions like genotype A is pandemic whereas genotype B and C are present in Asia, D in Southern Europe and US, E in Africa, F in the US, G in US and France and H in Central and South America (59).

Hepatitis C

HCV is an RNA agent similar to Flavivirus with a diameter of 55 nm. It has one serotype and multiple genotypes. The genetic variability of HCV hampers the efforts of scientists to design an effective anti-HCV vaccine.

**Hepatitis C Genotypes**

There are atleast six distinct HCV genotypes and 80 subtypes are described.

Hepatitis D

HDV is also called the 'Delta Agent' / 'Defective Virus' / 'Dane Particle'. It is a single-stranded RNA virus with a diameter of 36 nm and contains HDAg and the RNA strand. It uses HBsAg as its envelope protein. Thus, HBV co-infection is necessary for the packaging and release of HDV virions from infected hepatocytes.

Diagnosis

A number of sophisticated techniques viz. immuno electron microscopy and serological tests are available for detecting both the viruses and their antigens / antibodies. Detection of HBsAg has evolved and now done by reverse passive hemagglutination (RPHA) and more sensitive methods that utilize radioimmunoassay (RAI) or enzyme immunoassay (EIA). The presence of HBsAg indicates active HBV infection, and IgM anti-HBc determines whether HBV infection is acute or chronic. In addition HBV DNA can be detected by nucleic acid hybridization or PCR amplification.

Reservoir of Infection

Man is the reservoir for all the viruses. Both cases and carriers play major role and their continued survival is mainly due to chronic carriers which is presence of HBs Ag for more than 6 months.

Mode of Transmission (58, 65)

The capability of hepatitis viruses to transmit parenterally relates to existing in blood for long time and high viral levels in serum. HAV and HEV exist in blood for very brief intervals while HBV, HCV, HDV may be detected in the blood of asymptomatic carriers for decades. Hepatitis B virus is transmitted in the same way as human immunodeficiency virus (HIV), the virus that causes AIDS. However, HBV is 50 to 100 times more infectious than HIV.

**Parenteral Route**

Hepatitis B is a blood-borne infection. It is transmitted by infected blood and blood products through various modes like blood transfusions, dialysis, contaminated syringes and needles, infected blood handling, surgical and dental procedures, immunization, traditional tattooing, ear, nose and skin piercing etc. Accidental percutaneous inoculations by shared razors, needle stick

injuries and tooth brushes have been implicated as occasional causes of hepatitis B. With the introduction of detecting HBsAg in blood donor units, transfusion is not a common cause of transmission, except for high risk and health workers. HBV is now more commonly transmitted by nonparenteral routes.

**Perinatal Transmission**

HBV is commonly transmitted from HBsAg carrier mothers to their infants and also following acute maternal HBV infection in the third trimester. Presence of maternal HBeAg has increased risk of virus transmission to the newborn. While intrauterine transmission are noted, most infections occur at the time of birth or shortly thereafter. Infection of the baby is usually anicteric and is recognised by the appearance of surface antigen between 60-120 days after birth.

**Sexual Transmission**

HBsAg has been found in the saliva, vaginal secretions and semen of infected individuals which reflects leakage from the circulation. Both heterosexual and homosexual intercourse may transmit HBV. The sexually promiscuous, particularly male homosexuals, are at very high risk of infection with hepatitis B.

**Other Routes**

Transmission of HBV to household members of HBsAg carriers is well documented and many studies suggest that horizontal transmission, is responsible for a majority of HBV infections and carriers in parts of the world other than Asia. The exact mechanism by which this occurs is not known, the researchers believe that the spread occurs through extended period of household contact or due to unrecognized parenteral exposures to saliva or blood. Transmission by blood sucking arthropods (e. g. , mosquitoes, bed bugs) is suspected, but there is no convincing evidence to support this suggestion. Hepatitis C&D have similar modes of transmission.

**Host Factors**

Susceptibility is general

There is a direct relationship exists between the age of the patient and the likelihood to develop symptomatic infection. Usually the disease is commoner and milder in children and young adults. However, there is an inverse relationship with age and probability of developing chronic infection. About 90% of infants infected during the first year of life and 30% to 50% of children infected between 1 to 4 years of age develop chronic infection. The risk of death from HBV-related liver cancer or cirrhosis is approximately 25% for persons who become chronically infected during childhood.

The risk of chronic infection in adolescents and adults is 1% to 5%. Persons who are immunosupressed, have high rates of chronic carriage of HBV. Degree and duration of homologous immunity after attack are unknown but presumed to be long lasting. Certain occupational categories have been identified as associated with an excess risk of hepatitis B, C & D infection. The categories include dentists, nurses, laboratory technicians and the work areas include haemodialysis units, blood banks, surgical intensive care units.

Communicability Period

In hepatitis B, C & D blood remains infective many weeks before the onset of symptoms, through out the acute clinical course of the disease and during the chronic carrier state. Many persons may be carriers without having experienced a clinically recognized attack.

**Epidemiological Patterns**

Dramatic differences in HBV prevalence exist between various regions of the world. In parts of SE Asia and Africa, >90% of the population may have serologic evidence of past or current HBV infection and 10-20% of adults may be HBsAg positive. Also differences have been noticed between ethnically disparate groups living within the same geographic area. In United States, the seroprevalence generally increases with age and lower socioeconomic status and is higher among blacks and persons of Asian ancestry. Hepatitis B, C&D cases have been traced to clinics among patients who have received parenteral inoculations from contaminated and inadequately sterilized syringes and needles.

**HBV and HIV Coinfection**

Since HBV and HIV have similar modes of transmission, hence coinfection is common where 40 M worldwide are infected with HIV, almost 400 M are chronic HBV carriers. Geographically coinfection is seen in Sub Saharan Africa and Asia. In US chronic HBV infection occurs about 10 times more in HIV positive persons than HIV negatives. Persons with anti HBc are at increased risk of reactivating HBsAg after they develop HIV infection. In various studies liver related mortality was found much higher in men who were HIV positive than only HBsAg carriers. Also it is been found that HBV can increase the side effects related to Anti Retroviral therapy.

**Management**

Chronic hepatitis B in some patients is treated with drugs called interferon or lamivudine, which can help some patients. However, interferon or lamivudine therapy costs thousands of dollars and will never be available to most patients in developing countries. Patients with cirrhosis are sometimes given liver transplants, with varying success. Antiviral drugs such as interferon taken alone or in combination with ribavirin, can be used for the treatment of persons with chronic hepatitis C, but the cost of treatment is very high. It is preferable to prevent this disease with vaccine than to try and cure it.

**Prevention and Control**

Prevention and control of Hepatitis B, C and D infection is of particular importance for the Army, since these diseases are likely to lead to significant ill health and wastage of manpower. In addition, there is no treatment available, leading to substantial amount of physical and mental suffering. Finally, all these diseases have a very high potential of being transmitted by the infected person to his wife, and thereafter to the child in the womb, if the wife also gets infected. These diseases, thus, ravish the entire family.

Modern scientific knowledge has clearly demonstrated that despite their seriousness, these diseases are largely preventable. Prevention is even more relevant for the

Army, since the occurrence of these diseases in any unit is taken as a reflection of the overall discipline and Officer – men relationship. It is, therefore, imperative that Commanders at all levels ensure all possible measures for prevention of various blood borne infections. Thus, the basic principles on which prevention of these diseases devolves, are as follows :

(a) Imparting health education.
(b) Maintenance of high standards of morale and moral values.
(c) Adoption of prophylactic measures.
(d) Safe blood transfusion and injections.
(e) Administrative measures.

The prophylactic measures adopted for HBV infection include the following:

**Use of Condoms** : It is by now scientifically proven that condoms, if properly used, are very effective in preventing STDs, including sexual transmission of HIV and HBV infections. While avoidance of indulgence in illicit sexual acts remains the surest and ideal method of prevention of these diseases, there are likely to be a few persons who may still not be able to control their urge. For these reasons, the use of condoms should be promoted. Unit Commanders, in consultation with their doctors should work out ways and means of making condoms available for such persons. Efforts should be made to ensure that persons using condoms are not made fun of, or discriminated against, since such environment may prove inhibitory for persons to ask for condoms.

**Immunization**

Pre Exposure

(a) **The plasma derived vaccine** : It is a formalin inactivated sub-unit viral vaccine for intramuscular injection. It is given in 3 doses of 1 ml each at 0, 1 & 6 months. It gives 95 percent protection.
(b) **The RDNA - Yeast derived vaccine** is as effective in protection but more cost effective than the above vaccine. The schedule is 0, 1 & 6 months. Protection is up to 15 year and based on current scientific evidence, life long. Dose in adults is 10-20 micrograms and children less than 10 yrs should be given half of the adult dose. The hepatitis B vaccine does not interfere with any other vaccine and vice-versa. They can be given safely with other live vaccines also but at different sites. Vaccines when given at birth can be scheduled along with DPT. The vaccines should be stored at 2-8 degrees and freezing must be avoided.

Post Exposure

**Hepatitis B Immunoglobulin** : post exposurely for health care workers, newborn infants, sexual contacts exposed to acute hepatitis B patients should receive HBIG as early as possible (ideally with 6 to 48 hrs). Immunoglobulin (16 % solution) should be given at 0. 02 to 0. 12 ml per kg of body weight intramuscularly in two doses 30 days apart. If the person is HBsAg negative then active vaccination to be started.

Passive-active immunization

The simultaneous administration of HBIG and hepatitis B vaccine is more efficacious then HBIG alone as it does not interfere with the antibody response of hepatitis B vaccine.

**Safe blood transfusion and injections**

(a) Needles and syringes used for routine immunization must be autoclave for 20 minutes or boiled for 30 min.
(b) It is mandatory that all blood donors and blood products be screened for HBV and HCV infection and those found positive should be rejected. Voluntary blood donation should be encouraged because purchased blood has shown a higher risk of post-transfusion hepatitis.
(c) All blood units being transfused in Armed Forces Medical Establishments have been tested for HIV, HBV, Syphilis, Malaria (and other infections as specified in the instructions from time to time), and is free from these infections.
(d) All medical personnel practice proper "Universal safety precautions" and correct disinfection procedures.
(e) Hospital waste is properly disposed off as per legal specifications.
(f) Carriers should be told
    (i) Not to share razors or tooth brushes
    (ii) Use barrier methods of contraception
    (iii) Should not donate blood.

**Duties of Commanders**

Commanders at all levels will ensure that personnel and families take treatment only from the authorized sources, i. e. , from Armed Forces medical establishments, since proper safety of blood, syringes, needles and other instruments is ensured. Treatment from civil should be only in those exceptional, life saving emergencies, when Armed Forces hospital is not available in near vicinity, or else when referral to a civil hospital has been made by the Armed Forces Medical authorities themselves.

**WHO Initiative (66)**

WHO has called for all countries to add hepatitis B vaccine into their national immunization programmes in 1991. As of March 2000, 116 countries had included hepatitis B vaccine in their national programmes. However, many low income countries in sub-Saharan Africa, the Indian subcontinent do not use the vaccine. The price of the hepatitis B vaccine has been one of the main obstacles to its introduction in many of these countries.

The Global Alliance for Vaccines and Immunization (GAVI) was created in 1999. It is a unique coalition of public and private institutions where WHO has taken a leading role. The main mission of GAVI is to vaccinate as many children as possible against vaccine-preventable diseases. GAVI has introduced a new approach to international health funding: the Global Fund for Children's vaccines (GFCV). This fund will help 74 low-income countries to reinforce their national vaccine programmes and introduce hepatitis B, yellow fever and haemophilus influenzae type

Col RajVir Bhalwar

## Principles and Practice of Healthy Lifestyle

With modernization, rapid urbanization, industrialization and increasing level of affluence, the so called "modernization", the price that the society is paying is a tremendous load of "Non-Communicable" diseases, also referred to as "Chronic" diseases" and, often, as "Lifestyle Diseases". The list of major lifestyle diseases is displayed in Box-1. The issue is a global phenomena and not simply restricted to the developed, rich countries. In the context of our armed forces too, the problem of lifestyle and its consequent diseases needs to be addressed vigorously by all health care personnel.

**Box - 1 : Major "Lifestyle Diseases"**

- Obesity
- Heart Disease
- Hypertension
- Diabetes Mellitus
- Oral cancer
- Lung cancer
- Breast cancer
- Colonic cancer
- Other cancers
- Sexually Transmitted Diseases
- HIV & AIDS
- Mental Stress and it's sequelae
- Osteoarthritis
- Osteoporosis
- Liver Disease
- Asthma and

### What is "Lifestyle"

"Lifestyle", in the context of preventive health care, indicates the behavioral patterns which we routinely adopt and the way we tend to (involuntarily) live our daily life, unless coerced to change by some external stimulus. Lifestyle is thus mainly dependent on psycho-social and environmental factors and, to a smaller extent, on genetic influences. Lifestyle is developed in the form of a set pattern of behaviour, very gradually, over many years, in the way we eat, drink, exercise, use intoxicants, are predisposed to own health care and personal protection, sexual practices and so on. Since these behavioural patterns are acquired very gradually, changing them becomes a difficult proposition and needs a lot of persuasiveness as well as persistent approach on the part of the health care provider / health educator.

#### What are the major components of "Lifestyle"

As said earlier, lifestyle is more of attitudes and behaviours, about "predispositions". Thus, there would be a large number of components of "lifestyle" which affect health, from the way we exercise, to sexual mores to habitual hand washing before eating meals. However, from preventive point of view, the major facets of lifestyle are summarized in Box - 2, Box - 3 and Box - 4.

### National Scenario

India is experiencing large and rising burdens of chronic diseases, which are estimated to account for 53% of all deaths in 2005. Earlier estimates projected that the number of deaths attributable to chronic diseases would rise from 3·78 million in 1990 (40·4% of all deaths) to 7·63 million in 2020 (66·7% of all deaths). (1) Many of these deaths occur at relatively early ages. Compared with all other countries, India suffers the highest loss in potentially productive years of life, due to deaths from cardiovascular disease in people aged 35–64 years (9·2 million man years lost in 2000). By 2030, this loss is expected to rise to 17·9 million manyears (2). The estimated prevalence of coronary heart disease is around 3–4% in rural areas and 8–10% in urban areas among adults older than 20 years, representing a two-fold rise in rural areas and a six-fold rise in urban areas over the past four decades. About 29·8 million people were estimated to have coronary heart disease in India in 2003; 14·1 million in urban areas and 15·7 million in rural areas (3). The prevalence of stroke is thought to be 203 per 100000 population among people older than 20 years (4).

Data on cancer mortality are available from six centres across the country, which are part of the National Cancer Registry Programme of the Indian Council of Medical Research (ICMR). About 8 Lac new cases of cancer are estimated to occur every year. The age-adjusted incidence rates in men vary from 44 per 100000 in rural Maharashtra to 121 per 100000 in Delhi (5). The major cancers in men are mostly tobacco-related (lung, oral cavity, larynx, oesophagus, and pharynx). In women, the leading cancer sites include those related to tobacco (oral cavity, oesophagus, and lung), and cervix, breast, and ovary cancer. India has the largest number of oral cancers

**Box - 2 : The major components of unhealthy lifestyle**

- Lack of physical activity
- Faulty dietary habits
- Tobacco use
- Excessive alcohol intake
- Mental Stress
- Disregard to personal safety regarding
  - Accidents
  - Personal hygiene
  - Promiscuous Sex
  - Insect Vectors of Diseases

**Box - 3**

Lifestyle diseases or "Non-Communicable Diseases" have common risk factors as listed in the box above. Thus, by becoming physically active, eating a healthy diet, avoiding alcohol and tobacco and by managing mental stress, we will not only prevent IHD, but also diabetes, hypertension, cancers, road accidents, and stroke, since the determinants are common.

**Box - 4 : What socio-environmental changes have led to increasingly unhealthy lifestyles in populations ?**

- Rapid industrialisation / market economy
- Increased global earnings
- Materialism / consumerism
- Mechanisation
- Advertisement driven competitive food industry
- TV, Cables, VCDs
- Computers, Internet
- Increasing market of tobacco and alcohol, more so driven by advertisements
- Academic competitiveness among children
- Career competitiveness
- Migration towards urban areas
- Loss of "cushion" provided by traditional family life

in the world, due to the widespread habit of chewing tobacco.

India also has the largest number of people with diabetes in the world, with an estimated 19·3 million in 1995 and projected 57·2 million in 2025 (6). The prevalence of type 2 diabetes in urban Indian adults has been reported to have increased from less than 3·0% in 1970 to about 12·0% in 2000 (7). On the basis of recent surveys, the ICMR estimates the prevalence of diabetes in adults to be 3·8% in rural areas and 11·8% in urban areas. The prevalence of hypertension has been reported to range between 20–40% in urban adults and 12–17% among rural adults (8). The number of people with hypertension is expected to increase from 118·2 million in 2000 to 213·5 million in 2025, with nearly equal numbers of men and women (9).

With increasing life expectancy, the proportion of the population older than 35 years is expected to rise from 28% in 1981 to 42% in 2021 (10). During the decade 1991–2001, the population grew by 18% in the rural areas and 31% in urban regions (11). Urbanisation and industrialisation are changing the patterns of living in ways that increase behavioural and biological risk factor levels in the population.

An excess risk of death from coronary disease has been observed in men and women of south-Asian origin (12, 13). An increased risk of cardiovascular problems has been noted in Indian migrants to other countries.

A high frequency of metabolic syndrome (especially the characteristic dyslipidaemia of reduced HDL cholesterol and raised triglycerides) have been reported in Indian population groups (14, 15). The INTERHEART study (16) found that the clustering of coronary risk factors is quite common among indians.

Surveillance systems have been established to provide risk factor data from different parts of the country (17). The prevalence of tobacco use has been estimated in the National Sample Survey and the National Family Health Survey (18). In the Global Youth Tobacco Survey 25·1% of the students aged 13–15 years reported that they had ever used tobacco, whereas current use was reported by 17·5% (19). A national survey in 2002, reported that the overall prevalence of current tobacco use in men and boys aged 12–60 years was 55·8%, ranging from 21·6% in those aged 12–18 years to 71·5% in the 51–60 year age group (20). Many cross-sectional surveys have recorded a high urban prevalence of central obesity and overweight (especially when the lower thresholds recommended by WHO for Asian people are used). Women and men are equally affected (21, 22). Small birth size, with rebound obesity in early childhood, predicted diabetes and glucose intolerance in adulthood, in an Indian cohort, the so called "Barker's phenomena"(23).

Studies have revealed low levels of physical activity in urban areas and in the upper-income and middle-income groups. Low levels of physical activity have been reported in 61–66% of men and 51–75% of women, in urban surveys (22, 24). Most surveys have also shown higher mean concentrations of plasma cholesterol in urban population groups compared with rural groups, with a low mean concentration of HDL cholesterol (25). ICMR has observed that the prevalence of dyslipidaemia was 37·5% in individuals aged 15–64 years. Even in a relatively young industrial population (20–59 years), 62·0% had dyslipidaemia (26). Levels of awareness, treatment, and adequate control are low for hypertension, diabetes, and dyslipidaemia, especially in rural areas (26, 27).

With advancing health transition, the poor are increasingly affected by chronic diseases and their risk factors. (19, 28). Urban slums have high rates of diabetes and dyslipidaemia (29).

### World-wide Magnitude of the Problem

Chronic diseases represent a huge proportion of human illness. They include cardiovascular disease (30% of projected total worldwide deaths in 2005), cancer (13%), chronic respiratory diseases (7%), and diabetes (2%). Two risk factors underlying these conditions are key to any population-wide strategy of control - tobacco use and obesity. These risks and the diseases they engender are not the exclusive preserve of rich nations. An estimated total of 58 million deaths worldwide in a year, heart disease, stroke, cancer, and other chronic diseases will account for 35 million, more than 15 million of which will occur in people younger than 70 years. Approximately four out of five of all deaths from chronic disease now occur in low-income and middle-income countries, and the death rates are highest in middle-aged people in these countries (30).

### Magnitude in the Indian Armed Forces

Data among armed forces personnel due to major non-communicable diseases do indicate that we need to be vigilant and launch all out preventive health care programmes. The yearly hospital admission data (per

1000 personnel) for the period 2000 to 2005 for major

Table - 1 : Yearly hospital admissions (per 1000 personnel) due to major lifestyle diseases in Armed Forces (2000-2005)

| Year | Hypertensive Disease | | | Heart diseases | | | Diabetes Mellitus Type – 2 | | | Psychiatric Illnesses | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | Army | Navy | Air Force | Army | Navy | Air Force | Army | Navy | Air Force | Army | Navy | Air Force |
| 2000 | 2.25 | 2.60 | 2.30 | 0.64 | 1.79 | 0.77 | 0.76 | 0.88 | 0.76 | 1.71 | 4.44 | 0.92 |
| 2001 | 2.08 | 2.77 | 2.30 | 0.65 | 1.76 | 0.72 | 0.73 | 0.99 | 0.80 | 1.84 | 3.15 | 1.32 |
| 2002 | 2.91 | 2.17 | 2.81 | 0.86 | 3.11 | 0.85 | 1.02 | 1.30 | 0.80 | 3.38 | 2.80 | 1.06 |
| 2003 | 2.93 | 3.46 | 3.79 | 0.92 | 0.35 | 0.63 | 1.09 | 1.64 | 1.00 | 3.11 | 3.16 | 1.13 |
| 2004 | 2.90 | 3.47 | 4.87 | 0.99 | 1.31 | 0.53 | 0.96 | 1.16 | 0.82 | 3.38 | 4.81 | 1.43 |
| | | | | | | | | | | | | |

non-communicable diseases are given in Table - 1.(31).

Surveys among apparently healthy army personnel have also revealed that obesity, raised blood pressure, impairment of glucose tolerance, metabolic syndrome and physical inactivity are likely to be an issue which needs to be addressed energetically (32).

We shall discuss the major components of healthy lifestyle and the methods of addressing them from the preventive angle.

## Lack of Physical Fitness and Physical Inactivity

Substantial progress has been made during the past two decades in scientifically substantiating the role of physical exercise and fitness in a number of human diseases and more recently, the role of physical exercise and fitness in positive lifestyle. Indeed, of all the lifestyle factors, physical exercise seems to be one of the most important in relation to health. It has been quiet aptly said that physical exercise in the nature's panacea for preventing ill health. 'Physical Activity' and 'Physical Fitness' are two distinct entities. One may be physically active but may still not achieve a high level of fitness. For instance, if a 70 Kg man walks slowly, covering 8 kilometers in 3 hours, he would burn off almost 550 kilocalories (kcal); however he may not achieve 'fitness' by such activity, since the 'Intensity' is quite low. On the other hand if the same person does a 'Walk and Jog' schedule, overcoming half the distance (4 km) in half an hour, he may burn off only half the numbers of calories, but will achieve a pretty good level of fitness. The point to be noted is that both are important – some work (activity / exercise) needs to be performed to burn off calories and, additionally, such activities / exercises should be undertaken with reasonable amount of intensity (vigorousness) so that, in addition to burning the calories, "fitness" is also achieved. The above point is important since recent research has pointed out that most of the health benefits of physical exercise (as brought out later in a separate section) are actually due to the "Fitness" that results from the exercise and not from simply burning off the calories during such activities. (33). For instance, a housewife, during the course of her daily chores, or a person playing golf without carrying the clubs and walking at a slow pace for 2 hours, may burn off substantial amount of calories but may not be able to reap the complete benefits of exercise.

However, for those who are not exercising at all or else cannot exercise at moderate intensity levels even mild exercises will help. For planning a physical exercise program, the dictum should be 'Any exercise is good; more the better' (34 - 37). In fact people who have not been exercising for a long time should be encouraged to start with low intensity exercises or even by bringing about simple "life style changes" so that they become more active. Coaxing then to undertake more strenuous exercises from the very outset could be counter-productive. Subsequently, as they progress, they may be encouraged to gradually increase the level of exercise intensity.

## Benefits of exercise and diseases due to physical inactivity

It is often thought that physical exercise is a very good way of reducing the body weight and that is all which is good about physical exercise. This notion is correct only to a very small extent which should be emphasised upon the individuals and communities so that they draw the maximum benefits of physical exercise. Alone and by itself physical exercise is not a very efficient method of reducing weight. The major emphasis, if weight reduction is the issue, should be control on diet. Physical exercise can only be a useful adjunct. For example, just one average sized slice of bread will give 65 to 70 Kilocalories (kcal), to burn off which, one would need to go running for a Kilometer. Just four innocuous looking slices or a small sized "Samosa" will push in 300 kcal, which would need 4 kilometers of running/ walking to burn off these calories. If one doesn't do that, these 300 additional kcal per day will finally result into an extra 1 kg every month or an additional dozen of Kgs at the end of a year. Thus, to reiterate, if the major objective is weight loss or weight maintenance, proper diet should be the mainstay; physical exercise can be used only as a supplementary

**Box-5 : Health benefits of physical exercise and fitness**

- Helps keeping body weight in check.
- Increases the action of insulin hormone, thereby increasing the insulin sensitivity and the peripheral utilization of glucose, thus protecting against Insulin Resistance Syndrome (Syndrome X; Metabolic Syndrome) and NIDDM (type-2 diabetes), both major risk factors for IHD.
- Has a preferential action in mobilizing the fat depots, particularly the "Visceral" (Intra abdominal, peritoneal ) fat. By preferentially mobilizing this dangerous type of accumulated fat, physical exercise protects against dyslipidemias, IHD & NIDDM.
- Has a specific role in altering the lipid profile in a healthy fashion. Various studies have shown that the HDL levels are much higher while the triglycerides, LDL and Total cholesterol levels are much lower, among those who exercise regularly.
- Is associated with lowered levels of systolic and diastolic blood pressure, thereby protecting against hypertension.
- Has cardio-protective effect. Besides the improvements in insulin sensitivity, blood pressure, lipid profile and visceral fat deposition, physical exercise exerts its cardio-protective role by opening up the collateral blood vessels; increases the stroke volume and maximal ventilatory capacity; reduces myocardial oxygen demand at a given level of work; reduces fibrinogen levels, platelet aggregation and tendency of thrombus formation.
- Brings about a reduction in the level of anxiety and stress and induces a sense of confidence and well-being. To some extent, this effect is believed to be brought about by the release of "beta endorphins " which are natural occurring, opiate like chemicals.
- Tones up muscles and increases flexibility, thus protecting form injuries and falls.
- Helps in maintaining adequate bone mass density thereby protecting from osteoporosis and its complications.

modality. Notwithstanding the above, there are large number of health benefits of physical exercise and fitness, which are over and above the issue of weight maintenance, as shown in Box - 5 (38 - 63).

### Epidemiological evidence

WHO estimates indicate that globally, physical inactivity accounts for more than one fifth of the IHD, one tenth each of stroke and breast cancer and one sixth of all colon cancers. Physically inactive lifestyle accounts in 3. 3% of all deaths (i. e. 1 death out of every 30 deaths in the world can be attributed to physical inactivity). Physical inactivity also accounts for almost 19 million disability adjusted life years (DALYs) world-wide. World wide estimates as per a recent WHO report indicate that, on a long term average, physical inactivity carries an increased risk (as measured in terms of RR) of 1. 05 to 2. 63 for IHD, 1. 2 to 2. 89 for hypertension and stroke, 1. 08 to 4. 31 times for diabetes type – 2, 1. 02 to 2. 5 for colonic cancer, 1. 02 to as much as 5 times for breast cancer and 1.02 to 1.37 for osteoporosis (64).

In the 1980s and 1990s, various epidemiological studies demonstrated that less intensive physical activity also provides considerable health benefits. The focus has therefore shifted now to advocate, for the general population at large, to take to moderate intensity exercise by all adults and children, as brisk walking (5 – 6. 5 Kmph), recreational cycling and recreational swimming. In addition, the focus has also shifted to inculcate healthy lifestyle, by increasing activity levels in all the four 'domains' of life viz. , at workplace, in transport, at home and during recreation time.

### Does past physical activity / fitness help?

This aspect needs to be clearly understood by all medical personnel and explained to the community members. There is enough evidence to indicate that the various health related benefits of physical exercise are always due to "current" physical activity and not "past" activity. Thus, for one to draw the benefits of exercise, one should continue to be active; the benefits will occur only as long as one continues to be active (36). Physical activity in the past does not seem to help – one may have been an international level athlete during one's heydays, but that does not protect if one becomes inactive later in life.

### Does "Spot – reduction – exercise" works ?

Often, obese people, especially those with abdominal obesity are led to believe that abdominal strengthening exercises (as 'sit ups' or equivalent gymnasium gadgets) will "burn off" the fat around the abdomen. It needs to be explained that for burning off the fat "around" (actually inside) the abdomen, one has to burn off overall calories and restrict the diet. Abdominal exercises may only slightly help by 'toning' up the abdominal muscles but the energy spent in such exercises will be too little to have any impact on overall weight loss. It needs to be emphasised that 'sit ups' do not, by any chance, push away the fat from the abdomen. Vibrator belts and massage systems used over the abdomen are equally unscientific. The best (and generally the only) way to lose fat from the tummy is to do brisk aerobic exercise and cut down on dietary calories.

## The Exercise Program

A physical exercise and fitness schedule should be incorporated into the daily lifestyle. It needs to be emphasized that such program does not include only walking or jogging or only weight- training. An optimum

physical fitness program should cater to three major facets of physical fitness, viz, Endurance (Stamina = Cardio-respiratory efficiency); Muscular Strength ; and, Flexibility.

**Endurance**

It is the capacity to undertake sustained aerobic physical exercise using a high proportion of maximal oxygen uptake. The ideal means of improving endurance is by undertaking sustained aerobic training at the near maximal level, which a person can tolerate. Gradually, with continued training, at near maximal level, the maximal aerobic capacity increases, i.e., the person increases the 'Stamina'. Concurrently, with increase in stamina, the level of physical fitness increases and the person starts reaping more and more health benefits of physical exercise, as have been cited earlier. Any Endurance training program has three distinct components, viz,

(a) Frequency

This is measured by the number of sessions per week that are devoted to endurance training. Ideally, there should be 4 to 5 session per week; the minimum recommended is 3 per week.

(b) Intensity

Intensity is measured by the 'strenuousness' of the exercise. We shall deliberate on the measures of strenuousness a little later in a separate section. In general, it is recommended that to achieve the maximum gains, the physical exercise should be of at least "moderate" intensity. As one becomes more and more fit, one could (and should) aim to undertake more strenuous (high intensity) exercises.

(c) Duration

This is the time spent on exercise, in a given session. In general, during a session, approximately 60 minutes should be devoted for mild intensity exercises, 40 to 45 minutes for moderate intensity activities, while 20 to 30 minutes and 10 to 15 minutes are adequate for high intensity and very high intensity exercises, respectively. It also needs to be emphasized that the above suggested plans are only recommendations based on overall consensus and evidence. Ultimately, the program has to be tailored to meet the individual / community needs.

**Measuring the level of intensity**

Out of the 3 components of endurance training, while measuring the duration and frequency is quite straightforward, measuring the various levels of intensity often gets shrouded with confusion, particularly at the level of the user. A summary of various available guidelines to measure intensity of exercises and the overall recommendations are given in the succeeding paragraphs.

**Measuring exercise intensity on the basis of heart rate**

One of the oldest and quite widely used measure of exercise intensity is based on "Maximum Permissible Heart Rate (MxPHR)". The MxPHR for any individual is calculated as 220 (-) Age in years. For example, for a person aged 50 years, the MxPHR will be 220 (-) 50 = 170 beats per minute. In general, during an exercise session, this limit should not be exceeded. If a person is exercising at 50% to 60% of his MxPHR, it is taken as Low intensity exercise, 60% to 70% is Mild intensity, 70% to 80% is Moderate intensity, while 80% to 90% and 90% to 100% are taken as Severe intensity & Very severe intensity exercises respectively.

For example, the MxPHR for a 50 years old person would be 170. If the heart rate achieved by the person during a session of exercise is 50 to 60% of 170 (i. e. 85 to 102 beats per minute) he is exercising at low intensity level. Accordingly, for this person heart rate levels from 103 to 119, 120 - 136, 137 – 153, and 154 to 170 or even more, would qualify for mild, moderate, severe intensity and very severe intensity exercise.

**How to measure the heart rate achieved during an exercise session**

A practical method is as follows : Immediately on completion of an exercise session and definitely within 5 seconds of completion the individual starts counting the radial pulse, for 10 seconds. The first beat is counted as zero. The number of beats so counted in 10 seconds is multiplied by '6' to obtain the heart rate achieved during exercise.

**Measuring Exercise intensity according to Borg's scale of "Rating of Perceived Exertion (RPE)"**

The scale has the advantage of simplicity and can be used by anyone in the general community. The scale rates the intensity of exercise, as perceived by the person himself, on a visual analogue scale of 0 to 20, as shown in the Table - 2.

To start with, the exercise should be at a level of '12'score, i. e. the subject feels that the exercise intensity is between "Light" and "Somewhat hard". This level, in most subjects, is approximately equal to 60% of MxPHR. As fitness improves, the subjects should increase the intensity of exercise so that they are finally working at a level of 16 i. e. the perception about the exercise they are undertaking is that it is more than 'hard' but less than 'Very hard'. This level usually represents approximately 85% of MxPHR in most subjects.

**Measuring exercise intensity using Metabolic Equivalents**

Table - 2 : Borg's scale of RPE

| 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 | 16 | 17 | 18 | 19 | 20 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Nil | Almost Nil exercise | | | Very Very Light | | | Quite Light | | | Light | | | Somewhat Hard | | Hard | | Very Hard | | Excruciat-ingly Hard | |

**(METs).**

Recently the concept of METs is being increasingly used to prescribe the level of exercise for individual subjects. 1 MET is actually equal to a level at which a person will spend 1 kcal energy per kg body weight per hour and this level usually corresponds to the resting stage. This level also corresponds to an oxygen uptake level of 3. 5 ml / kg body weight per minute (65). As the level of MET increases, the intensity of exercise increases. Thus, a person weighting 70 kg at rest, i. e. at activity level of 1 MET will spend 70 K cal per hour while the same person exercising at the level of 6 MET will be spending 6x70 = 420 K cal in an hour. Moreover, the level of 6 MET will correspond to "moderate" level of exercise intensity. Thus, MET have dual advantage, in that in a single value they give an indication of both, the amount of energy expenditure as well as the intensity of exercise. According to general agreement, the MET levels corresponding to various intensity levels of exercise are shown in Box - 6 and the METs for common physical exercises are shown in Box - 7(65, 66).

Box - 6 : MET levels corresponding various intensity levels of exercise

| Level of exercise Intensity | Usual MET level | |
|---|---|---|
| | Men | Women |
| Rest | 1 | 1 |
| Very low intensity | 1 - 1.5 | 1 - 1.2 |
| Light | 1.6 - 3.9 | 1.2 - 2.7 |
| Low Moderate | 4 - 5.9 | 2.8 - 4.3 |
| High Moderate | 6 - 7.9 | 4.4 - 5.9 |
| Heavy Moderate | 8 - 9.9 | 6.0 - 7.5 |
| Unduly heavy | >10 | > 7.6 |

For example, let us say a subject weighing 70 kg is exercising by cycling at a speed of 16 km/h. He cycled for 8 km in half an hour. He will be exercising at 7 MET which is of 'moderate' intensity', rather almost touching the level of high moderate intensity exercise. During this half an hour, he will burn off (70 x 7 x ½) = 245 K cal of energy, this will be equivalent to burning off 30 grams of body fat.

## Recommendations for Physical Exercise

### Recommendations based on calorie expenditure

The minimum amount of calories to be expended in programmed physical exercise by the general population have been recently forwarded by CDC Atlanta and American College of Sports Medicine. These recommendations state that every adult should spend at least 200 kcal per day (i. e. 1400 k cal in a week) by physical exercise and this should be undertaken on "most days" (Preferably all days of a week) (67). This could be achieved by having a half – hourly session every day of brisk walking. The point to be noted is that these are the minimum recommendations and more exercise (in terms of more time or more intensity) is always better.

Box - 7 : MET levels for common physical exercises

| Activity | MET level |
|---|---|
| Walking 4.8 km/h (slow pace) | 3.0 |
| Badminton leisure | 3 - 6 |
| Walking 5.4 Km / h (slow pace) | 3.6 |
| Badminton match | 7 - 9 |
| Walking 6 km / h (brisk pace) | 4.3 |
| Dancing social | 3 - 7 |
| Walking 6.4 km/h (brisk pace) | 4.6 |
| Dancing aerobic | 6 - 9 |
| Walking 7 km / h (very fast pace) | 6.0 |
| Circuit weight training | 8 - 9 |
| Jogging 8 km/h | 8.7 |
| Roller skates | 5 - 8 |
| Running 9.6 km/h | 10.0 |
| Squash leisure | 8 - 10 |
| Running 12 km/h | 12.5 |
| Squash match | 11 - 12 |
| Bicycling 16 km/h | 7.0 |
| Tennis leisure | 6 - 8 |
| Swimming 20 mtr per minute | 6.0 |
| Tennis match | 9 - 10 |
| Swimming 40 mtr per minute | 12.0 |
| Volleyball | 3 - 6 |
| Golf, walking | 4.0 |
| Basket ball match | 7 - 12 |
| Golf, walking carrying bag | 5 - 6 |
| Basket ball non game | 3 - 9 |
| | |
| | |

More comprehensive recommendations on adequate calories to be spent have come from large scale studies among Harvard alumni and British civil servants. These recommendations in general suggest that to obtain the maximum health benefits of physical exercise, individuals should spend about 2500 k cal per week through regular and at least moderate intensity exercises. To spend these 2500 calories, an average person weighing about 65 kg

Table - 3 : Recommendations on exercise

| Intensity of Exercise | | | Target Heart | Duration | |
|---|---|---|---|---|---|
| Frequency By description | By MET level | By Borg's RPE scale | rate as % of MxPHR | (Mts per session) | sessions per week |
| Low Moderate | 4-5.9 | 13 | 70-80% | 60 - 75 | 5 - 6 |
| High Moderate | 6-7.9 | 16 | 80-90% | 45 - 60 | 4 - 5 |
| | | | | | |

will need to walk or jog about 35 kms in a week or roughly 5 kms every day.

**Comprehensive recommendations based on intensity, Duration & Frequency**

Besides the intensity of exercise and the calories to be burnt off, the duration (generally to indicate "how long during a given session") and frequency (to answer "how many times in a week?") are also equally important. The general guidelines are set out in Table - 3.

The good news is that the above mentioned exercise can be "accumulated" i. e. , it is not necessary to undertake a given session of exercise in 60 minutes at a stretch, Rather, 2 session of 30 mts each or even 3 session of 20 mts each over the day may also be good enough.

It is generally recommended that for achieving weight loss and subsequently maintaining it, people should accumulate 60 to 80 minutes of moderate intensity exercise every day. Although, to the general public, devoting 60 to 80 mts to exercise may sound a bit too much even impossible; however, once we emphasize on them that these 60 to 80 mts of exercise can be accumulated by undertaking frequent short sessions, things seem to become manageable for most individuals.

Most experts agree that the best schedule is to have 4 to 5 sessions per week, of moderate intensity exercises of 5 to 8 MET level, with each session lasting for 45 to 60 minutes. This will provide recesses for recovering, as also improve compliance, since the exercise-off days (2-3 per week) leave the participants with ample opportunities for other pursuits and social obligations. The optimum linear distance to be covered by brisk walking or jogging in a week is recommended to be about 35 km (20 miles).

**Resistance training**

Weight training and isometrics are often grouped under a general category of "resistance training". Current opinion is to encourage mild weight training as a part of exercise-fitness program. It is recommended that mild weights (20-30 pounds for men and 10-20 pounds for women) may be used, exercising all major muscle groups (chest, back, shoulders, arms, forearms, glutei, thighs and legs) keeping about 3 sets for each major muscle group and 10-15 repetitions in each set. Two or three weekly sessions of the above schedule are recommended. Care should be specifically taken not to indulge in "valsalva's maneuver" (breathing forcefully against closed glottis, as happens while straining at stools), while undertaking resistance training and even while undertaking aerobic exercises.

**Flexibility**

Gentle stretching exercises as forward bend, side bend and calf stretch are ideal. Yoga exercises are excellent for flexibility. It is best to incorporate flexibility exercises as part of overall exercise plan, during the initial "warming up" for 5 - 10 minutes & the final "Cool down" phase for another 5 - 10 mts.

**Progressing on the exercise program**

It is generally advisable to progress in three phases. In the first phase the subject starts at a low level of about 3 MET (as walking 4. 8 Kms in an hour) and over the next 4 - 6 weeks, gradually working up to a level of 4 - 5 MET (eg. , brisk walking at speed of 6. 5 to 7 km per hour) for 30 mts in a session, and having 4 - 5 such sessions per week. This level should be maintained for 4-6 weeks. Once the subject is comfortable at this level for 4-6 weeks (as evidenced by a reduction of about 5 beats per minute in the exercise heart rate at that intensity level of exercise or by a decreased feeling of exertion on the RPE scale or by ability to undertake higher level of MET exercises), the subject moves to phase – 2, wherein he/she undertakes exercises at MET level of 6 to 7 (see table of MET values, e. g. , brisk walk – jogging, covering 7 to 7. 5 km in an hour) for about 30 to 45 minutes every session, and maintaining at this level for 4 - 6 weeks. In the last phase, the subject again gradually works up, over 4 - 6 weeks to a level of 8 to 9 MET (Jogging, covering 7. 8 to 8. 5 km per hour).

**Bringing about "Physically Active" lifestyle changes**

"Structured Physical Activity" programmes, as have been discussed till now, are only one side of inculcating physical activity among individuals and communities. What is equally important is to educate and motivate persons and communities to inculcate a "physically active lifestyle" so that physical activity gets incorporated in each and every action of life. Emphasis should not only be towards incorporating "exercise sessions" in the daily time table or advising gymnasium activities. Equal emphasis should be placed on changing the overall lifestyle from one of luxury and sloth to one of physical activity at every possible moment, integrating physical activity into lifestyle with short, frequent bouts of moderate intensity exercise. This seems to provide the best answer and can be even better than structured exercise programmes. Some examples of positive lifestyle habits are shown in Box - 8.

**Box - 8 : Changing the daily lifestyle : Examples**

- Take stairs instead of the lift; make several trips.
- Put away the remote control of TV.
- Stand while answering the telephone.
- After every half an hour of office job, go out and walk in the corridor for 3 minutes.
- Park your car at the farthest possible point.
- Take a longer way around, to walk to the due destination.
- Don't use servants / children for "fetch-it' jobs; do them yourself.
- Go out for entertainment (eg, see a Movie in the theatre) rather than sitting before the TV.

The principal goal of active lifestyle is to increase energy expenditure without concern for the intensity of activity.

The basic principle is that very mild, even inapparent increases (as going out for shopping rather than ordering for grocery on telephone) may make much difference. In fact, emphasis should be on promoting low-intensity, leisure pursuits, which are seen as pleasurable (as walking a dog, gardening, etc. ) rather than simply stressing on occasional or periodic vigorous exercises. Similarly, "structured exercise" should also be encouraged but should not be presented as one which requires excessive physical effort; target should be on activities that can be easily incorporated in daily schedule.

### Practice Advocacy rather than Health Education

The effort of all health care professionals, whether in public health or in clinical domains, should be not simply to educate the community / individuals / patients, but rather to socially market the concept of physically active lifestyle. Such advocacy becomes especially important when dealing with high risk groups or with individual persons or patients.

**Box - 9 : Motivating the community members and subjects - Driving away any excuses for not exercising**

**Excuse : Lack of time**

- Take several spurts of 10 mts each, of exercise during lunch, tea time & dinner time.
- Park farthest away in the parking lot.
- Turn off TV/computer for at least 30 minutes and exercise instead.

**Excuse : Bad weather**

- Get a "treadmill" for home.
- Try an exercise video at home.
- Do stationary jogging / walking.

**Excuse : Holidays**

- Put a lot of effort into cleaning your house.
- Wash your car/two wheeler
- Go shopping and carry your packets of grocery.
- While going for shopping, park your vehicle far off, so that you walk for at least 2 to 3 Kms.

**Excuse : Feeling Fatigued**

- Remind yourself that exercise will give you more energy
- Try and "force" yourself for just 10 minutes of walk. Once you start off, chances are that you with

### Role of physicians in improving the lifestyle of subject / patient

Physicians may play a catalytic role in improving the lifestyle of people they come in contact with. An initial counselling session of 5 to 7 minutes by the physician followed by periodic telephone calls or personal interview sessions to keep up the motivation have been shown to be quite successful. Some motivatory examples to be conveyed to the community members are shown in Box - 9. The overall summary of key messages to be given to individuals are shown in Box - 10.

**Box - 10 : Key messages to be given to individuals and communities**

**There are two clear components** :-

Firstly, a formal, structured exercise and fitness programme;

Secondly, inculcating "physically active lifestyle" as a part of day to day life. Both are equally important.

**1. Structured Program:-**

Develop and meticulously follow a structured programme. Include all the three components (Endurance, Strength, Flexibility)

**Endurance**

- Most minimum : Brisk walking at least 2 miles (3.2 KM) every day or at least most days a week, covering 3.2 Km in 30 to 35 mts.
- Ideal :- Exercise at 6 to 8 MET (eg walking / jogging covering 7 to 8 Km in an hour), 45 to 60 mts per day, every day or at least 4 to 5 days a week.
- If you can exercise at even higher intensity or longer duration, the better it is.
- Instead of walking or jogging, substitute any other aerobic exercise (cycling, swimming, sports, etc.) which makes you happy.

**Strength :-**

Advisable to undertake resistance training with light weights (10 to 30 lbs) exercising all major muscle groups 2 or 3 times a week.

**Flexibility** :-

Undertake 5 to 10 mts of Yoga or other gentle stretching exercises before and after an exercise session.

**2. Physically Active Lifestyle :-**

Develop the attitude to be physically active always. Use stairs instead of lift, walk instead of driving, Remove the remote controls of TV, Fetch a glass of water yourself rather than asking your orderly, walk to you colleague's office and discuss rather than using the intercom, park your car at the farthest, and so on.

**3. Ensure Compliance :-**

Biggest hurdle in structured physical exercise or active lifestyle program is that you tend to lose out on compliance. Watch out.

### Diet and lifestyle

Proper diet is as important as physical exercise and fitness in context of lifestyle diseases. There is overriding evidence that various components of diet have strong association with IHD, Hypertension, Type – 2 Diabetes, Cancers, obesity and so on. The components of a healthy diet are shown in Box - 11. In brief, the individual components and recommendations given by WHO and various expert groups (68 – 71), are as follows :

Calories

Daily diet should provide calories which are actually

**Box - 11 : Principles of "healthy" diet**

- It should provide adequate amount of calories as required by the body, neither more nor less.
- Besides calories, it should provide all essential nutrients as protein, carbohydrates, fats, vitamins, minerals and water, as per need of the body.
- It should restrict the intake of fats, particularly saturated fats, dietary cholesterol, salt and refined sugars to within the recommended standards.
- It should promote the intake of complex carbohydrates, whole grains, fresh fruits and vegetables, while at the same time, discouraging the consumption of too much refining of grains.
- It should discourage consumption of "junk food", aerated drinks, and alcohol.

required by the body, depending on age, sex, existing body weight, amount of physical activity and other physiological requirements of growth, pregnancy, etc. In general, for a man weighing 55 Kg the daily requirements are 2400 kcal, 2800 kcal and 3900 kcal respectively if he is a sedentary worker (mostly chair bound jobs), moderately hard worker (sedentary jobs with 2 to 3 hours of brisk physical activity in a day) or hard worker (soldiers on active duties and training, agricultural & industrial labourers, etc). For a woman weighing 45 Kg the corresponding requirements are 1900, 2200 and 3000 kcal per day. Proportionately more calories will be required if body weight is higher. In context of armed forces and for purpose of planning healthy lifestyle diets, cadets / recruits or personnel on active duty involving exertional marches, climbs and training would come in the category of hard workers and may need even much more than 3900 calories. In peace time, personnel who are put to rigorous training schedules would also be considered as hard workers. Personnel who are generally performing chair bound duties but actively attending Physical training (PT) and games sessions could be taken as moderately hard working while personnel who are purely working on chair jobs and not regularly attending PT, games or any other structured exercise program could be taken as sedentary workers. Similarly, depending on the daily domestic tasks and exercise being undertaken, an officers wife may need 2200 to 2400 kcal while the wife of a PBOR may need 2400 to 2700 kcal.

### Dietary fats

The standard recommendations are that "energy from dietary fats should not be more than 30% of the total daily energy intake (preferably not more than 25% of the energy); within this limit, saturated fats should not provide more than 10% (preferably not more than 7%) of the total dietary energy". To practicalize this recommendation, let us say we have a JCO who, as per assessment, needs about 3000 kcal per day. A maximum of 30% of these 3000 kcal, i. e. , 900 kcal in a day could come from fats. Now, about 30% of this (i. e. 270 kcal) would, in any case, come from "invisible fats', which are present in the rice, wheat, legumes, nuts and condiments that we eat. Thus the remaining 630 kcal in this case could come from "open fat", i. e. , cooking oils, ghee, butter etc. Since conversion factor for fats is 9 kcal for each gram, 70 grams of open fats would be the requirement. Out of this, about 20 to 25 grams could be in form of saturated fats (butter, ghee) and about 50 gm in the form of vegetable oils. Thus, in a month, this person may consume 1. 5 Kg of vegetable oils and about half a Kg to 750 gm of butter / ghee. If this person has a family of 4 people (self, wife, two adult children) the total amount of fats consumed in such household could be about 5 to 6 Kg of vegetable oils and 2 to 2. 5 Kg of butter / ghee. Medical officers should give such practical, workable and easily understandable advise to personnel and families rather than giving technical jargon like "not more than 30% of energy should come from fats" which may not be understood by our clientele.

As regards which type of vegetable oil, one should advise that any oil which is culturally eaten and satisfies the taste is good enough, though coconut oil, hydrogenated oil and red-palm oil have a high percentage of saturated fat. It would be preferable if the cooking oils are "rotated" and a mix of oils as sunflower, safflower, rapeseed, soya bean, mustard or groundnut oil is used. What is more important is to strictly follow the guidelines for upper limit as suggested above.

### Dietary cholesterol

Recommendations are that dietary cholesterol should not exceed 300 mg (preferably not more than 200 mg) in a day. Egg yolk, Ghee, butter, high fat meat as undressed mutton /pork, thickened milk products are all rich sources of dietary cholesterol and need to be cautiously eaten.

### Dietary salt

Recommendations are that total salt intake should not exceed more than 6 grams a day, which works out to 180 grams a month. To ensure this, let us say a jawan has a family of total 4 adults. In such case he and his wife should be advised that the total salt consumed in his household in a month should not exceed 750 grams; that they may buy a one Kg pack at the beginning of the month and ensure that about one-fourth is still left at the end of the month. In addition, advise not to indulge in high salt foods (Common examples in Indian diets are pickels, chutneys, papads, sauces, soups, ketchups and tinned foods.) An additional healthy practice is to remove salt-sellers from the dining table.

### Refined sugars

As per guidelines, not more than 10% of daily dietary energy should be derived from refined sugars. For a person requiring 3000 kcal / day, this works out to 300 calories, i. e. , 75 grams sugar (conversion factor 4 kcal per gm). Thus in one month, the person should consume maximum of about 2 Kg sugar; for a family of 4 adults, the monthly purchase of sugar should thus not be more than 8 Kg.

### Fruits and Vegetables

These food items are rich source of Folic acid, and antioxidant vitamins and minerals, which are accepted to

be clearly protective against cardiovascular diseases and cancers. In one day, an adult should consume about 500 grams of fresh fruits and vegetables (not including potatoes). Thus, for a family of 4 adults, the weekly purchases should bring in almost 15 Kg of fruit and vegetables, concentrating on what is seasonally available and affordable.

Fibre

**Box-12 : Dietary guidelines for healthy lifestyle**

**Avoid eating food items which are :-**

- Fried (eg, Poori, Paratha, Samosa, Pakoda, etc)
- Creamed (eg, Custards, Ice cream, Thick creamy foods etc)
- Gravied (eg, gravied Matar Paneer, Butter Chicken, etc)
- Sweetened (eg, sweet-meats, chocolates, tinned milk, etc)
- Salt - Preserved or high in salt content (eg, papad, pickles, chutneys, sauces, etc
- Egg Yolk

**Prefer the following food items**

- Whole grains / split grains / coarsely refined flours
- Thin, watery, low energy items as thin soups
- Fresh fruits & vegetables
- Low fat dairy products as skimmed milk
- White meat (fish, skinned chicken)
- Baked, Steamed and grilled food items

**For a moderately hard working adult, the monthly consumption of following items should be NOT MORE than :-**

- 1.5 Kg of vegetable oil
- 0.5 Kg of Butter / Ghee
- 2 Kg of refined sugar
- 200 grams of salt

**An adult should eat 3 to 4 Kg fruits & vegetables in a week.**

Adequate consumption of dietary fibre has been shown to be protective against cardiovascular diseases, diabetes type-2, obesity, gall bladder disease and certain cancers particularly colonic cancers. Dietary consumption of fibre should be at least 30 grams per day (including both soluble polysacchrides as pectins and lignins found in fruits and vegetables as well as non-soloble polysacchrides (NSPs) found in grains and pulses. Adequate consumption of whole grain (sprouts, dalia, pulses, beans, etc) and fruits / vegetables as suggested above would ensure this consumption. A summary of dietary guidelines for healthy diet is given in Box -12.

### Tobacco & Lifestyle

Tobacco has been proven, beyond doubt, to be associated with a large number of serious diseases (see Box - 13). In fact, the single most important lifestyle factor as a risk for diseases is tobacco use. Globally, tobacco accounts for 27. 8% of all cardiovascular deaths, 13. 6% of all lung cancer deaths, 6. 6% of upper aerodigestive cancer

**Box -13 : Tobacco related diseases**

- IHD (RR 1.28 to 1.78)
- Stroke (RR 1.17)
- Lung cancer (RR 12 to 24)
- Oral cancer (RR 6.95 to 7.87)
- Liver Cancer (RR 1.40)
- Cancers of upper aerodigestive tract
- Peptic Ulcer
- COPD
- Buerger's Disease
- Hypertension
- Amblyopia

deaths, 6. 6% of other cancer deaths, 27. 2% of deaths due to COPD and 12. 8% of other respiratory deaths. Worldwide, tobacco use causes 4.83 million deaths, loss of 59 million DALYs and estimated economic loss of $200 billion per year. The medical recommendations regarding tobacco are very clear – individuals and communities should completely give up use of tobacco. In the armed forces, all medical functionaries should endeavour to educate and motivate troops and families regarding the adversities associated with tobacco use and to give up tobacco. In addition to educating and motivating, we must use all possible means to convince the Senior Commanders and ladies groups to exert influence in this regards, with a view to obtain the following ends :

(a) Make availability difficult (e.g. banning the sale of tobacco products in cantonment areas, near educational institutions, in messes and bars, in unit wet canteens, etc).

(b) Make the smokers feel that his smoking habit is "undesirable" (e. g. , ban smoking in auditoria, offices, meetings / gatherings, barakhanas, mess parties; create separate restricted areas as earmarked smokers rooms for people to smoke).

(c) Exerting influence through peer groups as ladies groups, religious teachers etc.

(d) Setting of personal example by influential persons as doctors, senior commanders, senior JCOs, etc.

### Alcohol

Habitual alcohol use is another major lifestyle factor associated with ill health and a large number of serious diseases, as depicted in Box - 14. Besides, it has additional social and emotional problems, and disrupts family and organizational health. A WHO report indicates that alcohol use accounts for 3. 2% of all global deaths and 4% of all global burden of diseases; it also accounts for 3.5% of all DALYs lost due to all causes. What is even more concerning is the recent trend wherein lay magazines tend to put across a conveniently distorted version of the medical research findings and tend to indicate that moderate drinking is good for health. This is, in fact, an issue which all medical persons would need to counter when talking to troops as well as commanders. While it is agreed that "moderate" alcohol intake may be associated

**Box - 14 : Alcohol related diseases**

- Hypertension & Stroke (RR 1.4 to 4.1, depending on intake)
- IHD (mild consumption may be protective (RR = 0.68); heavy consumption carries risk (RR = 1.33)
- Obesity
- Diabetes Mellitus type – 2
- Female Bresat Cancer (RR 1.14 to 1.62)
- Oral Cancer (RR 1.45 to 5.39)
- Road Accidents
- Other cancers (aerodigestive tract, stomach, pancreas, kidneys, bladder) (RR 1.8 to 4.93 depending on intake and site)
- Liver disease (RR 1.2 to 13 depending on intake) (cirrhosis, increased susceptibility to liver infections)
- Pancreatitis
- Degenerative neurological diseases
- Social and emotional problems
- Psychiatric problems and dependence
- Lack of efficiency and organizational issues.

with higher HDL-cholesterol levels and lower IHD mortality, the fact also remains that even continued moderate level alcohol intake is associated with a number of other diseases like road accidents, various cancers, obesity and hypertension. Secondly, it is quite difficult to maintain "moderation" - many of those who are initially moderate may become heavy drinkers gradually. Thirdly, there are various other more healthy methods (as brisk, regular physical exercise) rather than drinking, to increase the HDL levels. All these aspects should be emphasized on the clientele. The relationship between even mild drinking and obesity (with all the consequent ill health effects of obesity) is quite logical, as depicted in the

**Box -15 : Alcohol even in mild quantities, promotes obesity by :**

- Providing "blank" calories – each gram gives 7 kcal; I small peg gives 70 kcal, equal to running 1 Km !
- Promotes overeating
- Desire to eat rich, fattening food
- Reduces desire of physical activity

**Box - 16 : Defining "moderate" drinking**

- A "unit" of alcohol is defined as equivalent of 10 grams pure ethanol.
- This will be equal to 1 small peg of hard drink or 100 ml of Wine or half a bottle of Beer.
- Moderation means maximum of 3 units in a day for men ( and 2 units a day for women)

Box - 15. In addition, even two small pegs may raise the blood alcohol level beyond the legally acceptable limit (in India 30 mg %), and may interfere with the protective reflexes, causing road accidents. The hazards of alcohol use should be well communicated to our clientele and they should be motivated to give up alcohol. The recommendations should be

(a) There is nothing like medically prescribed or medically encouraged drinking to get good health; With all its well documented resultant diseases, alcohol should not be used.

(b) However, despite the above exhortation, if somebody still decides to drink, he or she may do so provided there is no other risk factor (Obesity, Diabetes, hypertension) and provided one drinks only in "moderation". The guidelines for "moderation" are in Box - 16.

(c) Besides restricting to moderation, adhere to the following principles : firstly, never drive after drinks (even after very mild drinking); secondly,

Col RajVir Bhalwar & Surg Capt VSSR Ryali

# Mental Health and Stress Management

Mental health is an important component of the total positive health. Every physical ailment has a mental component and every mental illness has a physical component. The WHO expert committee defines mental health as 'the capacity in an individual to form harmonious relation with others and to participate in or contribute constructively to change in the social environment'. The comprehensive concept of mental health has thus a four-fold goal before it: to understand and cure the different types of mental disorders and defects; to detect the cases of incipient mental breakdown early; to prevent, or at least to minimize the occurrence of the disorders and defects and improve the mental health of the community (72).

**Box - 1 : Classification of psychiatric disorders (ICD - 10)**

- Organic :- Acute e.g. delirium and chronic e.g. dementia
- Substance misuse
- Schizophrenia and delusional disorders
- Affective (mood) disorders
- Depression
- Mania
- Recurrent affective disorders
- Neurotic, stress related and somatoform disorders: -
- Anxiety disorders including generalised anxiety , phobic anxiety and panic disorder
- Obsessive compulsive disorder
- Reaction to severe stress
- Acute stress disorder incl Post-traumatic stress disorder & ddjustment disorder
- Dissociative disorder
- Somatoform disorder
- Neurasthenia
- Behavioural disturbances :- Eating disorders, sleeping disorders, sexual dysfunction and puerperal mental disorders
- Personality disorders e.g. thumb sucking, bed wetting, juvenile delinquencies.

Classification of psychiatric disorders is shown in Box - 1.

### Magnitude of the problem

Worldwide, About 500 million people are believed to be suffering from neurotic, stress related and psychological (somatoform) problems. A further 400 million suffer from anxiety disorders, 340 millions from mood disorders, 60 million from mental retardation and 45 million from schizophrenia. It causes a heavy burden of suffering and economic loss (73). In India (74) surveys on mental morbidity in various parts of the country suggest a prevalance rate of 18-20 per 1000. In the armed forces there has been an increasing trend, during the period 2000-05, as shown in the introductory part of this section (31).

### Prevention of psychiatric diseases

As with all other diseases, prevention is the first line of defence against psychiatric illnesses (75-78).

#### Careful recruitment

This is the most important stage. An assessment of the potential recruit's mental capacity and strength of personality is essential. Individuals showing somatic symptoms of anxiety e.g. tachycardia, hyperhidrosis and tremors should be rejected. The motive for recruitment should be ascertained and any one with poor or negative motivation should be rejected. A history of mental illness in the family, of severe domestic problems and also of personal instability are indications for rejection. A detailed psychological assessment is not always possible, but every attempt should be made to eliminate individuals with low intelligence, emotional instability, weak personalities and history of gross maladjustment in civil life.

#### Screening at the training centers

It is possible to detect susceptible individuals during the training periods at the centres where the recruits are under constant observation of their instructors. Apart from homesickness, which usually passes off within 2-3 months, a recruit who does not show satisfactory adjustment at the end of 3 months should be discharged as unsuitable.

#### Training and selection for specialist trades

Many breakdowns are precipitated by unhappiness and discontentment with their trades. Every effort should be made to select men according to their individual aptitudes and capabilities. This is very important with regard to the highly skilled specialist trades like radar operators, signalmen, engineers and so on who may breakdown at critical moments and for whom replacements may not be readily available.

#### Maintenance of high morale

This is essential for a fighting unit and is more important than even superior equipment. The basic ingredients are leadership and good man-management. In addition to these, adequate training and battle indoctrination before action are essential to keep the men mentally fit, confident and eager to fight.

#### Elimination of precipitating factors

The stress of service in forward areas and of actual battle cannot be eliminated. But there are a number of factors, which aggravate this stress and precipitate breakdowns.

These may be domestic problems like marital disharmony, financial difficulties, illness of the wife and children, and other social and cultural difficulties. A man can fight and work better if his mind is free from these problems. Frequent letters from home, regular remittances of money to his people, leave when he needs it, promotion in due course, and well-organised welfare services reduce these stresses and hence minimize the chances of breakdown. Proper living conditions, adequate food water and sleep are also important factors. Human nature is such that a man will put up with physical hardships if he knows that these are inevitable. But if he suspects that these are due to the leader's carelessness, his morale is quickly lowered and this constitutes a dangerous precipitating factor. No one is prepared to suffer and die because of bad leadership.

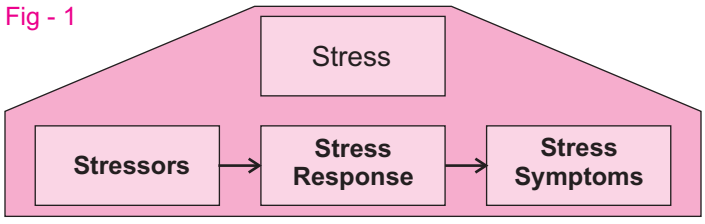
## Prevention and management of mental stress

There is a lot of talk going around these days about stress. Almost every week, some medical journal or lay magazine brings out an article on this issue. Most of the time, doctors also tell their patients to cut down on their stress. However, to the general public and patients, it is quite vague and confusing. What is stress? Why does it occur? Can we do away with it? Such questions can be quite intriguing. In contemporary times, any doctor engaged in health care of the community, especially from the armed forces, should be very well aware about all these aspects, so as to educate the clientele and be able to prescribe a road map for management of stress.

### What is a "stress response"

The term "Stress" is used as an umbrella term to cover all aspects associated with the phenomena. However, what really concerns us is the "Stress Response". This is the sum

Fig - 1



total of body reaction, both physiological and psychological, in response to a "stressor" i.e., an event occurring outside the body in the external environment. The stress response leads to various "Stress Symptoms" or "Stress diseases" (Fig - 1).

So, it is not really the "Stressor" (i.e the situation) that leads to stress but our perception of that event, the meaning we attach to it and the way we react or respond to it that leads to symptoms or diseases of stress.

To elaborate, stimuli from the environment or thoughts generated within the mind become amicable or inimical depending on whether they generate positive or negative effect. An inimical reaction brings on the fight stress response if one is angry and charged and the flight response if one is insecure or defeatist. Taking this argument forward will lead us to solutions for stress stimuli. We can alter our stress response from inimical to amicable and manage to cope with the stress stimulus. For example, let us say, to jump down to the ground from the roof, just 10 feet high, may be a tremendously stressful for most of us. Majority of us, on looking down at the ground, would feel "butterflies in the stomach". However, for a seasoned paratrooper, it would be fun. So, it is not the stressor (events, persons or environment) but our own interpretation and how we react that decides whether we will get "stressed" or not. As somebody has rightly said - it is not the "news" that stresses but rather the "editorial" that we ourselves write about the news (stressors) that leads to stress response.

### What is stress threshold?

Each of us respond to stress stimulus differently. In other words each of us has a different stress threshold. What determines this stress threshold? It is the training imparted to the paratrooper, in the example above, that makes him react differently. Other factors that influence the stress threshold are genetic make-up, family traits, cultivated habits, personality make-up and environmental factors.

### What is the biology of the stress response?

Nature has built the stress response into our biology and that of all animals for a protective and desirable reason, viz, to gear up the entire body to deal with acute physical emergencies. Just imagine our primitive ancestors, a few thousand of years ago. They were exposed to constant dangers- hunted down by tigers and bears, at the most unsuspected time. When a hungry tiger was about to take a leap on them, they had no time to contemplate sunset, so that they could hide in the darkness, even no time to objectively assess the approaching danger. To survive such flash emergencies, nature developed the instantaneous "stress response" or "fight or flight" response in our body (79 – 81). This quick response is mediated through the autonomic system (ANS), so named because it was presumed to be out of voluntary control. It has two divisions, the sympathetic and the parasympathetic. The sympathetic nerves tense up the body and set it aflame. The humors secreted by the sympathetic nerve endings are epinephrine and norepinephrine. Sympathetic stimulation is associated with increasing body temperature, speeding up the heart rate and respiration, burning up the food faster, increasing the glucose in the blood stream and raising the blood clottability all of which are required for the fight or flight response. In contrast the parasympathetic system cools the body and relaxes it so that it can recover after the fight or flight. The humor secreted by the parasympathetic nerves is acetylcholine. It is note worthy that the ANS contains components which not only bring about the stress response but also recovery from it.

The endocrine response mediated through the hypothalamus, pituitary and adrenal glands consists of a massive cascade of instantaneous physiological changes, mainly through hormones like noradrenaline and cortisol. Within milliseconds of their release, they would cause the heart to beat faster and more strongly and the blood

pressure to rise (so that more and more blood laden with oxygen and glucose could go to the muscles, to either fight it out or run away). The breathing would become deep and extra glucose would be pumped into the blood by the liver so that more of sugar and oxygen could be taken by the blood to the active muscles. Kidneys start saving water so that blood volume can increase, digestion reduces and blood from digestive organs is diverted to the active muscles. In addition, the blood clotting mechanism would increase so as to quickly seal off the wounds and minimize blood loss due to bleeding from injuries. All these massive physiological changes occur within the fraction of a second. Their purpose is to prepare us to take instant action against an acute physical stressor, by either fighting it or taking a flight.

The stress response is, in fact, protective for our body, rather life saving. So, where does it fit into the problems of stress that we are talking about? Well, the same stress response which was so useful and protective during the evolutionary stages of human race seems to have become a major hazard to our health. In our modern day life we seldom face the kind of physical danger for which nature had designed the stress response. The response was life saving for our ancestors when a hungry tiger suddenly pounced on them. Even today, we need it on some relatively uncommon occasions, as when a dacoit suddenly pops up from the bushes, while we are on a lonely track.

However, certainly we don't have to have your body and mind in such a state of alarm, and that too for prolonged periods of hours (may be, weeks or months), to negotiate modern day "stressors" or challenges like having a difficult boss, staying separate from the family, preparing for an important competition, difficulties in career, or lesser difficulties like having a flat tyre while driving on the highway. Unfortunately, even for these small hassles, the body's stress response remains massive or perpetual. The increase in blood pressure and heart rate, increase in blood sugar, increase in blood clotting mechanisms, taut muscles, lowering the immune defence of the body and reduction in the digestive process continue for long periods and lead to major diseases like hypertension, diabetes, peptic ulcer, infections due to reduced immune defence, muscular and joint pains, just to name a few. It is therefore essential for us to learn ways and means to calm down our reactions to the stressor, and to develop adequate "coping mechanisms" to tackle the stressors of day-to-day living.

### The adverse effects of stress

Stress affects our health in a wide variety of ways. The adverse effects are summarized below.

Psycho-somatic

These include IHD, hypertension, diabetes mellitus, peptic ulcers, predisposition to certain cancers, lowered immune functioning, arthralgias and myalgias, tension – headaches, etc.

Emotional

These include suppressed hostility (which in turn is a well documented risk factor for IHD), anger, panic, irritability, "burnout", fatigue, sleep disorders, anxiety, depression, and, suicide / attempted suicide.

## Roadmap to understanding stress and its management

### General overview

In today's world, especially from preventive point of view, stress is not something which happens to you. Rather, it is the "meaning" that you assign to the "events" that happen to you, i.e., how you "appraise" these events, that determines whether you will be affected by stress or not. It is, thus, your personal appraisal of the seriousness of the event and the adequacy of your coping resources, that determines whether you will or won't respond stressfully. The general map to understanding stress is as under.

Demands are those requirements placed on us, which are potential stressors. A demand can be something as minor as a wrong telephone call in the night, or as major as reporting of embezzlement of funds in your office. At this point, we are not calling a "demand" as a "stressor", because not every demand may end up becoming a stressor. Demands may be of four types.

Firstly, the most exacting demands are "self imposed". These often include perfectionist or highly ambitious expectations. The list of such demands may go on and on. Unfortunately, most of us have little tolerance for failing to meet them. Another set of very frequent demands that need to be coped up with are the "roles" that we are expected to play. i.e., those of husband / wife, father, subordinate, team-leader, and so on. As opposed to self-imposed requirements, role requirements come from other people (spouse, children, superiors, subordinates etc.) and are therefore much less under our control. Moreover, demands arising out of role-requirements can come up suddenly and unexpectedly, as the sudden requirement to care for a sick child.

The third type of demands are "significant life changes", such as coming down with a major, long term illness, moving on transfer to an uncongenial area which entails separation from near ones, loss of a loved one and so on. Finally, there is a fourth type of demand, viz., "daily hassles of life". In fact these can be more detrimental to your health than even major adverse events. These include a wide range of relatively minor events that plague your daily life, like an unexpected downpour, or your child's school suddenly deciding not to operate the school bus for the next one week, and so on.

### What happens once a "demand" is placed on us ?

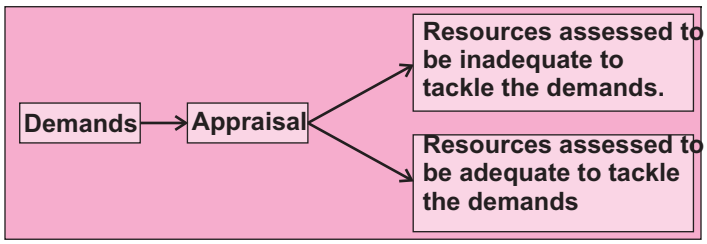
Once a demand is placed on us, it does not straightaway lead to stress. There are certain intermediary mechanisms that occur, before we experience stress. The awareness of "demand" is followed by our "appraisal" of the problem. This step is more important, since, as described earlier, the impact of a demand (stressor) is a function of, not only the event, but also the appraisal that we make of our own coping abilities to deal with it. The sequence of appraisal is as follows.

Firstly, the "primary appraisal", which involves evaluation

of the significance of the event. In fact, we ask ourselves "Am I in trouble?"

After the primary appraisal, comes the secondary appraisal. This involves the question "Can I handle it?"

Following the primary and secondary appraisal, if we feel that, firstly, we are in trouble, and secondly, we also feel that the demand (potential stressor situation) would outweigh our available coping resources, we are likely to experience the stress response, with many of its consequent "stress symptoms". On the other hand, if we appraise the demand as not being difficult, or else we see our "resources" as adequate to cope up with the demand, we experience a "challenge" and also the opportunity to increase our capability of 'coping". Thus, handling stress



may be a feast or famine situation. If we are able to cope up with the demands (stressors), we become energized; if not, we stand to be adversely affected by stress.

**Broad outline of the roadmap for preventing and managing stress**

The road map that we shall go through consists of the following sequential steps :

(a) Pre-emptive / preventive methods : The focus is to take prior steps to avoid difficult (stressor) situations and secondly, to ensure that difficult situations, if they occur, are seen as mild problems.

(b) Steps to develop adequate coping resources within the mind and body, which could be drawn upon, when faced with stressful situations.

(c) Developing the appraisal capabilities for analyzing, whether a given demanding situation does pose a threat and, secondly, if it does, to correctly appraise whether we have adequate coping resources to meet the demand. This step is quite important, because, depending upon the accuracy of our appraisal, we take either of the following two steps, as mentioned in paras (d) and (e) below.

(d) Problem focused coping : In case our appraisal indicates that our coping resources are adequate, we would take steps to combat the stressor.

(e) Emotion focused coping : If, on the other hand, the appraisal indicates that our resources are not enough to directly combat the stressor, we live with the stressor, but, at the same time, try to minimize the stress response.

Preventing / pre-empting stress & developing "coping resources"

This is quite pertinent as the better part of valour is to avoid unnecessary battles. This holds good for potential stressors too. To meet this end, we have two broad strategies, viz., firstly, by taking steps that difficult situations, even if they occur, will be seen as mild issues, and secondly, to avoid potentially stressful situations. The first of these pays us pretty well, though we have to start making efforts a long time before the appearance of potentially stressful situations. In addition, besides management of stress, these qualities, once developed, help us tremendously in improving our overall quality of life. Interestingly, these are not medical measures but managerial techniques which are given below.

**Learning and practicing decision - making techniques**

A number of decisions that we make about ourselves are much more important and have far reaching consequences than most of the other day-to-day decisions. For instance, choosing the wrong habit (drinking, gambling, etc.), the wrong occupation or friends, or making an unwise financial investment can create an endless string of future stressors. Consequently, learning and actually using proper decision making skills when faced with critical situations, can prevent much of stress later on. Wise decision making incorporates the sequential steps of firstly, defining the problem at hand, secondly, identifying the various alternative options at hand to tackle the problem, thirdly, deciding on the best option and finally, committing oneself to th selected course of action.

**Develop personal financial management skills**

Some of the major stressful situations in our lives result from financial crisis. These are often the result of poor financial management. Failure to take accurate stock of our existing income / projected income over the next one or two decades, reckless or impulsive spending, materialistic ambitions and a score of similar reasons, finally lead us into a situation when we don't have the finances at the time when they are most needed. While financial advisors and books on the subject are available and it may be worthwhile to take their advise, the minimum that everybody should do is to write down, on a paper, the income and expenditure. Having taken a written stock of the credits and potential expenses, one can sensibly match the resources. Whatever methodology you adopt to manage your finances, just remember that, firstly, improperly managed finances are one of the most important stressors of modern life. Secondly, one must avoid excessive desire that could fall in the category of "greed" (rather than essential or desirable for decent life), since, in our drive to fulfill such desire, we add further stress to our lives.

**Develop Time-management skills**

The work schedules as well as commitments in today's life, make time a premium entity. Managing available time in the most gainful and productive manner is a skill, which has to be learnt, practiced and sharpened over the years. Improper time management is an important cause of

getting stressed out.

**Make conscious and deliberate efforts to maintain good health.**

Even when one suffers from a disease as minor as common cold, one feels demoralized. Apparently, if one had to suffer from major diseases like heart disease, raised blood pressure and so on, the amount of stress that the person would be subjected to would be tremendous. One should therefore make conscious effort to maintain good health and prevent such diseases. Unfortunately, the value of prevention is often realized when one comes down with these diseases. In short, incorporating simple measures for a healthy lifestyle, like regular brisk exercise, giving up tobacco, avoidance of alcohol and eating a healthy diet would go a long way in prevention of some of the most dreaded diseases. One must remember that the boost that one gets from a state of good health is itself a tremendous stress-buster. On the same analogy, besides looking after one's own health, one should also deliberately and consciously look after the preventive health care of one's family members. Good health of your near one's prevents your stress.

**Undertake regular and brisk physical exercise** : By now, it has been clearly demonstrated by medical researchers that regular and brisk exercise is a major "stress-buster". In addition, the resulting physical fitness tends to shape up the psyche and physiology in such a way that we tend to become resistant to developing stress. With regular exercise, the body and mind get used to cope up with this adverse physiological challenge and the resulting high surge of stress hormones. In other words, the body and mind get acclimatized or "hardened" to stress in a very healthy manner. Secondly, it is also well known that brisk and regular exercise leads to release of beta-endorphins. These chemicals act on the brain and bring about a feeling of euphoria, well-being, confidence, alertness and decrease in pain sensations. It is almost like getting a kick after little dose of opium, though in a very healthy manner. This "high" state, caused by physical exercise due to endorphin release, persists for a few hours after exercise and has a very important role to play in both, reducing our threshold to stress as well as to subside the adverse effects, should a stressful situation occur.

**Train the family members for difficult situations** : Staying separated and fending for themselves is a task which many families have to undertake, when the head of family is away for prolonged periods, as a part of the service. An important reason for stress among the head of the family, when he is staying away, stems from the constant worries that occur about the family. It is therefore logical that people should visualize that occasions may come when the family has to stay separated. One should think of the problems that the family members would face during such situations and try to train the family members in dealing with the routine as well as the difficult situations. Once a person is confident that his family members would be able to fend for themselves during his absence, he will be much less stressed during the period of separation.

**Spend "Quality time" with your family**

Whenever one gets the opportunity, one should make sure that one spends at least a few hours of "QUALITY TIME" with the family members. By quality time we mean that you should get involved with them – play with them, teach them and so on, rather than simply sitting with them and surfing around the TV channels. From the psychological point of view, one of the major precursors of stress is the feeling of being "isolated" or "disconnected". On the other hand, when you spend quality time with your family members, you feel connected, without any feeling of isolation, which helps preventing stress.

**Develop Social Support Systems**

We, human beings, are social animals. At times of need, we should have social support. This is particularly true when we are faced with difficult and stressful situations. Therefore, it would be a very wise investment to put in some effort to develop some close friends towards whom we can look up for support during stressful situations.

**Avoid Ego struggles** : Many stressful encounters with others are, in fact, unnecessary ego struggles where the only prize is protection of your self-image, but the price is exposure to substantial stress, not only in the imminent future but also in the long run. We often argue with our colleagues, superiors, spouse and even children about trivial issues that really don't matter much. The point of argument in most of these situations is not really the subject of discussion but rather to decide who is to be declared "right" or the "winner". We sometimes act as if it is more important to be seen as "right" rather than be happy. It is best to avoid the tendency to forcefully convince others when it is not so critical to your own health and well-being. Doing so will help you escape a great deal of unnecessary stress. Try and seek "win – win" solutions to mutual problems and remember that 'compromise" is not as dirty a word as most of us think it to be.

**Adopt traditional cultures** : As Indians we have the advantage of a rich and ancient culture. Patanjali advocated Yoga as a means of attaining physical and psychological health 5000 years ago. Our culture has elaborated on the virtues of need based living, sharing, acceptance of good with the bad, and renunciation, which if combined with advantages of modern living will improve the quality of life many fold.

**Practice methods to get a good sleep**

Good sleep is very important for de-stressing us, as well as in assisting the repair of the physical and the mental breakdown that occurs during the whole day. Stress often interferes with our normal sleeping pattern. When we have anxiety or depression, we find it difficult to fall asleep, may wake up in the middle of the night and find it difficult to go back to sleep or get up too early feeling un-refreshed. Accordingly, practicing methods for getting a good sleep is likely to be of much help in both preventing stress as well as negating it's adverse effects. Some tips for getting good sleep are :

(a) Associate the bed with sleep only. Don't eat, read or watch TV while in bed.

(b) Avoid caffeine containing drinks (Tea, Coffee) or tobacco before retiring.

(c) Don't use alcohol to get sleep. Alcohol may make us drowsy and may initiate sleep, but interferes with the rhythm of normal sleep and causes rebound arousal of brain. The net effect is that it leads to more tiredness than relaxation.

(d) If you have difficulty in falling asleep or tend to have disturbed sleep in the night, then stop sleeping in the afternoons. This is believed to be a useful adjunct in managing stress (83).

(e) Undertake brisk exercise in the morning – you will have a nice sleep in the night. Schedule the brisk exercises for the morning (jogging, swimming, field games, cycling etc.) and light exercises (golf, light walking,) for the evening.

(f) Keep a regular sleep schedule – go to bed and get up roughly at the same time.

(g) If, on some odd occasion, despite all the above measures, you are still not able to get sleep, then do not try to "force" sleep by tossing and turning in the bed. Get up, sit down with a light reading and relax till the time you feel like dozing off.

**Practice "assertiveness" skills**

Assertiveness does not mean being aggressive. The former is a very good quality, while the latter damages the personality and the social support systems. Assertiveness is the honest expression of what you feel and want from others, without trying to force them to give it. Assertive behavior needs to be developed gradually and carefully. It is particularly useful when dealing with "difficult" people and the consequent stress.

Some of the characteristics of assertive behavior which need to be developed are :

(a) Speak up for yourself, for your needs and rights, while letting others to speak for themselves.

(b) Develop a sense of respect for yourself as well as for others.

(c) Protest, maybe politely but definitely, against unfair treatment or unjustified criticism.

(d) Take honest responsibility for your own wrongs / mistakes but, at the same time, do not take responsibility for someone else's lapses.

(e) Say "NO", maybe politely, when you feel that a particular task or favor being asked of you is unjustified or beyond your capabilities.

**Practice "Relaxation Techniques"**

There are certain proven techniques, which, if practiced for just 15 to 20 minutes a day, will help control stress related tension. These include Abdominal Breathing (Diaphragmatic breathing). To undertake abdominal breathing, sit comfortably, with your back upright. Place your left hand on the chest and right hand on the abdomen. Now, breathe in slowly, through the abdomen, so that the abdomen expands, but the chest should not expand. You can come to know of this by noticing your hands – if you are breathing through your abdomen, your right hand will rise but the left hand will move only very little. Now, gently exhale as much air as you can by slowly contracting your abdomen but not your chest. Once again, your left hand should move very little, while the right hand goes down perceptibly. Practice abdominal breathing for 4 to 5 minutes at any fixed time of the day. In addition, try breathing that way when faced with (or immediately after) a stressful situation.

**Progressive, Deep Muscular Relaxation**

For practicing this technique, you can either lie comfortably on your back, or else, sit in a chair. Begin by taking a slow and deep breath. At the same time, lift your heel a few inches off the ground and extend your legs, pointing your toes towards the knees, thereby tensing your thigh muscles and stretching your calf. Hold in this position for a count of seven. Now inhale deeply. Contract the muscles of your right arm and raise the arm by a few inches. Hold in this raised position for a count of seven, then let it fall down, limp. Relax for a few seconds, then repeat the same procedure with the right arm. Finally, gently roll your head from side to side and allow your neck to relax. Now inhale and tense up all the muscles of your face, including those of jaws, eyelids, cheeks, lips and forehead. Keep them squeezed for a count of seven, then let them go limp, let the jaw drop down and slowly exhale.

**Spiritual Practice and Meditation**

Engagement in spiritual practice in various forms has been shown to have a strong role in both, preventing the stress response, as well as for coping up with a deleterious stressful situation (82 - 85). Most of us tend to relate the word "spiritual" to organized religious activities. However, spirituality can also be practiced outside the formal / institutionalized religious environment. It needs to be noted that spiritual techniques cannot be a "one – time prescription" which one can indulge at week-ends. For optimum results, these techniques need to be adopted as part of daily lifestyle. The important methods of spiritual practice relevant to stress management are :

**Praying**

The power of praying has been of much interest to the medical fraternity in recent times. Praying, from the stress management point of view is like "connecting" us to a higher form. It reinforces our confidence and strengthens us with the feeling that we are not alone and that there is some higher power on which we can bank upon. This hope and confidence leads to release of certain hormones / chemicals in our body which strengthen the physiological functioning of various organ systems. It would be worthwhile devoting at least a few minutes once or twice a day for praying.

**Meditation**

The soothing physiological and psychological benefit of meditation is well known. Meditation does not belong to any particular religion and has a long history. Meditation essentially means "concentrating or focusing attention on an object and shutting off the mind to all other external

thoughts". With practice, one will realize that meditation is not something done once or twice a day for a few minutes. One can, in fact, bring that enhanced awareness to everything one does throughout the day.

Undertake meditation at a place that you have earmarked, so that you associate that place with meditation. Sit down in a comfortable position – in a chair, relaxed, hands on the lap or on the ground, cross-legged. Decide on the sound that pleases you which could be a verse or text from any religious book or a humming sound. Instead of a sound, the object of focus could be a light source or image, real or virtual, whichever suits you. Concentrate on the sound or image and remove any other thought that comes to the mind for the next few minutes that you are practicing meditation.

**Yoga**

There is enough evidence to indicate that Yoga is a powerful strategy for coping up with stress. An ancient Indian practice, Yoga is essentially a way of life. In general, try to practice Yoga daily or at least on 4 to 5 days in a week. It is not necessary to do complicated stretching exercises but even simple ones like a combination of sarpa-asana (Cobra posture), Dhanur-asana (Bow pose), Head rotation, shoulder rotation and shava –asana ( Corpse pose) can be reasonably good. Practice can be undertaken at any time but is usually best in the mornings. Ideal is a physical fitness schedule consisting of 10 to 15 minutes of Yoga, followed by 45 to 50 minutes of brisk exercise and lastly meditation and praying for 5 to 10 mts each.

Emotion focused coping

Our discussion so far has been directed at preventive measures and on development of coping resources. However, in anyone's life, there are some inevitable difficult situations. Growing old, suffering from chronic diseases, getting bypassed for promotion etc., are just a few examples of human predicaments that we must learn to live with. These are the situations where it would be wise for us to use the "Emotion Focused Coping" rather than the problem focused approach. The important components of emotion focused approach are listed below.

**Accepting the inevitable**

Once it appears that the problem is there to stay, it is best to accept the same. For those who have developed adequate coping resources, as faith in God, this becomes easier. One must draw lesson, in such times, from the prayer of St Assisi, which says "God, give me the courage to change what I can, the strength to accept what I can't and the wisdom to distinguish between the two".

**Don't discount the importance of hope**

Hope is a powerful ally in dealing with stress. The hope that things will improve goes a long way in reducing stress.

**Suppress the distressing thoughts** : If you have done what all can be done, then further mental processing of the problem can only make matters worse. This is because the body's physiology and hormonal system does not distinguish between fact and fantasy. The continuous mental processing creates a state of despondency. In such situations it is better to suppress our thoughts to control the resultant emotional responses.

**Reframing**

As stated before, stress response is not triggered by the problem but by the meaning attached to it. Thus, if we change the "meaning" attached to the situation, we can change the emotional response. This strategy is "reframing", in which we start looking differently at a situation, and, while accepting the problem, we look out for positive elements that might make the experience less stressful, by questioning "What could be good in this situation? There has to be something good! Or what can I learn from this situation?

**Discharging painful emotions**

We often become unhappy or even sick, due to bottled up emotions. Disclosing our feelings to a near one, or to a Doctor, often provides much relief. Another method is to write a personal diary, often referred to as "therapeutic writing". Maintaining a stiff upper lip may be a part of the self created "strong personality" for most of us, but it does not seem wise from what we know of the human emotions.

**Stress prevention in the armed forces : A check-list**

Armed Forces have peculiar types of stresses, like being faced very often with life and death situations, uncertainties about future and compounded by staying alone, away from near and dear ones. The guidelines given in the preceding paragraphs would be of considerable use in preventing and effectively tackling mental stress among industrial workers and armed forces. It is suggested that armed forces Doctors educate the commanders, personnel and families in these various steps as have been outlined above. Some additional tips for the military commanders are given below.

(a) Educate your subordinates on the various preventive / pre-emptive as well as stress – coping methods, as explained in detail in this chapter.

(b) Stay "connected" with your subordinates. This may take the form of physical contact like hugging or shaking hands or maintaining touch through playing together.

(c) Talk a lot to your subordinates and encourage them to talk about themselves, their families and their problems. This greatly helps in "opening up" and reduces stress.

(d) Allow, rather promote, humor and laughter. Make sure people speak out their painful experiences. This helps in "discharging" painful feelings and combats stress.

(e) As a leader, develop the art of "listening" to your subordinates. Send messages that you are listening to them carefully, as by giving head-nods or saying "yes" in between, or by repeating the last few words of what they have spoken.

(f) Encourage regular and brisk physical exercise in the form of organized physical training and sports. Besides having tremendous stress busting ability, physical exercise also promotes "togetherness" and combats loneliness and isolation.

(g) Keep everybody informed about your plans and job expectations (of course on a need – to – know – basis). One of the causes of stress in workplaces is the "lack of control on circumstances". By letting everybody know about the tasks to be performed and the reasons for the same, you would let the subordinates have a feeling that they are "in control" of the situation.

(h) Promote spirituality and meditation. Regular partaking in worshiping in an organized manner and organizing sessions on meditation / Yoga can reduce stress among employees. Discourage alcohol and tobacco. Restrict occasions where moderate alcohol consumption is permitted. Never let people drink alone in their bunkers / rooms.

(j) Encourage subordinates to write. A good method is to encourage them to frequently write letters to near and dear.

(k) Show your subordinates that you are fair and impartial. Convince them by talking to them frequently that the physical / mental difficulties faced by them are for the combined good of the team and are only for a temporary period only.

(l) Leave is an important aspect in Armed Forces as personnel stay away from near ones for prolonged periods. Such break from routine and meeting family disrupts the vicious circle of isolation and stress. Hence, leave should be provided regularly to the extent possible, subject to exigencies of service.

(m) Never discount the value of hope. Keep optimism alive in yourself and your subordinates.

(n) Establish a "buddy" system wherein each member of the pair is responsible for taking care of his buddy and keep vigil for early signs of stress. The early signs of stress are described below.

What are the early signs of stress ?

Early recognition of stress is important. The first step is be alert to the signals of stress emanating from our body and mind. Quite often your near and dear ones or the "buddies" notice them and it would be worthwhile to occasionally ask them if they have noticed such signs in you. The signs of stress are listed below.

(a) Headache, pain in neck, backache, aches in muscles and joints, fatigue and exhaustion, vague symptoms of indigestion, sleep problems (either difficulty falling asleep or getting up in between sleep)

(b) Feeling of being distressed / harassed, decreased interest in life and decline in cheerfulness.

(c) Deterioration of inter-personal relationships, whether at home, workplace or in social circles, increased "tiffs", frequent bouts of irritability and social withdrawal.

(d) Deterioration of performance, difficulty in concentration, forgetfulness, increased errors, reduced efficiency and decreased motivation.

(e) Initiation or increase of substance abuse (alcohol, tobacco etc.).

(f) Excessive and frequent eating of food / snacks or avoidance of food and gain or loss of body weight in a short span of time.

Medical Officers should emphasize on the clientele that these warning signs are subtle and may be easily missed, unless one is very observant. For noticing them, one will have to search for these signs and deliberately listen to one's mind and body. One may have to ask your near ones if they noticed these signs in him. If such signals are noticed, they should not be dismissed lightly. Serious action should be taken by bringing all the coping resources (as discussed earlier) into play. Secondly, the clientele should be assured to consider the Doctor as their best friend; to talk to him about their problem. One must realize that stress can occur to anybody . It is no disease to be shy about. It is just a reaction of one'sbody to the adversity in the environment. So, even if there is a slight doubt, one should talk to the family members, friends and with the Doctor.

Col RajVir Bhalwar

# Ischaemic Heart Disease (IHD); Syn: Coronary Heart Disease (CHD); Coronary Artery Disease (CAD)

IHD is the prototype example of lifestyle diseases. In affluent countries, it is the most devastating disease, often accounting for almost a quarter of all deaths. It has also been the most researched disease in modern times regarding it's epidemiology, risk factors, management and prevention. The term Cardiovascular Diseases (CVD) encompasses a wider spectrum of diseases which include IHD, heart diseases other than IHD, Systemic arterial hypertension, Stroke and, Peripheral vascular disease (PVD). Within the gamut of the term IHD, we have a wide spectrum of conditions, starting from asymptomatic coronary insufficiency at the mildest end and sudden death at the other, in between we have typical angina, atypical angina and acute Myocardial Infarction, representing increasing severity along the spectrum.

### Definition

IHD is defined as a state of lack of supply of oxygen to the myocardium vis a vis the demands, due to narrowing of the coronary arteries as a result of the atherosclerotic process.

### Magnitude of the problem and frequency

IHD places a mammoth load of disease and ill health on humanity. In developed countries, half of all deaths are due to CVD and a quarter due to IHD. In developing countries, the problem is no less; as economic development will occur, IHD may, by the year 2025, become a leading cause of death and disability in our country.

IHD derives its importance for a variety of medical and socio-economic reasons, as follows :

(a) The magnitude of problem in terms of sheer numbers is very high

(b) The disease has a very high "killing power" - even in developed countries with well established treatment and ambulance services, 25% of those who suffer from acute MI would die within one hour and would never reach the hospital; another 8 to 10% would die in the next 24 hours in the hospital and another 10% would die in the next one year.

(c) Even for those who survive, the quality of life in terms of physical capabilities is compromised, alongwith constant apprehension about the future.

(d) The treatment is quite costly and available at few selected centres.

(e) Most of the persons affected with clinical disease are in their middle age, and are in the maximal productive pahase of their life; they also have the maximum family and social obligations to fulfill at this age. Getting affected by the disease at this age therefore leads to tremendous loss to the organization and much suffering for the family.

The silver lining is that a large number of factors which place an individual at high risk of getting affected with IHD (called "coronary Risk factors") are well known to the medical world and potentially amenable to preventive efforts. IHD thus is very much a preventable issue.

The magnitude of problem has been brought out in chapter - 1 of this section (1 - 30). Some important findings are as follows :

### Global Problem

Of an estimated 58 million deaths globally from all causes in 2005, cardiovascular disease (CVD) accounted for 30%. This proportion is equal to that due to infectious diseases, nutritional deficiencies, and maternal and perinatal conditions combined (86). It is important to recognize that a substantial proportion of these deaths (46%) were of people under 70 years of age, in the more productive period of life; in addition, 79% of the disease burden was attributed to cardiovascular disease is in this age group (87). Between 2006 and 2015, deaths due to noncommunicable diseases (half of which will be due to cardiovascular disease) are expected to increase by 17%, while deaths from infectious diseases, nutritional deficiencies, and maternal and perinatal conditions combined are projected to decline by 3% (86). Almost half the disease burden in low and middle-income countries is already due to noncommunicable diseases (88).

### Indian scenario

The figures have been recently summarized by Reddy et al (89). Over the past 4 decades, the prevalence of IHD has risen two fold in rural and six fold in urban areas. At present, an estimated 3 to 4% of rural and 8 to 10% of urban adults are likely to be affected by IHD, thus putting the estimated IHD cases in India at 30 million (15 million each in rural and urban areas). In the armed forces also there is a disturbing, rising trend as has been described in chapter - 1 of this section.

## The determinants (Coronary risk factors)

With large scale, world-wide research over the past 60 years, both epidemiological as well as clinical, we are now well aware of various coronary risk factors, which place an individual at high risk of getting affected with IHD (90). These are listed in the Table 1. It needs to be noted that the search for coronary risk factors is an ongoing one and every year a few more are likely to be added to the list. Broadly, these may be classified as "modifiable" and non-modifiable" risk factors.

### Non-modifiable

As the name suggests, we can not "change" these factors; only thing is that if a person has any of them, he / she needs to be even more careful as regards modifiable factors. The non-modifiable risk factors are :

Age

Age > 45 years for males and > 55 years for females increases the risk.

Sex

Male sex is at a higher risk. However, after menopause, the risk for females increases and equalizes that of males by the age of 50 to 55 years.

Family history

History of definite MI or sudden death in father or 1st degree male relative before 45 years age or in mother or 1st degree female relative before 55 years age indicates high risk.

Race

Some races may be more predisposed. For example, South Asian populations are said to be at higher risk, possibly because of "thrifty gene"; the Finnish population are at a high risk while Japanese are at lower risk. The extent to which these differences are because of genetic factors that differ between races or else due to lifestyle factors peculiar to different races, is still not clear.

**Modifiable coronary risk factors**

These are summarized in the Table - 1

A discussion on the major risk factors emphasizing on the benefit achieved by controlling them is reviewed in the subsequent paragraphs.

Dyslipidaemia

Over the past two decades, the focus has shifted from "hypercholesterolaemia" to "dyslipipidaemia", giving due consideration to various other fractions of lipid profile. Of course, total serum cholesterol (TC) remains the single most important predictor of CHD risk both on individual as well as population level. The incidence of IHD is high among populations with mean serum TC > 200 mg / dl and low in populations with mean TC levels < 150 mg / dl. It is desirable that on individual level, the TC level should be kept below 200 mg / dl, while on population level, we should strive to keep the mean level below 160 mg / dl. Besides TC, LDL-Cholesterol levels have assumed importance. The ATP-3 recommends that on individual level, the LDL levels should ideally be < 100mg / dl; since this may be difficult for most people, levels of < 130mg / dl are considered as "near optimal". Levels of > 160 indicate high risk, while between 130 to 159 mg / dl indicate moderately increased risk.

HDL has been acknowledged to be the protective component. HDL levels > 40 mg / dl for males and > 50 mg / dl for females should be aimed. In addition to simply going by TC or HDL levels, the ratio of TC : HDL has been increasingly advocated. Ideally, this ratio should be maintained at < 3; ratio of > 4. 5 indicates high risk.

Finally, the role of raised triglycerides (TG) as CHD risk

Table - 1 : Modifiable Coronary Risk factors

| Well Established | | Emerging / Being researched | |
|---|---|---|---|
| **Lipid** | | ✎Mental stress (depression, low job control, suppressed hostility) and personality (type 'A') | calculated as TC – HDL) |
| ✎Raised Total Cholesterol (< 200 mg / dl : desirable; 200 – 239 : Borderline high; >= 240 : High) | **Non Lipid** | **Lipid** | **Non Lipid** |
| ✎Raised LDL – C ( < 100 mg/dl : optimal; 100 – 129 : near optimal; 130-159 : Borderline high; >= 160 : High) | ✎Tobacco use (even small amount of tobacco use increases risk) | ✎Raised TC : HDL-C ratio (> 4.5) | **Inflammatory markers** |
| ✎Raised triglycerides (<150 mg/dl : normal; 150 – 199 : Borderline High; >= 200 : High) | ✎Raised Blood Pressure | ✎"Lipid Triad"(concomitant presence of raised triglycerides, small dense LDL particles and low HDL | ✎Raised Total WBC count |
| ✎Low HDL-C ( < 40 mg/dl in men or < 50 in women) | ✎Diabetes Mellitus – type 2 or Impaired Glucose Tolerance | ✎Lipoprotein (a) | ✎Raised C-reactive Protein |
| ✎Metabolic Syndrome (Syndrome 'X') – a clustering of low HDL, raised triglycerides, hypertension, impaired glucose tolerance and obesity | ✎Obesity (either generalized or central) | ✎Raised Apolipoprotein – B | **Prothrombotic factors** |
| | ✎Physical Inactivity | ✎Low Apolipoprotein A-1 | ✎Platele-Hyperaggregability |
| | ✎Atherogenic diet (high in total calories, Total fat, saturated fats, cholesterol, salt and refined sugar; low in whole grains, cereals, legumes, fruits, vegetables, antioxidant vitamins, folic acid, fibre, and Omega-3 fatty acids | ✎Small, dense LDL particles | ✎Raised Fibrinogen |
| | | ✎Raised Non-HDL Cholesterol (this is VLDL + LDL and is routinely | ✎Raised Plasminogen Activator Inhibitor (PAI-1) |
| | | | ✎Tissue Plasminogen Activator (tPa) |

factor has been assuming increasing importance, especially in case of south-asian populations and in the context of metabolic syndrome (see later). Ideally TG levels should be maintained at < 150 mg/dl; levels of 200 mg / dl and above indicate high risk. Needless to say, from the preventive action point of view, dyslipidaemia is only an indicator. It results due to a wide variety of other risk factors especially atherogenic diet, smoking, obesity, and physical inactivity and hence, focus should be control of these risk factors for effectively addressing dyslipidaemia.

### Tobacco

There is a large body of evidence from prospective cohort studies regarding the beneficial effect of smoking cessation on coronary heart disease mortality (91). Some studies suggest that, about 10 years after stopping smoking, coronary heart disease mortality risk is reduced to that of people who have never smoked (92,93). Other reports suggest that a much longer time is required (94). A 50-year follow-up of British doctors demonstrated that, among ex-smokers, the age of quitting has a major impact on survival prospects; those who quit between 35 and 44 years of age had the same survival rates as those who had never smoked (95). The benefits of giving up other forms of tobacco use (as chewed tobacco) are also established (96-99). Recent evidence from the Interheart study (100) has highlighted the adverse effects of use of any tobacco product and, importantly, the harm caused by even very low consumption (1-5 cigarettes a day). The benefits of stopping smoking are evident; however, the most effective strategy to encourage smoking cessation is not clearly established. All patients should be asked about their tobacco use and, where relevant, given advice and counselling on quitting, as well as reinforcement at follow-up. There is evidence that advice and counselling on smoking cessation, delivered by health professionals (such as physicians, nurses, psychologists, and health counsellors) are benefi cial and effective (101 - 106). Several systematic reviews have shown that one-time advice from physicians during routine consultation results in 2% of smokers quitting for at least one year (103, 107). Data from observational studies suggest that passive cigarette smoking also produces a small increase in cardio vascular risk (108-110).

## Dietary risk factors

### Dietary fat and cholesterol

The relationship between dietary fat and coronary heart disease has been extensively investigated. Saturated fats as a whole have been shown to raise LDL-cholesterol levels (111-115). However, individual fatty acids within the group have different effects, with myristic and palmitic acids having the greatest effect on LDL-cholesterol (116, 117). Saturated fatty acids are not all equally hypercholesterolaemic. When substituted for saturated fatty acids in metabolic studies, n-6 polyunsaturated fatty acids (which are abundant in soybean and sunflower oil) and monounsaturated fatty acids (which are abundant in olive oil) lower total cholesterol, LDL cholesterol and triglyceride concentrations (115, 118). Trans-fatty acids come from both animal and vegetable sources and are produced by partial hydrogenation of unsaturated oils. Dietary intake of trans-fatty acids increases LDL-cholesterol and, at high intakes, lowers HDL cholesterol (113-115, 119-121). Metabolic and epidemiological studies have indicated that trans-fatty acids increase the risk of coronary heart disease (115, 122, 123).

A high intake of fat (more than 30% of total calories) generally increases intake of saturated fat and is associated with consumption of excess calories and weight gain. On the other low intake of fats and oils (less than 20% of total calories) increases the risk of inadequate intakes of vitamin E and essential fatty acids, and may contribute to unfavourable changes in HDL-cholesterol and triglycerides (124). It has also been demonstrated that replacing saturated and trans-unsaturated fats with monounsaturated and polyunsaturated fats is more effective in preventing coronary heart disease events than reducing overall fat intake (115, 123, 125). Current guidelines recommend a diet that provides less than 30% of calories from dietary fat, less than 10% of calories from saturated fats, up to 10% from polyunsaturated fats, and about 15% from monounsaturated fats (118). Metabolic studies have shown that dietary cholesterol is a determinant of serum cholesterol concentration (126-128).

### Omega-3 fatty acids, fish and cardiovascular risk

The main dietary sources of omega-3 fatty acids are fish and fish oils (which contain eicosapentaenoic acid and docosahexaenoic acid), and certain nut and plant oils, such as canola, soybean, flaxseed and walnut (which contain alpha-linoleic acid). Epidemiological studies and clinical trials suggest that people at risk of coronary heart disease benefit from consuming omega-3 fatty acids (129, 130, 131). The proposed mechanisms for a cardioprotective role include altered lipid profile, reduced thrombotic tendency, and antihypertensive, anti-inflammatory and antiarrhythmic effects (132-135).

### Dietary salt

Population studies have demonstrated that high salt intake is associated with an increased risk of high blood pressure (136). Several observational studies have linked baseline sodium intake, estimated from either 24-hour urinary sodium excretion or dietary intake, to morbidity and mortality. In a Finnish study, the hazard ratios for coronary heart disease, cardiovascular disease, and all-cause mortality, associated with a 100 mmol increase in 24-h urinary sodium excretion in men and women, were estimated as 1. 51 (95% CI 1. 14 to 2. 00), 1. 45 ((95% CI 1. 14 to 1. 84), and 1. 26 (95% CI 1. 06 to 1. 50), respectively (137). A prospective study in a Japanese cohort also showed that high dietary salt intake increased the risk of death from stroke (138). The efficacy of reduced sodium intake in lowering blood pressure is well established (139, 140). An average reduction of 77 mmol/day in dietary intake of sodium has been shown to reduce systolic blood pressure by 1. 9 mmHg (95% CI, 1. 2 to 2. 6 mmHg) and diastolic blood pressure by 1. 1 mmHg (95% CI, 0. 6 to 1. 6 mmHg) (138). Phase 2 of the Trials of Hypertension

Prevention studies has also documented that a reduced sodium intake can prevent hypertension (141). In a meta-analysis of dietary interventions to alter salt intake, a reduction of 100 mmol (6 g) per day in salt intake was associated with a fall in blood pressure of 7.11 mmHg (systolic) and 3.88 mmHg (diastolic) This information strongly supports other evidence that a modest, long-term reduction in population salt intake would immediately reduce stroke deaths by about 14% and coronary deaths by about 9% in people with hypertension, and by approximately 6% and 4% in those with normal blood pressure. (142). It is clear that intensive interventions, in particular the Dietary Approaches to Stop Hypertension (DASH) (143), are capable of reducing salt intake and lowering blood pressure. On the basis of the above, current recommendations on salt intake (< 5 g (90 mmol) per day) are appropriate (144).

### Fruits and vegetables

Fruits and vegetables may promote cardiovascular health through a variety of micronutrients, antioxidants, phytochemicals, flavonoids, fibre and potassium. The evidence on the role of the individual constituents is so far inconclusive. Ness & Powles (145) reviewed ecological, case-control and cohort studies examining the association of dietary fruits and vegetables with cardiovascular disease. For coronary heart disease, they found a significant protective association with consumption of fruits and vegetables or surrogate nutrients. Overall, the results support a protective effect of fruits and vegetables on stroke and coronary heart disease (146, 147). Joshipura et al. (146) evaluated the association between consumption of fruits and vegetables and risk of coronary heart disease in the Nurses' Health Study and the Health Professionals' Follow-Up Study. After adjustment for standard cardiovascular risk factors, people with fruit and vegetable intake in the highest quintile had a relative risk for coronary heart disease of 0. 80 (95% CI 0. 69 to 0. 93) compared with those with intake in the lowest quintile. Each increase of one serving per day in intake of fruits or vegetables was associated with a 4% lower risk of coronary heart disease (relative risk 0. 96; 95% CI 0. 94 to 0. 99). The relationships between intake of whole grains, refined grains, fruits, vegetables and total mortality risk / incidence of coronary artery disease and ischaemic stroke, were also evaluated in the Atherosclerosis Risk in Communities (ARIC) cohort (n = 15 792) (148). Over an 11-year follow-up period, whole-grain intake was inversely associated with total mortality and incidence of coronary artery disease. A recent meta-analysis of 10 prospective cohort studies (149) has also shown that the consumption of fibre from cereals and fruits is inversely associated with risk of coronary heart disease. On the basis of the available evidence, a daily intake of at least 400 g of fruit and vegetables is recommended (150).

### Physical inactivity

It has been estimated that inadequate physical activity is responsible for about one-third of deaths due to coronary heart disease and type 2 diabetes (151). There is evidence from observational studies that leisure-time physical activity is associated with reduced cardiovascular risk and cardiovascular mortality in both men and women (152-154) and in middle-aged and older individuals (155, 156). Several meta-analyses have examined the association between physical activity and cardiovascular disease (157-162). Berlin & Colditz (160) found a summary relative risk of death from coronary heart disease of 1. 9 (95% CI 1. 6 to 2. 2) for people with sedentary occupations compared with those with active occupations. A meta-analysis of studies in women showed that physical activity was associated with a reduced risk of overall cardiovascular disease, coronary heart disease and stroke, in a dose-response fashion (157). Physical activity improves endothelial function, which enhances vasodilatation and vasomotor function in the blood vessels (159). In addition, physical activity contributes to weight loss, glycaemic control (163, 164), improved blood pressure (165), lipid profile (166-168) and insulin sensitivity (169). The possible beneficial effects of physical activity on cardiovascular risk may be mediated, at least in part, through these effects on intermediate risk factors. Physical inactivity and low physical fitness are independent predictors of mortality in people with type 2 diabetes, which in turn is a strong risk factor for CHD (170). Overall, the evidence points to the benefit of continued regular moderate physical activity, which does not need to be strenuous or prolonged, and can include daily leisure activities, such as walking or gardening (157). Taking up regular light or moderate physical activity in middle or older age significantly reduces CVD and all-cause mortality, and improves the quality of life (156-158, 171, 172).

### Overweight

Prospective epidemiological studies have shown a relationship between overweight or obesity and cardiovascular morbidity, CVD mortality and total mortality (173-179). Obesity is strongly related to major cardiovascular risk factors, such as raised blood pressure, glucose intolerance, type 2 diabetes, and dyslipidaemia (173, 176, 178, 180). Meta-analyses of RCTs have shown that a weight-reducing diet, combined with exercise, produces significant weight loss, reduces total cholesterol and LDL-cholesterol, increases HDL-cholesterol, and improves control of blood pressure and diabetes (181 - 183). A meta-analysis of randomized controlled trials (184) found that a net weight reduction of 5. 1 kg (95% CI 4. 25 to 6. 03 kg), reduced systolic blood pressure by 4. 44 mmHg (95% CI 2. 95 to 5. 93 mmHg) and diastolic blood pressure by 3. 57 mmHg (95% CI 2. 25 to 4. 88 mmHg). The long-term benefit of weight reduction on blood pressure control has been confirmed in several studies, including Phase II of the Trials of Hypertension Prevention Collaborative Research Group (185, 186). Evidence also suggests that physical exercise and fitness is equally and independently important. In a review of data from 24 prospective observational studies, Blair & Brodney (187) found that regular physical activity attenuated many of the health risks associated with overweight and obesity. Physically active obese

individuals have lower morbidity and mortality than individuals of normal weight who are sedentary; physical inactivity and low cardiorespiratory fitness are as important as overweight and obesity as predictors of mortality. The appropriate upper limits of measures of overweight and obesity have been recently defined by various expert bodies. For South Asian populations, including Indians, the upper limits are (188 - 190)

**Waist Circumference** : 90 cms for males and 80 cms for females

**Waist** : Hip ratio (WHR) 0. 90 for males and 0. 80 for females

**Body Mass Index (BMI)** : 25 and above as overweight and 30 and above as obese. However, recent WHO recommendations tend to recommend an even lower cut-off for Asian populations as 23 and above as overweight and 27. 5 and above as obese.

### Alcohol

Many studies have shown a U or J- shaped association between mortality and alcohol consumption, in which people who drink light or moderate amounts have a lower death rate than nondrinkers, while those who drink large amounts have a higher death rate (191 - 199). People who drink heavily have a high mortality from all causes and cardiovascular disease. In addition, they may suffer from psychological, social and other medical problems related to high alcohol consumption (196 - 199). A meta-analysis of 28 cohort studies of alcohol consumption and CHD showed that risk decreased as consumption increased from 0 to 20 g/day (RR = 0. 80); there was evidence of increased risk at higher consumption. Smaller protective associations and more harmful effects were found in women. The amount of alcohol associated with the lowest mortality rates was between 10 and 30 g (1-3 units) per day for men and half these quantities for women (1 unit has already been defined in the earlier chapter). Various mechanisms have been proposed for the protective effect of modest alcohol consumption, including the demonstrated beneficial effects of alcohol on lipid profile, particularly an increase in HDL-cholesterol level, thrombolytic profile, and platelet aggregation (196, 199 - 201). The benefits of alcohol in light to moderate drinkers may be overestimated in observational studies, as a result of confounding because it is primarily the non-drinking group that causes the U-shaped relationship, and this may contain both life-long abstainers and people who stopped drinking because of ill-health; this could result in a spurious association suggesting that there is a safe level of alcohol intake. This would imply that there is no level of alcohol consumption that is beneficial with respect to coronary heart disease; rather, risk increases with increasing consumption in a linear fashion. Interestingly, earlier, the beneficial effect of hormone replacement therapy (HRT) on HDL-cholesterol convinced many that cohort studies showing a protective effect of HRT on coronary heart disease risk were valid. However, subsequent randomized controlled trials have found either no benefit or a harmful association; the earlier beneficial results were likely to be due to uncontrolled confounding. On the same analogy, it is possible that the protective association between light-to-moderate alcohol consumption and coronary heart disease is also an artefact caused by confounding. Light-to-moderate drinkers may be “light-to-moderate” in other behaviours, such as tobacco use which could be responsible for their lower risk of CHD (203). It is also important to note that alcohol consumption is associated with a wide range of medical and social problems, including road traffic injuries. Some individuals are also at risk of progression to problem drinking. Other risks associated with moderate drinking include fetal alcohol syndrome, obesity, haemorrhagic stroke, large bowel cancer, and female breast cancer (196, 204). Consequently, from both the public health and clinical viewpoints, there is no merit in promoting alcohol consumption as a preventive strategy.

### Psychosocial factors

Observational studies have indicated that some psychosocial factors, such as depression and anxiety, lack of social support, social isolation, and stressful conditions at work, independently influence the occurrence of major risk factors and the course of coronary heart disease, even after adjusting for confounding factors (205-207). Other psychosocial factors, such as hostility and type A behaviour patterns, and anxiety or panic disorders, show an inconsistent association (208, 209). Rugulies (205), in a meta-analysis of studies of depression as a predictor for coronary heart disease, reported an overall relative risk for the development of coronary heart disease in depressed subjects of 1. 64. Other studies have also found a strong association between depression and CHD (209-211). Depression was shown to be a predictor for risk of myocardial infarction in the Interheart case-control study (odds ratio 1·55). This finding was consistent across regions, in different ethnic groups, and in men and women (206). More recent trials have cast doubt on the causal nature of the association between depression and CHD. In a large randomized trial of psychological intervention after myocardial infarction, no impact on recurrence or mortality was found (212). Another large trial that provided social support and treatment for depression also found no impact (213). Kivimäki et al. (214), in a 25. 6-year prospective cohort study in Finland, found that metal industry employees with high job strain (a combination of high demands at work and low job control) had a cardiovascular mortality risk 2. 2 times that of their colleagues with low job strain. This association between stressful conditions at work and CHD is supported by other studies (209, 215). There is also some evidence that social isolation and lack of quality social support are independent risk factors for CHD onset and prognosis: the risks are increased 2-3-fold and 3-5-fold, respectively, in both men and women (216). The association has been demonstrated in subjects in different countries, and in various age groups (209, 216-219). While these findings provide some support for a causal association. Well planned trials of interventions are required to elucidate whether there is a true cause-effect relationship and, more importantly, whether intervention

reduces cardiovascular risk.

### Raised Blood Pressure

Raised blood pressure is estimated to cause about 7 million premature deaths throughout the world, and 4. 5% of the disease burden (64 million disability-adjusted life years (DALYs)) (86 - 88). It is a major risk factor for cerebrovascular disease, coronary heart disease, and cardiac and renal failure. Treating raised blood pressure has been associated with a 35-40% reduction in the risk of stroke and at least a 16% reduction in the risk of myocardial infarction (220). Raised blood pressure often coexists with other cardiovascular risk factors, such as tobacco use, overweight or obesity, dyslipidaemia and dysglycaemia, which increase the cardiovascular risk attributable to any level of blood pressure. Worldwide, these coexisting risk factors are often inadequately addressed in patients with raised blood pressure, with the result that, even if their blood pressure is lowered, these people still have high cardiovascular morbidity and mortality rates (221-223). Almost all clinical trials have confirmed the benefits of antihypertensive treatment at blood pressure levels of 160 mmHg (systolic) and 100 mmHg (diastolic) and above, regardless of the presence of other cardiovascular risk factors (220, 224). Observational data support lowering of these systolic and diastolic thresholds (225, 226). Several trials in patients at high cardiovascular risk (227-229) have confirmed these observational data, showing reductions in cardiovascular morbidity and mortality in people whose blood pressure is reduced to levels significantly below 160 mmHg systolic and 90 mmHg diastolic. These trials support the view that, in patients at high cardiovascular risk, with blood pressures in the range 140-160 mmHg (systolic) and 90-100 mmHg (diastolic), the treatment for such high-risk patients should begin at the lower blood pressure thresholds of even lesser than 160 mm systolic or 90 mm diastolic. There is also enough evidence that it is not only the diastolic level but that systolic BP level is also independently related to cardiovascular risk; in fact, as age advances, the level of systolic BP may be more important for CV risk than diastolic level. More details regarding the epidemiology, risk factors and prevention of hypertension are addressed in a subsequent chapter.

### Diabetes and Impaired Glucose Tolerance (IGT) / Impaired Fasting Glucose (IFG)

Cardiovascular disease accounts for about 60% of all mortality in people with diabetes. The risk of cardiovascular events is 2-3 times higher in people with type 1 or type 2 diabetes (230, 231) and the risk is disproportionately higher in women (230, 232). Patients with diabetes also have a poorer prognosis after cardiovascular events compared with non-diabetics (233, 234). Epidemiological evidence also suggests that the association between blood glucose and cardiovascular disease begins before diabetes manifests itself (233 - 237). The cardiovascular risk increases as glucose tolerance becomes impaired and then progresses to diabetes (338). Further, abnormal glucose regulation tends to occur together with other known cardiovascular risk factors, such as central obesity, elevated blood pressure, low HDL-cholesterol and high triglyceride level (239, 240). The Diabetes Control and Complications Trial (DCCT) (241) demonstrated that intensive treatment to ensure good glycaemic control substantially reduced the risks of cardiovascular events, neuropathy, nephropathy and retinopathy (242). The United Kingdom Prospective Diabetes Study (UKPDS) found that glycaemic control in people with type 2 diabetes reduced the frequency of microvascular complications, such as blindness, amputation, and end-stage renal disease (243). Each 1% increase in HbA1c level was associated with a 14% increase in the incidence of fatal or nonfatal myocardial infarction (244). A later study suggested that stringent blood sugar control in people with type 2 diabetes, combined with targeted reductions in blood lipids and blood pressure, reduced macrovascular events in diabetic patients with microalbuminuria (245). Good glycaemic control should be a key goal of treatment of diabetes, to delay the onset and progression of microvascular and macrovascular disease. The first approach to controlling glycaemia should be through diet alone, combined with physical exercise; if this is not sufficient, oral medication should be given, followed by insulin if necessary. Treatment should aim to achieve a fasting blood glucose level of 4-7 mmol/l (72-126 mg/dl); and an HbA1c level of 6. 5% or less. More details regarding the epidemiology, risk factors and prevention of diabetes type - 2 are addressed in a subsequent chapter.

### The Metabolic Syndrome (Syndrome 'X')

In 1988, The noted Diabetologist, Gerald Reaven had postulated that resistance to insulin action would occur mainly due to obesity, central obesity, physical inactivity, and possibly certain genetic reasons. Once insulin resistance developes, the body, in an effort to compensate, releases more and more insulin, resulting into fasting hyperinsulinaemia. Under the influence of this hyperinsulinaemia, there occurs a very unique and specific "clustering" of certain specific cardiovascular risk factors, namely, raised blood pressure, impaired glucose tolerance, and a unique dyslipidaemia manifesting with low HDL and raised triglycerides. This clustering was referred to as "Syndrome X" by Reaven (246) and it was postulated that once such clustering occurs, it is likely to be a major risk factor for development of IHD and Diabetes type -2. Large number of cinical and epidemiological studies over the past 2 decades have confirmed that the metabolic syndrome is, indeed, a reality. In fact, scientific evidence suggests that south Asians, especially Indians are likely to be at a high risk of developing this syndrome. Surveys among apparently healthy armed forces personnel have also revealed a substantial prevalence of almost 8% of this syndrome (32).

There are various defining criteria of this syndrome, of which the WHO criteria and ATP-3 criteria are the most widely used. The WHO criteria are (247) :

(a) Diabetes or IFG or IGT or evidence of insulin resistance (either of hyperinsulinaemia or

euglycaemic clamp glucose uptake in lowest 25%)

(b) **PLUS any two** of the following :

(i) Obesity as defined BMI > 30 or WHR > 0. 9 for males or > 0. 85 for females (>0. 80 for Indian females)

(ii) Hypertension as defined as blood pressure > 140 systolic or > 90 diastolic

(iii) Dyslipidaemia as manifested by triglycerides > 150 mg / dl or HDL < 35 mg / dl for males or < 40 mg / dl for females

(iv) Microalbuminuria defined as albumin excretion > 20 microgram albumin excretion / mt.

Hormone replacement therapy (HRT)

On the basis of data from observational studies (248), hormone therapy has been used for prevention of cardiovascular disease, osteoporosis and dementia. This practice has been called into question following publication of the results of several randomized clinical trials, which showed no coronary protection, and the Women's Health Initiative (249), which indicated that long-term use of estrogen plus progestin was associated with increased risks of cancer and cardiovascular disease. A Cochrane systematic review (250) of 15 randomized double-blind trials showed that the only statistically significant benefits of hormone therapy were decreased incidences of fractures and colon cancer with long-term use. In relatively healthy women, combined continuous hormone therapy significantly increased the risk of coronary events and venous thromboembolism (after one year's use), stroke (after 3 years), breast cancer (after 5 years) and gallbladder disease. Long-term estrogen-only hormone therapy also significantly increased the risk of stroke and gallbladder disease. In relatively healthy women over 65 years taking continuous combined hormone therapy, there was an increase in the incidence of dementia. Thus, HRT is not recommended as a preventive step against IHD, from public health point of view.

### The Effect of Multiple Risk Factors

All the leading CHD risk factors described above tend to act in a multiplicative mode when two or more are present (which, quite often, they are). This means that when multiple risk factors are present, their effect on increasing the coronary risk is not simply additive but rather "multiplicative" (in simple corollary, it is not 2+2+2 =6 but rather 2X2X2 = 8). Another aspect which must be kept in mind is that multiple risk factors, even if present in "moderate" quantum, tend to increase the coronary risk quite substantially, compared to when only one factor is present in high quantum. For instance, a person who is marginally obese (eg, BMI 25. 5), smokes 2 or 3 cigarettes a day, has a WHR which is marginally raised (e. g. , 0. 93), goes for brisk exercise only once a week, and has mild elevation of BP (eg, 150 / 96) would be having much higher overall risk than a person who smokes 10 cigarettes per day but has no other risk factor. This issue is important since we often tend to "condone" those who have mild elevations of multiple risk factors thinking that "moderation" is not bad !

**Box - 1 : Preventive strategies for IHD**

- Primordial Prevention
- Primary prevention
  - Population Strategy
    - ~ Mass Approach
    - ~ Targeted Group approach
  - Targeted High Risk Individual Strategy
- Secondary Prevention
- Tertiary Prevention

## Prevention and control of IHD

As said earlier, IHD is the prototype example of a serious, lifestyle disease. It needs to be addressed in a very concerted manner, by both, the medical functionaries as well as by Commanders / Administrators. The preventive strategies are summarized in Box - 1.

### Primordial prevention

The concept may sound "Utopian" to many, but it is a fact that certain countries / communities have been successfully adopting this strategy. The strategy can be used by those countries / communities where lifestyle has not, as yet, acquired the pattern associated with high CHD incidence and where the average level of critical risk factors is still favourable; however, economic advancements and changing life styles threaten to undermine this favourable situation and in these situations, we could take action to "prevent the very emergence of predisposing conditions, in countries and communities in which they have not yet appeared". This, in essence, is primordial prevention.

### Primary prevention

Primary prevention focuses on measures so that the pathological processes of IHD are either not initiated or else do not progress to develop into the disease. There are two mainstays of this approach : firstly, educating & motivating the individuals and communities with a view to achieve positive life style behaviour changes, and, secondly, supplementing these IEC (Information, Education and Communication) efforts by suitable socio-political, legislative and administrative steps. The ultimate objective is that individuals and communities live a healthy lifestyle, free of cornary risk factors. Primary preventive steps can be undertaken through two broad strategies, viz. , the "population approach" which focuses on large population groups, even the entire states or countries, and the "Targeted, individual, high risk strategy" which focuses on individuals who have a high probability of developing IHD, due to the presence of certain risk factors. The population approach can be of further two types, as follows :

"Mass Strategy"

Box-2 Key messages for I.E.C. : Primary prevention of IHD

- Eat a diet -
  - Just sufficient in calories
  - Total fats provide < 30% of calorie need
  - Saturated fats provide < 10% of calorie need
  - Trans-fatty acids to be eliminated from diet
  - Most dietary fat should be polyunsaturated (up to 10% of calories) or monounsaturated (10–15% of calories).
  - Refined sugars provide < 10% of calorie need
  - Salt consumtion (all sources) < 5 gm / day
  - Cholesterol < 200 mg / day
  - Low in gravied, fried, creamed and sugared food stuffs
  - Plenty of whole grains, cereals, legumes, beans & pulses
  - 400 to 500 grams fresh fruits / vegetables
  - Low fat dairy produce
- Undertake brisk walk every day, covering 2 miles (3.2 Km) in 30 to 35 mts daily; if you can exercise longer or at higher intensity, the better it is
- Supplement aerobic exercises (walking, running, cycling, sports) with light weught training and stretching exercises as yoga
- NO TOBACCO. If you don't use tobacco, don't start; if you do, stop.
- Avoid alcohol. If you must drink, not more than 3 small drinks s day for men (not more than 2 small a day for women); don't drive even after mild drinks; try not to drink daily.
- Regularly check your body weught and measure your waist and hip circumference; BMI should be kept at < 25 (preferably < 23) and waist < 90 cm or WHR < 0.90 for males (for females, < 80 cm or WHR < 0.80)
- Control and manage mental stress:-
  - Pray, meditate
  - Spend Quality time with family
  - Yoga
  - Manage your finances well
  - Exercise regularly
  - Look after health of yourself and family members
- Undergo periodic / annual medical examinations seriously; take precautions as told by your doctor
- If you have any symptoms of chest pain, fatiguability. Palpitation or breathlessness, seek medical attention.

**See further details in the chapter on healthy lifestyle in this section**

This focuses on large sections of populations, may be the entire District, state or even the country; in context of armed forces, IEC methods directed to the entire armed forces or a complete Division or Brigade would be an equivalent example. The strategy adopts a two pronged approach as follows :

(a) Education and Motivation by various IEC techniques, with a view to informing the community / population and to secure a healthy lifestyle change. The key issues of IEC are summarized in box - 2.

(b) Socio-political, administrative and legal actions to supplement the IEC steps, eg. , legislation and coercive steps against tobacco and alcohol; provision of gymnasia, playgrounds & walkways; encouragement for production of fruits and vegetables; subsidy on fruits and vegetables; administrative disincentives for obese persons; and so on.

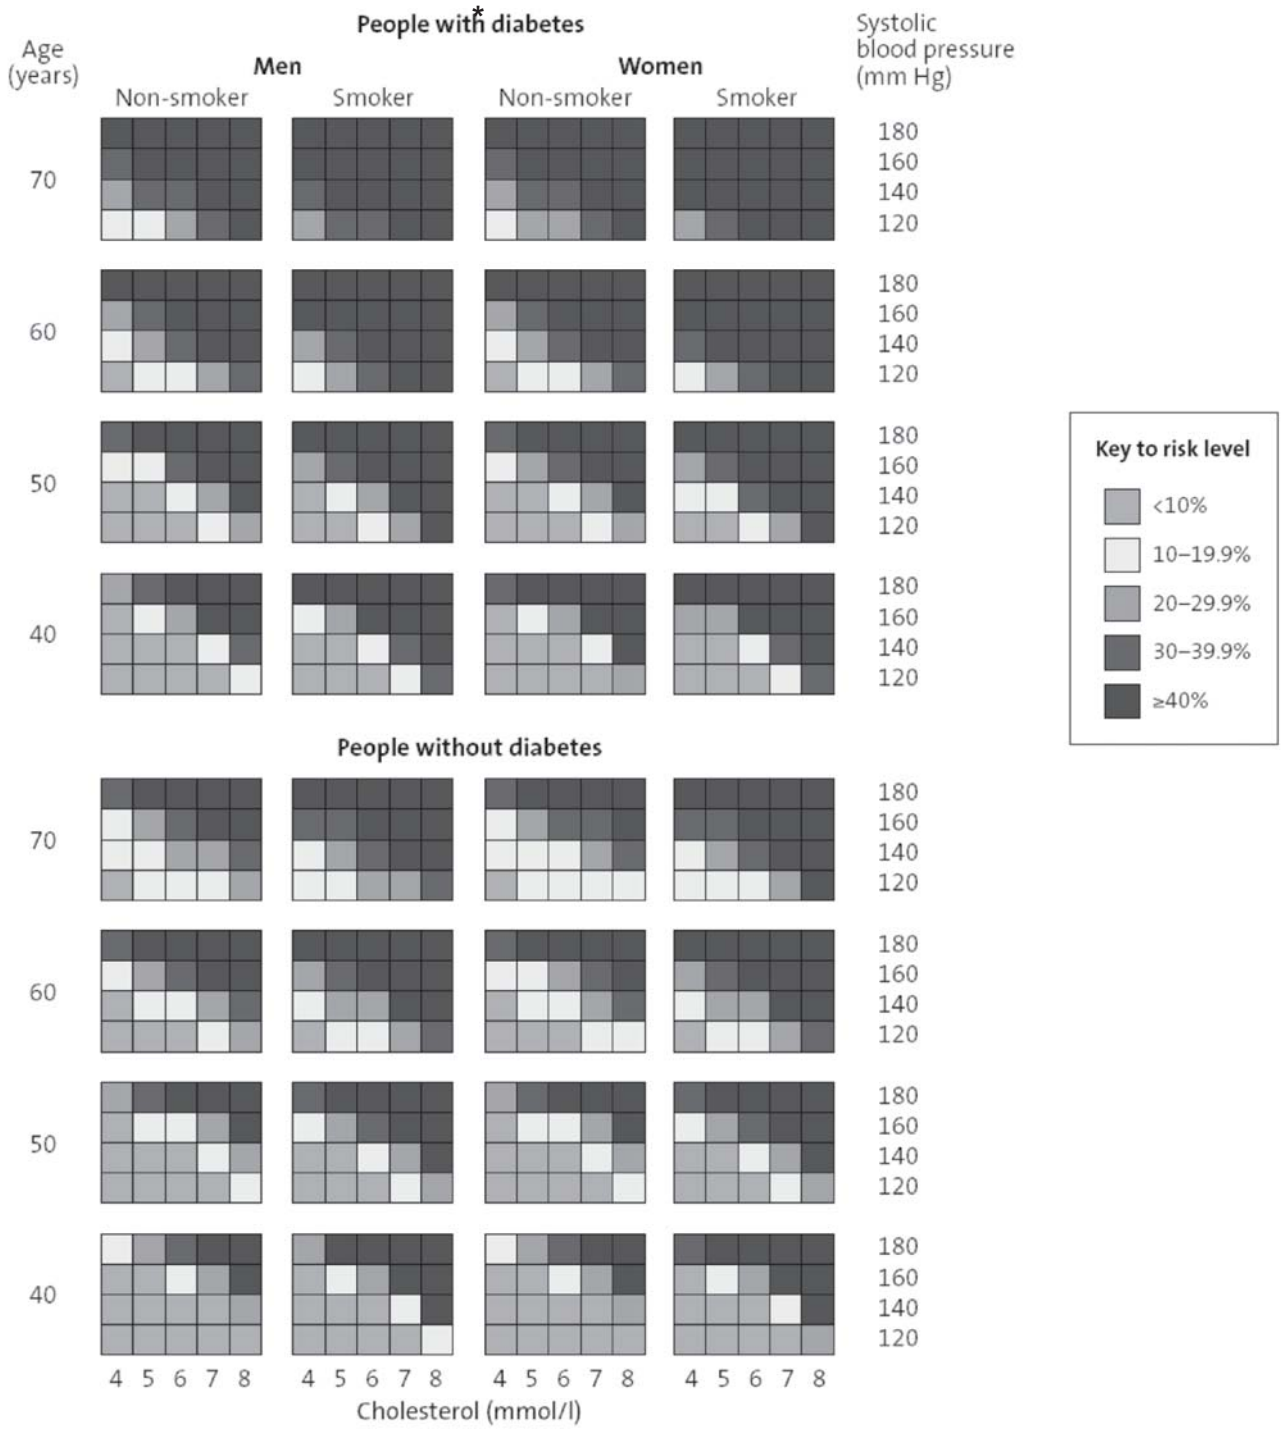
Targeted, "Group" strategy

This strategy focuses on the educational and motivational efforts, not on entire population or community, but rather on certain selected groups of persons who, due to certain characteristics, are at high risk of developing the coronary risk factors (e. g. , "newly rich" persons, executives, bureaucrats, businessmen; in the context of armed forces, JCOs / senior NCOs are an example), or people who can be of help in implementing the preventive programmes (e. g. , local leaders, policy makers, influential politicians and bureaucrats; in context of armed forces, senior commanders and senior functionaries of Wives Welfare Associations, Army School-Teachers), or, those groups who are in a "formative" stage and may develop healthy lifestyle if properly informed / motivated at this stage (e. g. , school & college children; in context of armed forces, Recruits, Cadets and school children of Army schools, Sainik Schools, and KVs).

Individual, high risk strategy

While population strategy is very effective in gradually bringing down the incidence of IHD in the total population, the process may be slow; secondly it relies on behavioural and lifestyle change by individuals which often may not easily happen, especially permanently. Therefore, the population strategy should be supplemented by the Individual High risk strategy, which aims at identifying those individuals, who have a higher probability of developing IHD, because of presence of certain major risk factors, so that concerted preventive as well as treatment efforts may be directed to these individuals. In the simplest form, when a doctor checks the age, sex, family history of IHD, BP and body weight of each of his adult patient, and educates / treats those who have a few of these risk factors, she is actually practicing the Individual High Risk Strategy.

Box - 3 : WHO Risk prediction chart for cardiovascular disease



* A person who has diabetes is defined as someone taking insulin or oral hypoglycaemic drugs, or with a fasting plasma glucose concentration above 7.0 mmol/l (126 mg/dl) or a postprandial (approximately 2 hours after a main meal) plasma glucose concentration above 11.0 mmol/l (200 mg/l) on two separate occasions).

Conversion factor for total Cholesterol is 1 mmol / l = 37.5 mg / dl

The recent advancement in this strategy in the development of "Individual Risk Prediction Charts" by the WHO for various regions of the world. (The chart applicable to Indian region is given on Box 3). Use of risk prediction charts to estimate total cardiovascular risk is a major advance on the older practice of identifying and treating individual risk factors, such as raised blood pressure (hypertension) and raised blood cholesterol (hypercholesterolemia). The total risk approach acknowledges that many cardiovascular risk factors tend to appear in clusters; combining risk factors to predict total cardiovascular risk is consequently a logical approach to deciding who should receive treatment. Risk scoring moves the focus of treatment from the management of individual risk factors to the best means of reducing an individual's overall risk of disease.

In the charts, the subjects are first of all divided into diabetic or non-diabetic. Within each of this category, the subjects are divided according to tobacco use (users or non users), age and sex. Thereafter, the subject is evaluated as per his / her Systolic BP and Total Cholesterol level, and the level of CHD risk is directly read from the chart. The risk, technically, indicates the probability that the given individual is likely to develop IHD in the next 10 years. In general, < 10% risk is equivalent of low risk (low risk does not mean "NO RISK"); 10 - 20% : modearte risk, 20-30% high risk; and > 30% very high risk.

It may be mentioned that if a person has clear history of having suffered from IHD or has clear family history then the person is to be taken as "high risk" irrespective of the score obtained in this chart. Once the person has been evaluated on the chart, the action to be taken is as per guidelines given in Box - 4

**Secondary Prevention**

Early detection of CHD at the incipient stage is quite relevant. The available tools are firstly, resting ECG using Minnesota code criteria for coronary insufficiency, a method which has been used in epidemiological surveys, but has low sensitivity and specificity for individual prediction. Secondly, a combination of Rose questionnaire which taps symptoms of angina on effort and resting ECG can be used. Better predictive values are obtained with exercise ECG, either alone or in conjunction with echocardiography. Exercise ECG however carries some risk and should be undertaken in presence of a physician. All these screening procedures will give better predictive value if used in high risk populations, as middle aged, obese, having hypertension or impaired glucose tolerance or dyslipidaemia. The most important practical aspect is to keep a high index of diagnostic suspicion and

**Box - 4 Actions to be taken after evaluation of the person on the risk chart**

- All persons, irrespective of risk category should be educated and motivated for healthy lifestyle change, as per box given above.
- Antihypertensive treatment : indvls with sustained BP readings > 140 / 90 mmHg : if risk category 1 or 2, continue lifestyle changes; if category – 3 give lifestyle changes but if despite lifestyle changes for 4 to 6 months BP is > 140 / 90mmHg, give treatment starting with a thiazide like diuretic or ACE inhibitor or calcium channel blocker or beta blocker. Indvls in risk category – 4 with BP > 130 / 90mmHg - start drug treatment alongwith lifestyle changes. All individuals with blood pressure at or above 160/100 mmHg, or lesser degree of raised blood pressure with target organ damage, irrespective of risk category, should definitely have drug treatment and specific lifestyle advice.
- Anti-diabetic drugs : Individuals with persistent hyperglycaemia of fasting > 6 mmol / l (110 mg / dl) should be given hypoglycaemic drugs irrespective of risk category
- Lipid lowering treatment (use statin) : Risk category 1 and 2, advise healthy lifestyle; category 3 : If despite lipid lowering diet, TC > 200 mg/dl or LDL > 120 mg/dl consider a statin alongwith lifestyle advise; category – 4 along with lipid lowering diet, give statin to lower TC to < 200 mg/dl and LDL to < 120 mg/dl. If TC > 320mg/dl, give statin irrespective of risk category.
- Antiplatelet drugs : consider low dose aspirin only in case of category – 4.

Col RajVir Bhalwar

# Diabetes Mellitus

**Definition / Identification**

Diabetes Mellitus is defined as a metabolic abnormality characterized by hyperglycaemia and disturbances of carbohydrate, fat and protein metabolism that are associated with absolute or relative deficiency in insulin secretion and / or insulin action (251). When fully evolved, it is characterized by fasting hyperglycaemia but it can also be characterized in the less overt stages and before fasting hyperglycaemia appears, most usually by the appearance of glucose intolerance. Most often, it tends to be asymptomatic ("silent killer") in which case the diagnosis depends on biochemical investigations. (252).

**Classification**

Diabetes mellitus consists of a group of metabolic disorders which have been classified by a WHO expert group as given in Table - 1 (251)

IDDM (now called Type -1 Diabetes or T1D)

IDDM comprises 5 to 10% of all diabetes. It is due to absolute insulin deficiency as a result of pancreatic beta cell destruction. It is characterized by abrupt onset of severe symptoms, proneness to ketosis and presence of one or more of the classical symptoms (polyuria, polydypsia and polyphagia). The age at clinical onset or diagnosis is usually below 30 years. All patients of this type need exogenous insulin for survival. Blood glucose levels are unequivocally elevated and glucose and ketones are usually present in urine.

NIDDM (now called Type – 2 Diabetes or T2D)

NIDDM forms the majority of the problem from lifestyle and non-communicable diseases point of view, comprising 85 to 90% of all diabetes cases. For the purpose of this chapter, the focus will be on T2D. The disease takes a very silent course and is quite often detected on a routine urine or blood screening test, with diagnosis being often made after 40 years age. It has a strong genetic (family history) component. In addition, obesity is frequently associated with T2D, though in developing countries, many of the subjects with T2D may not be obese if we go simply by weight for height standards.

IGT and IFG are progressive stages of the same disease of which T2D represents to most severe form. Both IGT and IFG are themselves a strong risk factor for future occurrence of diabetes. Proper lifestyle management (Diet, Exercise and Weight reduction) prevents progression to the later stage. In the natural course, about one-thirds each of IGT subjects will develop diabetes, or remain as IGT or revert back to normal. The microangiopathic complications (Retinal and Renal) which are characteristic of diabetes are rare in IGT; however, there is increased occurrence of atherosclerosis in IGT as compared to normal people.

MRD (Malnutrition Related Diabetes)

In developing countries in the tropics, young people with diabetes may present with a constellation of clinical features including onset usually below 30 years age, average or low body weight (BMI < 30) moderate to severe hyperglycaemia, usually non-proneness to ketoacidosis unless there are precipitating conditions as infections, the requirements of large dose of insulin for metabolic control and frequently a history of malnutrition in infancy and early childhood. The term "MRD" has been assigned to this syndrome.

**Diagnostic Criteria**

The diagnostic criteria, as enunciated by the American Diabetic association (ADA) and duly agreed by the WHO

Table 1 : Classification of Diabetes Mellitus

<table>
<tr><th colspan="8">A.Clinical cases</th><th rowspan="2" colspan="2">B. Statistical Risk classes<br>(Subjects with normal glucose tolerance but substantially increased risk of developing Diabetes)</th></tr>
<tr><td colspan="5">(i) Diabetes mellitus</td><td colspan="3">(ii) Impaired glucose tolerance (IGT) and impaired fasting glucose</td><td>(iii) Gestational diabetes mellitus (GDM)</td></tr>
<tr><td rowspan="2">Insulin Dependant Diabetes Mellitus (IDDM, Type - 1)</td><td colspan="2">Non Insulin Dependant Diabetes Mellitus (NIDDM, Type- 2)</td><td rowspan="2">Malnutrition Related Diabetes (MRD)</td><td rowspan="2">Other Types of Diabetes (associated with certain diseases as pancreatic disease, hormonal, drug induced etc.</td><td rowspan="2">Non - Obese</td><td rowspan="2">Obese</td><td rowspan="2">Associated with certain diseases</td><td rowspan="2"></td><td>Previous abnormality of glucose tolerance</td><td>Potential abnormality of glucose tolerance</td></tr>

Table - 2 : Diagnostic criteria for Diabetes Mellities, IGT& IFG

| Diabetes Mellitus | | IGT | IFG | |
|---|---|---|---|---|
| Plasma | Whole blood | Plasma | Plasma | Whole blood |
| Fasting >= 126 OR 2 hrs PP >= 200 | Fasting >= 110 OR 2 hrs PP >= 180 | Fasting < 126 AND 2 hrs PP >= 140 but < 200 | Fasting >= 110 but < 126 | Fasting >= 100 but < 110 |

**Notes :-**

- All value shown above indicate glucose levels in mg / dl
- 2 hrs PP value are after 2 hrs of 75 gms glucose orally in 250 – 300 ml water
- ADA has recently recommended downgrading the criteria of IFG to 100 mg / dl from above mentioned 110 mg. The

are as given in Table - 2 (253, 254).

### Complications of Diabetes

Diabetes owes it's importance to the fact that it is a silent killer. It leads to a large number of serious sequelae which are disabling, besides drastically reducing the quality of life. The complications / sequelae are listed in Box - 1.

Box - 1 : Sequelae / Complications of diabetes

**Acute**

- Hypoglycaemia
- Hyperglycaemia and Ketoacidosis
- Infections (especially fungal infections of skin and mucous membranes, urinary infections, anaerobic infections of deep tissues, mybacterial infections).

**Chronic**

- Atherosclerosis, manifesting in cerebrovascular and coronary artery disease.
- Diabetic eye disease (Retinopathy, cataract)
- Diabetic Kidney Disease
- Diabetic Neuropathy (peripheral as well as autonomic neuropathies)
- Foot Ulceration and infections

It needs to be noted that presence of diabetes carries a very high risk for IHD (RR of 3. 5 to 4 times). In addition, diabetes frequently co-exists with other coronary risk factors as hypertension, dyslipidaemia, obesity & metabolic syndrome.

### Magnitude of the problem

As per estimates of WHO, the number of people affected worldwide with diabetes were approximately 125 million which are expected to be almost 300 million by 2025. (255). The incidence is peculiarly high among populations living in Nauru islands and among Pima Indians of USA where the prevalence may be as high as 40 to 50%. In developed, induatrialized countries, prevalence rates of as high as 10 to 20% may occur(251). India has the unfortunate privilege of being the "Diabetes capital" of the world. The prevalence rates have been estimated to be 12% in urban areas and 4% in rural areas. More concerning is the fact that diabetes prevalence over the past 4 decades has increased fourfold (89). Another interesting phenomena is that Indians who migrate to affluent countries develop very high prevalence rates of 10 to 20%, indicating the high racial predisposition that Indians and other south asian populations have for diabetes, and which gets expressed whenever we get affluent conditions (251).

### Determinants

### Risk Factors for Diabetes

The two most important determinants of diabetes are firstly, genetic background (family history) and secondly, obesity. It has been very aptly said that for diabetes, "genetics loads the cannon and obesity finally fires it". As for IHD, the risk factors may be grouped as "Non-Modifiable" (Age, Sex, Genetic and Racial factors) and "Modifiable" (Obesity, physical activity, nutritional factors, stress, drugs, infections and chemical toxins, etc).

Genetic factors

NIDDM shows strong family aggregation. Twin studies and familial studies have provided firm evidence that the role of genetic factors is relatively high. Till now, no specific genetic marker has been identified, though some have been proposed. With the current status of knowledge, it seems that diabetes is a "polygenic" disease and not possibly due to defect in a single gene. History of diabetes among parents, grandparents and first degree relatives predisposes a person to high risk of developing diabetes.

Age

Increasing age increases the risk. Most cases are detected during the middle age.

Sex

There is no clear difference between sexes as regards the risk of diabetes.

Race

Some races are known to be at high risk as Polynesians, Eskimos, Pima Indians, etc. The possibility is also strong that south asian populations including Indians may be at high risk. One hypothesis is that this may be due to the effect of "thrifty genes". These genes developed as a part of nature's protective mechanisms, among populations who were, for many centuries, exposed to starvation, famines and lack of food. The thrifty gene developed to conserve whatever small amount of energy, which was available to such populations, in the form of body fat

stores. However, with economic improvements in such populations, the food supply improves greatly but the protective effect of thrifty gene also continues resulting into excessive levels of obesity and consequent diabetes.

Obesity

Obesity has been proven to be a very strong risk factor for diabetes type 2. the estimates of risk vary from RR of 1. 8 to 3. 2 in different populations. The role of obesity is independent of racial factors. In addition, central distribution of body fat (referred to as central, abdominal, visceral, apple-shaped or android type of fat distribution and measured in terms of waist circumference or Waist hip ratio) is upheld to be an important risk factor, independent of total body weight.

Physical inactivity

It has been clearly demonstrated that physical inactivity decreases insulin sensitivity. The risk of diabetes due to physical inactivity has been estimated to be as high an RR of 4. 31 in some large scale studies. The protective effect of physical activity is independent of obesity; this means that an obese person who is physically active and fit would have lower risk of diabetes (as well as lower risk of other life style diseases) than a normal weight person who is physically inactive and unfit. In addition, physical activity will also assist in keeping the body weight under control.

Nutritional factors

There is increasing evidence form both epidemiological as well as laboratory studies that increased dietary intake of saturated fat and decreased intake of fibre can result in lowered insulin sensitivity and impairment of glucose tolerance. In general, reduction in the overall calories, reduced intake of saturated fats & refined sugars and increased intake of grains, fruits and vegetables would be of utility in preventing diabetes.

Foetal and early childhood Influences

There has been increasing evidence (Barker's Hypothesis) that poor maternal nutrition during pregnancy and malnutrition during early infancy may be associated with insulin resistance, obesity, impaired glucose tolerance, raised blood pressure and occurrence of metabolic syndrome in the same person during his / her adult life. This underlines the value of ensuring adequate nutrition during pregnancy and during early childhood.

Stress

Several states of physical stress and trauma can lead to glucose intolerance through altered hormonal mechanisms but whether they can permanently lead to diabetes is not established. Similarly, the role of mental and social stress as contributory factor in diabetes mellitus has been suggested but remains unproven.

Drugs and Hormones

Phenytoin, diuretics (especially thiazides), beta blockers, corticosteroids and certain contraceptive steroids may, in susceptible persons induce glucose intolerance or even diabetes, but this usually resolves after withdrawl of the drug.

## Prevention and control

The broad strategy for prevention and control of diabetes will remain the same as that outlined for IHD earlier, including primary, secondary and tertiary levels of prevention.

### Primary prevention

Primary prevention would basically utilize the Information, education and Communication (IEC) strategy to educate and motivate the community and individuals. The key messages for IEC will remain the same as have been outlined for prevention of IHD in the earlier chapter. Primary prevention will, as for IHD, include the population strategy, educating both, the general community (mass approach) and specific groups (group approach) as outlined for prevention of IHD. Similarly, the primary prevention steps would also include the "individual high risk strategy", focusing on individuals who have strong family history of diabetes mellitus, who are changing from active to more leisurely lifestyle (as the JCOs / NCOs), are obese, have evidence of IFG or IGT, have other cardiovascular risk factors as hypertension and dyslipidaemia, and women who have history of Gestational DM or history of giving birth to babies weighing > 4kg.

### Secondary Prevention

This would be through early diagnosis and prompt treatment, mainly by way of screening programmes. The strategies could be either "population screening" by screening the entire population or a selected random sample, which is fruitful only if the prevalence of diabetes is very high or else for research or health planning purposes. Secondly, it could be a "selective screening" undertaken in groups of people known to be at high risk, as those with family history, obese persons (BMI > 25), aged more than 40 years in high prevalence populations, women giving history of GDM, those with history of IGT / IFG, or those with hypertension or dyslipidaemia. Thirdly, it could be an "Opportunistic Screening" employed when high risk individuals come in contact with the Doctor, eg obese person, hypertensive, having IHD, having family history, etc, once such a person reports sick.

### Tertiary Prevention

The role of Doctors as well as paramedical personel assumes importance in context of tertiary prevention – to follow up the patient, to advocate continuous treatment, to educate the patient about importance of treatment and the various precautions to be taken by them. The key issue to be kept in mind are outlined in Box - 2.

**Box - 2 : Key issues for tertiary prevention**

- Keep a follow up of the patient of diabetes
- Reassure about the possibility of leading a near normal life, with proper treatment and precautions
- Educate about
  - Do not miss the antidiabetic medicines
  - Do not miss the meals
  - Diabetic identification card
  - Carry some sugar or lozenges for any hypoglycaemic emergency
  - Foot care, footwear and daily inspection
  - Early identification of complications
  - Regular physical exercise, diet, no tobacco, avoid

Col RajVir Bhalwar

# Systemic Arterial Hypertension and Stroke

### Definition / Identification

Systemic arterial hypertension is defined as a state of chronically elevated arterial blood pressure, as compared to what is normally expected in context of the age of an individual.

### Levels

It needs to be noted that blood pressure is a "continuous" variable and hence it may be scientifically difficult to draw a arbitrary cut-off line to delineate normal from raised blood pressure; e. g. , blood pressure level of 130 / 86 would carry a higher risk for cardiovascular and other morbidity as compared to 120 / 80, though both would fall in the category of "normotensive". However, for the purpose of epidemiological, clinical and public health needs, the following is the categorization of hypertension, based on systolic and diastolic levels. This classification is based on the recent guidelines of WHO & ISH and from JNC - VII (256, 257) (Table - 1):

Table - 1 : Classification of Hypertension

| Grade | Systolic level (mm Hg) | | Diastolic level (mm Hg) |
|---|---|---|---|
| Normal | < 120 | AND | < 80 |
| Pre-hypertension | 120 to 139 | OR | 80 to 89 |
| Hypertension Grade - I | 140 to 159 | OR | 90 to 99 |
| Hypertension Grade – II | 160 to 179 | OR | 100 to 109 |

The above classification is a clear departure form the earlier WHO classification in which Blood pressure levels of 140/90 mmHg and above were taken to qualify as hypertension (258), since in this report even those with levels between 120 to 139 mmHg systolic and 80 to 89 mmHg diastolic have also been classified as "prehypertensive" thereby emphasizing the importance of concerted "lifestyle" modification and public education efforts for this group also.

### Classification

Hypertension can be classified in 3 different ways, as follows :

(a) **According to the level of blood pressure** : this has been described in the above table.

(b) **According to identifiable cause, if any**

About 5 to 10% of the cases of hypertension will have some identifiable cause for the raised BP. This is called as "Secondary" hypertension. Important causes of secondary hypertension are given in Box - 1.However, 90 to 95% cases will not have any identifiable cause; these are called as "primary" of "essential" hypertension. Certainly, the word "essential" gives an impression that these persons have to have raised BP, which is not correct; there is nothing like "essential" and most of these cases will also become normotensive with proper lifestyle changes.

(c) **According to the extent of target organ damage.** The various types of target organ damage that can be caused by raised BP are as given in Box - 1 (258, 259).

Box 1

**Causes of secondary hypertension**

- Induced by exogenous substances or drugs (Hormonal contraceptives, corticosteroids, sympathomimetics, cocaine, Tyramine containing foods & MAO Inhibitors, NSAIDS)
- Secondary to Renal Disease (Renal parenchymatous disease, Renovascular hypertension, Renin producing tumours)
- Associated with endoctine disorders (Acromegaly, thyroid disease, adrenocortical diseases, carcinoid tumours)
- Pregnancy Induced
- Coarctation of Aorta

**Target organ damage due to hypertension**

- Heart : IHD, LVH, Heart Failure
- Brain : Stroke, TIC
- Chronic kidney disease
- Peripheral arterial disease

### Hypertension as a risk factor for diseases

For purposes of public health and preventive medicine, hypertension and stroke are considered together since at the large population level, the major cause of stroke is raised blood pressure and efforts to prevent hypertension will pay a rich dividend for prevention of stroke. At the individualized clinical level, of course, there would be other causes of stroke that naturally, would need consideration.

Hypertension, like diabetes, is often referred to as "silent killer". For most of it's course, it produces hardly any signs / symptoms by itself; however, it damages the end organs substantially (cardiovascular system, Kidneys and Retina). Epidemiological estimates from large scale studies indicate that subjects with DBP of 105 mmHg have a ten times increased risk of stroke and five times more risk of IHD compared to subjects having DBP< 80 mmHg. Prolonged reductions in DBP by 5, 7.5 and 10 mmHg are respectively associated with at least 34%, 46% and 56% reduction in risk of stroke and at least 21%, 29% and 37% reduction in risk of coronary events (260).

It also needs to be clearly noted that both systolic as well as diastolic BP are important from the morbidity and mortality point of view. In fact, after 55 years age, SBP may become even more important than DBP from preventive point of view. Raised SBP has been associated with a higher RR of CHD, stroke, CCF, Renal disease and overall mortality. In the follow up of MRFIT trial, as compared to subjects with SBP < 120mmHg and DBP < 80mmHg, the RR of coronary events was 3.23 times higher for those with isolated diastolic hypertension (DBP > 100 mmHg with normal systolic, i. e. , < 140mmHg); the RR was 4.19 times for those with isolated systolic hypertension (SBP > 160 mmHg with DBP < 90 mmHg); and 4.57 times among those who had both, i. e. , SBP > 160mmHg and DBP > 100mmHg (261). Besides stroke and IHD, hypertension also substantially increases the risk of Congestive cardiac failure (CCF) by 2 to 4 times, and of end stage renal disease by 1.65 times (261, 262). Another important aspect to be remembered is that although raised blood pressure is independently associated with an increased risk of cardiovascular events, the risk is substantially increased by the presence of other risk factors namely smoking, dyslipidaemia and diabetes. Thus, equal blood pressure levels would carry different risks when associated with different combinations of risk factors and that too, at different levels. Therefore, raised blood pressure should not be seen in isolation but as a part of the overall, total cardiovascular risk assessment for the individual (263).

### Magnitude of the problem

#### World-wide

Hypertension affects approximately 50 million individuals in the United States and approximately 1 billion worldwide. As the population ages, the prevalence of hypertension will increase even further unless broad and effective preventive measures are implemented. Recent data from the Framingham Heart Study suggest that individuals who are normotensive at age 55 have a 90 percent lifetime risk for developing hypertension (264). The crux of the issue is that hypertension is now a major public health problem in all parts of the world (265 – 272). When cut-off values of 160 mmHg SBP and 95 mmHg DBP are taken, in most of the adult populations in the world, the prevalence comes to 10% to 20%. If cut off levels are lowered to the standard values of 140 mmHg SBP and 90 mmHg DBP, the prevalence would go up further, possibly to 25% to 30% of adult population (258).

#### Indian situation

In our country, prevalence of hypertension has been estimated to be between 20% to 40% in urban adults and 12% to 17% in rural adults. The estimated number of Indians with hypertension was 120 million in year 2000, which is likely to expand to 200 million by 2025, with equal numbers among men and women. (89).

#### Armed forces

Hypertension has been showing a gradual but consistently increasing trend, which needs to be adequately tackled. The data has been presented in the first chapter of this section.

### Determinants (Risk factors)

As for other lifestyle diseases, the risk factors for hypertension can be grouped as modifiable and non-modifiable.

### Non-Modifiable risk factors

#### Age

All studies have demonstrated a positive association between age and blood pressure (273). SBP increases consistently till almost the seventh or eighth decade, while DBP increases till fifth decade, becoming stationary thereafter, leading to an increase of pulse pressure and increased incidence of systolic hypertension in the elderly. However, the age related rise in blood pressure is not an inevitable phenomena of nature since in some isolated populations with very low habitual salt intake, the blood pressure does not increase with age, indicating that with controlled salt intake, the rise of blood pressure can be checked, despite ageing.

#### Sex

In childhood there is no difference in BP, between sexes; from adolescence onwards, the average BP is higher in males. However, this difference narrows down after women attain the age of 50 years, and thereafter, may even get reversed (273).

#### Heredity

Family history of elevated blood pressure is a strong risk factor for future development of hypertension.

#### Genetic factors

The genetic basis of high blood pressure has been well supported by experimental research, and while some monogenic hypertensive disorders in humans have been described (eg, ACE-II and angiotensinogen gene polymorphism), for the most part, hypertension is currently regarded to be a “polygenic” condition.

#### Ethnicity

Black races have been described to be having higher risk of hypertension; whether this is due to certain racial factors or else due to socio-cultural differences between black and white races is not clear. More recent research indicates that south asian populations including Indians, may be more predisposed to developing hypertension and metabolic syndrome.

### Modifiable risk factors

#### Dietary salt

There is substantially convincing evidence that dietary salt intake over and above the physiological requirements, is a strong risk factor for hypertension. It has been estimated that a 100 mmol per day lower intake of sodium over the lifetime would result in 9 mm smaller rise in SBP between 25 to 55 years of age; this would translate to a reduction in mortality by 16% in IHD, 23% for stroke and 13% deaths from all causes. Well established public health recommendations indicate that dietary salt

consumption, from all sources should not exceed 5 to 6 grams a day for an adult (274, 275).

### Dietary Potassium

In contrast to sodium, dietary potassium is protective. More precisely, it is the ratio of sodium to potassium which is more relevant. Thus, at a given level of dietary salt intake, blood pressure could be lowered by increasing the potassium intake. The case is therefore quite strong to encourage consumption of fresh fruits and vegetables (400 to 500 grams per day for an adult), which are rich sources of potassium (275, 276).

### Other macro and micro-nutrients

The role of saturated fats, dietary cholesterol, fibre (protective), antioxidant vitamins (protective), dietary calcium (increased intakes are protective) have all been postulated, though there is still no convincing evidence. However, keeping in view the fact that these nutrients have been shown to have a role in other lifestyle disease as IHD and diabetes, it would be desirable to adhere to the healthy lifestyle recommendations, in totality.

### Overweight

There is strong and consistent evidence that overweight / obesity is associated with hypertension, with the RR being 2 to as much as 6 times. The proportion of hypertension attributable to obesity has been estimated to be 30 to 65% in western countries. It is also estimated that for 10 Kg increase in weight (with all other risk factors held constant) the SBP would increase by 2 to 3 mm and DBP by 1 to 3 mm (277). Besides obesity, central obesity due to excessive intra abdominal (visceral) fat, as measured by waist circumference or WHR has been clearly shown to be a risk factor for hypertension, independent of whether generalized obesity is present or not. Hypertension and obesity / central obesity, in addition, are factors which cluster together in metabolic syndrome.

### Lack of physical activity

It has also been convincingly demonstrated by epidemiological and clinical data that physical inactivity is an important risk factor for hypertension. Sedentary and unfit normotensive individuals have 20% to 50% increased risk of developing hypertension in the next few years as compared to their fit and more active peers (278). WHO estimates indicate that the RR for developing hypertension due to physical inactivity is between 1.2 to 2.9, in different research studies.

### Alcohol

Alcohol consumption has been consistently related to blood pressure in different epidemiological studies. The risk effects are independent of obesity, central obesity, physical inactivity, age, sex and smoking. The RR of alcohol for causing hypertension has been estimated to be 1.4 to as high as 4.1, depending on the quantity and regularity of alcohol consumption (WHO global estimates). When 2 or more drinks are consumed daily, SBP increases by 1 mm and DBP by 0.5 mm on an average; daily drinkers have SBP and DBP levels which are higher by 6.6 mm and 4.7 mm respectively compared to those who drink only once a week (275, 279).

### Tobacco use

Tobacco use and hypertension, when present together, interact and greatly increase the cardiovascular risk compared to when either of them would have been alone. The direct risk of tobacco in causing rise in blood pressure is not very clear. However, WHO global risk estimates indicate that the RR of hypertension due to tobacco use is 1.17 times higher.

### Psychosocial stress

There is evidence that acute mental stress causes an increase in blood pressure. There is, however, not enough evidence to prove that long term stress causes chronic increase in blood pressure. Overall, the available evidence is insufficient to allow for definite conclusions of causality; methodologically sound research is required in this area. Nonetheless, stress management techniques would be of help in controlling acute stress and acute increases in blood pressures.

### Early childhood experiences

The “Barkers Research Group” has undertaken a large amount of research in various settings and strongly hypothesized that foetal malnutrition (as evidenced in form of low birth weight) and malnutrition during infancy and early childhood may be a strong risk factor for subsequent development of hypertension, diabetes, obesity, dyslipidaemia and metabolic syndrome in later adult life (280). These observations raise interesting possibilities of ”foetal programming”. The findings need to be substantiated by prospective studies.

### Tracking

The phenomena of “tracking” means that the level of risk factors during childhood and adolescence tends to track into the youth and late adulthood also. Thus, children who have higher levels of body weight, blood pressure, blood glucose and cholesterol, will tend to have the same level of these parameters during adulthood also. For example, in one of the large epidemiological studies, people in their 40’s with elevated BP as a group, had higher blood pressure readings than normal at the age of 7 years (281).

### Other environmental factors

Exposure to noise, air pollution and water pollution have all been implicated as a risk factor for hypertension, but no concrete epidemiological evidence is still available. Protection of public against environmental hazards is, in any case, a worthwhile public health measure.

### Increased heart rate

It has been noted in studies that resting heart rate of hypertensives is higher than normotensives. Whether hypertension leads to raised heart rate, due to haemodynamic adjustments or else, whether increased heart rate is a marker for prediction of hypertension, is not still clear.

### Low socio-economic status

In a number of populations in developed countries,

consistently higher levels of BP and a higher prevalence of hypertension have been noted in lower socio-economic groups. Contrarily, in those countries whose economies are improving, higher prevalence is seen in higher socio-economic groups. Thus, in developing countries, the higher prevalence in higher socioeconomic strata probably represents the initial stages of the epidemic of cardiovascular diseases; as the epidemic advances in these countries, there is likely to be a reversal of the social groups affected.

White coat hypertension

Measurement of BP by a doctor, may raise the concern and lead to a rise in BP in the subject, a phenomena called as white coat hypertension. It is therefore important to reassure the subject, and take the blood pressure in a relaxed state.

## Prevention and control of hypertension

Prevention and control of hypertension is addressed as per the same strategies, as has been discussed for IHD and diabetes.

### Primary Prevention

This would be by utilizing the mass approach or the group approach. The strategy utilizes the IEC approach to educate the community (mass approach) of the dangers of hypertension and the fact that it is a silent killer and most of the times the patient may not have any outward symptoms but the disease may progress. Education should be provided as regards the risk factors and adoption of healthy lifestyle to prevent the onset or progress of the disease. Education would also be directed towards specific groups (group approach) as outlined for prevention of IHD. Similarly, the primary prevention steps would also include the "individual high risk strategy", focusing on individuals who have strong family history of hypertension, who are changing from active to more leisurely lifestyle (as the JCOs / NCOs), are obese, or are likely to be physically inactive (as office workers).

### Secondary Prevention

This would be through early diagnosis and prompt treatment, mainly by way of screening programmes. The strategies could be either "population screening" by screening the entire population or a selected random sample, which is fruitful only if the prevalence of hypertension is very high or else for research or health planning purposes. Secondly, it could be a "selective screening" undertaken in groups of people known to be at high risk, as those with family history, obese persons (BMI > 25), aged more than 40 years in high prevalence populations, or those with diabetes or dyslipidaemia. Thirdly, it could be an "Opportunistic Screening" employed when high risk individuals come in contact with the Doctor, eg obese persons, diabetics, having IHD, having family history, etc, once such a person reports sick. Since measurement of blood pressure is a very simple, inexpensive and non-invasive procedures, it would be a very fruitful step if all medical persons make it a point to measure the blood pressure of all adult patients who come to them, irrespective of the presenting symptoms.

### Tertiary Prevention

The role of doctors as well as paramedical personel assumes importance in context of tertiary prevention – to follow up the patient, to advocate continuous treatment, to educate the patient about importance of treatment and

Col RajVir Bhalwar

# Cancers

### Definition / Identification

The term cancer encompasses a very wide variety of heterogenous disorders occurring in different parts of the body, with very different clinical manifestations. However, there is a special reason for grouping such diverse diseases under a single heading. The reason is that cancers, as they are defined, are "Group of heterogenous disorders characterized by Clonality (arise from a single stem cell that clones into carcinomatous cells), Autonomy (the cell division and growth is uncontrolled), Anaplasia (lack of cell differentiation) and Metastasis (distant spread)". It is these common features that bind cancers into a single entity for the purpose of description. Secondly, various cancers, despite their diversity in clinico-pathological manifestations, have some risk factors in common, a phenomena that again binds them together and can be fruitfully utilized for the purpose of prevention. As we shall see in the course of this chapter, these common risk factors are primarily a reflection of unhealthy lifestyle and hence, the contemporary saying is that cancers are, by and large, diseases of unhealthy lifestyle and are potentially preventable.

### Magnitude of the problem

Cancers reflect a major load on human health by way of morbidity, mortality and, above all, human suffering.

**Worldwide,** approximately 10 million new cases and more than 6 million deaths (12% of all deaths) occur due to cancers every year, as per estimates for the year 2000.It is estimated that more than 22 million people would be living with cancers, worldwide at any given point of time (282). These figures represent an increase of around 19% in incidence and 18% in mortality since 1990.In terms of incidence, the most common cancers worldwide are lung (12.3% of all cancers), breast (10.4%) and colorectum (9.4%). Lung cancer is the largest single cancer in the world (1.1 million annually). The top three causes of death from cancer are those of the lung (17.8% of all cancer deaths), stomach (10.4%) and liver (8.8%). Developing countries contribute to more than half of the total cancer cases worldwide. By 2020, the new cases are expected to reach at least 15 million a year and deaths 10 million. The projection of new cases of cancer per year, for 2020, is 6 million and 9.3 million respectively from developed and developing countries.

**In India,** approximately 8 lakh new cases of cancers are expected to occur every year (89). Large majority of these are tobacco related and hence potentially preventable. It has been estimated that 48% of cancers among men and 20% in women are due to tobacco. Cancer incidence in India is estimated to be around 70 – 90 per 100, 000 populations with 700, 000 – 900, 000 new cases of cancer every year. If survival is taken as three years on an average, at any given time there will be about 2, 500, 000 cancer patients in the country, In 2000, five and a half lakh deaths in the country were due to cancer. The commonest cancers in men are those of lungs, stomach, oral cavity and oesophagus, while in women, those of cervix uteri, breast, oral cavity, ovary, oesophagus and stomach are the commonest.

In India, a network of cancer registries was started across the country under the National Cancer Registry Programme (NCRP). There are at present six population based cancer registries(PBCRs) (five urban and one rural) and five hospital based registries (HBCRs) generating data on cancer in the country under NCRP. The details of national cancer registries are given in the section on national health programmes.

### Problem in Armed Forces

The hospital admission rates due to cancers per 1000 serving personnel from 2000 onwards are given in Table - 1. However, the data needs to be interpreted with caution since armed forces reflect a "young" population, with large majority of the personnel retiring before 50 years age; hence hospital admission rates due to cancer among serving personnel may not correctly reflect the magnitude. Hence, what is very important for the armed forces medical officers is to impress on the commanders and personnel, the need to follow "healthy lifestyle" which will go a long way in preventing not only cancers, but also other serious problems as IHD, diabetes and hypertension also.

Table - 1 : Hospital admissions / 1000: Neoplasms

| Year | Army | Navy | Air force |
|---|---|---|---|
| 2000 | 0.43 | 0.56 | 0.24 |
| 2001 | 0.64 | 0.72 | 0.17 |
| 2002 | 0.94 | 1.82 | 0.32 |
| 2003 | 0.85 | 0.51 | 0.30 |
| 2004 | 0.92 | 0.77 | 0.39 |
| 2005 | 1.06 | 0.78 | 0.35 |
| 2006 | 0.95 | 1.00 | 0.31 |

### The major risk factors for Cancers

Tobacco

Tobacco smoking is the main known cause of human cancer-related deaths worldwide. An increase in risk of lung cancer (relative to a non-smoker) is consistently evident at the lowest level of daily consumption, and is also proportional to the duration of smoking. In general the relative risk (RR) of lung cancer due to smoking is of the order of 10 to as high as 20 times. Smoking of black tobacco cigarettes represents a greater risk for most tobacco-related cancers than smoking of blonde cigarettes; similarly smoking filtered cigarettes entails a lower risk for most tobacco-related cancers than unfiltered and high-tar cigarettes. However, it needs to be noted and emphasized that a "safe" cigarette does not

exist; all smoking tobacco products entail a carcinogenic risk. In addition to lung, tobacco also causes cancers of the larynx, oral cavity, pharynx, oesophagus, pancreas, kidney and bladder (283). In non-alcohol drinking male smokers, risk of developing cancer of the oral cavity is about double that for non-drinking non-smokers. Elevations of ten-fold or more are evident for cancer of the larynx and five-fold or more for oesophageal cancer. A common feature of lung and other smoking-induced cancers is the decreased risk which follows smoking cassation ("quitting") relative to continuing smoking (283). The relative risk of cancer at most sites is markedly lower than that of current smokers after five years' cessation, although risks for bladder cancer and Adeno-carcinoma of the kidney appear to persist for longer before falling. Despite the clearly established benefit of cessation, the risk for ex-smokers does not decrease to that for "never smokers".

Other cancer types may be a consequence of smoking. These include cancer of the stomach, liver, nose and myeloid leukemia. Exposure to environmental smoke (passive smoking) is a definite risk for lung cancer and possibly laryngeal cancer; the relative risk has been estimated at about 1.15-1.20 times.

Smokeless tobacco use (the commonest being tobacco chewing as "quid") has been associated with increased risk of head and neck cancer, particularly oral cancer. Since chewing of tobacco-containing products is particularly prevalent in southern Asia, especially India, it represents a major carcinogenic hazard in this region.

Alcohol consumption, exposure to asbestos and exposure to ionizing radiations interact with smoking in increasing the risk of cancers. For alcohol drinking and smoking, risk for cancer of the larynx, oesophagus and oral cavity increase multiplicatively.

### Alcohol drinking

Causal association of drinking alcohol has been definitely established in respect of oral, oesophageal and liver cancers (284). A causal association is also established in the case of breast cancer and is probable for colon and rectal cancer (284, 285). There have been suggestions of a possible carcinogenic effect of alcohol drinking on other organs, such as the lung, but the evidence is still inconclusive (286). For all cancers caused by drinking alcohol, the risk of cancer increases with the level of consumption, up to an intake of about 80 g of ethanol / day (equal to 8 small pegs of hard drinks as Rum or whisky). The risk of head and neck cancer is 5-10 times higher in heavy drinkers than in abstainers, the carcinogenic effect of alcohol appearing to be more potent in the oral cavity, pharynx and oesophagus and weaker in the larynx. The relative risk of breast cancer in women with a high consumption of alcohol is approximately two-fold. Alcohol drinking and tobacco smoking show a synergistic interaction in the etiology of cancers of the oral cavity, pharynx, larynx and oesophagus.

Alcohol drinking is estimated to be involved in the etiology of 3% of all cancers (that is, 4% in men, 2% in women). In women, approximately half of the neoplasms attributed to alcohol drinking are breast cancers.

### Occupational exposures

The first reports of associations between risk of cancer and employment in particular occupations appeared during the 18th century (287) and 19th century (bladder cancer in workers exposed to dyes (288)). However, the majority of studies establishing a link between an increased risk of cancer and a particular working environment were published between 1950 and 1975 (289). At present, 25 chemicals or mixtures, for which exposures are mostly occupational, have been established as human carcinogens, the important ones being asbestos, crystalline silica and heavy metals. Aromatic amines have been shown to increase the risk of bladder cancer; benzene that of leukemias and that of myelogenous leukaemia in particular (290); Asbestos and other fibers have been associated with lung cancer and mesothelioma. Cancer of the lung can be caused by exposure to inorganic arsenic in mining and copper smelting and among workers in chromium plants and chromium alloy workers. Nickel refining also carries a carcinogenic risk.

Coal tar, coal gas production and iron founding are associated with cancers of the skin and of other sites, including the urinary and respiratory systems. Work in iron and steel founding is also associated with an elevated risk of lung cancer. Nasal adenocarcinomas are caused by exposures in the furniture and cabinet making industry, mainly among people exposed to wood dust. Similarly, among painters, 40% excess risk of lung cancer has been consistently recorded.

### Environmental pollution

In the present context, "environmental pollution" refers to a specific subset of cancer-causing environmental factors, namely, contaminants of air, water and soil. The carcinogenic pollutants for which most information is available include asbestos (referring here to non-occupational exposure), toxic agents in urban air pollutants and chlorination by-products and other contaminants of drinking water. Various studies suggest that environmental pollution accounts of 1-4% of the total burden of cancer in developed countries (291, 292). Non-occupational exposure to asbestos may occur domestically and as a consequence of localized pollution. Cohabitants of asbestos workers may be exposed to dust brought home on clothes. Non-occupational exposure to asbestos may cause lung cancer, particularly among smokers (293). Ambient air pollution has been implicated as a cause of lung cancer. It is possible to attribute some carcinogenic risk to particular atmospheric pollutants, including benzo(a)pyrene, benzene, some metals, particulate matter (especially fine particles), and possibly ozone.

Drinking water may contain a variety of potentially carcinogenic agents, including chlorination by products and arsenic. Chlorination by products results from the

interaction of chlorine with organic chemicals. Among the many halogenated compounds that may be formed, trihalomethanes and chloroform are those commonly found. Studies on bladder cancer have suggested an increased risk associated with consumption of chlorinated drinking water (294). Doubts remain as to whether such associations are causal because of the way in which the studies measured exposure.

Arsenic causes cancer in the skin, lung and other organs. The main source of environmental exposure to arsenic for the general population is through ingestion of contaminated water. High exposure to arsenic from drinking water is found in several areas of Alaska, Argentina, Bangladesh, Chile, India, Mexico, Mongolia, Taiwan and the USA. There is strong evidence of an increased risk of bladder, skin and lung cancers following consumption of water with high arsenic contamination (295, 296).

Food contaminants

Food may be contaminated by mycotoxin – producing fungi. The most studied are Aflatoxins, which occur as food contaminants in hot, humid parts of the world, with diets based upon maize and groundnuts (peanuts). Aflatoxins are products of the aspergillus fungi and particularly accumulate during storage of grains. Together, aflatoxin exposure and HBV infection are the main risk factors according for the high incidence of hepatocellular carcinoma in some regions of Africa, Asia and South America (297). Incidence of oesophageal cancer has been related to the occurrence of another fungus, viz. , F. verticillioides or its toxins in maize. Similarly, Ochratoxin A, also a fungal metabolite may contaminate grain and pork and pork products and lead to urothelial urinary tract tumors.

Certain organochlorines, including DDT and other pesticides, are bioconcentrated in the human food chain. DDT in particular has been associated with increased risk of pancreatic cancer, breast cancer, lymphoma and leukaemia in humans.

Certain heterocyclic amines are formed during cooking of meat and fish at high temperature. Heterocyclic amines are carcinogenic in various organs of mice, although their carcinogenic potential in humans has not yet been established (298). Another group of chemicals, the Polycyclic aromatic hydrocarbons are generated in meat when it is fried, roasted or cooked over an open flame, and many members of this chemical class are carcinogenic.

**Radiation**

Ionizing radiations are one of the most intensively studied carcinogens (299-301). Exposure to ionizing radiations from natural as well as from industrial, medical and other sources, can cause a variety of neoplasms, including leukaemia, breast cancer and thyroid cancer

Sunlight is by far the most significant source of ultraviolet irradiation and causes several types of skin cancers, particularly in highly-exposed populations with fair skin. Extremely low frequency electromagnetic fields generated by electrical power transmission have been associated with an increased risk of childhood leukaemia, but the findings are not conclusive. (302).

Mobile telephones are the greatest source of radio frequency exposure for the general public. The evidence of the carcinogenicity of radio frequency fields is not clear. The experimental evidence is also limited, but suggests that radio frequency fields cannot cause DNA mutations.

Chronic infections

Infectious agents are one of the main causes of cancer, accounting for 18% of cases worldwide, and the majority occurring in developing countries. The most frequently affected organ sites are liver (hepatitis B and C, liver flukes), cervix uteri (human papilloma viruses), lymphoid tissues (Epstein-Barr virus), stomach (Helicobacter pylori) and the urinary system (Schistosoma haematobium). The mechanism of carcinogenicity by infectious agents may be direct, e. g. , mediated by oncogenic proteins produced by the agent (e. g. , human papilloma virus) or indirect, through causation of chronic inflammation with tissue necrosis and regeneration. Strategies for prevention include vaccination (hepatitis B virus), early detection (cervical cancer) and eradication of the infectious agent (Helicobacter pylori).

Chronic carriers of HBV, have around 20 times higher risk of developing liver cancer than non-carriers (303). It has been estimated that 60% of cases of primary liver cancer worldwide and 67% of cases in developing countries can be attributed to chronic persistent infection with HBV. About 20% of cases of liver cancer in the world are attributed to HCV.

Many molecular epidemiological studies (304 - 306) have consistently shown higher relative risks for invasive cervical cancer due to HPV. In fact, HPV DNA is found in virtually all invasive cervical cancers, indicating that HPV is a necessary cause (307). Moreover, about 80% of anal cancers and 30% of cancers of the vulva, vagina, penis and oro-pharynx can be attributed to HPV. HIV infection enhances the risk of Kaposi sarcoma by approximately 1, 000-fold, of non-Hodgkin lymphoma by 100-fold, and of Hodgkin disease by 10-fold. Infection with Helicobacter pylori is one of the most common bacterial infections worldwide. In developing countries, the prevalence of H. pylori among adults ranges from 80 to 90% whilst in developed areas it is around 50%. It is clear that H. pylori plays a role in gastric cancer, but other cofactors (e. g. , diet) are also contributory (308).

Diet and nutrition

A principal environmental factor, now generally recognized as major determinant of cancer incidence, is diet. It is estimated that up to 30% of human cancers are probably related to diet and nutrition. The western diet and lifestyle are generally associated with high incidence of cancers of the colorectum, breast, prostate and endometrium. Based on available evidence, the major factors in diet related to cancers are :

**Vegetables and fruits**

The most consistent finding on diet as a determinant of

cancer risk is the association between high consumption of vegetables and fruits and reduced risk of several cancers. Adequate consumption of vegetables and fruits is associated with reduced risk of cancers of the pharynx, larynx, lung, oesophagus, stomach and cervix uteri, while only vegetables, but not fruits, seem to protect against cancers of the colon and rectum. Large scale studies confirm these observations, suggesting, for example, that a daily consumption of 500g of fruits and vegetables can decrease incidence of cancer of the digestive tract by as much as 25% (309).

**Salt and salt-preserved foods**

Several studies have reported increased relative risks of stomach cancer in relation to the increased consumption of salt and salt-preserved foods. Salted, smoked, pickled and preserved foods (rich in salt, nitrite and preformed N-nitroso compounds) are associated with increased risk of gastric cancer. Such high salt intake, together with Helicobacter pylori infection, may contribute to the development of atrophic gastric and hence gastric cancer. Consumption of Chinese-style salted fish has been specially associated with increased risk of nasopharyngeal cancer in South-East Asia (310).

**Meat**

Epidemiologic studies on meat consumption and cancer risk supports the existence of a specific association with colorectal cancer risk. This association seems to have been found more consistently for consumption of red meat (beef, lamb and pork) and processed meat (ham, salami, bacon, etc. ) for which consumption of 80 g per day may increase colorectal cancer risk by 25 and 67% respectively (311).

**Refined sugars**

Increased consumption of simple sugars (mono-and disaccharides) may be associated with increased colorectal cancer risk, while consumption of complex polysaccharides, non-starch polysaccharides and/or fiber is associated with lower risk.

**High overall fat / saturated fat intake**

The hypothesis that high fat intake is a major cancer risk factor in the Western style diet has been at the centre of most epidemiological and laboratory experimental studies. The results are, however far from clear and definitive. The only moderately consistent result seems to be the positive association between consumption of fats of animal origin (except for fish) and risk of colorectal cancer.

**Food additives**

Although some animal bioassays have revealed an increased incidence of urinary bladder cancer, there is inadequate evidence for carcinogenicity of saccharin in humans (312). The proportion of dietary- related cancers considered attributable to food additives is very low (313).

**Micronutrients**

Research on vitamin and cancer in humans has focused mainly on carotenoids and vitamin A (retinol), vitamin E, vitamin C and some of the group of B vitamins (folic acid, B6). The biological basis of the interest in these vitamins is their involvement in either of two metabolic mechanisms commonly called the antioxidant effect (carotenoids, vitamins C and E) and methyl donation (folic acid, B6). Studies have shown quite consistently that individuals with lower carotenoid levels have increased lung cancer risk. Less consistent and weaker protective effects of carotenoids have also been reported for cancer of the oesophagus, stomach, colorectum, breast and cervix. Low dietary intake of vitamin C has been found to be associated with increased risk of cancers of the stomach, mouth, pharynx, oesophagus and, less consistently, with cancers of the lung, pancreas and cervix. Although results on vitamin E and cancer are less strong and consistent than those on carotenoids and vitamin C, several studies have suggested that low vitamin E intake is related to increased risk of cancers of the lung, cervix and colorectum. There is rising interest in the possible cancer-preventive effect of folic acid; some prospective studies have shown that high dietary intakes and higher blood levels may be associated with reduced risk of cancers and adenomatous polyps of the colorectum. Folate deficiency leads to an accumulation of homocysteine. High homocysteine level have recently been found to be strongly associated with death from myocardial infarction, total mortality and colon cancer risk (314). Among other micronutrients, zinc and selenium deficiency may increase cancer risk (315).

Overweight, obesity and reduced Physical Activity

Western type of diet (characterized by highly caloric food rich in animal fat and protein), often combined with a sedentary lifestyle and hence energy imbalance and obesity, increases the risk of colon, breast, prostate and endometrial cancers. The strongest and most consistent association with body mass has so far been seen for endometrial cancer, the risk of which is increased two-to six-fold in obese compared to lean women, both before and after menopause. Majority of case control and prospective studies have also found that Obesity is a strong risk factor for endometrial cancer, as well as or breast cancer in postmenopausal women.

Genetic susceptibility

Inherited cancer syndromes (e. g., retinoblastoma, neurofibromatosis, etc. ), usually involving germline mutation may account for up to 4% of all cancers. Inherited mutations of the BRCA 1 gene account for a small proportion of all breast cancers. Environmental factors may modify the cancer risk of individuals affected by inherited cancer syndromes.

Reproductive factors and hormones

Female sex hormone metabolism, reproductive factors and menopausal status affects the development of endometrial, ovarian and breast cancer. Use of combined oral contraceptives accounts for a slight increase in risk of breast cancer, but is protective against ovarian and endometrial cancers. Hormone replacement therapy is associated with increases in risk of breast and endometrial cancers. For breast cancer, incidence rates rise more steeply with age before menopause than after.

Furthermore, breast cancer risk is increased in women who have early menarche, or who have late menopause, whereas an early age at first full-term pregnancy and high parity are associated with reduced risk of cancers of breast, ovary and endometrium (316). Ovarian cancer risk does not show strong relationship with menstrual history, but is clearly and inversely related to parity (317).

## Epidemiology of common cancers

### Lung Cancer

Lung cancer is the most common tumour worldwide, with 900, 000 new cases each year in men and 330, 000 in women. It is leading causes of death from cancer. In men more then 80% of lung cancer cases are caused by smoking; in women the attributed risk is less (about 70% in Northern Europe; 45 worldwide). In India also, it is the commonest form of cancer among males. Some occupational exposures and air pollution (including passive tobacco smoke) make a minor contribution to incidence. No population-based screening procedures have been established. No effective treatment is available; the five-year survival rate for lung cancer patients is less than 15%.

### Breast Cancer

Breast cancer is the most common malignancy affecting women, with more than one million cases occurring worldwide annually. Affluent societies carry the greatest risk, with incidence rates of >80 per 100, 000 population per year. In India, it is the second commonest cancer among females. Though it can be detected early and treated with effective measures like self / clinical breast examination or mammography. In our country only 15% patients present in the localized stage; in 75% regional lymph nodes are already involved while 10% have distant spread at the time of reporting.

The worldwide breast cancer epidemic has many etiological factors, including diet and diet related lifestyle factors, obesity (for post-menopausal breast cancer), high caloric diet, low intake of dietary fibre, physical inactivity, low intake of fruits and vegetables and alcohol use; hormone related and reproductive factors (early menarche, late or no pregnancy, late menopause, use of oral contraceptives, regular ovular menstrual cycle and lack of breast feeding); previous history (family history of breast cancer; history of benign breast disease); and, exposure to ionizing radiations at the time of development of breasts. The positive aspect of breast cancer is that it is possible to detect it at an early stage and treat it effectively. In some regions of the world, including North America, Western Europe and Australia, breast cancer mortality rates have started to decline, mainly due to improvements in early detection and treatment (chemotherapy and tamoxifen). Five-year survival rates are higher than 70% in most developed countries. Breast cancer screening trials of mammography have also shown that mortality can be reduced by up to 30%.

### Cancers of the female reproductive tract

Cervical cancer is the second most common cancer of women worldwide with more than 470, 000 new cases per year and about 230, 000 deaths every year. More than 80% occur in developing countries. In India, it is the commonest cancer among females, with more than a lakh new cases being detected and 75000 deaths every year. Sexually transmitted infection with human papillomavirus is fundamental to development of carcinoma of the cervix. HPV prevalence increases with multiple sexual partners and poor genital hygiene. Early age at first sexual contact and multiparity are other risk factors.

Population based screening with pap smear has improved early detection and survival. Five-year survival rates are up to 70%. In our country, it is recommended that ideal age at screening should be 35 to 50 years, as chances of detecting pre-cancerous lesions are maximum in this group. Other screening methods being studied for their efficacy in population screening include Unaided Visual Inspection (UVI), Visual inspection using 4% acetic acid (VIA) and visual inspection using Lugol's Iodine.

Endometrial cancer mainly affects postmenopausal women in developed countries; worldwide, 188, 000 new cases are diagnosed annually and obesity is a major risk factor. About 190, 000 cases of ovarian cancer occur each year, predominantly among postmenopausal women in developed countries; five-year survival rates are about 40%.

### Oral and other head and neck cancers

The most common cancer in the head and neck, namely oral cancer, ranks eleventh worldwide (390, 000 new cases per year), while cancers of the pharynx (65, 000 cases) and larynx (160, 000 cases) are less common. In India, oral cancer is one of the commonest cancers among males, mainly due to smokeless tobacco (tobacco chewing), which is the single most important risk for oral cancer. Other risk factors include alcohol use, betel nut chewing, and chronic trauma to oral mucosa by sharp tooth or ill-fitting dentures. Multiple primary carcinomas are not uncommon. Oral cancer is eminently suited to early detection and treatment by regularly inspection of oral cavity for leukoplakia / erythroplakia or ulcers. Early-stage tumours can be surgically resected, However in developing countries like ours, many patients present late in the disease. Overall, oral cancer patients have a five-year survival rate of less than 50%.

### Stomach Cancer

Cancer of the stomach is among the most common malignancies worldwide, with some 870, 000 new cases every year. Mortality from stomach cancer is second only to lung cancer. In India also it is one of the commonest cancers among males, alongwith cancers of lung and oral cavity. Patients are often diagnosed with advanced disease and five-year survival rates are poor, usually less than 30%. Infection with Helicobacter pylori is considered as an important risk factor in the development of stomach cancer.

Incidence is declining worldwide. In most European countries it has fallen by more than 60% during the past 50 years. This trend is mainly due to markedly decreased consumption of salt-preserved food, increasing avoidance

of a high-salt diet and availability, in many countries, of fresh fruits and vegetables throughout the year.

### Oesophageal Cancer

Cancer of the esophagus is the sixth most common cancer worldwide (more than 400, 000 cases per year). Incidence varies markedly, and is highest in western and south-central Asia. The major risk factors are tobacco and alcohol abuse. Other risk factors include consumption of very hot beverages and malnutrition. Most cancers of the oesophagus are detected at an advanced stage; five-year survival rates are less than 15%.

### Colorectal Cancer

Cancers of the colon and rectum are rare in developing countries, but are the second most frequent malignancy in affluent societies; over 940, 000 cases occur annually worldwide. An important etiological factor is unhealthy lifestyle involving a diet rich in fat, refined carbohydrates and animal protein, combined with low physical activity. Studies suggest that risk can be reduced by decreasing meat consumption and increasing intake of vegetables and fruit. Colonoscopy is the most reliable means for early detection. Progressively improved treatment has resulted in a five-year survival rate of about 50%.

### Liver Cancer

About 560, 000 new cases of liver cancer, usually hepatocellular carcinoma, occur annually, and contribute significantly to cancer mortality worldwide. More than 80% of cases occur in Asia and Africa. The incidence rate is more than twice as high in men as in women. In Africa and Asia, hepatocellular carcinoma is most frequently caused by hepatitis B virus infection; concomitant dietary exposure to aflatoxin multiplies the risk. In Japan, this cancer is predominantly caused by hepatitis C virus infection. In western countries, liver cirrhosis due to chronic alcohol abuse is the major etiological factor. Hepatocellular carcinoma has very poor prognosis, survival from time of diagnosis often being less than six months; only 10% of patients survive five years or more.

### Cancers Of The Male Reproductive Tract

Prostate cancer accounts for about 200, 000 deaths annually worldwide, predominantly afflicting older men in developed countries. Risk factors include high caloric intake and low physical activity. Black men have the highest, white men intermediate and Asian men a lower risk. Recorded incidence is increasing in many countries, partly as a result of screening for elevated serum levels of prostate-specific antigen. Testicular cancer mainly affects young men, with close to 50, 000 new cases each year worldwide. Incidence is increasing in many developed countries; its etiology is largely unknown. The mean five-year survival rate is higher than 95% mainly due to the efficiency of chemotherapy using cisplatin; long-term disease-free survival can even be achieved in cases of metastatic testicular cancer.

### Bladder Cancer

Bladder cancer is the ninth most common cancer worldwide, with 330, 000 new cases and more than 130, 000 deaths per year. Bladder cancer is primarily attributable to smoking, which accounts for 65% of male and 30% of female cases in some developed countries. Other important causes include analgesic abuse (phenacetin), some types of cancer chemotherapy and historically, occupational exposure to chemicals such as 2-naphthylamine. In Egypt and some Asian regions, chronic cystitis caused by Schistosoma haematobium infection is a major risk factor. Treatment based on endoscopy, surgery, radiotherapy and cytotoxic drugs often permits long-term survival in developed countries, where 65% of patients live for at least five years after diagnosis.

### Leukaemia

Leukaemia is the eleventh most common cancer worldwide with more than 250, 000 new cases each year. The etiology of leukemia is largely unknown, although a small proportion of cases is attributed to treatment with anticancer drugs or exposure to ionizing radiations. The genetic characteristics of many leukaemias are being elucidated. Treatment of acute leukemia has made much progress and helped to establish general principles of cancer chemotherapy and management. Survival varies greatly according to type, with acute lymphoblastic leukemia patients having a five-year survival rate of up to 70%, whilst for those with acute myeloid leukemia it is only 20-30%.

### Lymphoma

Malignant lymphomas are classified as either Hodgkin's disease or non-Hodgkin's disease or non-Hodgkin lymphoma. Hodgkin's disease affects mainly children's and the elderly in developing countries and young adults in more developed countries; 62, 000 new cases are diagnosed annually. The incidence of malignant Non-Hodgkin lymphomas is increasing worldwide; more than 280, 000 new cases occur annually, predominantly in more developed countries. Advances in chemotherapy have led to a five-year survival rate for Hodgkin disease of more than 70% and that for non-Hodgkin lymphomas has increased to 60-70%.

### Pancreatic Cancer

Pancreatic cancer is the 14th most common cancer worldwide, with approximately 216, 000 new cases per year. Highest incidence rates occur in more developed countries. In countries with high smoking prevalence, more than 40% of cases are attributable to tobacco consumption. Familial risk, often involving hereditary pancreatitis, is evident in up to 10% cases. No effective early diagnostic test or population-based screening procedure is available. Five-year survival rates are poor (less than 5%) and the vast majority of pancreatic cancer patients die within a year of clinical diagnosis.

### Renal Cancer

Cancer of the Kidney is the 15th most common cancer in the world and quite prevalent in developed countries. Close to 190, 000 cases are diagnosed each year worldwide and men are generally affected more frequently than women. Tobacco smoking is an

established cause. Excess body weight (obesity) has also been identified as a risk factor, particularly in women. Patients with late stage diagnosis face a poor prognosis. Recent advances in imaging allow the early detection of asymptomatic tumours. The five-year survival rate is approximately 50%.

## Prevention and control of cancers

Cancers represent serious maladies which have great potential for prevention, as well as early diagnosis and effective treatment. Prevention of Cancers should be a totalistic approach, targeting all levels of prevention, viz. , primary, secondary as well as tertiary levels.

### Primary prevention

Community education and motivation

As is evident from the foregoing discussions, the commonest (as also serious) cancers, viz;, lung, oral cavity, breast, cervix uteri, stomach, upper aerodigestive tract and colorectum, are greatly related to "unhealthy lifestyle" which has been the discussion of this entire section. Education and motivation of the community to adopt simple healthy lifestyle steps, as depicted in Box - 1.will go a long way in preventing not only various serious and common cancers but various other serious diseases also.

**Box - 1 : Key message**
**Community education for cancer control**

- Stop Tobacco in any form today itself ; do not start if you are non-user.
- Stop alcohol; if you cannot stop, drink in moderation.
- Eat at least half a Kg of fresh, seasonal fruits and vegetables every day.
- Eat plenty of whole grains, pulses, beans and legumes in diet.
- Keep salt consumption to < 5 grams a day; avoid food items which are salt-preserved, smoked or cooked in re-heated oils
- Exercise briskly : at least 2 miles (3.2 Kms) of brisk walk in 30 minutes every day.
- Avoid Ghee, butter, deep fried, thick-gravied, creamed and sugary foods.
- Avoid "Red Meat" (lamb, beef, pork).
- Maintain your body weight with proper combination of diet and exercise (BMI at < 25; waist at < 90 for males & < 80 for females)
- Avoid sexual promiscuity.
- Maintain hygiene of genital organs.
- Take vaccination against hepatitis - B.
- Do a self examination of oral cavity and breast (females) once a month, as described.
- Report to the doctor if you have any "warning signs" (described later)
- Proper protection in occupational settings.

Tobacco Control

Comprehensive tobacco control, including implementation of regulatory measurements and encouraging personal commitment, require coordinated involvement of government, professionals and planners. Tobacco control involves health promotion and education, advocacy, support for cessation, community mobilization, taxation and other fiscal measures, livelihood alternatives, regulation, legislation and enforcement. Policy level interventions would include levy of taxes (to raise cost of tobacco products and act as a disincentive for purchase), regulation of tobacco products (for constituents, emissions, health warnings, and misleading health claims) and measures to reduce supply (ban on sale to youth, curbs on smuggling, and programmes to aid tobacco farmers and workers to switch over to alternative livelihoods). There is a tobacco control legislation titled "The Cigarettes and Other Tobacco Products (Prohibition of Advertisement and Regulation of Trade and Commerce, Production, Supply and Distribution) Act 2003". This comprehensive piece of legislation, intended to protect and improve public health, encompasses a wide array of evidence-based strategies to reduce tobacco consumption. This includes provisions for prohibition on direct and indirect advertisements on tobacco products, prohibition on smoking in public places, prohibition on sale of tobacco products to persons less than 18 years age or within 100 yards of an educational institution, and display of statutory health warnings in a conspicuous and legible manner on tobacco products. Each of these provisions is accompanied with corresponding penalties that can be imposed.

Alcohol

Control of alcohol requires actions similar to those for tobacco control. The action should be targeted towards individual and community and include taxation, general public education and motivating highly vulnerable groups like young people to avoid starting consumption.

Sexual and reproductive factors

Sexual and Reproductive Factors are associated with cancer of the uterine cervix and breast, as explained in forgoing paragraphs. Human Papilloma Virus (HPV) has now been identified as the etiological agent responsible for cervical cancer. HPV prevalence increases with high risk sexual behavior and poor sexual hygiene. Education regarding sexual hygiene and safe sexual behavior should be provided for prevention of cancer cervix. Safe sexual behavior protects women from the risk of cancer by preventing infection with HPV. Breast cancer is not much amenable to primary prevention, to any large extent. Early detection is the main strategy for improving survival in breast cancer.

Diet, physical exercise and avoidance of obesity

Proper diet, regular moderate intensity physical exercise and avoidance of obesity are important for prevention of breast, upper aerodigestive tract and intestinal cancers,

as has been described in detail earlier.

**Certain lifestyle measures may help in reducing risk of cancer**

(a) Avoid being underweight or overweight.
(b) Engage in regular, brisk physical activity.
(c) Consumption of alcohol and tobacco should be stopped.
(d) Limit consumption of salted, deep fried foods.
(e) Choose predominantly plant based diets rich in grains, legumes and fruits and vegetables.
(f) Restrict the intake of red-meat (beef, pork, lamb) and preserved meat.

Occupation

Occupational cancers constitute 5 – 10% of all cancers. Limiting exposure to potentially carcinogenic substances through personal protective gear, rotation of workers, mechanized handling of such chemicals may help reduce cancers from occupational exposures.

Environmental pollution

Maintaining proper vehicle emission standards, promoting alternative sources of energy instead of biomass fuel, taking measures to reduce the emissions of CFCs and anti-tobacco measures in home / public places will be of help.

Radiation protection

Personal protective devises and dosimeters by personnel engaged in radiological procedures, avoidance of exposing patients to unnecessary X-rays and adequate safeguards in nuclear facilities should be ensured.

Infection

The important infections in relation to cancer prevention, in Indian context, are HBV and HBC, HPV, and H pylori. Vaccination against HBV, use of universal precautions in health care settings, proper sterilization of syringes, needles and other medical equipment, blood safety, safe sexual practices, avoidance of sexual promiscuity, maintenance of genital hygiene, and treating the patients with symptomatic infections of H pylori are the mainstays in this regards.

Reduction of exposure to ultraviolet radiation

Encouragement of sun-protective behavior is the most effective public health measure to reduce incidence of skin cancer in populations, and especially in children. Available options include sun avoidance by using shade, wearing protective clothing and using sunscreens. Efficacy is expressed through the "sunscreen protection factor" (SPF). Most commercial preparations are presented as having SPF values of up to 15-20.

Chemoprevention

Chemoprevention is defined as reduction of the risk of cancer development through the use of pharmaceuticals or micronutrients. The breast cancer drug tamoxifen reduces the risk of developing a second cancer in the other breast. A lower risk of colon cancer has been observed following regular use of aspirin and related non-steroidal anti-inflammatory drugs which reduce the risk of recurrence of adenomas. Trials to establish chemo-preventive activity by micronutrients, including carotenoids and retinoids, among people at high risk, have been inconclusive. At present, tamoxifen is the only cancer prophylactic drug being used in medical care, under close supervision of a specialist.

### Secondary prevention

Secondary prevention aims at diagnosing the condition at a very early, preferably asymptomatic stage and effectively treating it. In context of cancer prevention, it takes two forms : firstly by educating the community at large regarding "early danger signs" so that they could report to medical facility for further evaluation, should these signs appear. Secondly, secondary prevention uses certain well established screening procedures for early detection.

Early warning signs

Community should be educated regarding the following signs / symptoms and report to the medical facility should they occur These include

(a) Unexplained change in bowel or bladder habit.
(b) A white patch or ulcer in the mouth that does not heal.
(c) Obvious change in a mole or wart, like rapid increase in size, bleeding or ulceration.
(d) Bleeding form body's orifices eg – haematuria, bleeding in stools, bleeding PV etc.
(e) Persistent indigestion / difficulty in swallowing / difficulty in breathing.
(f) Persistent fever unresponsive to treatment.
(g) Unexplained loss of weight.
(h) Chronic cough or hoarseness of voice especially in a smoker.

## Screening for common & important Cancers

### Screening For Breast Cancer

Early diagnosis of breast cancer, by promoting breast awareness among all women and clinical breast examinations for women, preferably in the age group 40-69 years, should be encouraged. Women should be educated and encouraged to inspect and manually examine all quadrants of the breasts with the flat of hand, and the axillae, once a month, ten days after the menstrual period. Every women should also be made aware of the following signs

(a) A change in size
(b) A nipple that is pulled in or changed in position or shape
(c) A rash on or around the nipple.
(d) Discharge from one or both nipples
(e) Puckering or dimpling of skin
(f) Lump or thickening in the breast
(g) Constant pain in the breast or armpit

Breast Examination by a health professional

With the flat of the hand, both the breasts are palpated in a circular manner starting from the nipple and areolae in a clockwise manner towards the periphery and the axillary tail of the breast in sitting and lying down positions. Then the axillary, supraclavicular region and liver are also examined.

Mammography

The epidemic increase in breast cancer incidence has led to the introduction of population-based mammography screening. The analysis of large randomized trials has shown that in women aged 50 to 69 years, mammography screening can reduce mortality from breast cancer by 25-30%. For women in the age group 40-49 years the screening efficacy is significantly less.

### Screeining for Cervical Cancer

In most developed countries, cytological screening (Pap test) has led to significant reduction in the incidence of and mortality from cervical cancer. Screening should preferably begin at 35 years of age, as at younger ages, dysplasia detected through screening rarely progresses to cancer, but adds to programme cost in treatment. Alternative strategies such as visual inspection are being tested for use in low-resource settings where laboratory facilities for cervical cytology are inadequate. Test performance of visual inspection with Acetic Acid (VIA) suggests that it has similar sensitivity to that of cervical cytology in detecting cervical intraepithelial neoplasia, but has lower specificity. Further studies are underway to judge how appropriate and feasible it will be to introduce VIA-based cervical cancer screening programmes on a population-wide basis. There is increasing interest in the use of HPV DNA testing for screening. The test, however, requires financial and sophisticated technical resources. A very important aspect of cervical cancer screening which should be noted by all medical functionaries is to ensure proper response rates, especially from those who are 'disadvantaged", since they are the ones who are expected to have a higher prevalence. Secondly, it is also equally important to ensure final confirmatory tests and aqdequate treatment if required, among those who test positive on screening tests.

### Screening for oral Cancer

Oral cancer and its precancerous lesions, including leukoplakia, can be readily detected by visual inspection of the oral cavity not only by trained health workers and doctors, but to a large extent by the subject himself.

**Self Examination of oral cavity** : This is important for detecting oral lesions at an early stage. All habitual tobacco users should do it once a month. The following procedure should be followed : Rinse the mouth with water and stand before a mirror in adequate light. Look in the mirror for any abnormal white or red patch, ulcer or roughened area, or granular area or swelling in the mouth. If any such area is seen, the suspicious area should be felt with the fingers (normal oral mucosal is soft and pink). Consult a doctor if any abnormal area is found

**Examination by a health professional** : Utilize every opportunity to examine the oral cavities of tobacco users. All parts of the oral cavity should be examined; oral cavity includes lip, anterior 2/3 of tongue, floor of mouth, buccal mucosa, gingival mucosa, hard palate and retromolar area. Population screening for oral cancer results in the diagnosis of large numbers of oral pre-cancers and early stage tumours. However, a reduction in incidence of, and mortality from, oral cancer resulting from such interventions remains to be demonstrated.

### Screening for other Cancers

Prostatic Cancer

Prostate-specific antigen (PSA) testing is now being widely used in developed countries, for the early detection of prostate cancer. Elevated levels of PSA are closely, but not definitely, associated with prostate cancer. False positive results may lead to unnecessary treatment. PSA analysis should be combined with a digital rectal examination, the latter providing an assessment of the volume of the gland, since PSA is also released into the bloodstream of patients with benign prostate hyperplasia and other prostatic diseases.

Colorectal Cancer

Faecal occult blood test (FOBT) is a very cost-effective screening method available, but its specificity and sensitivity are limited. Endoscopy provides the definitive method for detecting colorectal cancer and its precursor lesions, e. g. , polyps. However, its application to population-based screening is limited by cost and availability of qualified specialists.

### Tumour markers

Certain cancers release biological products into the circulation, which can be measured for increasing the level of diagnostic suspicion. The common ones are :

Alpha feto protein (AFP)

This is increased in Liver cancer and certain tumours of testis and ovary. It is also increased in cirrhosis and hepatitis.

Beta human Chorionic Gonadotrophin (B-hCG)

Increased in choriocarcinoma and testicular tumours. Also increased in hypogonadism and hydatiform mole.

Carcino Embroyonic Antigen (CEA)

Increased in colorectal, breast and stomach cancers and Cholangiocarcinoma. Also raised in liver disease and among smokers.

CA-125

Raised in epithelial ovarian cancers. Also raised during pregnancy, menstruation, endometriosis, ascites and pleural effusion.

Prostate Specific Antigen (PSA)

Raised in prostatic cancer as also in prostatitis and BHP.

### Tertiary prevention

Tertiary prevention is also quite important in cancers. It consists of proper treatment of disease, especially advanced disease. The available options are Surgery, Radiotherapy and Chemotherapy. It also involves

Col RajVir Bhalwar

# Injuries and Accidents (Non-Enemy Action)

Non-enemy action injuries constitute the leading cause of sickness in the Armed Forces. These injuries vary to a great extent in degree of severity and may be trivial requiring only outpatient treatment or may be serious necessitating prolonged hospitalization. The latter group may remove the individual from work for a considerable time before his injury reaches finalization. Proper rehabilitation of such a long term injury also poses a great problem. As has been very aptly stated, care in injuries and trauma is quite a prolonged process, which often begins in the field by emergency medical services (EMS) and is finally completed by rehabilitation specialists (318).

### Trends in Armed Forces

The trend in hospital admissions for Injuries Non Enemy Action (NEA) (All forms) has been on the increase over the decade especially in Army and Navy where it ranks first among the causes of morbidity. However in Air Force, injuries NEA rank second, next to respiratory diseases. The trends is depicted in Table-1.

Table-1 : Hospital admissions / 1000 : Injuries NEA

| Year | Army | Navy | Air force |
|---|---|---|---|
| 2000 | 18.95 | 32.40 | 22.50 |
| 2001 | 20.24 | 22.34 | 19.04 |
| 2002 | 21.16 | 20.53 | 15.94 |
| 2003 | 23.17 | 9.50 | 15.54 |
| 2004 | 22.38 | 13.50 | 16.37 |
| 2005 | 23.44 | 19.63 | 16.07 |
| 2006 | 18.41 | 24.16 | 16.29 |

## Epidemiology

Injuries non-enemy action, result from the interaction of various agent, host and environmental factors. The relative importance of these factors varies in different types of accidents. Among the various groups within the broad category of Injuries NEA, the two major categories are Road Traffic Accidents (RTAs) and Training Injuries. The epidemiology of trauma and its related mortality has been discussed in detail by various workers (319, 320). The important epidemiological variables, according to the triad of agent, host and environmental factors are as follows :

### Agent Factors

The important agent factors are as follows :

Goods and Equipment

The troops handle complex arms and equipment and this may expose them to injury e. g. operating or lifting heavy equipment, use of tools such as hammer, chisel and cutting instruments may involve some individuals in injuries.

Vehicles

A poorly maintained vehicle may be the cause of accident e. g.

(a) Improper working of brakes and lights.
(b) Machinery without guards or with inadequate guards.
(c) Poor maintenance of machinery and equipment.
(d) Uneven and poorly maintained playgrounds, tracks, paths and so on.
(e) Faulty design and poor maintenance of buildings.
(f) Faulty electric connections and fittings and poorly maintained electric gadgets.

### Host Factors

The host factors, directly or indirectly, play an important role in the causation of injuries. The important host factors are as follows :

(a) Improperly trained worker is more liable to injuries.
(b) Lack of interest in training /work
(c) Physical disabilities such as vision, poor agility, etc. , predispose to injuries.
(d) Carelessness and willful negligence while working
(e) Faulty work methods
(f) Use of loose fitting and unsafe clothing.
(g) Mishandling of goods, tools and equipments.
(h) Consumption of alcohol while driving or working.
(j) Tiredness due to long working hours

Psychological Factors

Psychological Factors as persons improperly selected for the job, boredom / fatigue of job, lack of basic amenities and welfare measures.

Injury Proneness

Some individuals may be naturally injury prone and inspite of all efforts they will show a higher incidence of injuries than others under the similar circumstances. It has been estimated by epidemiological surveys in certain industries that between 10-25 percent of the workers are accident-prone. This accident proneness is attributed to defective neuro-muscular control in these persons. In case of RTAs, the thrill associated with over-speeding, sudden application of brakes, and general disregard of traffic / safety rules seem to characterize the drivers often involved in vehicular accidents (321).

### Environmental Factors

Terrain

When troops are deployed in difficult terrain like high mountains, jungles and marshy areas, they are more likely

to sustain injuries while engaged in exercises and training.

Climatic Conditions

Adverse climatic conditions like rain, fog and glare increase the risk of sustaining injury.

Roads

Poorly maintained roads, roads with sharp bends and narrow roads greatly increase the risk of mechanical transport accidents.

Working Environment

Unhealthy working environment such as inadequate lighting and thermal discomfort, excessive noise and poor house-keeping increase the risk of injuries at work places.

Overcrowding

Overcrowding of machinery and men at work places enhances the risk of injuries.

## Prevention

Most of non-enemy action injuries are preventable if attention is paid to the important preventive measures. Various steps for injury prevention have been elucidated in detailed texts (322 - 324). Road safety has been a major sphere of action by the WHO (325), as well as for the United Nations Organization (326). WHO had dedicated the theme for the year 2004 to prevention of RTAs and the need has been recognized in our country also (327). The following two strategies are important for prevention of accidents and injuries

### Health Promotion

All ranks must be well informed on the various causes of injuries and their prevention. Physical fitness of personnel must be ensured by a balanced diet, good living conditions and proper medical and health care including periodical health check-ups. In addition high standard of morale by good man-management, by good leadership and by provision of adequate recreational facilities will go a long way in reducing the incidence of injuries.

### Specific Protection

It is ensured by various measures as enumerated in Box - 1

### Early First Aid and Definitive Management

it is extremely important to impart first aid and resuscitation, and life / limb saving surgery at the earliest. The "Golden Hour" concept is a rejoinder in this regards. Meticulous training of all ranks in first aid, equipping all personnel / body of troops with first aid kits, rigorous training of paramedical personnel in immediate first aid and critical care, and provision of prompt evacuation facilities to the hospital will go a long way in reducing the morbidity and mortality.

## Burns

Burns may be defined as injury to the tissues of the body arising from exposure to heat, electric conduction or radiation. These are amongst the commonest emergencies both during peace and war.

**Box - 1 : Measures for specific protection against accidents**

- Training of all ranks in the handling of stores and equipment in general.
- Training in specialized trades like MT driving, arms and ammunition, special vehicles/machines and industrial processes.
- Providing healthy work environment.
- Proper maintenance of vehicles, arms and equipment, electrical fittings, etc.
- Antifire precautions.
- Eliminating all types of stresses both at work and at home as far as possible.
- Guarding of dangerous machines.
- Enforcement of personal protective measures in workshops and other work places wherever indicated.
- Supervision of workers.
- Investigation of all injuries with a view to take necessary preventive measures.
- Good house-keeping.
- Proper maintenance and lighting of buildings.
- Securing electrical fittings and eliminating live wires.
- Ensuring adequate precaution, by education regarding handling of stoves, gases, pressure cookers and electrical appliances.

### Epidemiology

In the study of burn injuries the burnt patient is the host, the source of injury is the agent and home and working place constitute the environment. It is the interaction between these factors which results in a burn injury. It is also well documented that a large majority of burns are caused by either carelessness or ignorance and are completely preventable. In addition, a number of cases of accidental burns are related to smoking or else due to carelessness under influence of alcohol (328, 329). Age has an important relationship with burn injuries and their causation. The studies carried out in India have shown that adults and adolescents constitute the majority of cases of burns. As regards Sex, studies carried out by most of the workers have shown that the incidence of burn injuries is higher among females as compared with males. Burns are associated with diseases like epileptic fits, cardiovascular accidents, giddiness, parkinsonism, paralysis and debility. Loose fitting clothing have been found to be responsible for the causation of burns in a large number of cases.

Environment plays an important role in burn injuries by bringing about the contact between agent and the host. It may be domestic or work place environment. The domestic environment consists of the type of home, number of rooms and overcrowding. The work place environment consists of the nature of fire-guards and the

degree of safety precautions. Males suffer more burns injuries at workplace & female suffer more from domestic burns. The domestic burn injuries are more common as compared to those in workplace. Some of the important environmental factors are overcrowding, poor housing, open fire cooking, practice of cooking at the guard level, and, faulty electric connection and fittings.

**Assessment of Severity**

By Extent

An approximate clinical rule in wide use is the 'rule of nines' which acts as a rough guide of percentage of body surface area involved due to burns. As a general rule, an adult with more than 20% and a child with more than 10% body surface involved will require intravenous fluid replacements. A rough guide is that if the age and percentage of burns add together to a score of 100, then the burn is likely to be fatal. The assessment criterion is as follows :

(a) Head, face & neck = 9%
(b) Chest (front & back) = 2 x 9%
(c) Upper limbs = 2 x 9%
(d) Abdomen and back = 2 x 9%
(e) Thighs (front & back) = 2 x 9%
(f) Legs (front & back) = 2 x 9%
(g) Genital area = 1%

By Depth

Deeper the burn, poorer is the prognosis. According to the depth, burns are classified as follows :

(a) **Superficial** : Epidermis only is involved.
(b) **Partial Thickness** : Epidermis and part of dermis are involved
(c) **Deep or Full Thickness** : Epidermis and dermis are involved. It may also involve subcutaneous tissues or even muscles.

By Site

The sites which bear poor prognosis are face, neck, perineum and chest

**First Aid**

Stop the burning process by extinguishing the flames by wrapping the patient in a blanket or any other readily available garment such as the bystanders own clothing. With electric burns, it is important to switch off any live current and with chemical burns, the contact with the chemical should be avoided.

Cool the burnt surface. Immediate cooling of the part is beneficial and should continue for 20 mins. Irrigation with cold water under a tap is best, especially in scalds and chemical injuries. Hypothermia must be avoided. Do not use ice or iced water. The burn should then be wrapped in clean linen and patient transported immediately to hospital.

**Emergency Treatment**

The priorities in the management of a major burn injury is :

A - Airway maintenance
B - Breathing and ventilation
C - Circulation
D - Disability -neurological status
E - Exposure and environment control
F - Fluid resuscitation

It is important to secure large bore intravenous line at an early stage. Having estimated the percentage burnt surface area and measured the body weight, initial fluid resuscitation can be planned. The simplest formula for adults is: 3-4 ml/kg body weight /% burn in first 24 hours. Half of this volume is given in first 8 hours and the rest in next 16 hours. Hartman solution is preferred but other isotonic fluids may be used. A urinary catheter is essential. Urine output is the best guide to adequate tissue perfusion. In an adult one should aim for 30-50 ml of urinary output /hour.

Medical Officers are also advised to refer to further detailed guidelines on burns as available in standard texts (330).

**Prevention**

Burns, like any other injuries are largely preventable. Certain actions are likely to go a long way in this direction.

Box - 2 : Guidelines - Prevention of burns

- Never leave a kindling “bukhari” unattended in a room
- Always put off the bukhari before going to sleep
- Avoid smoking; NEVER smoke while lying down in bed.
- Never throw about the cigarette butts. Extinguish them properly in an ash-tray and dispose in a dust-bin.
- Avoid pressure stoves; prefer wick type stoves.
- After cooking, always close the main supply valve on the cylinder of LPG cylinders, and not simply the regulator on the stove alone.
- Do not put on loose clothes when working near flames. Loose ends of sarees / chunaris should be properly secured in proximity to the body.
- Remember that alcohol consumtion and proximity to an open flame (even as minor as a lighted match stick) make dangerous combination. AVOID this combination.
- Never store petrol, kerosene, and insecticides in any area where flame is likely to be put on.
- Keep safe distance from crackers during festivals; discourage young children from handling crackers.
- Never light up a stove for cooking / warming of food, while traveling in a train or bus or truck, whether military or civil vehicle.
- NEVER use any match box, lighter, cigarettes or any

# Oral and Dental Health

## Introduction

During the past few decades, oral health authorities in the fields of epidemiology, education, services, health education and disease prevention have given special attention to the highly prevalent oral health problems like dental caries and periodontal diseases. With these approaches, dramatic improvement in scientific knowledge and technology has taken place in the field of oral health.

## Structure of the Tooth

The teeth are hard-calcified structures set firmly in bone sockets in the maxilla and mandible by means of a root or roots. The part visible in the oral cavity is the crown, which is separated from the roots by a narrow portion called the neck or cervical portion of the tooth. The crown is covered with hard shiny enamel. The tissue covering the root is the cementum. The ivory-like structure that forms the bulk of the tooth is the dentine. Enamel lacks the capacity for self-repair since it contains no cells. It resists wear only through its extreme degree of hardness. Dentine is capable of repair, but it is less hard and resistant than enamel. Investing between the roots of teeth and socket wall formed by alveolar bone is the thin periodontal ligament, the fibre-bundles of which help to suspend and anchor the teeth in place. Its cushioning effect also helps in protecting periapical tissues from likely compression during mastication. The dental pulp occupies hollow pulp chambers and pulp canals in the crown and roots of teeth. It contains a plexus formed by connective tissue fibres, nerve endings, blood vessels, tissue cells and lymphatics which communicate with their major source of supply through apical foramina in the roots ends.

The gingival, periodontal ligament, alveolar bone and cementum which support the teeth. are collectively termed as periodontium.

## Dentition

The first detention brings forth the deciduous or "Milk teeth". There are twenty teeth in this set; ten in each jaw. The tooth buds begin to form about the sixth week of prenatal life and calcification starts about the sixteenth week of prenatal life. The position of the first permanent molar determine to a great extent, the position of the other teeth. Therefore, early examination and care will help to ensure their retention throughout life. Decidous teeth are shed about the 7th year onwards, when the permanent teeth follow. There are 32 teeth in the permanent set; 16 in each jaw. Calcification of permanent teeth begins in the jaws about the time of birth. The last four teeth to erupt are the third permanent molars, or "wisdom teeth". They do not erupt until about the age of 18 years or later and may even never erupt. Sometimes they become "impacted" below the gum surface necessitating extraction to preserve the heath of the adjacent teeth . Dentition schedule is shown in Table - 1.

## Tooth Numbering

Table - 1 : Dentition schedule

| | Maxillary | | | Mandibular | | |
|---|---|---|---|---|---|---|
| | **Formation Begins** | **Eruption** | **Shedding** | **Formation Begins** | **Eruption** | **Shedding** |
| **Deciduous Teeth** | **Intra uterine** | **Postnatal** | | | | |
| Central incisors | 4 months | 7½ months | 7 years | 4½ months | 6 months | 7 years |
| Lateral incisors | 4½ months | 9 months | 8 years | 4½ months | 7 months | 7-8 years |
| Canines | 5 months | 18 months | 11-12 years | 5 months | 16 months | 10 - 12 years |
| First molar | 5 months | 14 months | 9-10 years | 5 months | 12 months | 8-9 years |
| Second molar | 6 months | 24 months | 11-12 years | 6 months | 20 months | 10 - 11 years |
| **Permanent teeth** | **Postnatal** | | No definite Schedule | | | No definite Schedule |
| Central incisors | 3-4 months | 7-8 years | | 3-4 months | 6-7 years | |
| Lateral incisors | 10-12 months | 8-9 years | | 3-4 Months | 7-8 years | |
| Canine | 4-5 months | 11-12 years | | 4-5 months | 9-10 years | |
| First pre molar | 1½ years | 10-11 years | | 1½ - 2 years | 10-12 year | |
| Second pre molar | 2-3 years | 10-12 years | | 2-2½ years | 11-12 years | |
| First molar | At birth | 6-7 years | | At birth | 6-7 years | |
| Second molar | 2½ -3 years | 12-13 years | | 2½ -3 years | 11-13 years | |
| Third molar | 7-9 years | 17-21 years | | 8-10 years | 17-21 years | |

The system in current use in the services is as per Federation Dentaire International system. Modified Palmer System. In this two-digit system, the first digit indicates the quadrant and the second digit a particular tooth in that quadrant. Quadrants are allotted the digit 1 to 4 for the permanent and 5 to 8 for the deciduous teeth in a clockwise sequence, starting at the upper right side; permanent teeth within the same quadrant are allotted the digits 1 to 8 whereas deciduous teeth (1 to 5) from the mid-line backwards. The digits should be pronounced separately: thus the permanent canines are teeth one-three, two three, three-three and four three. Numbering system is as follows :

Permanent teeth

| **(Upper right)** | **(Upper left)** |
|---|---|
| 18-17-16-15-14-13-12-11 | 21-22-23-24-25-26-27-28 |
| 48-47-46-45-44-43-42-41 | 31-32-33-34-35-36-37-38 |
| **(Lower right)** | **(Lower left)** |

Deciduous teeth

| **(Upper right)** | **(Upper left)** |
|---|---|
| 55-54-53-52-51 | 61-62-63-64-65 |
| 85-84-83-82-81 | 71-72-73-74-75 |
| **(Lower right)** | **(Lower left)** |

### Functions of Teeth

Besides mastication, the teeth help in phonetics and also contribute towards aesthetics. The process of mastication involves incision and grinding of food. The incisors serve to incise the food and the premolars and molars do the grinding. The food is broken into smaller portions and is thoroughly mixed with saliva before it is swallowed. For efficient performance of their function the teeth must be correctly aligned in arches and meet in normal occlusion. Occlusion means a contact relationship of the teeth when the jaws are closed. Normally mastication is done at one side only at a time. Chewing ability depends upon the soundness of teeth, firmness of their embedment, hardness of enamel, uniformity of occlusion and strength of the jaws. Chewing the fibrous foods such as meat, radish, celery, carrots, apples and so on develops the jaws and at the same time keeps the gums in proper tone by stimulating blood circulation through them. Children should be taught to chew their food thoroughly, but not to crack nuts or very hard items, less it may damage the enamel, so that the teeth and the supporting structures develop properly as a well functioning organ. Teeth that are properly aligned and occlude normally, help in proper pronunciation of words. Facial appearance, beauty, and symmetry depend upon well-developed jaws and a full compliment of teeth developed in proper alignment. If the teeth are mal-aligned or have spaces between them or a few teeth are missing, the speech becomes faulty and lacks clarity. The unpleasing expression due to irregular or missing teeth may cause self -consciousness, which leads to inferiority complex that may ultimately, result in social maladjustment. Teeth and their supporting structures thus considerably influence and affect the personality.

It has always been commonly believed that with the advancing age the loss of teeth should be considered a natural and inevitable occurrence. However, it is now recognised to be a direct result of pathological process. It was earlier inferred, although rather incorrectly, that below the age of 35 years, the tooth loss was the result of dental caries, where as beyond the age of 35 years it results from 'pyorrhoea'. However, from the epidemiological studies world over, it has been established that diseases of four different supporting structures of the teeth (termed collectively as' periodontum') can have their origin even amongst the school going children. Such global surveys therefore indicate, that although drastic and damaging results might be discernable in a majority of population, beyond the age of 35 or more, the damaging influences on the periodontal tissues can be traced to have commenced even as early as 12-15 years of age. The universal axiom that " prevention is better than cure " still holds true, and to be more effective, this too must therefore commence during the school- going age.

### Dental Plaque

Dental plaque is thin, tenacious, firmly adherent and well organized biofilm adhering to the tooth surface, restorations and dentures. It is different from other deposits on the tooth surface such as materia alba and calculus. Materia alba refers to soft accumulations of bacteria and tissue cells that lack organized structure of dental plaque and are easily displaced with water spray. Calculus is a hard deposit that forms by mineralization of dental plaque and is always covered by a layer of unmineralized plaque. Dental plaque is composed primarily of more than 325 different bacterial species and one gram of plaque contains approximately $2 \times 10^{11}$ bacteria. The dental plaque may be cariogenic, causing dental caries or calculogenic, causing periodontal diseases.

### Dental Caries

It is an irreversible progressive disease of the calcified dental tissue characterised by loss of tooth structure resulting from the dissolution of the tooth mineral and the destruction of its organic matrix. Streptococcus mutans, lactobacilli and other strains from calculogenic plaque act upon refined carbohydrates like sucrose, lactose etc. and produce organic acids which cause demineralization of tooth enamel / cementum. The parts of teeth most vulnerable to carious attack are the pits, fissures and proximal surfaces of teeth. Regardless of where caries starts, if unchecked, it proceeds and spreads from the enamel into the dentine and then reaches the dental pulp. Once the pulp is infected, acute pulpitis may occur which is in an acute inflammatory response in the pulpal tissue and most often becomes chronic leading to inflammatory response in periapical tissues.

Diagnosis

Although bacteria on the teeth are the direct cause of dental caries, a large number of microbiological, environmental and host factors interact to determine whether or not an individual will be affected and if affected, how and to what extent. Dental caries is therefore a multifactorial disease.

In the past, diagnosis of dental caries involved the use of a mouth mirror, an explorer and perhaps bite wing radiographs. "Tug back" or a feeling of resistance when the explorer was moved on the tooth surface led to an almost confirmed diagnosis of caries. Treatment of dental caries as per Black's "Extension for prevention" necessitated considerable loss of tooth substance beyond the actual carious lesion. The modern approach to diagnosis and treatment based on a series of important advances differs from Black's rules in almost all respects. The diagnostic process does not focus only on the presence of lesions but is expanded to include identification of factors that lead to the formation of lesions. This approach therefore makes a distinction between the caries lesion and the caries disease and comprises several important stages :

(a) Clinical and radiological examination to detect early lesions.

(b) Evaluation of factors causing formation of cavities.

(c) Diagnosis of caries disease

(d) Control of identified etiological factors

(e) Treatment of caries lesions

(f) Formation of maintenance programme.

Future diagnosis of caries may be improved by the use of subtraction radiography or lasers. Practical tests like levels of streptococci mutans and lactobacilli, secretion rate and buffering capacity of saliva are among the factors that can now be evaluated reliably.

### Prevention

The multifactorial nature of caries allows scope for a number of different approaches for prevention of this disease. It should also be recognized that certain etiological factors have vastly different consequences, depending on the total mix of factors. For example, the consequence of a diet rich in sucrose is quite different for a person who is frequently exposed to fluorides than for one who has very little exposure.

(a) **Diet** : The contribution of sucrose to implantation, colonization and metabolic activities of cariogenic bacteria has been clearly established and has led to search of sucrose substitutes. Non-sucrose sugars like high fructose corn syrup, invert sugar, glucose, fructose are found to be less cariogenic than sucrose. Caloric sweetener like palatinose, non-caloric sweeteners like aspartame, cyclamate and saccharin and sugar alcohols like sorbitol, xylitol and maltitol can be substituted for sucrose in food products, medicines and toothpaste.

(b) **Fluoride** : Recent reports from Australia and United States have confirmed the safety and efficacy of fluoride in preventing dental caries. The United States has set a limit of 4 mg / litre as the maximum allowable level in drinking water and recommends a level of 0. 7 to 1. 2 mg / litre. During decreases in the pH of the dental plaque free fluoride is available and helps in remineralization process. Moreover fluoride used on a regular basis becomes concentrated in dental plaque and appears to interfere with enzymes used by the bacteria in metabolizing sugars. Fluoridated toothpaste, rinses, gels and tablets are important delivery system. Water, salt and milk are highly cost effective vehicles and should be implemented wherever technically feasible.

(c) **Sealant** : The use of dental sealant is an effective way to prevent pit and fissure caries. One of the barriers to increased use, however is the fact that successful placement and retention of sealant are highly dependent on technique and the availability of appropriate equipment.

(d) **Antimicrobials** : Infants acquire the bacteria that colonize the oral cavity and digestive tract usually through normal handling by their mothers or other care givers. Investigators have found that it is possible to interfere with the process of transmission of mutans streptococci by treating mothers and other close family members with antimicrobials like chlorhexidine gluconate 0. 2 or 0. 12%.

### Immunization

An improved understanding of genetics of oral bacteria is also leading to new approaches to development of safe and effective oral vaccines. The possibility of creating a polyvalent vaccine effective against caries, as well as measles, poliomyelitis and other serious infections is under consideration. With successful programme to reduce the effects of etiological agents & increase host resistance, a new approach to treatment of the caries lesion can therefore be outlined as follows :

(a) Incipient Lesion

  (i) Remineralization using topical fluoride therapy.

  (ii) Counselling on dietary and other risk factors.

(b) Initial Cavitation

  (i) Application of a sealant.

  (ii) Restoration with preventive materials after minimal excavation and preparation with hand or rotating instruments if necessary.

(c) Moderately Sized Lesion

  (i) Restoration conserving maximum amount of tooth substance.

(d) Deep Lesion

  (i) Restoration, conserving maximum amount of tooth substance.

  (ii) Endodontic therapy, if necessary.

This new approach can also be applied to retreatment using same steps and repairing physical defects only if

symptoms are evident in the teeth or supporting tissues.

### Periodontal Diseases

The inflammatory diseases, viz. , gingivitis and periodontitis are quite common.

Gingivitis

While caries has been linked strongly with only a few organisms, the development of gingivitis appears to be caused by nonspecific bacterial plaque flora, which changes over time from predominantly gram positive to more gram negative. In gingivitis the gums become spongy, red, swollen, bleed when brushed or touched, stand away from teeth, often causing little pain and discomfort. Gingivitis therefore is often neglected until it has reached an advanced stage. Gingivitis does not necessarily develop into periodontitis. However, periodontitis is always preceded by gingivitis. The disease can spread to involve deeper supporting tissues viz. periodontal ligament, cementum and alveolar bone. Due to apical migration of junctional epithelium there is formation of a gap between teeth and gums known as the periodontal pocket. Such pockets harbour dental plaque and calculus which, if untreated, ultimately leads to alveolar bone resorption, mobility of teeth and exfoliation.

### Diagnosis

Traditional approaches to periodontal diagnosis include assessment of gingival health and measure of pocket depth, alveolar bone height and loss of periodontal attachment. In addition, the presence or absence of dental plaque and supra and sub gingival calculus is recorded. Assessment of gingival health continues to rely on visual evaluation of the tissues and the extent to which gingival gentle probing can provoke bleeding. The height of alveolar bone is assessed from radiographs. A complete assessment of the periodontal situation should include quantification of the loss of attachment around the teeth (pocket depth and gingival recession as measured from the cemento – enamel junction or some fixed points). It is important to note that pocket depth, bone height and periodontal attachment, represents only the cumulative results of past pathological events and do not reflect the rate of progression of lesions unless measurements of radiographic assessments are made at short time intervals. Many diagnostic tests aimed at detecting early events in the disease process such as bacterial cultures, DNA probes, immunofluorescent assays, specific antibody determinations and the measurements of hydrolytic enzymes, break down products and cytokines are currently being studied. Markers of host defence mechanisms, such as chemotactic responses and phagocytic capability of polymorphonuclear leucocytes have also been investigated.

There is no single organism that is pathognomonic of a change from gingivitis to adult periodontitis. Several species like Porphyromonas gingivalis, Prevotella intermedia, Eikenella corrodens, Wolinella recta, Treponema denticola and Capnocytophaga are present in various combinations in patients with adult periodontitis. The association between a gram-negative anaerobic microflora and periodontitis has been extensively demonstrated and elimination / control of this flora will reduce risk of periodontitis.

### Treatment

Epidemiological studies from many countries show that severe periodontal destruction is less prevalent than it was thought to be 10 to 15 years ago. Improvements in oral hygiene are believed to be the primary factor in this change. Due to increased life expectancy, periodontal care will also be needed by many elderly people who are medically compromised, have physical and mental handicaps, or take medications with potentially harmful side effects.

At present, the prevention of periodontitis is based on mechanical removal of plaque, plus antimicrobial and antiseptic mouthwashes, if necessary. Where Oral hygiene levels are generally high, fewer than 10% of adult population develop advanced periodontal destruction. However, treatment of gingival inflammation (gingivitis) and maintenance of gingival health depend on adequate plaque control through self-care. Instruction in good oral hygiene and constant practice early in life may lead to good habits, which will help to prevent the formation of calculus. Regular examinations and frequent removal of calculus are also beneficial. Regular brushing of teeth, using proper brush and correct technique needs no emphasis. Rubbing and cleaning with finger and rinsing the mouth vigorously with water, after eating, also helps.

Moderate or advanced periodontitis can be treated by elimination of bacterial infection and establishment of effective plaque control. It has been conclusively demonstrated that the large majority of periodontal problems can be treated using non-surgical, conservative approaches. With a better understanding of the biology of connective tissue and of the regenerative potential of periodontal tissues, guided tissue regenerative procedures have been shown to enhance formation of new alveolar bone. This approach has great potential value for individual teeth but can not be applied as a general public health measure.

A rare condition, Juvenile periodontitis, seems to be familial and is characterized clinically by inflammation and rapid progression of periodontal lesion. Presence of Actinobacillus actinomycetecomitans may be an early marker of this disease.

Necrotizing ulcerative gingivitis and its most severe form, noma, appear to be associated with malnutrition in children in some parts of the world. Necrotizing ulcerative gingivitis and stomatitis are also sometimes associated with HIV infection.

Lesions of oral mucosa related to secondary immunodeficiency are similar to the oral manifestations of HIV infection. These lesions are often encountered following organ transplantation, radiation or chemotherapy – all procedures that are being used increasingly.

### Malocclusion

People today usually recognize irregular teeth or obvious jaw deformities and seek treatment from orthodontist. Orthodontic treatment is aimed primarily at malocclusion that lies within the normal range of variation, though even severe deformities can be managed with combined orthodontic and surgical treatment. Most cases of malocclusion are not pathological in origin and so the potential for prevention or biomedical treatment is very limited. The main emphasis in this field is assessment of the effect of various forms of treatment and on improvements in appliance design. Examples of advances in these areas include :

(a) Improved design of brackets, arch wires and headgear.

(b) Improved aesthetics through bonding agents and ceramic brackets.

(c) Standardized indices and reliable measures of malocclusion treatment needs and outcomes.

(d) Increased understanding of the mechanics and long term effects of treatment.

(e) Computerized programmes to aid in diagnosis customised appliance fabrication and analysis of treatment.

**Missing Teeth**

Over the years, tooth loss has decreased significantly due to improvements in scientific knowledge and technology. Increased life expectancy and life long sequelae of dental caries and restorative treatment still means that edentulousness and replacement of teeth will remain issues of concern. Most people want to retain their teeth and when this is not possible, they seek tooth replacement. The concept of loss of all teeth at older age is no longer valid. The aim of at least 20 functioning teeth, not requiring prosthesis mentioned by the WHO is not an absolute goal but rather a step towards the retention of all natural teeth by future generations. Prostheses that endanger the remaining dentition and / or supporting tissues are to be discouraged. The development of bonded replacement is a major achievement in this field.

**Dental Implants**

In the recent past, dental implants have been successfully used for replacing missing teeth without unnecessarily damaging adjacent tissues or compromising function. The principle of osseo-integration of dental implants using high biocompatible materials and appropriate prosthetic concepts has provided the oral health profession with opportunities that transcend the original concept of tissue restitution. During the past decade, implementation of this principle in the treatment of total and partial edentulousness has contributed to a rapid increase in replacing removable dental prosthesis with fixed restorations.

**Oro facial lesions**

Through continuous research over the years it is well established that a number of systemic diseases have oral manifestations. Oro-facial lesions include primarily viral, bacterial and fungal infections, ulceration, pre cancerous lesions, oral cancers and oral manifestations of systemic diseases. Prevention is still impossible in many cases and treatment remains largely symptomatic rather than curative. However, comprehensive evaluation of the patient, including assessment of life style and risk profile is essential in all treatment of oro-facial lesions. This evaluation includes a search for systemic disease as a possible causative factor and assessment of any other predisposing factors.

(a) Oral submucous fibrosis (OSF)

Oral submucous fibrosis was initially described in 1966 by Pindborg and Sirsat as an insidious, precancerous, chronic disease that may affect the entire oral cavity and that sometimes extends to the pharynx. Although it is occasionally preceded by the formation of vesicles, OSF is always associated with a subepithelial inflammatory reaction followed by fibroelastic changes of the lamina propria, accompanied by epithelial atrophy. Various factors have been implicated in the development of OSF, the most common of which is chewing areca nut. Associations with tobacco use and vitamin deficiency have also been reported. Symptoms of OSF include the following: Trismus due to oral fibrosis and scarring, pain and a burning sensation upon consumption of spicy food, increased salivation, change of gustatory sensation, hearing loss due to stenosis of the eustachian tubes, dryness of the mouth, nasal tonality to the voice, dysphagia to solids, impaired mouth movements (eg, eating, whistling, blowing, sucking). Classification system for the management of OSF.

(i) Group I : earliest stage, interincisal distance of greater than 35 mm.

(ii) Group II: interincisal distance of 26-35 mm.

(iii) Group III: Moderately advanced cases, interincisal distance of 15-26 mm Fibrotic bands are visible at the soft palate, and pterygomandibular raphe and anterior pillars of fauces are present.

(iv) Group IVA: Trismus is severe, with an interincisal distance of less than 15 mm and extensive fibrosis of all the oral mucosa.

(v) Group IVB: Disease is most advanced, with premalignant changes throughout the mucosa

**The medical management** : Cessation of the habit followed by use of Steroids, Placental extracts, Hyaluronidase. Surgical management in severe cases: excision of the fibrous bands, buccal pad of fat grafting or Split-thickness skin grafting following bilateral coronoidectomy.

(b) Aphthous stomatitis

This most common oral condition has been usually associated with stress, nutritional deficiencies and malabsorption syndrome. Various symptomatic treatment options have been proposed but improvements seen are considered to be due to placebo effect.

(c) Lichen Planus

It is a common oral mucosal disease of unknown etiology, which often occurs without simultaneous skin lesions. In the ulcerated form, the disease often presents significant therapeutic problems. Occasionally, patients may present

with lesions called lichenoid reactions, which are sometimes related to drugs and / or graft versus host reactions.

### Impacted tooth

The definition of an impacted tooth is "tooth that can not, or will not, erupt into its normal functioning position, and is, therefore, pathologic and requires treatment.

Mandibular and maxillary third molars, followed by maxillary canine are the teeth most commonly impacted. Failure of teeth to erupt into their normal position in the arch may result in problems that include pericoronitis, pericoronal abscess, periodontal disease, caries, and root resorption of adjacent teeth, dentigerous cysts or odontogenic tumors.

Clinical features include: redness, swelling and tenderness of the gingiva around the impacted tooth, unpleasant taste when biting down on or near the area, halitosis, pain radiating to ear, trismus, and palpable lymph nodes of submandibular region.

Treatment of impacted third molars involves surgical extraction of the teeth.

### Craniofacial injuries

One of the commonest consequence of RTA is a head injury with Craniofacial fractures. Basic principles of management of these fractures are similar to those of fractures in other regions, however it must be kept in mind the presence of vital structures in the region. The armamentarium required for treating such fractures is quite different from the regular orthopedic appliances. Soft tissue injuries also require careful attention. The repair of soft tissue injuries must be done delicately and diligently in layers so as to prevent and minimize scar formation over the face. The common maxillofacial fractures are described below.

### Mandibular fractures

Mandible is a strong tubular long bone bent into a blunt V-shape. There are areas of weaknesses along which the mandible frequently fractures following trauma. It is a unique bone because of ginglimoid, diarthroidal, fibrocartilagenous joint between the mandibular condyles and glenoid fossa. Mandible plays an important role in mastication, speech and esthetics of the face. The commonest area of mandible to fracture is the angle, but in case of multiple fractures the condyles are the commonest. The fractures of the mandible are displaced along the pull of the muscles attached around the fractured site. Bilateral parasymphysis fractures may cause the tongue to fall back and compromise the airway. The diagnosis of mandibular fractures can be confirmed from presence of swelling, tenderness and step along the borders of the mandible, deranged occlusion, mobility between the teeth segments, irregular arch form, sensory disturbance along the distribution of mental nerves. The radiographic investigations include PA mandible open mouth 10 deg, Lateral oblique view mandible, reverse townes view. Specialized Radiologic investigations include orthopantamagraph which gives a clear picture of whole of mandible. Intraoral periapical (IOPA) radiographs are used for visualizing the teeth and surrounding alveolar bone.

The goals of management of mandibular fractures is to restore form and function. The most important factor to be considered is to return the patient to his natural dental occlusion, failing which patient may not be able to chew food properly and will have discomfort. Treatment consist of either open or closed reduction. Following open reduction internal fixation is done using miniplates and screws. As far as possible intra oral approaches are used to prevent a scar on the face. Closed reduction of fractures in the dentate segment is achieved by stainless steel arch bars which are firmly tied to the upper and lower teeth using steel wires. Fractures are mobilized and intermaxillary fixation is carried out to achieve patients natural occlusion. Miniplates and screws are commonly used for fixation, although wires are also used but with inferior results.

### Midface fractures

The midface consist of the maxillae, nasal bones, zygomatic complex and the bones forming the orbit. The commonest bone to fracture are the nasal bones and followed by zygomatic complex. The midface consist of strong vertical and horizontal buttresses between which are thin fragile bones. These buttresses help to transmit masticatory stresses to the skull base. A fracture of any of the buttresses requires to be anatomically reduced and fixed to prevent imbalance in the transmission of forces and consequent discomfort and pain to the patient. The central midface fractures are also known as Le Fort fractures. Le Fort I fractures are low horizontal fractures just above the level of the nasal floor. Le Fort II level fractures are pyramidal beginning over the nasal bone extending into the orbit upto ethmoids and then leaving the orbital floor inferiorly and laterally to fracture middle of the ptyregoid plates III. Le Fort III level fractures are also called craniofacial dysjunction. Here the fracture begins at the fronto-nasal suture region and the entire facial skeleton is displaced along the cranial base postero-inferiorly, giving the patient a dish face appearance and almost always associated with severe head injury and CSF leak. Some times airway also gets compromised in midface fractures. Management of all the midface fractures is by open reduction and internal fixation where ever possible using intraoral or coronal and brow incisions

### Zygomatic complex fractures

Zygomatic bones form the malar prominence or the cheek bone which are important for facial esthetics and also play an important role in protection of the orbital contents as they prevent a direct injury to orbit unless the injury is by a very small object. It is one of the commonest fractures of the craniofacial skeleton. The zygomatic arches which are present on the sides are especially fragile and fracture readily on impact. The zygomatic bone is a roughly quadrangular strong bone and any impact fractures along its articulations with frontal, maxillary, sphenoidal and temporal bones. Clinically the fracture can be appreciated by presence of depression on the malar eminence,

dimpling on the lateral aspect of face, restricted mouth opening can occur if the zygomatic arches fracture inwards and impinges on the coronoid process of mandible. Step and tenderness can be appreciated at the frontozygomatioc suture region, infraorbital rim, junction of body and arch and intraorally over the zygomatic buttresses in the region of maxillary first molar. The goals of management include restoration of facial form and function. Isolated zygomatic arch fractures can be managed by closed reduction by passing instrument like periosteal elevators or more specialized Rowe's elevator, Bristow's elevator along lateral brow, temporal or an intraoral vestibular approach and elevating the arch. However if fractures are older than 15 days an open reduction and internal fixation using a hemicoronal incision is required. Fracture of zygomatic complex requires open reduction and internal fixation. Normally a three or two point fixation is required to stabilize the fractured segments. The fixation is carried out on the frontozygomatic region by a lateral brow approach, Zygomatic buttress using a vestibular approach and along the infra orbital rim via transconjuctival, subciliary approach (in case of three point fixation) using micro or miniscrews and plates. Usually a two point fixation along frontozygomatic region and over the buttresses suffices.

### Oral Cancer

Worldwide, oral squamous cell carcinoma is one of the most common cancers. Epidemiological and cancer surveillance studies have shown that its prevalence varies from country to country but about 30% of all cancerous lesions of oral cavity occur in our country. Genetic factors, malnutrition, smoking and alcohol abuse are main predisposing factors while some of the oral white and red lesions show variable transformation rates to cancer. At present histopathological investigation of the lesions remains the method of choice for diagnosis but blood antigens, cell surface carbohydrate fractions, DNA cytology, oncogene expression and flow cytometry have an important part to play in early detection.

Treatment of oral carcinoma remains largely surgical, chemo and radio therapeutic. The 5-year survival rate has improved in recent times. Patient's quality of life has undoubtedly been enhanced by improved diagnostic and surgical techniques and rehabilitation but only the very earliest detection of disease can improve survival, as patient's behavior is unlikely to change radically in the short term

### Oral Manifestations of HIV Infections and AIDS

In most of the countries, HIV epidemic is spreading with alarming speed. WHO prediction for the year 2001 was 10 million AIDS cases and 40 million HIV seropositive individuals. In many cases, oral lesions are the first signs of HIV infection and members of the oral health profession should therefore be well trained in recognizing these lesions. The following oral conditions have been reported to occur in HIV infected patients.

(a) Candidiasis
(b) Erythematous, hyperplastic, pseudomembranous hairy leukoplakia
(c) HIV – gingivitis
(d) HIV – Necrotizing gingivitis
(e) HIV – Periodontitis
(f) Kaposi's sarcoma
(g) Non Hodgkin's Lymphomas

In patients with AIDS, treatment of oral Candidiasis should follow general recommended guidelines; use of a triazol drug or Fluconazole may be required. Necrotizing gingivitis and Stomatitis are also frequently encountered. Good oral hygiene is essential, supplemented with antibiotic treatment if necessary. The drug of choice is often Metronidazole. For Kaposi's sarcoma various treatments are used including radiotherapy, surgery and intralesional cytotoxic drugs such as Vinblastine, Vincristine and Bleomycin. Like Candidiasis, hairy leukoplakia is a strong predictor of AIDS.

# Aviation Health

## Introduction

The general principles of maintenance of health and prevention of diseases are the same in the Air Force as in Navy and in Army. However, in recent years, the tremendous increases in the speed, altitude and range of flight of modern aircraft have widened the range of variations in the external environment to which aircrew are exposed. Due to this the aircrew has now become almost completely dependent on specialized equipment for survival in the isolated and extraordinary cabin environment. The design and development of such equipment, instructions for its use by aircrew and its maintenance by ground crew, are of immense aeromedical importance. The IAF medical officer's particular concern with regard to the health of the flyers is to provide him with protection against stresses and strains caused by flying operations. Besides, his periodical physical examination, his care during sickness and injury and application of the conventional preventive medical procedures, the health care of flying personnel requires proper understanding of the physiological problems of flights. Ailments and conditions, which would be considered trivial or minor in other occupations, may be potentially hazardous in the case of a flyer. The safe piloting of an aircraft, under all conditions of weather, specially during landing and take off, during the performance of aerobatics at high speeds and during aerial combats demands a high degree of physical and mental fitness and alertness in all flying personnel whatever may be the nature of their duties in flight. By constant vigilance and endeavour, the medical services are expected to help in maintaining the flyers at the peak of their physical and mental efficiency.

The specific conditions pertaining to aircrew and Air Force personnel in aviation are as under :

(a) Hypoxia.
(b) Rapid decompression & Decompression sickness.
(c) Heat Stress
(d) Motion Sickness (Air Sickness)
(e) Psychiatric and Psychological problems
(f) Accelerations, Supermanouverability
(g) Vibrations
(h) Noise, Otitic barotrauma and barosinusitis
(j) Visual problems in Aviation

## Hypoxia

The effects of oxygen deficiency in the upper atmosphere are due to reduced partial pressure of oxygen ($PO_2$) in inspired air at altitude and are of vital importance in aviation. The altitude hypoxia leads to oxygen deficiency in tissues, which manifests in the form of physiological, psychological and psychomotor impairments of varying degrees, and may even cause death. In a healthy individual in early stages, the symptoms are fatigue, mild headache, drowsiness, frequent yawning, lethargy & poor judgment. The relationship of partial pressure of oxygen in the alveoli and haemoglobin saturation is given by the Oxygen Dissociation Curve (Fig - 1)

### Time of Useful Consciousness

Time of useful consciousness (TUC) is the period of time from the interruption of the oxygen supply or exposure to an oxygen-poor environment, to the time when capability to perform useful function is lost. The individual is no longer capable of taking proper corrective and protective action to undo his predicament. Table -1 reflects the various altitudes with the corresponding average TUC. These times have been established from observations over a period of years (Flight Surgeon's Manual US AF).

At altitudes higher than 3,048 m (10,000 ft), there is likely to be impaired judgment, overconfidence, tendency to commit mistakes but inability to realize them, repetitive

Table - 1 : Time of useful consciousness

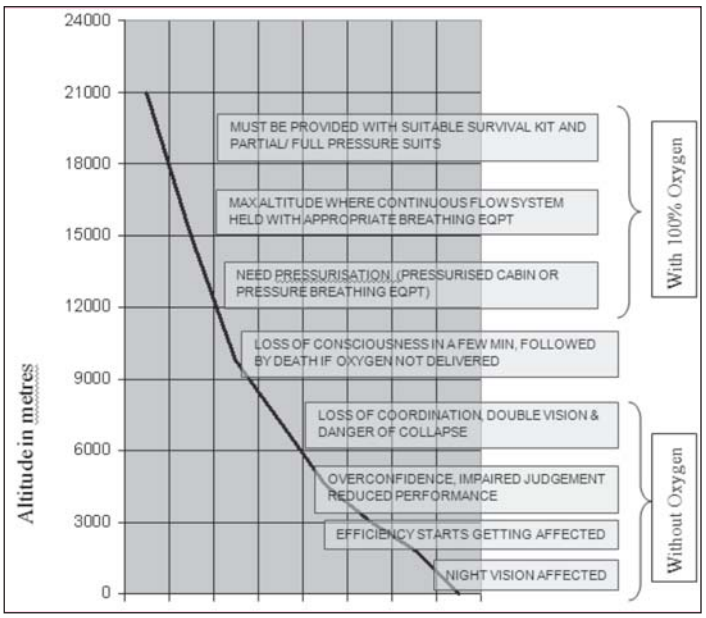
| Altitude (Ft) | TUC |
|---|---|
| 18000 | 20 to 30 Min |
| 22000 | 10 Min |
| 25000 | 3 to 5 Min |
| 28000 | 2. 5 to 3 Min |
| 30000 | 1 to 2 Min |
| 35000 | 0. 5 to 1 Min |
| 40000 | 15 to 20 sec |
| 43000 | 9 to 12 Sec |
| 50000 | 9 to 12 Sec |

thoughts and fixed ideas, loss of memory, changes in behaviour with outbursts of hilarity. At a later stage, the subject begins to show tremors and becomes generally clumsy in his movements. If hypoxia is severe, it leads to convulsions, unconsciousness and even death. The effects of oxygen lack in relation to altitude and pressure are shown diagramatically in Fig 2.

### Prophylactic and Remedial Measures

(a) Use of Oxygen

Fig - 2 : Effect of oxygen lack in relation to altitude and pressure



Normal alveolar oxygen tension must be maintained during flight by use of oxygen through well fitting oxygen masks. The flow of oxygen is regulated through a 'continuous flow or demand system' which must be periodically checked to ensure serviceability. It is advised to use oxygen under the following situations :

(i) At heights above 3000 m during day flying and at heights above 1200 m during night flying for aircrew.
(ii) Passengers, other than aircrew are expected to use oxygen above 3600 m cabin altitude.
(iii) For casualties and the sick, oxygen is used at the discretion of the medical officer.

(b) 100% Oxygen

In an established case of acute hypoxia, 100 percent oxygen must be used. Respiratory and circulatory adjuvants should be used simultaneously in the event of a coexistent respiratory failure or circulatory collapse and may be combined with mechanical or manual artificial respiration, if indicated.

## Decompression Sickness

The atmosphere consists of a mixture of approximately 21 percent oxygen, 78 percent nitrogen and I percent other gases (including carbon dioxide). The total atmospheric pressure at ground level is 1ATA (14.8 psi)

under which pressure, some nitrogen and oxygen are dissolved in the human tissues. Since oxygen is used in the body, little of it exists in the free and uncombined form. Nitrogen being an inert gas is held in solution in the body purely in the dissolved form. It is more soluble in fats than in water. The body fats dissolve 5 to 6 times more nitrogen per unit mass than does the blood. At high altitudes under reduced atmospheric pressure, nitrogen diffuses out of the body tissues and fluids in the form of bubbles. These bubbles may lodge in various areas of the body and produce symptoms by direct mechanical pressure. They also produce indirect effects through production of biochemical substances at the blood bubble interface causing vasoconstriction and intravascular clotting. The bubbles may lodge outside or inside the capillaries causing compression or obstruction. All these situations produce multitudes of disturbances and symptoms.

**Clinical features**

'Symptom-complex' caused by the bubbles of nitrogen released in the tissues and blood stream complicate those produced by expansion of gases within the body cavities which occur on exposure to reduced atmospheric pressures. All these symptoms, excluding those due to hypoxia and cold, fall under a group of features termed 'Decompression Sickness' which may follow exposure to altitudes above 7500 m. The severity of sickness depends on the rate of ascent, altitude, duration of exposure and on the individual susceptibility. Age and obesity, influence individual susceptibility. The symptoms consist of bends, chokes, gas pains, skin manifestations, neurological symptoms, circulatory collapse, fainting, unconsciousness and even death.

(a) Bends

This is the most frequent symptom and is characterized by pain in or near the joints. Residual stiffness and dull ache may persist for a few days after exposure.

(b) Chokes

This respiratory distress of sudden onset is characterized by retrosternal discomfort, sense of suffocation and apprehension, rapid shallow breathing, marked inspiratory distress, non-productive cough and sometimes cyanosis.

(c) Cutaneous manifestation

These consist usually of itching in the thighs, arms and trunks. Rarely erythema or petechiae may develop.

(d) Neurological manifestations

These are varied neurological manifestations, visual field defects being the commonest. These defects are usually transitory but may persist after descent. There may be mental confusion, giddiness or unconsciousness.

(e) Circulatory and pulmonary manifestations

These may be primary or secondary associated with bends and/or chokes. In a severe case it may even lead to circulatory failure, pulmonary oedema, pleural and pericardial effusions, coma and death. Postmortem findings in cases of collapse are essentially those of shock.

(f) Gas pains

These are due to expansion of intestinal gases under reduced external pressure.

**Prophylactic and preventive measures**

(a) Cabin / Cockpit pressurization

To prevent the ill effects of flying at great heights, mainly the decompression sickness, hypoxia and abdominal distension, the most adequate measure is the use of a pressurized cabin or cockpit. All aircraft designed to fly at high altitudes are now pressurized.

(b) Denitrogenation of the body tissues

Denitrogenation of the body tissues before ascent to critical altitudes is done by breathing 100% oxygen at ground level for ½ to 1 hour. This reduces the incidence of bends above 10,000 m by more than 50%.

(c) Diet Control

Gas pains, however, do not respond to above treatment. Avoidance of gas forming food items in diet that are known to cause abdominal distress at ground level minimizes the likelihood of gas pains.

(d) Management of a case

Immediate descent to ground level and no further ascent for at least 48h is the immediate remedial measure. If anything occurs other than itching and uncomplicated 'bends', the subject must be treated as a case of potential post-decompression shock and observed for at least 24h. Blood pressure and haematocrit readings should be taken periodically. If BP starts falling or the haematocrit reading starts rising, the patient must be transferred to the nearest service or civil hospital and treated to maintain the circulatory blood volume with intravenous plasma or dextran. Normal saline and dextrose are less effective. Paraldehyde may be administered to allay excitement; however morphine should not be given. Decompression up to 2 - 3 atmospheres is life saving and is the treatment of choice, where facilities exist. If a hyperbaric chamber is nearby and the patient has continuing symptoms, he should be moved to the chamber and immediately treated as per the hyperbaric treatment table. The effectiveness of treatment decreases as the duration of time between the onset of symptoms and treatment increases. If there is no hyperbaric chamber nearby, arrangements should be made for immediately transporting the patient to the nearest hyperbaric facility capable of administering proper treatment. The patient should be kept on 100% oxygen by aviators mask during transportation to the chamber. (De Hart Textbook of Av Med)

**Rapid Decompression**

A breech in the integrity of pressurized cabin can give rise to the problem of sudden decompression. The severity of effects of rapid decompression depends upon the volume of the cabin, area of the opening in the cabin and the pressure differential between the cabin altitude and the ambient altitude.

The general effects of rapid decompression are due to sudden expansion of gases within the closed cavities of

the body. Sudden expansion of the internal gases can produce severe pain and can produce a shock like reaction if the gases are not allowed to escape. Apart from this, if the glottis is closed then considerable damage to the lungs can occur. Low temperatures may further complicate the effects of rapid decompression cold injuries. Rapid decompression is an emergency and the pilot is advised to descend to lower altitudes as fast as possible.

## Hazards due to Extreme Temperature Variations

### Atmospheric Climate

In a tropical country like India where the climatic variations range from extreme heat to extreme cold, it is essential that the IAF medical officers are conversant with the environmental problems faced by the aircrew when exposed to extreme weather conditions.

### Heat Stress

Heat stress is of greater importance as compared to the cold stress as most of the operational flying is done in hot and dry or humid climates of the West and Eastern parts of this country. As far as heat is concerned, the body is said to be at thermal equilibrium if the gain of heat due to metabolism, convection, conduction and radiation is equal to the heat loss. The various indices of heat stress are WBGT, FITS (Fighter Index Of Thermal Index), ET (Effective Temperature), CET (Corrected Effective Temperature), WDI (Wet Dry Index or Oxford Index) (Fig - 3).

Sources of Heat

(a) Metabolic heat.

(b) Aerodynamic heat or kinetic heating. This is produced by the friction between the surface of the aircraft and the air especially during high speed low altitude run in low level interception, dive bombing and low level flying.

(c) High heat load inside the aircraft, parked in the hot sun, mostly from the accumulated radiant heat and the ambient air temperature. During the hot summer months in Northern India, the temperature inside a fighter / bomber aircraft sometimes reaches as high as 60˚C or even more.

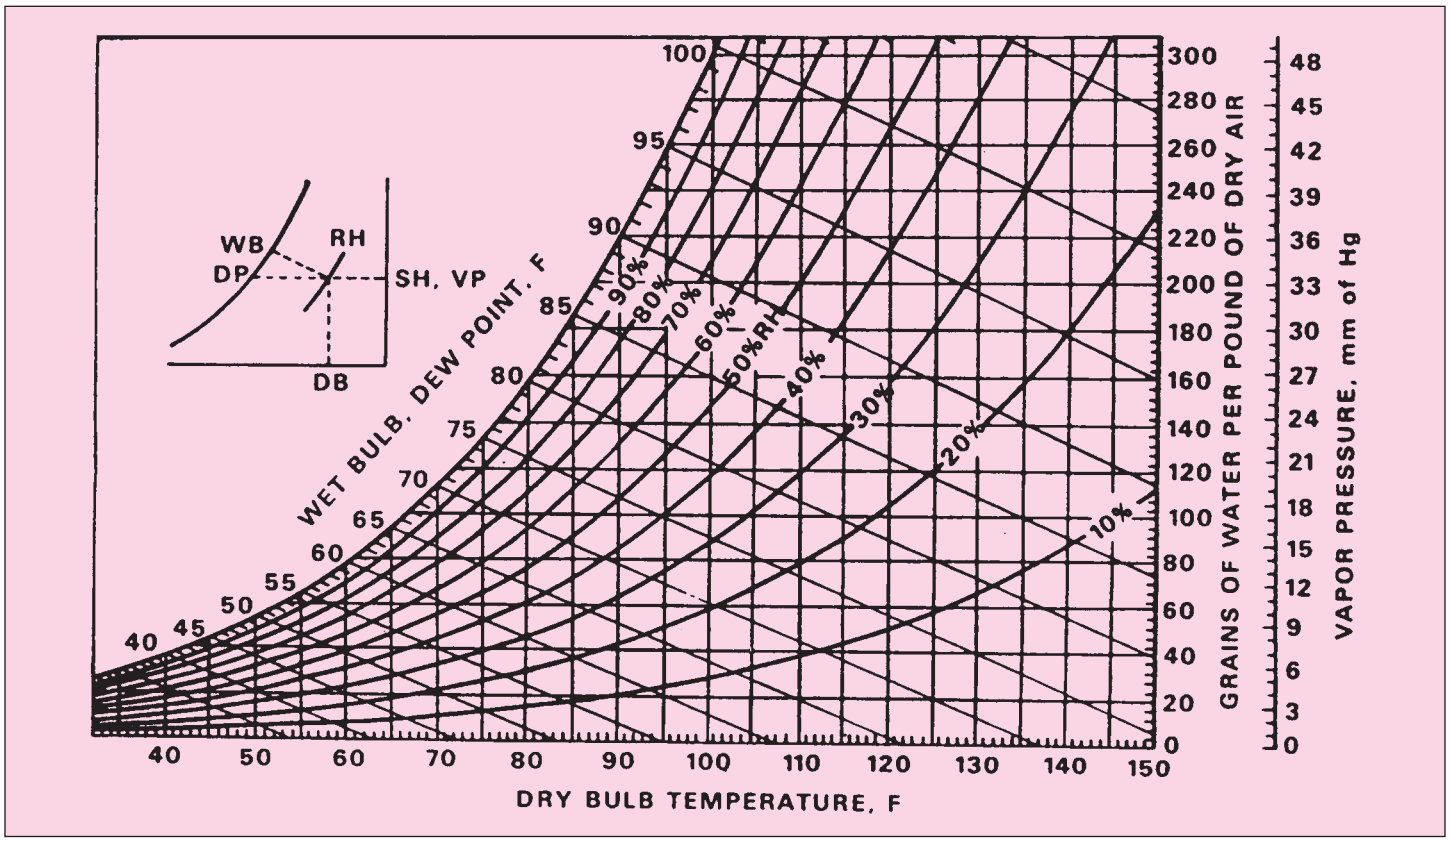
(d) Wearing flying clothing assembly viz, anti 'G' suit, partial or full pressure suit, partial or full pressure helmet, flying gloves, boots, goggles, overall, and sometimes snow and sea survival kits, prevent heat loss from the body and almost block all the channels of heat transfer from the body.

Effects of Heat Stress

The ill effects of heat on a pilot are directly proportional to

Fig - 3 : Psychrometric chart at sea level.

**Variables include dry bulb temperature, water vapor pressure, absolute humidity, wet bulb temperature, relative humidity, and dew point temperature.**



the degree of heat load inside an aircraft and the duration of heat exposure. The later is dependent upon the time taken by the pilot to reach parked aircraft from the aircrew room, time spent on preflight check and to get clearance from the control tower, and taxiing the aircraft to the take off point. This, on an average, works out to approximately 30 min under normal conditions. This does not take into account the delay in take off for various reasons which may extend the exposure time considerably. Heat strain indices include Heat Accumulation Index, Modified Craig's Index and $P_4SR$. Studies conducted at IAM under simulated conditions have shown the following ill effects :

**(a) Psychological Effects**

(i) Irritability.

(ii) Lack of concentration.

(iii) Tendency to fiddle with instruments and other things even when not required to do so.

**(b) Subjective Symptoms**

(i) Sense of suffocation.

(ii) Abdominal discomfort.

(iii) Heat cramps especially in calf muscles.

(iv) Giddiness.

(v) Generalized feeling of discomfort.

**(c) Objective Signs**

(i) Rise in oral temperature between 38.3˚C - 39.3˚C.

(ii) Rise in skin temperature.

(iii) Rise in pulse rate sometimes reaching up to 140/min.

(iv) Rise in tidal volume.

(v) A gradual rise in systolic pressure with gradual fall in diastolic pressure, with consequent increase in pulse pressure. At later stages both systolic and diastolic pressures tend to drop and indicate the end point of tolerance.

(vi) Extra systole in the ECG tracings in some cases.

(vii) Neuromuscular in-coordination.

(viii) Severe sweat loss. An average loss of approximately 500 $g/m^2$ body surface has been reported after 45 min exposure to severe heat stress.

**(d) Physical Injuries**

Blisters have been known to occur when the heated metal parts of the aircraft or harness come in contact with the bare skin surface.

Preventive Measures

The effects of heat stress can be prevented by providing adequate cooling to the pilot. The cooling can be provided either by air conditioning or by providing cool microenvironment between the skin surface and the clothing.

**(a) Air Conditioning**

The conventional type of air conditioning system which makes use of freon gas is not feasible in the modern day fighter aircraft due to its bulkiness, high power consumption, and increased pay load. In the aircraft, air conditioning is usually provided by air-cycle cooling. The hot air is tapped from the engine compressor before the combustion stage. It is passed through primary heat exchanger where the ram air (atmospheric air) acts as the coolant. It is then passed into a cold air unit where it is further cooled by the process of expansion. This cold air is then distributed in the cabin. There are certain disadvantages in this system such as -

(i) The system works only when the engines are running. It is thus useless when the aircraft is parked on the tarmac.

(ii) It makes use of ram air i. e. the aircraft must be in motion to get the best effect and since, at lower altitudes the ram air is hotter than at higher altitudes, the efficiency of the system is much reduced at lower altitudes.

**(b) Cool Micro Environment**

(i) **Air ventilated suit** : This is a suit consisting of numerous tubes stitched into the suit material. The tubes are provided with multiple small holes. The cooling is provided by pumping cold air or dry ambient air through the tubes. Cooling takes place by convection and evaporation.

(ii) **Liquid cooled suit** : This is a close fitting suit made of stretch nylon, which consists of a number of capillary tubes distributed all over the body. A cool liquid (glycol + water mixture) is pumped through this suit and thus provides cooling by eliminating heat.

**Cold Conditions**

Cold environmental conditions in winter and at high altitude tend to lower the temperature in the interior of the aircraft. This gives rise to discomfort, loss of efficiency and in extreme conditions may lead to frostbite. However, such occasions are not frequent. In today's flying conditions, the pilot is exposed to cold only during emergency situations like failure of the pressurization system, either due to enemy action or mechanical failure and bale out at high altitude or over snow bound areas. Besides, a thorough check of the air conditioning system before taking off, provision of impervious clothing with adequate insulation, flying boots, chamois leather gloves, proper head gear and / or the snow survival pack would help in preventing cold injuries. Dangers of cold, snow survival and preventive measures should be taught to and be understood by all flying personnel.

## Motion Sickness (Air Sickness)

Motion sickness causes nausea and, vomiting with variable mental depression during any form of motion. In the air it results from variation in the speed and direction

of motion of an aircraft. There is a very wide range in individual sensitivity, but majority readily adapt to any form of motion. Up to 15% of all flying trainees become air sick at least once during the training period but only about 5% become air sick more than once. Persistent air sickness is not very common.

**Prophylactic and Remedial Measures**

(a) Careful Selection of Aircrew

This should be made by eliminating individuals prone to persistent motion sickness. Individuals showing susceptibility to air sickness and failure to acclimatize should be evaluated psychologically.

(b) Adaptation

This is the most effective preventive measure. Aircrew on their first flight may get severe air sickness but rapidly cease to be troubled by it as their training proceeds. Only a very small minority fail to get adapted. Restriction of head movements may prevent the onset of motion sickness. However, complete prevention of air sickness in military aircraft is difficult to achieve because of the design of the aircraft and the weather conditions in which sorties are flown. Violent maneuvers should be avoided whenever possible, especially when abinitio trainees are on board.

(c) Food and Drugs

There is a great individual variation in the relationship of air sickness to full or empty stomach and to the ratio of liquid to solid food that is taken immediately before or during a flight. Prophylactic therapy is useful in individuals liable to mild air sickness only until he becomes conditioned to the motion of the aircraft. Once adaptation has developed, the therapy should be discontinued. Drugs are usually not permitted for aircrew, but may be given to those engaged in flying at infrequent intervals such as passengers or paratroopers. Of the few drugs useful, hyoscine hydro bromide 0.3 - 0.6 mg taken one hour before take off is still the most useful. The side effects of dose are negligible and it has good anti-air sickness properties. Drugs are of little value in those individuals who get persistent or severe air sickness or fail to adapt.

(d) Motion sickness desensitization programme

This programme incorporates systematic desensitization by simulators viz. Barany's chair / DISO simulator along with psychotherapy and yogic exercises, to tone up the autonomic nervous system.

## Psychiatric and Psychological problems

Aircrew is exposed to a variety of stresses, which place heavy demands on their physical and mental stamina. Any flying accident, particularly a fatal one, in the squadron brings this fear back into the conscious and the aircrew especially an inexperienced one may start feeling that he may be the next victim. This fear affects his performance and he starts committing mistakes, further shaking his confidence in his own ability and thus a vicious circle may set in.

Besides the psychiatric assessment done at various multispecialty AF Hospitals, psychological assessment is done at IAM. Commonly used psychometric tests are- 16 Personality Factor Test, Eyesenck's Personality Inventory and Rorschach's Test.

Aircrew is aware that it is impossible to predict in-flight emergencies and he may land in difficult situations from which it may sometimes be impossible to extricate himself. Split second delay in decision-making may prove fatal. During an in-flight emergency, he alone is responsible for safety of aircraft and its cargo. He has, therefore, to use all his mental and physical reserve to bring the aircraft safely back to the base. No doubt, he can abandon the aircraft if he finds the emergency situation beyond his capabilities but his pride makes him stick to the aircraft till the last moment before abandoning it. To perform best, he has to be at absolute mental ease and must be calm and composed in the face of worst of situations. Fatigue impairs his performance. Hypoxia, 'G' forces, bad weather, hypoglycemia, long flying hours and tenures of duty without leave, lack of sleep, vibration, mental worries, domestic problems, and administrative work loads, all predispose to aircrew fatigue impairing his performance especially in the face of emergencies. Under the circumstances, he may need a higher than normal level of stimulus to respond.

**Preventive Measures**

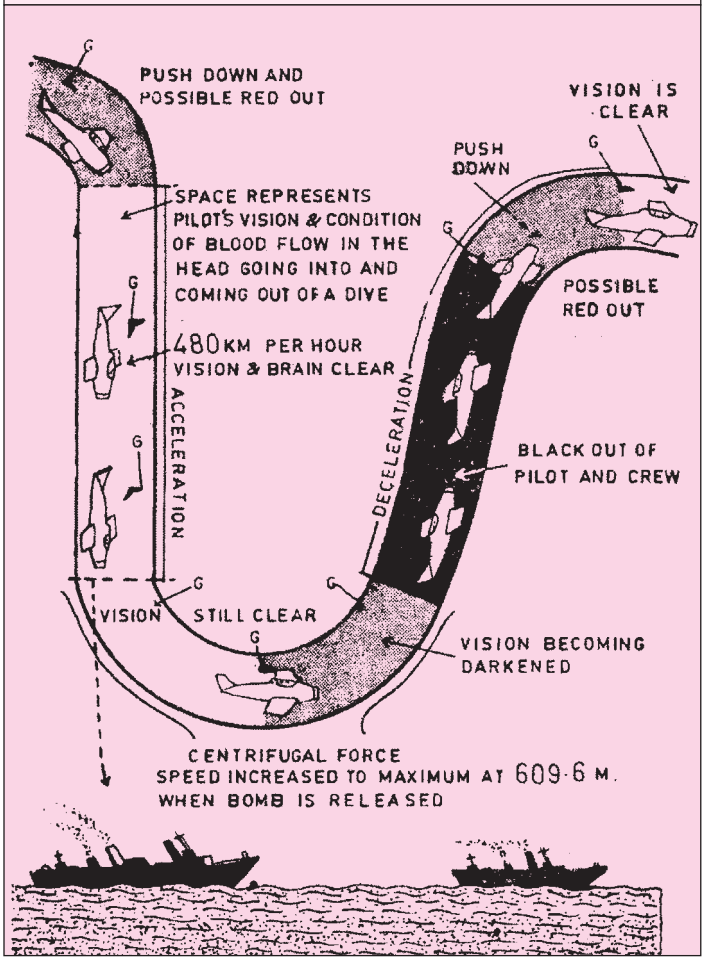
Squadron medical officer should constantly endeavour to understand the aircrew individually, their personal problems, their personality and response to training; their love or aversion for flying and their ability to mix freely with others. A patient and tactful handling of unsure and borderline aircrew can do wonders to build up their confidence. Aircrew should be made to feel that, accidents and fatalities are meant for others and not for them. Flying must continue regardless of the fatal accidents. This is the only way to build up aircrew confidence. This rule is especially applicable to borderline flyers. Nothing can be more detrimental to aircrew morale than interruption of flying after fatal accidents. Easy approachability of a friendly squadron medical officer will encourage the aircrew to come to him with their personal problems and if he can help them solve these problems, he will have not only established himself as a friend of aircrew but can play a very important part in building up aircrew morale. He should be on the look out for the earliest signs of aircrew fatigue and take immediate action with the authorities to deal with it. Comfortable accommodation, adequate sleep, relaxation, rest and recreation, nutritious and palatable food, proper spacing of sorties and short spells of leave after long duty hours are a few of the essentials where a squadron medical officer can help by interceding with the commanders. In the event of a cumulative and chronic fatigue, it may become necessary for a squadron medical officer to take aircrew temporarily off flying.

## Effects of Acceleration

With the introduction of highly maneuverable, high speed jet aircraft, the effects of high accelerations have become important. For considering the details of physiological

effects of acceleration, it is necessary to understand the

Fig - 4 : Effects of acceleration, deceleration, Centrifugal force and push down



terminology used in acceleration :

**(a) Speed**

It indicates the magnitude of motion and is usually expressed as km/mile/m or ft/per second (ft/sec, or m/sec).

**(b) Velocity**

It is the distance travelled per unit time in a given direction and indicates both magnitude of motion and its direction. Thus, it is a vector quantity. It is expressed as ft or m per second in a given direction e. g. 40 ft / sec, south.

**(c) Acceleration**

It is the rate of change of velocity per unit time and as such can be affected by change of speed in magnitude or direction or both. It is expressed as m or ft/ $sec^2$.The same unit is used for deceleration also.

**(d) Jolt**

It indicates the force of onset of acceleration and is expressed in 'g' per second. The higher is the Jolt, the greater are the effects on the body.

**(e) Weight**

It is the force with which a body is pulled by the gravitational force of the earth. A mass weighing 10 kg weight under normal acceleration of earth (one 'G' = 32.2 ft / $sec^2$) will weigh 30 kg if the acceleration force is increased 3 times.

**(f) G Unit**

This is the ratio between the imposed acceleration and that produced by earth's gravity. An imposed acceleration of 96.6 ft/$sec^2$ is thus equal to 3 G units. It is one way of expressing the accelerative force by which physiological effects can be easily understood. Under 3G conditions, the same body will weigh three times its original weight.

**(g) Inertial force**

This is the force with which a body resists the change when disturbed from a state of rest or constant velocity. This is proportional to the accelerative force and is in the opposite direction. As an example, it is the inertial force which presses a person back into the seat of an automobile during forward acceleration or pushes him forward during deceleration. Depending on the direction of the inertial force the following terminologies are used :

(i) **Positive 'G'**
Inertial force acts from head to foot.

(ii) **Negative 'G'**
Inertial force acts from foot to head

(iii) **Transverse 'G'**
Inertial force is directed through antero-posterior axis of body i. e. chest to back or back to chest.

(iv) Inertial force directed through lateral axis of body i. e. right to left or left to right.

**Types of Acceleration**

(a) Linear Acceleration

These are produced when changes in speed occur without any change in direction. These can be positive, negative, transverse, or lateral e. g. crash-landing.

(b) Centrifugal Acceleration

This is produced when a moving body changes direction along the area of a circle. It is positive, negative, transverse or lateral depending upon the position of the human body e. g. aerobatic maneuvers like loops, dives etc.

(c) Angular Acceleration

This is imposed when the body undergoes changes in speed as well as in direction e. g. rolls.

**Physiological Effects of Acceleration**

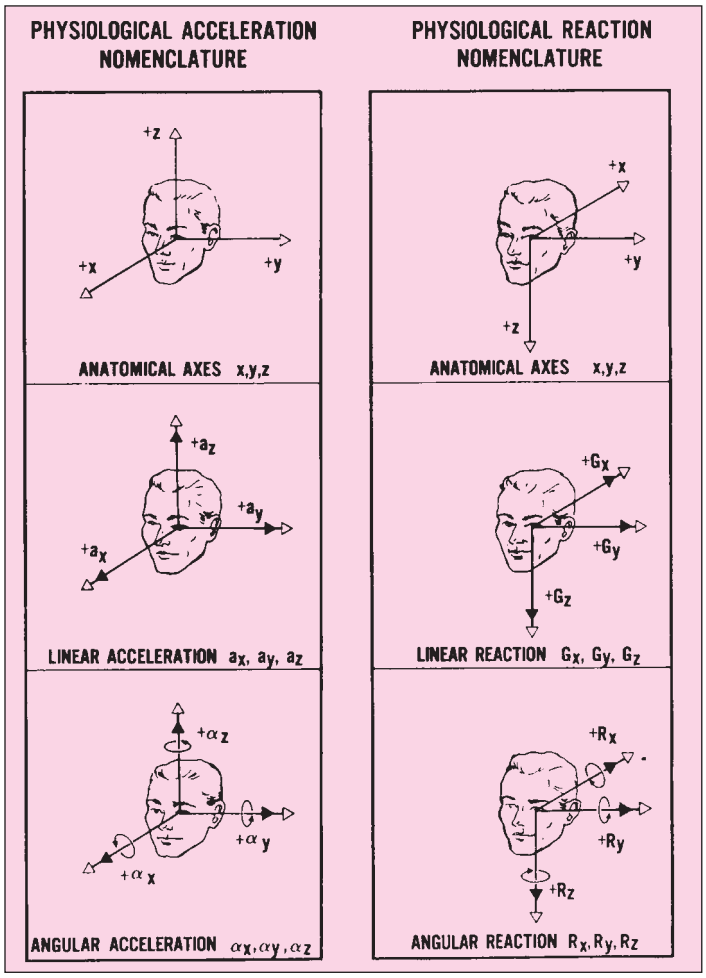
The effects depend upon the magnitude, rate of onset, duration and direction of these accelerations and on the area of the body surface exposed to these.

**Linear Accelerations**

Rapid changes in speed during catapult takeoffs and arrested landings in carrier borne naval aircraft, crash landings, ejection escapes from aircraft and parachute opening impose linear accelerations of varying

magnitudes. Generally these accelerations are abrupt

Fig 3: Description of the Anatomical Position



with a high rate of onset, have large magnitude and are of short duration. In this type of acceleration, duration is too short to produce any physiological changes. Main effect is the structural failure in the body e. g. ruptures tears and fractures. Injuries produced by the impact of the human bodies against lethal structures in the cockpit or due to the jolt, can be serious or even fatal.

(a) Ejection Escape

Escape of the pilot or crew from aircraft flying at high speed is not possible without assistance. The seats of these aircrafts are charged with cartridges that fire when the pilot pulls the firing handle. The seat along with him leaves the aircraft, gaining an upward velocity of 20 to 25 m/s in a fraction of a second and imposes 18 to 20 'G' loads on the pilot. Fig - 5 shows the action and inertial forces. The pilot's body is subjected to a collapsing and a compressing force that puts high loads on the dorso lumbar vertebrae. The likely injuries are compression fractures of the lower dorsal and upper lumbar vertebrae. Proper alignment of the spine by sitting erect so that the back fits in with the seat-back contour and the vertebral bodies take the load squarely and evenly. This is considered as an essential safeguard against spinal injuries. Since an unsupported head would flex violently during ejection a 'canvas-blind' that follows the firing handle comes over the face and keeps the head against the head rest during the jolt. Recent designs of seats have employed rocket motors under the seats. These rocket assisted seats do not have to depend entirely upon the cartridges for their escape velocity so that the 'G' acceleration loads get reduced to 16 G or less.

(b) Parachute Opening

The velocity of a freely falling body in air comes to a steady value when the air resistance equals the weight of the man and the unopened parachute. This value is called 'Terminal Velocity' and is higher at high altitudes. The person escaping from an aircraft will do so at the aircraft velocity which will soon be washed off by the air drag to the limits of terminal velocity. If a parachute is opened before this, it decelerates the free fall velocity over a very short time. The abrupt change over from the initial high velocity to the parachute speed imposes very high 'G' loads on the person. These loads may tear the parachute canopy. The upward drag imposed through the parachute harness produces serious injuries if the jolt is high. The commonest injuries produced by a parachute opening shock (POS) are lacerated wounds under the axilla, injury over antero-lateral aspect of lower abdomen, injury over upper 1/3 of thigh and buttocks, fracture of symphysis pubis and injury of the scrotum and testicles. Therefore, aircrew ejecting out from a high speed aircraft is instructed to wait for the attainment of terminal velocity before opening the parachute. Since the terminal velocity is lower at lower altitudes, they are also trained to wait to reach lower altitudes before operating the parachute. In modern ejection seats an automatic parachute deployment system has been incorporated to ensure opening of the parachute at a pre set altitude.

(c) Crash landings

A crashed aircraft impacts the ground in various attitudes with differing magnitudes of horizontal and vertical velocities. Angle of the terrain, its texture and nature determine the distance over which the impact velocities are finally brought to zero. The forces imposed are abrupt and high. Since the jolt values are high, severe stresses are imposed on the human body and the restraint systems (Fig - 4). Injuries are produced not only due to forces per se, but also due to physical throwing forward of the body when one's restraint systems fail. One of the most important requirements in a survivable crash is the material integrity of seats and straps.

**Centrifugal or Radial Acceleration (Positive 'G')**

Combat aircraft undergo quick changes of direction during their missions involving interception, dog fights, and air to air attacks. The maneuvers are fast and impose centrifugal 'G' loads on the pilot. The human tolerance to the 'G' loads primarily depends upon the physiological effects produced by shift of blood in large blood vessels that lie in the line of the centrifugal force in a normally seated pilot. This acceleration is slow in onset, moderate in magnitude and of longer duration. The centrifugal acceleration increases the virtual weight of solid heavier particles in its line of action and produces the

Table - 2 : Nomenclature of the reaction forces in acceleration

(Gell c. Table of equivalents for acceleration terminology, recommended for general international use by the aerospace medical panel, agard. Aerospace med. 1961; 32 : 1109).

**A. Direction of Acceleration**

| Linear Motion | AC Standard | Acceleration |
|---|---|---|
| Forward | +ax | Forward acceleration |
| Backward | -ax | Backward acceleration |
| Upward | -az | Headward acceleration |

| To left | Right lateral G | -Gy | Eyeballs-right |

sedimentation towards the bottom of the glass tube full of fluid. If the glass tube is replaced by a rubber tube, the centrifugation makes the tube swell at its bottom due to pooling of the fluid that shifts away from the upper parts of the tube in the line of centrifugal force. The Cardiovascular system can be visualized as consisting of many interlacing rubber tubes in which the blood tends to shift and pool towards distal parts under the influence of a centrifugal force. The magnitude of 'G' acceleration is directly proportional to the square of the velocity and inversely to the radius of turning aircraft i. e. $G = V^2 / 32r$ where V = Velocity in ft / sec and r = Radius of turn in ft. Since weight (i. e. force) is equal to the product of mass and 'G' acceleration, the weight of every part of the body and the fluids in it changes proportionately. A turn that produces a centrifugal acceleration equal to 3G for example will increase the weight to three times its original weight.

### Subjective Manifestations of Positive Centrifugal Acceleration

There is a feeling of being pressed into the seat, limbs become heavy and can only be lifted with additional effort. At 3G, it becomes impossible to get up from the seat. Face mask and goggles tend to slip down if improperly fitted. The mouth opens, lower eyelids droop and face muscles sag down giving appearance of an aged person. Tingling sensations in the legs may occur.

(a) Grey out

At about 4.0 to 4.5 G, the cephalic mean blood pressure drops due to the shift of blood to distal parts and it can just overcome the intraocular tension, As a result the peripheral vision suffers and the pilot's vision becomes dim or hazy.

(b) Black out

At about 4.5 to 5.0 G the fall in cephalic mean blood pressure is serious enough to curtail retinal circulation and the central vision is lost. Consciousness is, however, retained because the little pressure still present is enough to perfuse the blood through the low resistance cerebral vessels. During actual flight the level of unconsciousness is not reached if the pilot relaxes on the controls as soon as blackout sets in. The blackout stage, therefore, marks the limit of human tolerance in so far as operation performance is concerned. The recovery from blackout is immediate as soon as the pilot eases on the controls. On recovery, the subsequent performance may not be adequate enough for taking stock of things that happened during the blackout. The delays involving psychomotor performance due to this cause may be hazardous at critical stages of fight.

(c) G-induced Loss of Consciousness

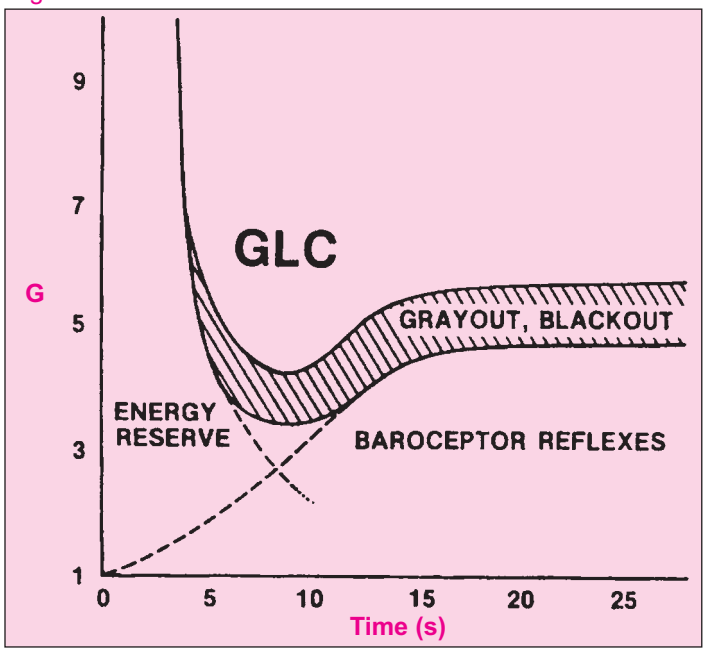
G-induced loss of consciousness (GLOC) has become an issue of major research and operational interest. GLOC is "a state of altered perception wherein (one's) awareness of reality is absent as a result of sudden, critical reduction of cerebral blood flow as a result of increased G forces"

The loss of aircraft and aircrew are, of course, a major concern, but every GLOC episode does not result in loss of an aircraft. But this is obviously an issue of major operational concern. Research on the degree of incapacitation caused by GLOC has indicated that there is an average total incapacitation (unconsciousness) time of 15 seconds followed by a period of relative incapacitation (confusion and disorientation) of 12 to 15 seconds, resulting in a total time of incapacitation of between 24 and 37 seconds. Research is now focusing on ways to prevent GLOC episode as well as to shorten the periods of

Table - 3 : ROR G Tolerances of 1000 subjects (1 g/sec onset rate).

| Criterion | Mean Threshold (G units) | Deviation (G units) | Standard Range (G units) |
|---|---|---|---|
| Grey out or loss of peripheral vision | 4.1 | +/-0.7 | 2.2-7.1 |
| Peripheral vision | 4.1 | +/-0.7 | 2.2-7.1 |
| Blackout | 4.8 | +/-0.8 | 2.7-7.8 |
| Unconsciousness | 5.4 | +/-0.9 | 3.0-8.4 |

Fig - 6 : G-Time Tolerance Curve



incapacitation.

**G-Protection**

Several protective strategies to increase G tolerance and to prevent GLOC have been under development and in some cases already put into operational use. These strategies include centrifuge training, weight training, newer G suits and G valves, altering the seat back angle in the aircraft, and the use of positive pressure breathing both assisted (with counter pressure) and unassisted.

Objective

With the onset of 'G', the muscle tension in the spinal and limb muscles increases so as to maintain control and posture. The descent of the diaphragm and ribs impedes respiration, which becomes faster and shallower. The heart shifts its axis and becomes more vertical. The fall of mean pressure in carotid sinus initiates the compensatory reflex that produces an increase in the peripheral vascular tone. This tends to decrease the pooling of blood and raise the mean cephalic blood pressure. Generally, the compensatory mechanism cannot become effective after 4G. At this level of G, the venous return from the dependent parts becomes insignificant (due to increase in weight of the blood column in the veins). The pooling of blood in the limbs is accommodated by the increase in volume of the tissues and when sustained, leads to oedema and petechial haemorrhages. Pilots who were subjected to high G loads during maneuvers while breathing 100% oxygen at low altitudes and wearing anti G suits have been known to have atelectasis at the base of the lungs.

Prophylaxis

Since the highest G threshold is an essential requirement for a combat pilot, certain measures are adopted to raise this limit. These are :

**(a) General**

Continuous practice, consistent flying, good morale, motivation, freedom from anxiety and fatigue, good health, absence of clinical or sub clinical ailments, nourishing food, adequate sleep are important.

**(b) In-flight Actions**

By these methods an additional gain of 1G tolerance can be achieved.

(i) **Crouching** : While still keeping the instruments and the exterior in view, crouching reduces the vertical height of the blood column between the heart and the head. This reduces the extent of fall of mean blood pressure in the cephalic region.

(ii) **Anti G Straining Maneuver** : Straining of abdominal muscles as in forced expiration with a partially closed glottis raises the intra-thoracic and intra-abdominal pressures and prevents pooling of the blood.

**(c) Use of Anti G Suit**

An anti G suit consists of a garment that contains built-in rubber bladders over the calves, thighs and lower abdomen. These bladders get automatically inflated by an anti 'G' valve that regulates the pressure. They prevent increase in the volume of the tissues and help prevent the pooling of blood. An additional tolerance of 1.5 to 2G is obtained in this manner. It is important that the suits are always kept fully serviceable.

**Negative 'G'**

Whenever the inertial reaction promotes shift of blood and tissues from foot to head, the 'G' producing this reaction is called negative 'G'. Standing on the head itself imposes 1'G' negative (-1 'G') and produces congestion of the face, neck and eyes. Same would happen during inverted flights. When this 'G' is applied at a rapid rate and for prolonged periods, the shift of blood towards cephalic region produces a throbbing headache, as if the skull would burst. The conjunctiva gets congested and hemorrhages may occur. The limiting factor towards tolerance of this 'G' is the occurrence of severe subjective symptoms. When this 'G' is imposed as jolt, as in downward directions and tumbling during a free fall at high altitudes the abrupt shift of blood produce rupture of small blood vessels of conjunctiva and the skin of the face and neck. Occurrence of mental confusion is a common feature during this type of accelerations. During negative 'G' maneuvers the pilot sometimes sees red mist in his field of vision (Red out).

Fig - 7 : Mk II Anti G Suit

Avoidance of negative 'G' maneuvers is the only way of preventing the effects of negative 'G'. Except for mild negative 'G' suffered in inverted flying and pushovers, performance of any maneuvers that impose higher negative 'G' values is prohibited.

**Angular acceleration**

This occurs when the centre of rotation lies within the aircraft or the man himself. The rotation is around the axis of the object itself as occurs during spinning and rolling. The main effect produced is that of disorientation. In case of uncontrolled rotations occurring due to tumbling and spinning of the human body after escape from an aircraft at high altitudes, additional effects on vascular system such as haemorrhages in conjunctivae, skin of the face and neck are produced due to violent shift of blood. However, as spinning and rolling are essential flying practices to get confidence over the aircraft, they are unavoidable. Practice, training, and visual cues obviate occurrence of disorientation. To prevent tumbling and spinning of man and the seat after escape, special stabilizers' have been designed and incorporated in the modern ejection seats.

## Vibrations

Varying degrees of low frequency vibrations are encountered during flight especially in low level high speed flights principally as a result of air turbulence. At times, these vibrations are severe and bring about a decrement in aircraft performance. The effects on human body depend on the frequency, amplitude, duration and periodicity of vibrations. When the induced frequencies are close to the natural frequencies of the whole body or the individual organs, the effects felt are amplified. Such frequencies range between 5 to 12 Hz. Vibrations originate in the propellers of piston engine aircraft and rotor blades of helicopters, engines, gear boxes and transmission systems, air turbulence and gusts of wind, in aircraft escape systems, in parachuting and during weapon firing. The effects of vibrations are-

(a) Annoyance, discomfort and fatigue.
(b) Decrement in psychomotor performance and in performance of fine and skilled tasks.
(c) Hyperventilation.
(d) Impairment of vision and speech. R/T conversation becomes difficult.

**The protection strategies involve :**

**(a) Control at Source**

(i) Avoiding turbulent and bad weather whenever operationally feasible.
(ii) Reduction from internal sources e. g. modification of design of propellers, engines etc.

**(b) Control of transmission**

(i) Modification of airframe design
(ii) Relocation of seats and their orientation vis-a-vis source of vibrations.

**(c) Minimizing effects on human body**

(i) Minimizing exposure to vibrations.
(ii) Modification of design of display and controls.
(iii) Training and experience.
(iv) Physical fitness.

## Effects of noise

Noise is an annoying sound. Some workers have defined it as a complex form of sound with no fixed periodicity and consisting of a mixture of various frequencies. Types of noise can be continuous, intermittent, impulse, fluctuating and explosive. Effects of noise depend upon the three parameters; duration, frequency and sound pressure level (SPL). The following examples of sound values illustrate the noise intensity.

Noise in aviation is produced by aircraft on the ground and in the air. On the ground the source of noise is the running of the engines during taxiing and take off and landing and also during test runs of the engine. The personnel most susceptible to this noise are the technical ground staff and the crew who are located close to the runway. On the other hand, the noise from aircraft while flying, usually affects people on the ground during low level flights and also during sonic boom when the aircraft crosses the speed of sound. Exposure of the unprotected ears to sound levels with the overall sound pressure exceeding 85 db, may lead to a loss of hearing which will appear as an elevation of the hearing threshold. It is usually temporary with partial or complete recovery in course of time. The degree of permanent hearing loss that persists indefinitely depends on the individual susceptibility, presence of any aural disease, and whether or not the protective ear plugs or noise barriers were used; character of noise as regards its overall intensity level and frequency spectrum; and the time factor related to the duration of exposure, whether the noise is continuous or intermittent, and intervals between exposure to noise. The first evidence of such a noise induced permanent hearing loss is seen as a 'dip' at 4000 cps frequency in a pure tone audiogram. At this stage the process may be reversed. If exposure is continued the loss becomes progressive and irreversible.

Table - 4

| | |
|---|---|
| 80 to 90 decibels | Police whistle at 5 m, Motor horn at 7 m, Fire siren at 23 m |
| 90 to 100 decibels | Pneumatic drill at 3 m, NEWS- paper press room, inside cabin of aircraft not soundproofed |
| 100 to 110 decibels | Boiler shop, whistle of steam engine, steel riveting machine at 5 m |
| 110 to 112 decibels | (This is the threshold of painful feeling). Thunder (overhead), heavy gunfire (in close proximity) un-muffled aircraft engine |

**Conservation of Hearing**

(a) Assessment of the Noise Environment

This would entail assessment of the overall sound pressure level noise, Octave Band analysis and the exposure time, with a view to identify, designate and monitor areas where personnel are likely to be exposed to hazardous noise.

(b) Audiometric Assessment of Personnel

This includes establishing base line reference audiogram and monitoring audiometry of personnel who are routinely assigned tasks in the hazardous areas, as indicated above. This will enable early detection of hearing loss and institution of appropriate measures.

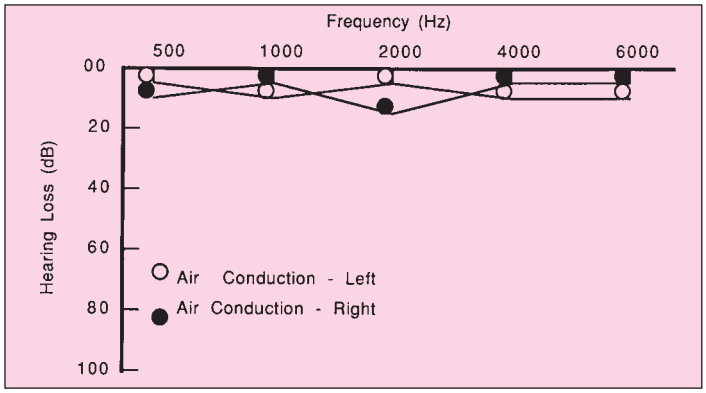
**(i) Conductive Loss**

A conductive hearing loss affects only air conduction curve, which is depressed according to the severity of the hearing loss. The gap between air and bone conduction curves is called the air-bone gap and is diagnostic if it is equal to or more than 10db. Lesser air bone gap can be correlated with Weber's test.

**(ii) Sensorineural hearing loss.**

A sensorineural loss affects both air and bone conduction

Fig - 8 : Normal Audiogram



curves equally, so they are depressed approximately to the same degree and tend to intertwine, (Fig - 9). There is usually no air-bone gap. However, less than 10dB gap may be present in some cases.

(C) Noise Abatement Measures and Personal Protective Devices

This entails issue and individual fitting of personal protective equipment and supervision of the use and care of the equipment.

(d) Central Control and Coordination of the Entire Programme

Fig - 9 : Conductive hearing loss - right ear

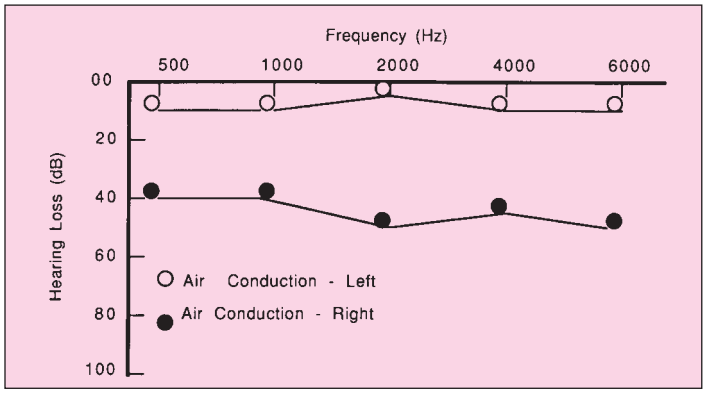


Fig - 10 : NIHL - Bilateral High Frequency Hearing Loss. Aviator's notch at 4000 Hz

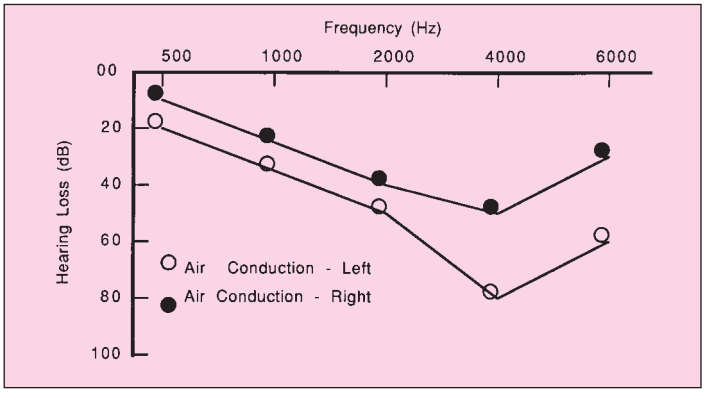

The total programme, out of necessity, could cover many more aspects of the problem such as education of all personnel on the effects of individual measures against noise, deafness investigation, engineers efforts in replacement of noise, replacing noise producing machines by noiseless ones, restrictions on noise production etc.

Table 5 : Recommended Noise Exposure Limits

| dBA | Duration of Exposure Hours | Minutes |
|---|---|---|
| 82 | 16 | 960 |
| 85 | 08 | 480 |

## Effects due to rapid Ascents & Descents on ears

In military aviation, for tactical reasons, ascents and descents are executed at a very rapid rate. This may result in the crew being subjected to a rapid and wide variation

of atmospheric pressure and may result in otitic barotrauma (aerotitis) and sinus barotrauma (aerosinusitis). During ascent the atmospheric pressure decreases and causes expansion of air in the middle ear and sinuses. As the ascent is continued excess air escapes periodically through the Eustachian tube and nose, and the inner pressure is equalised with the outside pressure. On descent however, the atmospheric pressure increases pushing the eardrum inwards. To increase the middle ear pressure and restore the eardrum to the normal position, air has to enter through the eustachian tube, which is difficult due to the anatomical peculiarities of the tube. Similarly, the air cannot readily enter the sinuses. An active effort has to be made, as by swallowing, chewing or yawning, or by Valsalva's maneuver (i. e. a forced nasal expiration with mouth closed). If the pressure differential created by descent exceeds a certain limit, active swallowing or even voluntary forced nasal expiration may fail to equalise the pressure, with the result that the conditions of aerotitis and/or aerosinusitis supervene. These have a definite chain of symptoms characterised by pain, deafness, and inability to clear the ears, tinnitus and vertigo. Otoscopic examination may reveal injection and invagination of the tympanic membrane, effusion or bleeding into the middle ear cavity and sometimes rupture of the drum head. In aerosinusitis severe headache particularly along the frontal sinuses occurs.

**Prevention**

As the flying personnel are pre-selected, usually aerotitis results due to either inadequate knowledge about it or due to various contributory factors like a severe cold. The following precautions should be observed to prevent aerotitis and aerosinusitis by aircrew and passengers :

(a) Autoinflate the ears by swallowing, chewing and forced nasal expiration. As each of these methods can clear only a limited pressure differential, it is not desirable to delay the equalization of pressure.

(b) Not to fly when suffering from cold, sore throat and other respiratory infections.

(c) If there is pain in the ears during descent, further descent should be stopped and valsalva must be carried out. If the flight conditions permit, slight ascent reducing the pressure differential, will clear the ears and the descent to ground level at a lesser rate may be possible without damage.

(d) To report to the medical officer on landing for a check up in case of any difficulty experienced with the ears during a sortie.

## Visual Problems in Aviation

Aviation requires the pilot to have high acuity of vision, rapid perception, quick adaptation to darkness or light, good ocular muscle balance to bring about rapid accommodation and convergence and coordinated eye movements and good colour vision.

Under normal conditions on the ground, the ocular functions are not usually taxed but in aviation various factors affect visual performance such as glare, reversal of light distribution, hypoxia, empty visual field, speed and acceleration.

**Effects of Glare**

It may be sub-divided into three types

(a) Veiling Glare

It is caused when excessive light illuminates the whole field of vision without the source of light being in it. If a dark object is placed in a very bright field, the excess light makes it appear less dark, reduces its contrast with its background and its visibility. This glare is uniformly superimposed on the retinal image of the object and is termed 'Veiling Glare'.

(b) Dazzle Glare

It is caused by the very bright source of light in and against the dark background field of vision. The headlights of an in coming car at night gives rise to this type of glare produced by adventitious light, refracted and scattered in the eye so as not to form part of the retinal image.

(c) Scotomatic Glare

It is caused by the bright source of the light in and against the uniformly bright field of vision. A pilot searching for an aircraft in the direction of the sun is subjected to this type of glare. It is produced by light of such intensity as to fatigue the retinal sensitivity to below the comfortable level for visual perception.

Protection

Veiling glare is the commonest of the three encountered in flight and can be prevented by shading the eyes with the visor in the half down position. Dazzle and Scotomatic glare can only be prevented by using a filter, which reduces the luminosity of the visual field. A filter with a flat transmission curve for the whole visible spectrum is preferred. It should have a 15 per cent transmission between 400 and 700 nm with not more than a 5 per cent deviation, and a negligible transmission in the infrared and ultraviolet regions. The 'sun glass' type of spectacle has certain disadvantages. To be shatterproof, the glass must be of full thickness, which makes the spectacle too heavy and uncomfortable. Steaming of the glass may occur. The spectacle is not very stable under high 'G' forces and may be pulled off by gusts of wind. Spectacles are also difficult to remove and replace in-flight without unhooking the oxygen mask and taking off the helmet. Plastic visors either mounted on or integrated with a helmet are now in general use. The visor can either be fixed in intermediate positions over the eyes or else pushed out of the field of vision when not required

**Reversal of light distribution at High Altitudes**

At ground level, glare comes from the sky, which is bright with the sunlight scattered by large particles of moisture and dust held in suspension. At high altitudes, the atmosphere is purer, having less suspended particulate matter, the sky above gets darker, whilst the atmosphere below dense with its light scattering particles appears brighter. At an altitude above the cloud layer, light is also reflected from the under cast clouds. Thus, there is a

complete reversal of light distribution. The glare source is below and the sky above is dark. At 40, 000 ft a pilot finds himself in such an environment. This reversed light distribution has two effects -

(a) The contrast between sunlight and shadow increases, principally because shadows become darker. The areas of the cockpit, which are in the shade get very dark and the instruments, cannot be read. It is necessary to make special provision for lighting the instrument panel and to increase its luminance by painting the interior of the cockpit, especially behind and at the pilot's side, with a light coloured matt paint which would diffusely reflect light on to the instrument panel especially whilst the aircraft is being flown towards the sun.

(b) The glare in the peripheral visual field depresses the central retina. Whilst the pilot gazes outside, his eyes are exposed to the bright cloud floor beneath him. When he glances at his instrument panel he sees it through the positive after image of the cloud floor, which persists for a while on his retina. There now appears a haze in front of his instruments, and he finds it difficult to read the pointers and the graduation marks, especially if they are in a shadow.

**Effects of Hypoxia on Vision**

Hypoxia causes visual changes by depression of the visual pathway and comprises of the following -

(a) Peripheral constriction of the visual field occurs at 3350 m under day light conditions.

(b) A marked and progressive reduction of night vision occurs 5% at 1220m, 25% at 3700m & 40% at 4275m.

(c) Prolongation of the persistent positive after - image is noticed at as low an altitude as 1500 m.

(d) Prolongation of the recovery time after dazzle occurs in slight oxygen deficiency at lower altitudes.

(e) Ocular muscle balance shifts towards esophoria.

(f) Accommodation is weakened.

**Empty Field Myopia**

A visual field, wherein there is no visible detail for the eye to focus upon, is termed an 'empty visual field'. A cloudless blue sky at high altitude (night myopia), fog, a uniformly overcast sky merging into snow covered ground (Arctic white-out) all offer an empty visual field. In the absence of focusable details the following effects are seen in empty visual fields -

(a) The accommodation cannot be relaxed completely and remains in a state of constant activity, fluctuating about a level of 0.5D, thereby rendering an emmetrope, myopic by this amount. The effect of this myopia is to double the minimum visual angle i. e. targets have to be twice the size to be detected. The pick-up range is halved, assuming that the image is formed at the fovea. If it is formed elsewhere, the acuity falls off so that reduction in the pick-up range will be more than half. In effect, the target appears smaller and its distance is consequently over-estimated - if on a converging path, the approach speed appears greater than it really is.

(b) Accurate fixation is not possible since there is no visible detail to which the fovea can be directed, and hence it is difficult to scan an empty field. Due to this and the constant to and fro movements of the eyes while observing the various illuminated instruments on board, the pilots suffer from ocular fatigue, specially during night and blind flying. The instrument panel is designed so that the instruments, which are most frequently looked at are aggregated in the line of vision.

(c) The perception of motion in a target moving against the empty background is extremely difficult, as the featureless background provides no parallactic displacement.

(d) In snowy 'white out' conditions due to absence of contrast, the depth perception is affected making landing more difficult.

**Effects due to Speed of Aircraft on Vision**

Speeds at which the jet aircrafts are flown make demands on the latent periods required for perception, appreciation, cerebration and volition. A perfectly ordinary situation such as sighting an object a mile away, can turn into a calamity because the pilot cannot see, identify, decide and act as soon as object comes into his field of view, as these events take an interval of time which is worth hundreds of thousands of feet in a high speed aircraft. Consider a pilot is flying at 960 km/h when another aircraft comes into his peripheral vision. He travels 27 m before he 'sees' it i. e. before the image is transmitted from the retina to the brain. He travels 280 m, before he has recognized it as an aircraft. He travels about 2 km before he can actually change his flight path to avoid or attack. At 2880 km /h these distances are trebled and he has covered nearly 5 km before he alters his flight path. For two aircraft on opposite courses the distance they travel relative to each other would be double those given in table 6.Suppose two aircrafts broke cloud on a collision course at 2880 km/h. If they emerged 150 m apart they should crash before either pilot had seen the other aircraft. If they emerged 5 km apart they would crash before the pilots have decided what action to take and if they emerged 8 km apart, they still will not have enough time to change the flight paths of the aircrafts. Even at 960 km/h the pilots would have to see each other 3 km away at the very minimum before they could avoid collision. The importance of good visual acuity is thus evident. The better the visual acuity the greater the pick up range and the more time the pilot has at his disposal to decide upon and carry out a course of action.

When a pilot shifts his gaze to his instrument panel to read an instrument and then looks outside, a time interval of 2.39 seconds has elapsed and at 960 km/h, he has travelled blind for 641m. At 2880 km/h his vision is

Table - 6

| Operations | Time in seconds | | Distance travelled in meters | | | |
|---|---|---|---|---|---|---|
| | | | (at 960 Km/h) | | (at 2880 Km/h) | |
| | During operation | From 1st sighting | During operation | From 1st sighting | During operation | From 1st sighting |
| Sensation (light travels from retina to brain) focusing with central vision | 0.10 | 0.10 | 27 | 27 | 80 | 80 |
| Motor reaction to prearrange eye movement | 0.175 | 0.275 | 47 | 74 | 141 | 221 |
| Eye movement | 0.05 | 0.325 | 13 | 87 | 40 | 261 |
| Focusing with Fovea | 0.07 | 0.395 | 19 | 106 | 57 | 318 |
| Perception (minimum recognition) | 0.65 | 1.045 | 174 | 280 | 523 | 841 |
| Deciding what to do (estimated minimum) | 2.0 | 3.045 | 536 | 817 | 1608 | 2451 |
| Operating controls | 0.40 | 3.445 | 108 | 924 | 322 | 2773 |
| Aircraft changes flight path | 2.0 | 2.445 | 536 | 1460 | 1608 | 4381 |
| | | | | | | |

interrupted for more than 1.5 km. Therefore, good cockpit lighting and well designed and correctly located instruments are of prime importance in high speed aircraft since poor lighting and poor design will greatly lengthen the instrument reading time. The above intervals are absolute minimum due to the unchanging characteristics of the human eye, mind and muscle. Anything that interferes with the pilot's vision such as haze or a grey out, fatigue, hypoxia etc. further increase the time interval. The majority of mid air collisions are attributable to the failure of the pilot to see the other aircraft. With the advent of head up display (HUD), now being incorporated in most of the modern aircrafts, the necessity of shifting the vision from outside to inside during critical phases of flight, is being eliminated. In this system, the necessary instrument information required by the pilot is projected at infinity in the pilot's line of vision while he is looking outside.

### Effects of Acceleration on Vision

Positive 'G' or head to foot acceleration, drains the retinal vessels causing a peripheral constriction of the visual fields leading to a 'grey out' and eventual 'black out'. Negative 'G' or foot to head acceleration, results in pooling of blood in the head and causes engorgement of the conjunctival and extra ocular vessels and oedema of the extra ocular tissue, interfering with the action of the extra ocular muscles resulting in diplopia.

Table - 7 : Pick up range at various visual acuity Levels fuselage-dimensions 214 cm

| Visual acuity | Pick up range (Meters) | Time interval |
|---|---|---|
| 6/12 | 3.6 Km | 4.4 seconds |
| 6/9 | 4.6 Km | 5.8 seconds |
| 6/6 | 6.6 Km | 8.9 seconds |
| 6/5 | 8.5 Km | 10.7 seconds |
| 6/4 | 10.5 Km | 13.3 seconds |

### Dark Adaptation

A good dark adaptation is essential for night flying. The rods are responsible for dark adaptation. The rods are sensitized through rhodopsin which functions under very low brightness levels ranging from moonless cloudy nights to about three quarters moonlit nights. The vision is limited to the perception of vague outlines, demarcated by the difference in the brightness between the objects and their backgrounds. No colour is perceived. The 6.5 million cones and 125 million rods vary in their distribution in the human retina. There are no rods in the fovea, which contains the densest concentration of cones. 5° beyond the fovea the cone density falls to a low level, the rapidly increasing rod density reaches its maximum 10° to 20° from the fovea. The night visual field is characterised by a central scotoma, and maximum sensitivity to dimly illuminated objects is obtained 15° from the point of fixation (off centre of vision). An individual passing from daylight to a dark room at first sees nothing, gradually his vision gets dark adapted. Maximum rod sensitivity is reached after 30 to 35 min in the dark. Since the rods are relatively insensitive to red light, a stay for a similar period in dim red light has the same effect. Exposure of the dark adapted eye to bright light results in a fall in its sensitivity in direct proportion to the intensity of the light and duration of the exposure. Vitamin 'A' is an essential link in the formation of visual purple and hence its deficiency results in poor night vision. Hypoxia has an adverse effect reducing the retinal sensitivity to a marked degree. Alcohol and smoking have a similar effect by affecting utilization of oxygen.

Precautions

The following precautions should be taken to maintain good night vision in flight :

(a) The natural ability for dark adaptation of an individual selected. Night vision should be tested while selecting personnel.

(b) Preflight adaptation with red goggles or dim red light for half an hour.

(c) The use of oxygen from ground on all night flights.

(d) The avoidance of alcohol and tobacco for 12 h prior to night flying.

(e) The practice of 'off centre' viewing of dim objects on dark nights.

(f) The use of a systematic scanning technique.

(g) Keeping windscreens and canopies scrupulously clean.

(h) Preserving dark adaptation in flight by avoiding bright light and using only red lights in the cockpit.

(j) Staring at isolated points of light at night to be avoided.

(k) An optimum intake of vitamins should be ensured for dark adaptation.

## Liquid Oxygen System (LOX)

LOX is a cryogenic liquid which has a boiling point of -183˚C. One litre LOX = 840 Lt of oxygen in gas phase = 1.13 kg (2.527 lb). It is light blue in colour, odourless, tasteless and promotes ignition. LOX is stored in a special double walled high vacuum container and is being provided in lieu of gaseous oxygen in some of the modern aircraft because of the space and weight penalty imposed by gaseous oxygen.

The system is in use in some of the Indian aircraft viz. Jaguars, Mirage 2000 and under trials in LCA. LOX is associated with hazards mentioned below

**(a) Fire Hazard**

Fig. 11 - Liquid Oxygen System (LOX)

No oil, grease, kerosene, wood or paint should be allowed to come in contact with LOX. Its mixture with powdered organic or inorganic materials is likely to explode.

**(b) Volume Change during Vaporization**

LOX contained in the vessel vaporizes by gaining heat from the surroundings with a large change in volume. It is, therefore, dangerous for a container to be completely sealed since it would explode as the volume increases.

**(c) Effects of low Temperature**

LOX causes freezing and destruction of tissues whenever it comes in contact. There is, however, no pain until thawing occurs. Parts of skin coming in contact with the uninsulated pipes may be torn off due to freezing of moisture of the skin as it comes in contact with the pipe, may cause it to get glued to the metal of the pipe. Inhalation of cold gas may produce discomfort. Eyes may be damaged because of the cold gas coming in contact with it.

**Protective measures**

(a) Avoid contact with skin. On spillage, LOX spreads over large areas. One must stand clear of the spilled fluid.

(b) LOX should be kept in well-ventilated open space.

(c) Dry leather gloves should be worn while handling LOX. Eyes should be protected with a face shield while handling.

(d) Overalls should be donned while handling and should have no turn ups and pockets. No watches, rings or bangles should be worn while handling LOX.

(e) First Aid

(i) Remove all tight clothing.

(ii) Place the affected part in a water bath at 42˚ to 45˚C and NOT dry heat. In case of extensive exposure, the whole body may be immersed in a warm water bath.

(iii) Thawing should be done gradually because it will lead to pain. Morphine may be given for pain.

(iv) Cover the part with a dry sterile dressing.

(v) Administer Tetanus toxoid booster.

(vi) Patient should avoid alcohol or smoking.

(f) Shock should be treated if it arises.

## LASERS in Aviation

LASERS are used primarily in target acquisition, ranging, and aiming, and so far are not primarily antipersonnel or anti-material weapons. However, they may be employed to dazzle or flash blind, and therefore, of course, frustrate the pilot's attempt to zero in on a target. Since there are very many LASER wavelengths, no protective eye wear (that can be seen through) can protect against all types.

In some ways, LASER exposure is similar to ordinary light, indirect exposure to bright sunshine is of course harmless, but looking directly at the sun magnifies its power 10, 000 times and will catastrophically burn its focal point, the macula, in only a few seconds. For this reason, visible wave length LASER (400-700 nanometers)

is the most dangerous to eyes. Also, near infra-red wave lengths still focus on the retina and are used in many target designators.

#### Ophthalmology

The current laser protective goggles are a compromise and protect against the most commonly used wavelengths. Serious eye (or even bodily) injury at present is a problem mostly in accidental exposure to personnel working with LASER and at very close ranges.

Evaluation of LASER eye injuries follows standard procedures for any eye examination. "Treatment" of LASER eye injuries is basically triage since there is no specific therapy for most retinal injuries and the eyelid and corneal injuries are treated like any other burn.

## Problems in Missile Bases

Missiles are playing a vital role in many spheres of tactics and defence strategy. A number of toxicological problems are, however, associated with missiles. Special chemicals are used for missile propulsion because extremely high speeds have to be attained within a very short period. Some of these chemicals are highly toxic to human beings, animals and plants and cause air, water and soil pollution.

The dangers from missile operations are due to exhaust gases originating from solid propellants like carbon monoxide, sulphur dioxide, hydrogen sulphide, hydrogen chloride, and from liquid propellants like carbon dioxide, nitrogen dioxide, nitric oxide. Nitrogen tetraoxide and unsymmetrical dimethyl hydrazine (UDMH). The toxic hazard arises mainly from missile maintenance procedures and missile operational procedures. Fuel handlers, missile maintenance personnel and the launch crew are exposed to the maximum risk of exposure, which occurs through inhalation, ingestion and direct contact with skin and eyes. The chemical composition of fuels, oxidizers and propellants used in missiles is classified information but it must be remembered that oxidizers are extremely poisonous substances and may cause severe burn on the skin and eyes. Toxicity may occur through their inhalation also. Fuel also is a strong poison. Their inhalation or spillage on body may lead to toxic manifestations and burns. These manifestations may be headache, cardiac asthenia, haematological changes, central nervous system disorders, irritation of lungs and eyes. Other chemicals used in maintenance of missiles are alcohol, spirit, petrol, carbon tetrachloride, grease etc. and cause irritation of eyes, aplastic type of anaemia and central nervous system disorders.

During missile operation, the missile is placed on the launcher for firing which is remotely controlled. Cordite, which is the main explosive of first stage, leaves hardly any smoke. In the absence of smoke, an unwary victim may consider the launching site as harmless, though it leaves behind numerous toxic exhaust gases like carbon monoxide, hydrogen suphide, hydrogen chloride, carbon dioxide, nitrogen dioxide, nitric oxide etc. These gases remain suspended in the air and may pose a toxic hazard.

#### Safety Precautions

(a) Because of the fuming and corrosive properties of fuels, special suits have been designed for personnel handling the equipment. They are covered from top to bottom. Breathing is done through oxygen masks and cylinders carried on the backs. Gloves and boots are provided as a safeguard against spillage of fuels.

(b) A quarterly medical check up is carried out for all fuel handlers. Apart from general examination, haemoglobin estimation, blood cell count and ESR are carried out. Each handler is given 1lt of milk daily.

(c) Treatment is carried out immediately. Thorough wash is given by clean water. Sodium bicarbonate or soap solution is then poured over the affected area and covered with sterile cotton wool and gauze. Patient is transferred to an airy room and all his tight garments loosened. Oxygen inhalation is administered in serious cases.

## Effects of Noxious Gases & Vapour in an Aircraft

Contamination of the atmosphere in the cockpit of an aircraft may result from exhaust gases, fire extinguishing agents, acrolein, aldehydes and vapours of gasoline, hydraulic fluid, coolant etc.

#### Exhaust Gases

The composition of exhaust gases varies according to the grade of aviation fuel and the fuel to air ratio of the engine. Of the various exhaust gases, carbon monoxide, methane and hydrogen sulphide result from incomplete combustion of the fuel. An increasing completeness of the combustion with the optimum fuel to air ratio increases the percentage of relatively nontoxic carbon dioxide in the exhaust gases with a corresponding decline in the percentage of carbon monoxide but as the mixture becomes richer, the carbon monoxide content of the exhaust gas increases. Single engine aircraft with its engine directly in front of the fuselage are subject to greater contamination than the multi engine aircraft with laterally situated engines. Liquid cooled single engine aircraft are more likely to be contaminated by exhaust gases than air cooled radial engine ones. Aircrafts which are originally free from contamination or with only slight amount of carbon monoxide detected at the initial test may allow leakage due to deterioration from wear and tear or as a result of structural modifications introduced while in service. Periodical tests will reveal such contamination and serve as a check on the adequacy of the maintenance service.

The maximum permissible concentration of carbon monoxide (CO) in flight in the cockpit is 0.005%. When flying personnel suspect the presence of CO in the aircraft, either because of the odour of the exhaust fumes or because of untoward symptoms such as headache, nausea, dizziness or dimness of vision they should turn off exhaust heaters if in use and wear oxygen masks and breath 100% oxygen so as to avoid breathing cockpit air. When xylidine containing aviation fuel is used, the oxides of nitrogen appear in exhaust gas. The oxides of nitrogen are more toxic than carbon monoxide. Oxides of nitrogen

are present in much lower concentration in exhaust gas than carbon monoxide. Thus, if carbon monoxide pollution is controlled, protection against the oxides of nitrogen will automatically be afforded.

**Gasoline Vapours**

(a) Aviation gasoline is a complex fuel consisting of a mixture of aliphatic and aromatic petroleum hydrocarbons and special additives such as tetraethyl lead and tricrasyl in varying proportions. The maximal safe concentration for exposure to vapour of ordinary gasoline is about 500 parts per million or 0.05%. The symptoms and pathological changes induced by gasoline are caused by its irritant and lipolytic actions. The action of the volatile aliphatic saturated hydrocarbons is essentially physio-chemical. These compounds are highly soluble in fat and are absorbed particularly in the lipid constituents of the nervous system and the blood corpuscles, where they exert their detrimental effects. Acute poisoning is marked by burning of eyes and lacrimation and severe cerebral manifestations such as restlessness, excitement, disorientation, disorders of speech, vision and hearing followed by convulsions, coma and death.

(b) Tetraethyl lead - Tetraethyl lead is fairly volatile and hence absorbed through the pulmonary epithelium. Absorption of toxic amounts is followed by a prodromal period of 2 to 8 days, after which various neurological manifestations such as general weakness, muscular disturbances, various sensory abnormalities, and psychiatric aberrations appear. The permissible amount of tetraethyl lead in the various specification of aviation fuel is insufficient to produce harmful effects through the inhalation of gasoline vapours. The hazards of lead poisoning occur only under special conditions of handling the fuel where gross spillage occurs in confined storage places.

**Hydraulic Fluid Vapour**

A small leak from a hydraulic pipe or gauge under pressure produces a fine spray of fluid, which spreads quickly, or large leaks may produce a pool of liquid on the floor and the cockpit air attains a high degree of concentration of the volatile constituents of the hydraulic fluid. Hydraulic fluids with petroleum base and castor oil base are at present used for the aircraft hydraulic system, the gear shock struts, the auto pilot and the shimmy damper. In several models both fluids are used for different parts. The former type of fluid contains the mineral oil and a viscosity index polymer, both of relatively low volatility, and their vapours possess low toxicity. The later type of fluid contains diacetone, butylcellosolve, ethylene and propylene glycol and octyl and isoamyl alcohols in varying proportions. The volatile constituents, especially butylcellosolve, the glycol derivatives and the alcohols, are toxic when inhaled. The alcohols, for example, are about 12 times as potent a narcotic as ethyl alcohol. In addition, they cause considerable irritation of eyes and respiratory tract as well as headache and vertigo. Butylcellosolve vapours cause irritation and impairment of judgement and vision. The toxic effects are accentuated by high temperature and altitude.

**Vapours from Fluid, Fire Extinguishing Agents, Acrolein and Aldehydes**

(a) Coolant Fluid

Coolant fluid, for use in liquid cooled engines, consists of ethylene glycol diluted with varying amounts of water. Ethylene glycol is toxic when ingested. Although it is fairly volatile, it does not exert any important toxic effects through inhalation of its vapour, and no instances of in flight intoxication by coolant fluid vapours have been reported.

(b) Fire Extinguishing Agents

The following compounds have been used as fire extinguishing agents

**(i) Carbon Tetrachloride**

This was the first vapourising liquid used for extinguishing fires. The chief danger lies in breakdown to phosgene gas, which is highly toxic, anaesthetic and a liver poison. It is rarely used these days.

**(ii) Carbon Dioxide**

This is the extinguishing agent used in 'Carbon Dioxide Extinguisher', 'Dry Chemical Extinguisher' and 'Gas Cartridge Extinguisher'. In a confined space carbon dioxide released under pressure may cause a feeling of suffocation, narcosis, elevated blood pressure and collapse with death. Direct contact of the skin with carbon dioxide 'snow' may produce severe skin burn. The carbon dioxide extinguishers are not commonly used because of high weight penalty.

**(iii) Soda Acid Extinguisher and Foam Extinguisher**

These are less toxic agents. Compressed carbon dioxide acts as a propellant in these extinguishers. In the former, sodium sulphate solution is sprayed whilst in the latter, extinguisher foam from the combination of sodium bicarbonate, water, ferric chloride and aluminium sulphate is produced.

**(iv) Methyl Bromide**

This is most effective although toxic. It produces vesication of skin and by absorption through lungs can produce a wide range of CNS symptoms. In mild cases the onset is usually delayed. Fatal cases are primarily due to pulmonary oedema.

**(v) Acrolein and Other Aldehydes**

These are the breakdown products of lubricating oils. May be present in varying quantities in exhaust gases. These can also be produced by oil leaks on to hot surfaces and fire. 5 ppm gives rise to irritation of the eyes and upper respiratory tract. Presence of these vapours usually indicates that CO may also be present.

**Flying Fatigue and Long Duration Flying**

Nervous exhaustion caused by the cumulative effects of daily fatigue results in a progressive drain of total energy. Over a period of days, sleep becomes less refreshing and the aircrew feels unfit to work which may further lead to other psychological symptoms. In aviation, there are various factors at work which cause fatigue, e. g. stress of taking off and landing at high speed, the mental anxiety of night flying or flying through cloud and fog and the discomfort of a confined and cramped position. The vitality is lowered through cold draughts, the effects of noise on the auditory nerve, hypoxia at high altitudes and the injurious effects of carbon monoxide fumes contaminating the cockpit or the cabin atmosphere. Preventive measures to combat these fatigue producing factors are summarized below :

(a) Auto pilots, artificial horizon, aerial compass, wireless and Night Vision Goggles have done much to simplify night and blind flying.

(b) Attention to the design and positioning of seats have overcome cramping to some extent.

(c) Air conditioning, though it can provide an agreeable temperature in all climates without draught, yet owing to undesirable extra weight has not been found generally practicable in all service machines.

(d) Electrically heated flying clothing are recommended for conditions of extreme cold. An air-ventilated suit for use under extreme tropical conditions has been in use in some aircrafts.

(e) Sound proofing in airliners and the provision of special air pads in service machines, as already described, have materially overcome the noise factor.

(f) Oxygen is provided to counteract hypoxia.

(g) Attention to the positioning of the exhaust has done much to overcome the fume nuisance. However, the occurrence of a persistent headache not relieved by aspirin demands a close investigation for the possibility of carbon monoxide poisoning of a mild degree.

## Spatial Disorientation

Spatial disorientation is a term used to describe a variety of incidents occurring in flight in which the pilot fails to sense correctly the position, motion or attitude of the aircraft or of him or herself within the fixed coordinate system provided by the surface of the earth and the gravitational vertical. A disorientated pilot is thus uncertain or unaware of his position or the attitude of his aircraft. In flight, the problem of disorientation is much greater than it is on the ground. Here the man does not have physical contact with the ground to orientate himself. Moreover, the aircraft operates on its own power independently of the force and direction of gravity and thus can create sensory confusion leading to disorientation.

The factors which aggravate disorientation are :

(a) Fatigue

(b) Inexperience

(c) Hypoxia, cold, alcohol and drugs

(d) Emotional stress

(e) Lack of visual cues viz. cloud flying, night flying etc.

(f) Changeover from visual to instrumental flying and vice versa

(g) Violent maneuvers

(h) Diseases of vestibular system

### Operational Significance

The following measures adopted safeguard the aircrew from the effects of spatial disorientation :

(a) Selection

Candidates selected must have no vestibular disability which may aggravate or predispose to disorientation in flight.

(b) Indoctrination and training

The most obvious safeguard against the disturbing effects of disorientation is absolute reliance on instruments. Understanding why it occurs, respecting its existence as a hazard, coupled with explicit faith in instruments will always overcome its disabling effects.

(c) Instrument Flying Practice

To have faith in instruments one must be in constant practice It is more so after being on ground for some time e. g. after a prolong desk job, medical grounding for sometime or after leave.

## Specific Hazards in IAF

### Escape from Aircraft

There is a continuing requirement for medical personnel in aviation to be knowledgeable about aircraft escape systems. Squadron Medical Officers have multiple responsibilities in this regard. First, a Squadron Medical Officer must understand the operation of escape systems. A Squadron Medical Officer must be prepared to answer queries concerning biomedical aspects of escape. The second responsibility of a Squadron Medical Officer is to have a clear understanding of ejection, crash landing, ditching, and bailout dynamics in order to properly diagnose and treat the injuries that are likely to be received by an aircrew. An aviator who is suddenly propelled into a windblast of several hundred knots or is involved in a crash can be subjected to unusual and very damaging compression and torsion forces. When a rescued aviator is returned to a carrier or medical facility, the Squadron Medical Officer must be able to recognize the injury or possible injury immediately and deal with it effectively.

### Crew Resource Management (CRM)

Crew Resource Management training has been developed in response to growing evidence that interpersonal factors contributed to a substantial proportion of aviation accidents (Cooper et al 1980). This type of training originally called 'Cockpit Resource Management' is now used widely and indeed is mandated by many aviation regulatory authorities. CRM is application of human

factors in the aviation system. John K Lanber, a psychologist member of National Transportation Safety Board (NTSB) has defined CRM as **"using all available resources information, equipment and people to achieve efficient, effective and safe flight operations".** CRM includes optimizing not only the person machine interface and the acquisition of timely appropriate information but also interpersonal activities including leadership, effective team formation and maintenance, problem solving, decision making and maintaining situational awareness. Thus, training in CRM involves communicating basic knowledge of human factors concept that relate to aviation and providing the tools necessary to apply these concepts operationally. A typical CRM program begins with a seminar that provides background in group dynamics, the nature of human error and the issues that arise when people work with machines. Members of a cockpit crew are asked to review accident case studies that highlight the importance of the interactions among the crew members. CRM has expanded the use of simulator as a training tool. Initially, simulators were employed only to evaluate and teach pilots flying skill. Today they enable crew to test themselves in tackling complex problems ranging from bad weather to mechanical failures that cannot be resolved by simply following a procedure outlined in the flight manual.

### Night Vision Goggles

Night vision goggles (NVG's) are designed to electronically amplify moonlight and starlight to display images on a small video screen mounted within the apparatus. Images produced by NVG's are elicited by photons striking a photocathode, which in turn causes a release of electrons within an adjacent micro channel plate. An electric field then guides the electrons to a phosphor screen which produces an amplified light image. The image produced is green, which disallows for any color discrimination of objects. A clamp voltage mechanism is present to protect against excessively bright light sources (search lights, flares, flashlights, lasers, etc).

### Aircraft Accident Investigation

The requirement for a Squadron Medical Officer to participate in the deliberations of an Aircraft Mishap Board is contained in the IAP-4305.Aircraft Accident Investigations elaborates on the various duties of the Squadron Medical Officer as a member of this board. There is a requirement that the Aircraft Mishap Board and the Squadron Medical Officer work together and address issues that may arise during accident investigations and which may be of significance. The Aircraft Accident Report and the Squadron Medical Officer's Report must be complementary. This does not mean that they must say the same thing. It is interpreted to mean that the same issues must be treated and evidence must be presented that the two sides have communicated on medical issues of significance and that each has developed its position addressing that problem.

### Women in Aviation

The changing roles for women within most societies have caused military planners to consider an expanded occupational potential for women in the military.

Anthropometric selection screens out individuals who are incompatible with the workspaces they occupy and with equipment they work. Potential female pilots should meet the present male crew entry standards. Each pilot should be able to meet the operational requirement for reach, vision and clearance for configuration of seat and rudder pedals. This is 'fitting pilot with cockpit' and this cannot be avoided as long as differences in crew station geometry are prevalent. Four anthropometric dimensions that are critical for selection are stature, sitting height, thigh length and leg length. Sitting height is selected due to its influence on head clearance. Thigh length is chosen because of its clearance with seat pan and main instrument panel. Leg length was chosen because of its influence on reach to rudder pedals. Accommodation assessments are based on aircraft requirements for head clearance, leg reach and clearance. Weight measurements are also taken to study the ejection seat occupant weight limitations and to lay the minimum weight criteria for all types of ejection seats.

Anthropometric criteria that must be satisfied for current

Table - 8 : Anthropometric Criteria for Fitness

| Parameters | Minimum value (cm) | Maximum value (cm) |
|---|---|---|
| Height | 162.5 | ..... |
| Sitting Height | 81.5 | 96.0 |
| Leg Length | 99.0 | 120.0 |
| Thigh Length | ---- | 64.0 |

IAF aircrew are listed in Table - 8.

#### Harness System

Breast anatomy imposes aero medical limitations that are amenable to properly fitting equipment. For example care needs to be taken when fitting the parachute harness. The harness can rise from 10 to 20 cm as a result of compressing the buttocks during opening shock and can cause breast injury if the straps are adjusted below the breasts. However, women under going G stress testing in the centrifuge have reported no breast discomfort.

#### Other Ergonomic Problems

a) The initial entry Standing Height requirement for flying duty officers is 162.5 cm and for ground duty lady officers is 142 cm.

b) While working on Air Traffic Controls, sitting height shorter than 80 cm may find inadequate panel vision.

c) About 50% of females below 150 cm height have lower popliteal height than 39 cm, which is the standard minimum height at the seat of an office chair. While shoes render some compensation, the

prolonged sitting in the chair may lead to postural discomfort.

(d) **Menstrual Cycle :** IAM carried out a project on female pilots and performance with regards to Pre Menstrual Syndrome. The observations are -

(i) Indian women pilots are affected by pre menstrual symptoms two days prior to menstruation with abdominal pain, a feeling of tiredness and backaches.

(ii) There is no demonstrable reduction in performance but some did report sick during menstrual cycle.

(e) **'G' Tolerance**

(i) Tolerance to 'G' was tested in the Human Centrifuge at IAM. The subjects did not wear anti G-suit.

(ii) The subjects were given ROR runs at I G per second and the peak G was maintained for 15 seconds. Thereafter the subjects after a period of relaxation were given GOR run at 0.I G per second. These runs were given until PLL was noticed.

(iii) The study showed that relaxed G tolerance of Indian females is at par with their male peers, and acceleration tolerance need not be a concern for induction into fighter fleet (AR&DB 802).

(f) **Tolerance To Hypoxia**

(i) This study was carried at the Altitude Chamber at IAM. The physiological parameters recorded were arterial oxygen saturation, pulse rate, respiratory rate, minute expiratory volume and end tidal carbon dioxide. These were recorded at ground level, 15, 000 ft, and 18, 000 ft.

(ii) The physiological changes on induction to high altitude seen in Indian females had no significant variation seen in males.

(g) **Psychological Factors** : Female and male individuals are expected to react differently in most situations. Based on this theory, Hamburg Testing Center in Germany carried out a study on 'Sex Difference Concerning Performance and Personality Trait'. It identified differences in Technical Comprehension, Spatial Orientation and to minor degree in Mathematical Reasoning between both sexes. Mastery in technology was seen more with men. However, it was observed that gender differences in Spatial Orientation have decreased during the last decade.

## Sanitation in Flight

The following are some of the important measures

### (a) Water Supply

The ultimate responsibility for the water supply lies with the commander of the aircraft. But it is the duty of the medical officer to satisfy himself that safe drinking water is supplied. Adequate supply of safe water should be arranged as per the nature of flight and type of aircraft. Special attention should be paid to the containers and provision should be made for their periodical cleaning and sterilization.

### (b) Food

It is undesirable to arrange cooking during flight in military aircraft. Food ready for consumption is carried in the aircraft for the crew and passengers. Necessary provision for supplying a hot meal should be made for flights of long duration. Food to be consumed during the flight should preferably be light with a high energy value.

### (c) Disinfection of catering equipment and utensils

All portable food transportation equipment, food contact surfaces such as shelves, tables, cutting boards, meat blocks, refrigerators, stoves, hoods, ray racks, including all “multi-used” eating and drinking utensils, should be kept clean and free from dust, dirt and other contaminating material. After a thorough washing, best sanitization treatment is a final fresh water rinse at a temperature of at least 85˚C (185˚F) for at least 30 seconds.

### (d) Emergency Rations

All aircrew carry their emergency flying rations along with other survival equipment. The emergency rations are packed in airtight containers. The medical officer should inspect regularly these rations for their fitness for consumption and life period of food contents.

### (e) Disposal of Wastes

Smaller aircrafts are fitted with a rubber relief tube for disposal of urine. Larger aircrafts are provided with a commode, which should contain a small quantity of 5% solution of cresol. After landing, the accumulated contents should be disposed off and lavatories must be cleaned with 5% cresol solution and replaced in the aircraft. For collection of vomit and spit, paper or suitable bags should be provided which should be properly disposed off after landing.

### (f) Ventilation problems of Aircraft

The main criterion is the removal of body odour. It is recommended that air velocities be confined to 20-60 ft/min and that special attention be given to the distribution of air to prevent draughts or dead air space in any part of the cabin. The amount of fresh air supplied should be at least 35-40 $ft^3$ ($1m^3$) /min considering that the net air space per person will generally be 100 $ft^3$ ($3m^3$) or less. In pressurized cabins when it is necessary to re-circulate the air, the entire ventilating system should be flushed with fresh air as frequently as possible.

## Disinfection

Disinfection of aircraft is carried out as per the International Regulations laid down. These are given in the Government of India's “Indian Aircraft Manual 1964” as Schedule VI, Chapter IV, Part II. The procedures are as follows :

### (a) Disinfection of Aircraft

The airport health authorities should be consulted when a case of infectious disease has been carried aboard an aircraft. On the rare occasions when this occurs, the notification may arrive several days after the infected person has traveled by which time the aircraft will probably have departed and carried several hundred of passengers on a number of flights. Under these circumstances disinfection may not be practicable or useful.

It is because of this eventuality that the regular use of an efficient bactericide (as already mentioned) in the daily cleaning routine of aircraft interiors and the incorporation of a bactericide in the chemicals added to aircraft toilets are important procedures, ensuring that the aircraft has at least received some form of disinfection. Should an infectious disease be diagnosed either during the flight or immediately on arrival, and before the aircraft departs again, disinfection may be of value.

The method and materials used will depend on the nature of the infectious disease, as well as on the recommendations of the health authority that is responsible for requesting the disinfection. The disinfectants most commonly employed are sodium hypochlorite diluted to strength of 100 mg/l and a 5% solution of formalin, which itself is a 40% solution of formaldehyde gas in water. The spraying can be done with a hand pump, knapsack sprayer or stirrup pump. The nozzle tip should be capable of producing a flat fan spray of a uniform pattern with a spray angle of 60˚. The size of the nozzle should be 0.4 mm. All removable articles should be disinfected in the usual way.

Sodium hypochlorite is often used when disinfecting aircraft after the carriage of a person infected with a food- or waterborne disease such as cholera. Personnel (wearing waterproof gloves) should swab the following areas with the sodium hypochlorite solution, which should remain in contact with these surfaces for 30 minutes before they are rinsed with warm water and dried to remove any residual chlorine:

(i) All surfaces in the toilet compartment.

(ii) All surfaces and food containers in the galley.

(iii) All meal tables, seat armrests and ashtrays in the cabin.

The aircraft water system should be completely drained into a specially allocated toilet cart and discharged into the sewerage system. The aircraft water system should then be treated with hypochlorite.The toilet system should be drained and flushed in the normal way, but before servicing in the usual manner, chemical fluid containing a bactericide should be allowed to stand in the toilet system for at least 2 hours.

The fabric covers of the seat in which the infected person sat, and those of the seats in the row in front and the row behind should be removed, soaked in the disinfectant solution for 1 hour and, after air drying, sent for dry cleaning, suitably marked. As this situation occurs so rarely, and the resulting cost is insignificant, it would be a sensible alternative simply to destroy the covers by incineration. The remaining seats and carpets should be vacuum-cleaned and the dust incinerated.

All hard surfaces, including those mentioned above (already treated with sodium hypochlorite), should be swabbed with the formalin solution, which, after 30 minutes' contact, should then be rinsed away with warm water. (The personnel engaged in this work should wear not only water proof gloves but face masks in addition)

Special needs

There are occasions when special action is needed during flight - for example, when seats or carpets are soiled by a sick passenger. This sickness might be the result of an infection, and part from the nuisance caused to other passengers-there might be a health hazard. Since a major cleaning, involving the replacement of soiled seat covers cannot be undertaken until arrival at the next airport, the cabin crew should be supplied with material for use in such an emergency. Aerosol dispensers containing a detergent/bactericide/odour-counteragent will satisfactorily deal with the problem until more effective action can be taken on the ground. In cases where a special cleaning will be needed on arrival, a radio message should be sent so that arrangements can be made beforehand and delays prevented.

The methods used by some airlines to decontaminate surfaces in the case of a spill or leakage of etiological agents (infectious substances) include the following:

(i) The use of carboxide (a mixture of 10% ethylene oxide and 90% carbon dioxide), which needs to be applied at the rate of 136 kg for every 28$m^3$ of space (300 1b/1000 ft).The temperature in the aircraft must before than 21$^oC$ (70$^oF$) and the relative humidity 30%. The aircraft is sealed and the gas admitted through plastic or copper tubing with perforated holes along its length, until a cabin pressure of 48kPa (71bf/$in^2$) is obtained. This pressure should be maintained for 6-12 hours.

(ii) A mixture of ethylene oxide and Freon II can also be used at the rate of 68 kg for every 28 $m^3$ of space (150 1b/1000 $ft^3$).

(iii) A third method is the introduction of betapropiolactone in vapour form at the rate of 4.5 l for every 700 $m^3$ of space (1.2 gal (US), 1 gal (UK)/25000$ft^3$). For this, relative humidity must be over 70% and temperature 21$^oC$ (70$^oF$). Exposure time is e hours, and the aircraft can return to service after a further 2 hours, since the vapour is rapidly dispersed. Betapropiolactone must be 98% pure, otherwise a polymer will form a settle on surfaces as a sticky coating that is difficult to remove.

When any of the above three ingredients is used, disinfecting should be carried out only by trained personnel.

**(b) Procedure of Disinfestation of Aircraft**

The interior of the aircraft (inclusive of all places likely to harbour mosquitoes such as cockpits, freight compartments, cabins) should be sprayed with a

pyrethrum, DDT aerosol containing not less than 0.4% pyrethrum and 3% DDT, at the rate of not less than 8 to 10 seconds per 30 cubic meter (1000ft$^3$) of free air space. The stop cock in the case of an aerosol dispenser other than the Westing House type being kept open not less than half a turn during the operation and in the Westing House type the cap being removed completely. All opening into the aircraft shall be kept tightly closed during spraying and for a period of not less than five min thereafter.

## International Health Regulations

The fifty eighth World Health Assembly ratified the revised Health Regulations 2005 which have since been adopted by India. The following information relevant for international travel is extracted from the International Health Regulations 2005.(1).

### Definitions

**Affected** : means persons, baggage, cargo, containers, conveyances, goods, postal parcels or human remains that are infected or contaminated, or carry sources of infection or contamination, so as to constitute a public health risk;

**Affected area** : means a geographical location specifically for which health measures have been recommended by WHO under the International Health Regulations 2005.

**Aircraft** : means an aircraft making an international voyage

**Airport** : means any airport where international flights arrive or depart

**Arrival of a conveyance means :**

(a) In the case of a seagoing vessel, arrival or anchoring in the defined area of a port

(b) In the case of an aircraft, arrival at an airport.

(c) In the case of an inland navigation vessel on an international voyage, arrival at a point of entry.

(d) In the case of a train or road vehicle, arrival at a point of entry

**Competent authority** : means an authority responsible for the implementation and application of health measures under the International Health Regulations 2005.

**Container :** means an article of transport equipment

(a) Of a permanent character and accordingly strong enough to be suitable for repeated use.

(b) Specially designed to facilitate the carriage of goods by one or more modes of transport, without intermediate reloading

(c) Fitted with devices permitting its ready handling, particularly its transfer from one mode of transport to another.

(d) Specially designed as to be easy to fill and empty.

**Contamination** : means the presence of an infectious or toxic agent or matter on a human or animal body surface, in or on a product prepared for consumption or on other inanimate objects, including conveyances, that may constitute a public health risk. ("conveyance" means an aircraft, ship, train, road vehicle or other means of transport on an international voyage)

**Conveyance operator :** means a natural or legal person in charge of a conveyance or their agent.

**Crew** : means persons on board a conveyance who are not passengers.

**Decontamination** : means a procedure whereby health measures are taken to eliminate an infectious or toxic agent or matter on a human or animal body surface, in or on a product prepared for consumption or on other inanimate objects, including conveyances that may constitute a public health risk.

**Departure** : means, for persons, baggage, cargo, conveyances or goods, the act of leaving a territory.

**Deratting** : means the procedure whereby health measures are taken to control or kill rodent vectors of human disease present in baggage, cargo, containers, conveyances, facilities, goods and postal parcels at the point of entry.

**Disease** : means an illness or medical condition, irrespective of origin or source, that presents or could present significant harm to humans.

**Disinfection** : means the procedure whereby health measures are taken to control or kill infectious agents on a human or animal body surface or in or on baggage, cargo, containers, conveyances, goods and postal parcels by direct exposure to chemical or physical agents.

**Disinsection** : means the procedure whereby health measures are taken to control or kill the insect vectors of human diseases present in baggage, cargo, containers, conveyances, goods and postal parcels.

**Health** : measure means procedures applied to prevent the spread of disease or contamination; ahealth measure does not include law enforcement or security measures

**Ill person** : means an individual suffering from or affected with a physical ailment that may pose a public health risk.

**Infection** : means the entry and development or multiplication of an infectious agent in the body of humans and animals that may constitute a public health risk.

**International voyage** : means

(a) In the case of a conveyance, a voyage between points of entry in the territories of more than one State, or a voyage between points of entry in the territory or territories of the same State if the conveyance has contacts with the territory of any other State on its voyage but only as regards those contacts.

(b) In the case of a traveller, a voyage involving entry into the territory of a State other than the territory of the State in which that traveller commences the voyage.

**Isolation** : means separation of ill or contaminated persons or affected baggage, containers, conveyances, goods or postal parcels from others in such a manner as to prevent the spread of infection or contamination

**Medical examination** : means the preliminary assessment of a person by an authorized health worker or by a person under the direct supervision of the competent authority, to determine the person's health status and potential public health risk to others, and may include the scrutiny of health documents, and a physical examination when justified by the circumstances of the individual case.

**Public health emergency of international concern** : means an extraordinary event which is determined, as provided the International Health Regulations 2005:

(a) To constitute a public health risk to other States through the international spread of disease and

(b) To potentially require a coordinated international response;

**Public health risk** : means a likelihood of an event that may affect adversely the health of human populations, with an emphasis on one which may spread internationally or may present a serious and direct danger.

**Quarantine :** means the restriction of activities and/or separation from others of suspect persons who are not ill or of suspect baggage, containers, conveyances or goods in such a manner as to prevent the possible spread of infection or contamination.

**Surveillance** : means the systematic ongoing collection, collation and analysis of data for public health purposes and the timely dissemination of public health information for assessment and public health response as necessary.

**Responsible authorities**

Each State Party shall designate or establish a National IHR Focal Point and the authorities responsible within its respective jurisdiction for the implementation of health measures under these Regulations. The National IHR Focal Points shall be accessible at all times for communications with the WHO. The functions of National IHR Focal Points shall include:

(a) Sending to WHO IHR Contact Points, on behalf of the State Party concerned, urgent communications concerning the implementation of these Regulations.

(b) Disseminating information to, and consolidating input from, relevant sectors of the administration of the State Party concerned, including those responsible for surveillance and reporting, points of entry, public health services, clinics and hospitals and other government departments.

**Notification**

Each State shall notify WHO, by the most efficient means of communication available, by way of the National IHR Focal Point, and within 24 hours of assessment

of public health information, of all events which may constitute a public health emergency of international concern within its territory in accordance with the decision instrument, as well as any health measure implemented in response to those events. If the notification received by WHO involves the competency of the International Atomic Energy Agency (IAEA), WHO shall immediately notify the IAEA.

Following a notification, a State shall continue to communicate to WHO timely, accurate and sufficiently detailed public health information available to it on the notified event, where possible including case definitions, laboratory results, source and type of the risk, number of cases and deaths, conditions affecting the spread of the disease and the health measures employed; and report, when necessary, the difficulties faced and support needed in responding to the potential public health emergency of international concern.

Information-sharing during unexpected or unusual public health events

If a State Party has evidence of an unexpected or unusual public health event within its territory, irrespective of origin or source, which may constitute a public health emergency of international concern, it shall provide to WHO all relevant public health information. In such a case, the provisions of notification shall apply in full.

Role of competent authorities

**The competent authorities shall:**

(a) Be responsible for monitoring baggage, cargo, containers, conveyances, goods, postal parcels and human remains departing and arriving from affected areas, so that they are maintained in such a condition that they are free of sources of infection or contamination, including vectors and reservoirs.

(b) Ensure, as far as practicable, that facilities used by travellers at points of entry are maintained in a sanitary condition and are kept free of sources of infection or contamination, including vectors and reservoirs.

(c) Be responsible for the supervision of any deratting, disinfection, disinsection or decontamination of baggage, cargo, containers, conveyances, goods, postal parcels and human remains or sanitary measures for persons, as appropriate under these Regulations.

(d) Advise conveyance operators, as far in advance as possible, of their intent to apply control measures to a conveyance, and shall provide, where available, written information concerning the methods to be employed.

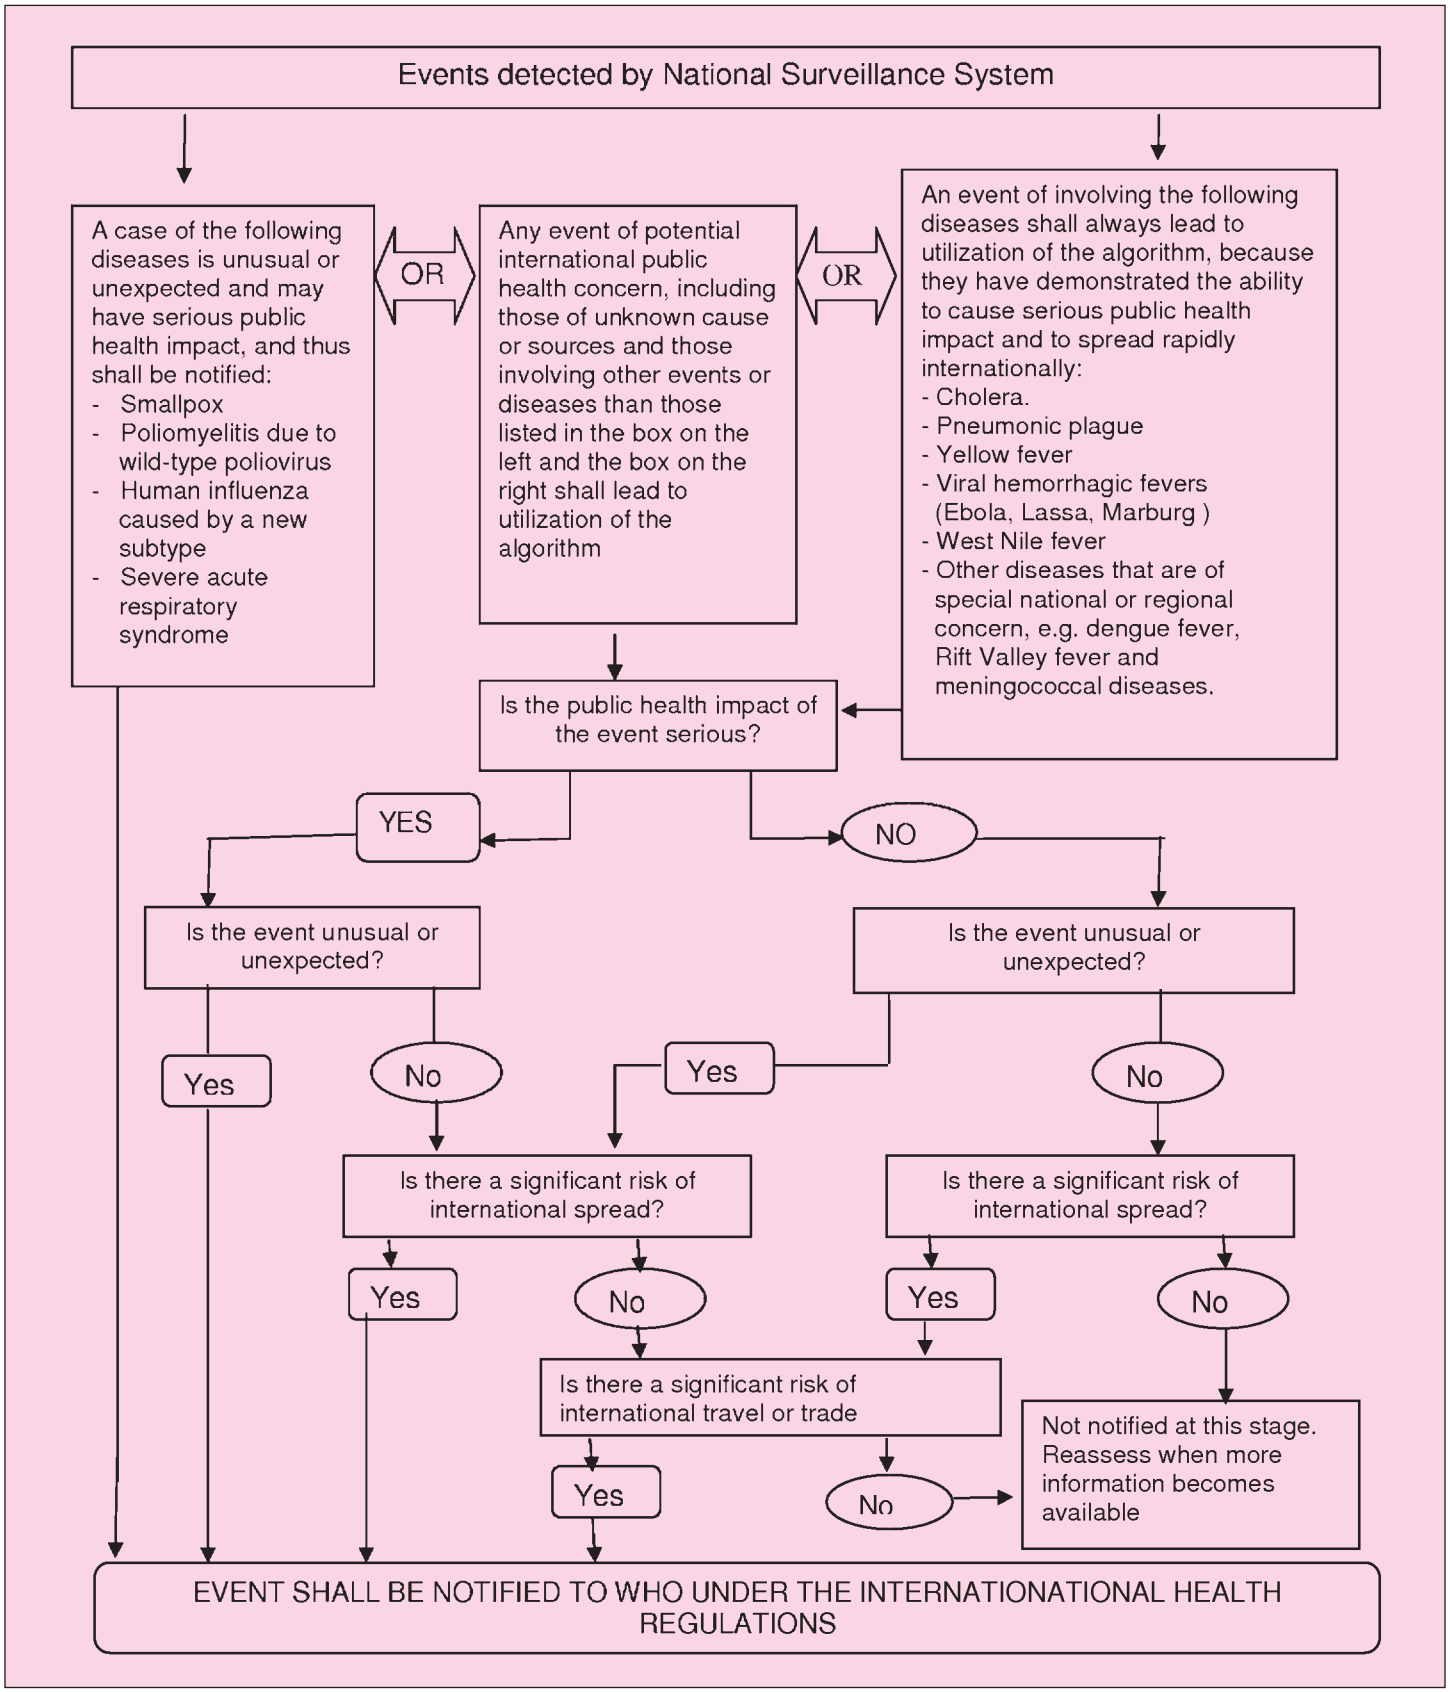
(e) Be responsible for the supervision of the removal and safe disposal of any contaminated water or food, human or animal dejecta, wastewater and any other contaminated matter from a conveyance.

(f) Take all practicable measures consistent with these Regulations to monitor and control the discharge by ships of sewage, refuse, ballast water and other potentially disease-causing matter which might contaminate the waters of a port, river, canal, strait, lake or other international waterway.

(g) Be responsible for supervision of service providers for services concerning travellers, baggage, cargo, containers, conveyances, goods, postal parcels

after each use, and treated in the same manner as portable toilet containers.

Public Health Emergency of International Concern



and human remains at points of entry, including the conduct of inspections and medical examinations as necessary.

(h) Have effective contingency arrangements to deal with an unexpected public health event

(j) Communicate with the National IHR Focal Point on the relevant public health measures taken pursuant to the International Health Regulations 2005.

Health measures recommended by WHO for travellers, baggage, cargo, containers, conveyances, goods, postal parcels and human remains arriving from an affected area may be reapplied on arrival, if there are verifiable indications and/or evidence that the measures applied on departure from the affected area were unsuccessful.

Disinsection, deratting, disinfection, decontamination and other sanitary procedures shall be carried out so as to avoid injury and as far as possible discomfort to persons, or damage to the environment in a way which impacts on public health, or damage to baggage, cargo, containers, conveyances, goods and postal parcels.

**Health measures on arrival and departure**

Subject to applicable international agreements and relevant articles of the International Health Regulations 2005, a State may require for public health purposes, on arrival or departure:

(a) With regard to travellers :

(i) Information concerning the traveller's destination so that the traveller may be contacted.

(ii) Information concerning the traveller's itinerary to ascertain if there was any travel in or near an affected area or other possible contacts with infection or contamination prior to arrival, as well as review of the traveller's health documents if they are required under the International Health Regulations 2005; and/or

(iii) A non-invasive medical examination which is the least intrusive examination that would achieve the public health objective.

(b) Inspection of baggage, cargo, containers, conveyances, goods, postal parcels & human remains.

On the basis of evidence of a public health risk obtained through the measures provided in the previous pragraph, or through other means, States may apply additional health measures, in accordance with the International Health Regulations 2005, in particular, with regard to a suspect or affected traveller, on a case-by-case basis, the least intrusive and invasive medical examination that would achieve the public health objective of preventing the international spread of disease.

No medical examination, vaccination, prophylaxis or health measure under the International Health Regulations 2005 shall be carried out on travellers without their prior express informed consent or that of their parents or guardians, except as provided in paragraph 2 of Article 31, and in accordance with the law and international obligations of the State.

Travellers to be vaccinated or offered prophylaxis pursuant to the International Health Regulations 2005, or their parents or guardians, shall be informed of any risk associated with vaccination or with non-vaccination and with the use or non-use of prophylaxis in accordance with the law and international obligations of the State. States shall inform medical practitioners of these requirements in accordance with the law of the State.

Any medical examination, medical procedure, vaccination or other prophylaxis which involves a risk of disease transmission shall only be performed on, or administered to, a traveller in accordance with established national or international safety guidelines and standards so as to minimize such a risk.

**Requirements Concerning Vaccination or Prophylaxis for Specific Diseases**

Vaccination against yellow fever (2)

Recommendations and requirements for vaccination against yellow fever:

(a) For the purpose of the International Health Regulations 2005:

(i) The incubation period of yellow fever is six days.

(ii) Yellow fever vaccines approved by WHO provide protection against infection starting 10 days following the administration of the vaccine.

(iii) This protection continues for 10 years.

(iv) The validity of a certificate of vaccination against yellow fever shall extend for a period of 10 years, beginning 10 days after the date of vaccination or, in the case of a revaccination within such period of 10 years, from the date of that revaccination.

(b) Vaccination against yellow fever may be required of any traveller leaving an area where the WHO has determined that a risk of yellow fever transmission is present.

(c) If a traveller is in possession of a certificate of vaccination against yellow fever which is not yet valid, the traveller may be permitted to depart, but the provisions of paragraph (g) may be applied on arrival.

(d) A traveller in possession of a valid certificate of vaccination against yellow fever shall not be treated as suspect, even if coming from an area where the Organization has determined that a risk of yellow fever transmission is present.

(e) States shall designate specific yellow fever vaccination centres within their territories in order to ensure the quality and safety of the procedures and materials employed.

(f) Every person employed at a point of entry in an

Model international certificate of vaccination or prophylaxis

## MODEL INTERNATIONAL CERTIFICATE OF VACCINATION OR PROPHYLAXIS

This is to certify that [name] ....., date of birth ....., sex ....., nationality ....., national identification document, if applicable ..... whose signature follows .....
has on the date indicated been vaccinated or received prophylaxis against:
(name of disease or condition) ..... in accordance with the International Health Regulations.

| Vaccine or prophylaxis | Date | Signature and professional status of supervising clinician | Manufacturer and batch No. of vaccine or prophylaxis | Certificate valid from..... until ..... | Official stamp of administering centre |
|---|---|---|---|---|---|
| 1. | | | | | |
| 2. | | | | | |

- This certificate is valid only if the vaccine or prophylaxis used has been approved by the World Health Organization.
- This certificate must be signed in the hand of the clinician, who shall be a medical practitioner or other authorized health worker, supervising the administration of the vaccine or prophylaxis. The certificate must also bear the official stamp of the administering centre; however, this shall not be an accepted substitute for the signature.
- Any amendment of this certificate, or erasure, or failure to complete any part of it, may render it invalid.
- The validity of this certificate shall extend until the date indicated for the particular vaccination or

area where the Organization has determined that a risk of yellow fever transmission is present, and every member of the crew of a conveyance using any such point of entry, shall be in possession of a valid certificate of vaccination against yellow fever.

(g) A State in whose territory vectors of yellow fever are present, may require a traveller from an area where the WHO has determined that a risk of yellow fever transmission is present, who is unable to produce a valid certificate of vaccination against yellow fever, to be quarantined until the certificate becomes valid, or until a period of not more than six days, reckoned from the date of last possible exposure to infection, has elapsed, whichever occurs first.

(h) Travellers who possess an exemption from yellow fever vaccination, signed by an authorized medical officer or an authorized health worker, may nevertheless be allowed entry, subject to the provisions of the foregoing paragraph of this Annex and to being provided with information regarding protection from yellow fever vectors. Should the travellers not be quarantined, they may be required to report any feverish or other symptoms to the competent authority and be placed under surveillance.

Air-sickness containers

Used containers should be stored during flight in the toilet compartment. They should not be put down the toilet, and a notice to this effect should be placed in the toilet compartment. They should be re-moved from the aircraft by the toilet servicing team and disposed of along with the aircraft toilet wastes. If any receptacle is used on the aircraft for storage of used sickness containers, it should be thoroughly cleaned, washed and disinfected

# Naval Health

## Introduction

Oceans cover nearly 71% of the earth's surface. The ocean depth ranges from shallow continental slopes to the deepest point 36,200 ft below MSL at Mariana trench in Pacific Ocean. Hence, the life at sea, is confronted with various environmental factors different from those on land. Restricted space, close community life, limited resources, limited supplies of rations, and lack of dispersion affects the physical and psychological environs of sailors. Disposal of wastes is a comparatively easier proposition free from risk of contamination of food, fouling of living place and fly breeding as is usual on land. However strict standards of sanitation have made disposal of human waste from ships at harbour a complicated process to render it environmentally safe. The duties of the medical officer are principally the same at sea as on land except that at sea he is the sole adviser to his commanding officer without aid from any other colleague. Medical officers should take all opportunities to learn and familiarize at first hand the problems of life onboard the ship, the peculiar hazards that the personnel of each trade confront and the solutions to them. He should also know the layout of the ship as well as be conversant with its daily routine and administration.

The sickbays and hospitals afloat constitute the centres of all medical activities onboard the Ship. The planning and arrangement of sick bays and hospital space in naval vessels will never remain static, being dependant on changes in the ship's design, nature of operation and doctrines of medical and surgical practice. A description of a current medical department onboard the ship, therefore, may not be applicable after passage of time. Moreover, the scope of the medical facilities provided in a vessel depends upon the complement of attached personnel and role of the ship. Thus, in a submarine or in small surface ships, medical care is rendered by a medical assistant with a minimum of equipment and supplies; while a larger war ship with its medical officer, dental officer, medical assistant and superior equipment and supplies is in a position to render complete and definitive medical care. The practice of medicine onboard the ship does not materially differ from that practiced ashore. But due to shortage of storage space, careful planning is necessary in determining and ensuring the supply of a basic minimum quantity and quality of essential medical stores and equipment.

## Naval Health Problems

General principles of hygiene and sanitation for maintenance of health and prevention of disease afloat are also similar to those on land. Some of the problems afloat, however, need special attention and forethought, in planning the various preventive measures. In a modern navy the problems vary with the size, type, role and construction of the ship. The medical officer must know the basic problems likely to be encountered in various types of ships, submarines and in naval aviation. Problems connected with habitability, sanitation, food supply and preservation and pest control will frequently engage his attention in addition to the curative treatment for diseases and injuries which he will be expected to carry out as his main function. The preventive medical aspects comprise of the following :

(a) Habitability conditions of ships
(b) Submarine microclimate
(c) Diving illnesses
(d) Survival & death at sea
(e) Problems in naval aviation
(f) Water supply
(g) Food supply and preservation
(h) Disposal of refuse
(j) Pest control measures
(k) Prevention of communicable disease, quarantine rules and International Health Regulations.

### Habitability Conditions of Ships

#### Ventilation

The medical officer serving afloat should be able to define the criteria that constitute 'environmental comfort' for ship's personnel and assess the limits of tolerance for varying climatic conditions. The ship design should meet the requirements of the habitability conditions in terms of temperature, humidity, air movement and heat radiation. The environment must maintain the body heat balance, must not contain any harmful gases, and provide a sufficient supply of oxygen. All modern ships are provided with centralized atmosphere monitoring system (CAMS) for measuring temperature, humidity, air movement, radiation levels of inboard & outboard and other climatic data. Heat from the machinery spaces in the sealed hull must be removed by the 'balanced system' of ventilation. The air-duct terminals must be located to the best advantage of the occupants. The supply of fresh air to a warship with watertight compartments without weakening the ship's stability needs engineering ingenuity.

Since, it is not always feasible especially under operational conditions, to provide optimum environmental conditions, the ship designer and medical officer may be required to determine the limits of tolerance under such circumstances. The P4SR values, corrected effective temperature and the comfort zones provide a guide for assessment of such limits. As a rough and ready rule, a rise in body temperature and pulse rate in any individual, especially when resting in the place of his work, necessitate remedial action. Spot cooling is used in certain hot places such as the engine room, where it is difficult to provide sufficient fresh air to maintain satisfactory temperature throughout the space. Near each watch

station, a high velocity blast of cool air is introduced so as to produce a spot of comfort in front of the blower terminal into which the watch-stander can move whenever required. This system is effective even at high ambient temperature as the spot- temperature is considerably lower than the ambient temperature in the compartment.

Oxygen lack or depletion, and accumulation of noxious gases may occur in closed spaces. All such spaces should be thoroughly ventilated before entering. An oxygen apparatus should be kept ready; a 'life line' should be attached to the person entering such a compartment. Various noxious constituents and contaminants and their effects on body are discussed in a subsequent para. Air-conditioning of selected places, or better still the complete vessel, is the most effective way to ensure healthy habitable conditions for the personnel. In air-conditioning, atmospheric conditions in a compartment, which are artificially modified are temperature, humidity, air motion and purity of air. The plant cleanses, cools, moistens or warms the air as required. The whole system consists of a refrigerating plant, cooling or warming chamber, humidifiers, air filters, blower, exhaust fans, air duct louvres and blast sets. Modern ships are completely air-conditioned.

Effects of Noise, Vibration, Non-ionizing Radiation and Illumination

The ill effects of noise, vibration and non ionizing radiation on the human body have been studied at length and have been sufficiently qualified and quantified. Safe levels and protective measures have also been extensively enumerated, both for navies and industrial workers in the developed countries. Most of the effects of exposure to noise, vibration & non-ionizing radiation occuring at our working place (i.e. onboard ships) can pose significant health hazards, unless proper preventive measures are in place. It is our primary responsibility to ensure that the prime fighting force is not handicapped by any occupational hazards. Ship borne MO's have a pivotal role to play in prevention, detection, early diagnosis & treatment, as well as in providing proper advice to the command and health education.

**(a) Noise**

In a ship that is both the home and place of work for the seamen, one is obliged to live with some noise twenty-four hours a day. This problem may be much more severe than land based combinations of separate working and living areas. Ears of naval personnel may be subjected to a variety of sounds onboard. Noise has many sources and can have a widespread effect: both aural and non-aural noise induced acoustic disorders (NIAD), depending upon the type of noise and duration of exposure. As there is no treatment for noise induced hearing loss (NIHL), it is imperative that education, proper monitoring, adequate training and preventive measures are instituted onboard.

**(b) Vibration**

Vibration is the transmission of oscillation energy from its source to another object. Vibration can have localized effects on the circulatory system, bones and joints, nerves or muscles or it can have generalized effects on the whole body as such. It can enter the body at the hands, feet, seat, or the back. The personnel most commonly exposed to vibration are engine room and electrical sailors as well as shipwrights and seamen using pneumatic tools. To prevent the deleterious effects of vibrations it is necessary to redesign ships by applying proper ergonomics and instituting regular health education.

**(c) Non-ionizing Radiation**

The part of electromagnetic radiation that does not cause nuclear changes is called non-ionizing radiation. Non ionizing radiation extends from ultra violet radiations through the visible range up to the infrared range and the radio frequency cum microwave radiation zone. These radiations are present in varying amounts onboard and can have significant harmful effects. Of particular concern are emissions from sunlight, radar, communication and video display units (VDUs). Preventive measures are generally restricted to education, proper sign posting and use of protective equipment. In the long term, modification of equipment and spacing can be envisaged to offer better protection.

**(d) Lighting**

Adequate lighting onboard ship is essential for efficiency and safety. Fatigue and eyestrain develop rapidly in poor illumination. Work performance is reduced, accidents increase and the individual's morale deteriorates. Good lighting is important, especially in the engine room, galley, chartroom, and companionways. In the engine-room, high-level illumination free from glare is desirable. Lights should be located so that crewmembers will cast the least possible shadows upon their work, and equipment will not create pools of darkness. Adequate illumination in the areas where food is served and prepared is essential for proper food handling and for the maintenance of adequate standards of sanitation.

**Submarine Microclimate**

The ventilation system in a submarine needs special consideration. It has three functions. It must maintain acceptable conditions of habitability for the crew; it must provide sufficient air for the engines when they are operating; and it must meet battery ventilation requirements under various conditions of battery operations. The whole ventilation system is invariably the 'balanced system' with the combination of the plenum and exhaust, designed to provide efficient ventilation when the submarine is surfaced. The ventilation of submarines, however, is difficult during submerged cruising, when air has to be recirculated. Depletion of oxygen, increase of carbon dioxide and moisture vitiate this air by the ship's crew. Heat produced by the machinery, by gases from cooking and batteries, and under some unusual circumstances evolution of chlorine and other noxious gases act as health hazards. Close monitoring is therefore necessary when the submarine is cruising submerged. The habitability of the submarine from the point of atmospheric conditions depends upon pressure, movement, temperature, humidity, and constituents of the air.

In a submarine, air for the engine enters through the main

air induction valve located in the conning tower and through outboard piping to the engine room via hull valves. The air supply for ventilation enters through the hull air induction valve, also located in the fin through a separate outboard valve to the hull supply fan. Air is then distributed by the hull supply fan within the submarine through the main ducts running the entire length of the ship and branching into each compartment. Forced draft blowers take air through the main supply duct and distribute it to the various compartments. Exhaust is delivered to the engine room to be discharged through the engines when they are running, and overboard when they are static. When the vessel is submerged, the air is not exhausted through the engines but is returned to the supply system through the air-conditioning unit, which filters, cools and dehumidifies it. For the purpose of recirculation of air, cross connection is provided between exhaust fan discharge and the supply fan intake. These methods of air movement are supplemented by the use of compartment electric fans and portable blowers.

The temperature within a submarine is often extremely high, especially in the tropics. While cruising submerged, some cooling is obtained through the hull's contact with the cooler sea water. Relative humidity in submarine often approaches the saturation point during an extended submerged run from the moisture given off by the occupants, by the process of cooking and from the batteries, causing considerable discomfort to the crew. In the absence of air-conditioning, it causes the bulkheads to drip, moistens all clothing, mattresses etc. making them continually damp, thus adding to the health hazards amongst the crew. The air conditioning unit can control the temperature and humidity as well as the air circulation.

(a) Oxygen

During an extended submergence, vitiation & contamination may alter the composition of air. Oxygen concentration should not be allowed to fall below 17%, as otherwise symptoms of hypoxia such as weakness, vertigo, cyanosis, nausea and collapse may follow. There is also danger of oxygen leaking from oxygen propelled torpedoes. Hence oxygen level in the torpedo compartment need to be measured periodically i.e. at least every 1/2hr with the help of central monitoring system or by using portable analysers. If the level of oxygen falls to 19 - 18%, then oxygen is to be released from oxygen banks or by using regeneration chemicals (Peroxide of sodium/potassium) or by hydrolysis of water. Besides oxygen depletion on account of its consumption, increase in CO2 or other gases also need emergency release of oxygen after elimination of such gases.

(b) Carbon Dioxide

The normal carbon dioxide production may be 20 L / man per hour. Additional amount of $CO_2$ comes from galley, oxidation of CO and leakage from engine exhaust particularly after a crash dive or during snorting. The effects of carbon dioxide are directly proportionate to its partial pressure. A submarine carrying a normal complement of its crew may safely operate submerged for about 20 hours without requiring to absorb $CO_2$. In general, $CO_2$ tension of 3 % causes mild symptoms; between 3 to 6 % causes headache, discomfort and deep breathing; between 6 to 9 % extreme distress, panting and collapse may be caused and concentration above 9 % is rapidly fatal. Increasing the oxygen tension has no beneficial effect unless the excess of $CO_2$ is removed. Hence it is important to eliminate as much carbon dioxide as possible from the atmosphere, particularly if flooding for escape is contemplated. The removal of carbon dioxide is accomplished by the use of $CO_2$ absorbents viz. Soda lime (NaOH), regeneration chemical ($Na_2 O_2$) which absorbs $CO_2$ and releases $O_2$, MEA (Monoethanolamine) which absorbs $CO_2$ when cooled and releases it when heated or molecular sieves.

(c) Carbon Monoxide

It is produced by incomplete combustion of any kind of fuel and is a constituent of the exhaust gases from engines. It is also found after fires or explosions in closed compartments where there is an insufficient supply of oxygen to afford complete combustion. If the presence of this gas is suspected in a compartment, no one should enter without wearing an appropriate respirator. Symptoms are produced basically due to hypoxia resulting from carboxyhaemoglobin. The symptoms include exhaustion with breathlessness, feeling of nausea, increasing weakness, dizziness and vertigo, a noticeably pink tongue, pallor and finally loss of consciousness. First aid treatment for CO poisoning constitutes allowing the patient to breathe fresh air or oxygen and artificial respiration. Prevention is by using absorbent filters in ventilation system or burners, which help in reducing CO in the compartment air. Definitive treatment is Hyperbaric Oxygen therapy.

(d) Hydrogen

It is physiologically harmless but chemically active. An air mixture containing 4.1 % hydrogen in oxygen is explosive. Hydrogen in a submarine is produced by electrolysis within the storage batteries, particularly during charging. Separate ventilating system is provided for the batteries and the air is discharged outboard during surface runs and inboard during submerged runs. Hydrogen burners located in battery compartments continuously burn the hydrogen evolved from batteries and also oxidises carbon monoxide and hydrocarbons. Each battery compartment contains hydrogen detectors for determining the %age of hydrogen continuously and an alarm alerts the watch keeper if $H_2$ levels exceed more than 4%. The maximum permissible amount in the battery ventilating system is 3%.

(e) Chlorine

It is produced in a submarine when seawater comes in contact with the sulphuric acid in the batteries. It is two and half times heavier than air and remains close to the deck unless disturbed by air currents. A concentration of 1 ppm causes coughing, 10 ppm is dangerous if breathed

for half an hour and 100 ppm may be fatal if breathed even for a few minutes.

(f) Tobacco Smoke

It presents a real hazard in a submerged submarine. The bad effects are due to the nicotine absorbed and the foul odour. There is irritation of the eyes and the respiratory tract. The smoke in the rebreathed air of the enclosed space exerts its harmful effects upon personnel not habituated to tobacco. Therefore, the use of tobacco is forbidden. Acceleration of the pulse rate caused by nicotine causes confusion in the estimation of cardiovascular tolerance and response to deleterious environment expressed in terms of pulse rate.

(g) Other Pollutants

In the closed atmosphere the other pollutants are accumulated due to toasting & frying in galley which produces CO, CO2, acrolein etc, foul odours like sulphur dioxide, hydrogen sulphide & ammonia come from WCs, arsine and stibine from batteries and bacteria from men. These pollutants are to be absorbed by using Hopcalite and activated carbon filters.

(h) Air Pressure

The air pressure in a submarine is normally equal to the atmospheric pressure. While diving, the pressure increases slightly due to the compression of the hull, mild leaks of High Pressure Air and venting (blowing) of the tanks inboard. During 'submarine escape' the air pressure inside the flooded compartment must exceed the pressure of the outside seawater for opening the escape hatch. Preparatory to an escape from a sunken submarine, the partial pressure of the gases in the compartment will increase while eqaualising pressure of inside with that of outside. As the outside water pressure rises by one atmosphere (1 kg/cm$^2$) for every 10m depth, at a depth of 50 m the pressure will be equal to 6 atmospheres. The partial pressure of oxygen would, therefore be increased to 6 times, exerting the physiological effect of 2.2 atmospheres of pure oxygen on the body. Prolonged breathing of this concentration of oxygen may be dangerous. The partial pressure of Nitrogen in the compartment also increases correspondingly resulting in "narcotic effect", which is equivalent to 1 oz of Martini intoxication for each 10m of depth.

(j) Effect of Submarine Sailing on Crew

Submariners during the period they are at sea, are exposed to various unfavourable factors which lower their endurance. In addition to the factors mentioned above, the other factors, which influence submariners are given below. Preventive measures include proper selection of men from their health point of view. Psychological selection is essential because individual peculiarities can be detected during this examination. Planning of proper living and working conditions in the submarine right from the design to construction stages is essential. In other words optimum hygienic living and man-machine adaptation on sound ergonomic principles should be planned.

**(i) Emotional and Psychological Stress**

Every submariner shoulders specific additional responsibility during underwater sailing. All these create a charged emotional situation. Coupled with this is the isolation from land, separation from families, limited information regarding families and world affairs.

**(ii) High Noise Level**

An average noise level in a submarine is around 80 to 90 decibels and in the engine room this may be as high as 100 to 110 decibels. The damaging effect of this continuous noise on the functional capacity of man increases with high temperature, humidity and presence of noxious gases.

**(iii) Vibration**

The vibration level in submarine is 2 to 3 times higher than the safe physiological limits.

**(iv) Changes in Central Nervous System**

In the second half of the cruise, men start complaining of headache, irritability, disorder of sleep and depression etc. A careful neurological examination reveals such findings as tremors of fingers & eyelids, unequal tendon reflexes, impaired thermal and pain sensitivity. As a result of above changes, there is reduction in the mental working capacity, which may be reflected in their professional activity.

**(v) Changes in Sensory Organs**

- **Eyes:** After a long cruise, the adaptation to darkness takes longer time. Acuity of vision is considerably reduced. Field of vision is narrowed. Myopia in submariners is higher as compared to those in other naval personnel. This may be due to over fatigued ciliary muscles due to close viewing of small objects for a long time.
- **Ears:** The leading specific factors, which influence the auditory organs, are the level of noise and to a lesser degree the pressure changes. Problem of deterioration of acuity of hearing in engine room crew is also important. Prolonged underwater sailing will reduce both air and bone conductivity.

**(vi) Changes in Cardiovascular and Respiratory Systems**

In the second half of a long cruise, the crew starts complaining of pain in the precordium, palpitation, oedema of lower extremity and dyspnoea on exertion. Clinical examination may reveal tachycardia, a fall in diastolic and rise in systolic blood pressure leading to increased pulse pressure. During the cruise, the respiratory rate is increased and the vital capacity is lowered. This may be due to the adaptation of a submariner to increased carbon dioxide level.

**(vii) Changes in Digestive System**

The changed working conditions and food habits may cause the following changes in the digestive

system of submarines viz. loss of appetite, belching, heart burn, constipation etc.

## Diving Disorders

Divers are directly exposed to water whereas submariners are protected by the pressure hull and are mainly confronted with problems of closed space living. Submariners, however face direct exposure to watery environment during escape training and in rare contingency of actual escape from a sunken submarine. The basic concern of underwater medicine is the support of life and activities in an unfamiliar environment. This calls for physiological adjustment and supplementation with the help of suitably designed equipment when directly exposed to watery media and atmosphere control in case of closed space living in submersibles.

### Physics of Diving

(a) Pressure

The earth is surrounded by atmosphere, which has a pressure standardised as 760 mm of Hg measured at sea level. Instead of mercuric column, if seawater is used, the barometer shows 10m. i.e.

1 ATA (Atmosphere absolute) = 760 mm of Hg
= 10 m sea water
= 1 Kg/ $cm^2$
= 1 Bar

The commercial divers are already working at 600 m depth. That means the diver is exposed to 61 $Kg/cm^2$ pressure. The diver is able to sustain and work under such great pressure because the human body contains 75% liquid and 25% solids, both of which are not compressible as per Pascal's law. The effects of diving on the human body are caused by the gas present in the body both in physical and dissolved forms, which obeys certain physical laws viz. Boyle's law, Dalton's law and Henry's law etc, which will be discussed later.

(b) Buoyancy

Archimedes Principle states that "A body immersed in a liquid, either wholly or partially, is buoyed up by a force equal to the weight of the liquid that is displaced by that body." Whether an object floats or not depends upon the relative magnitudes of the weight and upthrust. There are three possible cases: negative, positive or neutral buoyancy. The effects on divers are:

**(i) Ballast Weights**

Under normal conditions a diver in the water is positively buoyant. It is necessary to increase his weight by the addition of ballast weights in order to bring him to a state of neutral or negative buoyancy when totally immersed. The weight required varies depending on the type of equipment being used, amount of underclothing and area of operation (i.e. density of the water) .

**(ii) Change of Buoyancy with Depth**

A self-contained diver in an underwater swimming dress is buoyant because of the air in his lungs and air trapped in the dress. To assist his descent he vents his suit at the surface before swimming down. As the water pressure increases and compresses the air in his dress, his displacement is reduced, he is made more negatively buoyant and his speed of descent is increased.

**(iii) Suit Inflation and Dangers of Blow-Up**

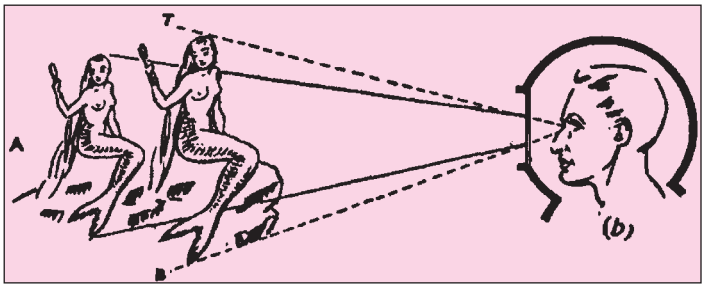
If a diver on the bottom having slight negative buoyancy inflates his dress, he displaces a greater amount of water and assumes positive buoyancy and speeds his ascent to the surface. The diver has means of deflating his dress by releasing air from his cuff and so checking this tendency to surface. The standard diver must take action quickly, since he is in danger of being 'blown up' to the surface.

(c) Underwater Vision

Even in the cleanest ocean water, only about 20% of the incident light reaches a depth of 10 m and only 1% reaches 85 m. Coastal waters with more suspended material scatters the light and restricts the vision. When the diver focuses in water, there is refraction at cornea-air interface and also at air-glass-water boundary. This results in an apparent size increase of about 30%. This makes objects appear closer than they are. Masks also restrict vision by narrowing the peripheral fields and distort objects. (Fig - 1)

(d) Underwater Sound

Fig - 1 : Underwater Vision



In air, sound travels at about 335 m/sec. In water, sound travels almost five times as fast as in air. While this allows a diver to pick up sounds more easily underwater, it does present the diver with some difficulties. The sound energy is lost when being transmitted from air to water; therefore, for divers to hear sounds from the air above them, the sounds must originally be very loud. Directional discrimination by the human ear is dependent upon the ability to detect the difference in time of arrival of sound in each ear. Sound is received, or detected, by vibration response to the sound that reaches the eardrum. In air, we are able to discern the different times that sounds reach our two ears, allowing us to readily detect the direction from which the sound is originating. Since sound travels at a much higher speed underwater, however, the time interval between arrival at each ear is usually indiscernible by the diver. It is therefore difficult to determine the direction of any sound source underwater. Another negative characteristic of sound travel underwater to the diver is the low attenuation of sound intensity over large distances. Low attenuation of sound underwater makes it difficult for divers to determine if the noise emitted is from

a source directly overhead, or several hundred feet away. This also makes it difficult to ascertain what direction the sound is traveling, or whether it is approaching or moving away.

Breathing oxygen-helium gas mixture or air at high pressures changes the voice to a higher pitch. The higher the pressure the greater this effect becomes until at great depths the voice becomes so distorted that telephone communication is almost impossible. This effect is due to the different speed of sound in gases of different densities. The fact that sound in water travels much faster than in air makes it almost impossible to pinpoint a source of sound underwater, and it is possible to obtain only a general idea of the direction.

(e) Phases of Diving

Diseases / accidents peculiar to underwater activities depends upon the phase of diving which are as under:-

(i) Descent to bottom.

(ii) Stay at bottom.

(iii) Ascent to surface or decompression.

### Effects of Pressure on Human Body

Effects of pressure on human body during a dive are as under:-

(a) Direct Physical Effects or Barotraumas

The physical effect is due to a direct effect of increased pressure by a column of water on the human body. It causes drastic changes in the volume of air in the various air containing cavities of the body and may profoundly change the respiratory dynamics which is of considerable importance to diving.

(b) Indirect Biological Effects

The biological effects are indirect in nature and are due to change in partial pressure of the gases breathed and depend on the saturation / desaturation of the tissues with dissolved gas and change of body functions by abnormal gas tension.

### Classification of Diving Medical Problems

Medical problems encountered by the divers may be classified according to the phase of diving as under: -

**(a) Phase of Descent to Bottom**

(i) Otitis, sinus, dental barotrauma.

(ii) Face or thoracic / body squeeze.

(iii) Acute hypoxia.

(iv) Hyperbaric arthralgia.

(v) High pressure nervous syndrome (HPNS) .

**(b) Phase of Stay at Bottom**

(i) Respiratory problems at depth.

(ii) Oxygen, $CO_2$, CO toxicity.

(iii) Inert gas narcosis.

**(c) Phase of Ascent to Surface and there after.**

(i) Decompression sickness.

(ii) Pulmonary barotrauma.

### Decompression Sickness (DCS)

DCS, Caisson disease and bends are the same conditions produced by the evolution of nitrogen bubbles into the body fluids and tissues.

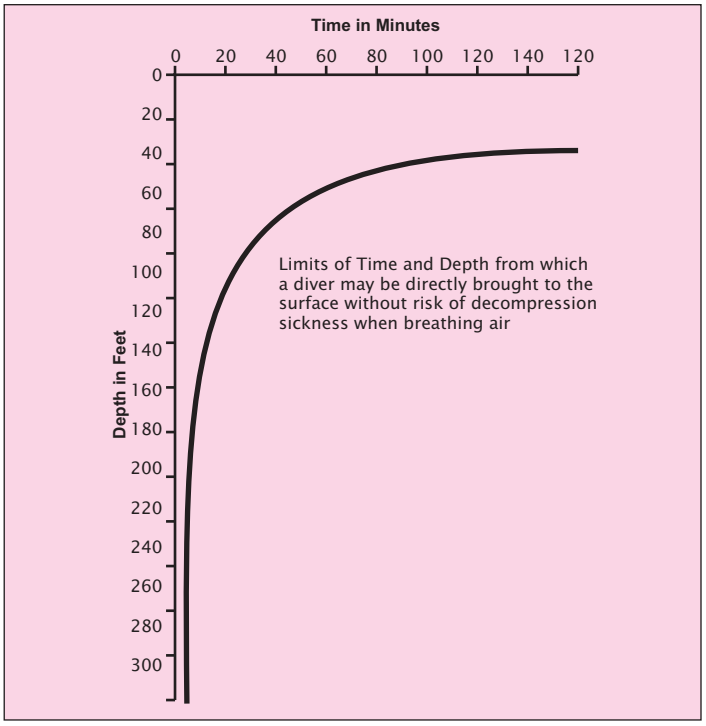
(a) Aetiology

Any medium under pressure absorbs excess gases in accordance with Henry's Law. If the pressure is suddenly reduced the dissolved excess gases come out from the liquid in the form of bubbles. Body tissues of a man under pressure also take up gases in accordance with the solubility of the various gases in the tissues. For example, fat tissues take up 5 times more nitrogen than other tissues in the body. It is the inert gas such as nitrogen, which is important in the production of bubbles. There is a certain pressure duration relationship that can be accepted by the body without producing DCS (Fig-2) .

(b) Pathology

DCS is the result of evolution of bubbles in the body fluids and tissues as well as of the mechanical and humoral effects that it triggers. The main pathology is secondary to vascular occlusion by bubbles. Any organ can be affected in this process. Some of the common examples are air embolism in pulmonary system, occlusion of the vessel in cerebral circulation leading to embolic stroke infarction and occlusion of coronary arteries producing myocardial damage. Gas bubbles also act as foreign surfaces, which attract platelets and activate Hageman factor to trigger off the coagulation system. This process leads to formation of microthrombi. The delayed effects of these asymptomatic silent emboli manifest as damage to long bones by way of aseptic bone necrosis or to the central nervous system as generalised degeneration of neurons.

Fig - 2



(c) Signs and Symptoms

DCS could present with acute and fulminant symptoms or delayed and mild symptoms. Generally the shorter the time intervals after surfacing from a dive, the graver are the symptoms. By and large these symptoms which appear after 1 1/2 h on surfacing are of the milder variety. But DCS can occur upto 24 h after surfacing from a dive.

**(i) Severe DCS**

The fatal and fulminate symptoms are produced because of gas emboli of the pulmonary system (choke syndrome) , the central nervous system and /or the coronaries. The patient can have severe dyspnoea, any kind of paresis or paralysis, speech disturbance, cerebellar disturbance, mood disturbance and disturbance of consciousness. Paraperesis and paraplegias are common; so are convulsions. If any of the above signs and symptoms are present, the patient has to be immediately repressurised in a Recompression Chamber (RCC) following the various therapeutic tables without wasting time for investigations and diagnosis.

**(ii) Mild DCS**

Usually comes after an interval of minutes or hours of surfacing from a dive. It manifests as pain in a joint or as an itchy skin rash. Such symptoms may also be a part of severe DCS, when it is to be treated as a part of the whole spectrum of the disease and not as the mild variety.

(d) Treatment

If a diving manual, Indian Naval BR 2806 is available at the site of treatment, one should proceed as per the instructions contained in articles 5502 to 5523. However, most of the decompression sickness encountered in diving at less than 70 meters depth can be effectively treated by the oxygen tables. (Table - 1 & 2)

(e) Treatment of DCS in the Absence of RCC

In the absence of the compression chamber, a patient of DCS should be administered 100% O2 by oronasal mask. Give plasma expanders like Dextran to prevent sludging

Table -1 : Oxygen recompression therapy (for mild cases only)

| Gauge Depth (metres) | Stoppages | Elapsed time | Rate of ascent (metres/minute) |
|---|---|---|---|
| 18 | 20 ($O_2$) | 0000-0020 | - |
| 18 | 5(Air) | 0020-0025 | - |
| 18 | 20 ($O_2$) | 0025-0045 | - |
| 18-9 | 30 ($O_2$) | 0045-0115 | 3m in 10 mins |
| 9 | 5 (Air) | 0115-0120 | - |
| 9 | 20 ($O_2$) | 0120-0140 | - |
| 9 | 5 (Air) | 0140-0145 | - |
| 9-0 | 30 ($O_2$) | 0145-0215 | 3 m in 10 mins |
| Surface | | 0215 | |

TABLE- 2 : Oxygen recompression therapy (for fulminant cases)

| Gauge Depth (metres) | Stoppages | Elapsed time | Rate of ascent (m/min) |
|---|---|---|---|
| 18 | 20 ($O_2$) | 0000-0020 | - |
| 18 | 5(Air) | 0020-0025 | - |
| 18 | 20 ($O_2$) | 0025-0045 | - |
| 18 | 5(Air) | 0045-0050 | - |
| 18 | 20 ($O_2$) | 0050-0110 | - |
| 18 | 5(Air) | 0110-0115 | - |
| 18-9 | 30 ($O_2$) | 0115-0145 | 3m in 10 mins |

| 9 | 15 (Air) | 0300-0315 | - |
| 9 | 60 ($O_2$) | 0315-0415 | - |
| 9-0 | 30 ($O_2$) | 0415-0445 | 3m in 10 mins |
| Surface | | 0445 | |
| | | | |

of RBC and haemoconcentration. Aspirin may be given for limb bends. In fulminating cases Low Molecular Weight Heparin is indicated.

(f) Air Evacuation of Diving Casualty

Diving casualties may be transported in aircrafts, which can maintain a cabin altitude of upto 1000 feet or in helicopters which maintain altitude of 500 ft.

(g) Prevention

DCS can be prevented by the strict adherence to diving schedules given in diving manuals. The air diving table followed in the Indian Navy is given in Table - 3. As adipose tissues take up considerable amount of excess gas, obese people should not be allowed to dive. Working at high altitudes and in extreme cold conditions can predispose to DCS. As the ambient pressure of atmosphere is low at high altitude, the table is to be modified as given in the diving manual.

Table - 3 : Air Diving table

| Depth not exceeding (m) | Bottom time (min) | Stoppages at different depths (m) | | | | | Total time for decompression (min) |
|---|---|---|---|---|---|---|---|
| | | 25m | 20m | 15m | 10m | 5m | |
| 9 | No limit | | | | | | |
| 10 | 230 | - | - | - | - | - | 1 |
| | 420 | - | - | - | - | 5 | 5 |

| | 30 | - | - | - | 5 | 25 | 30 |

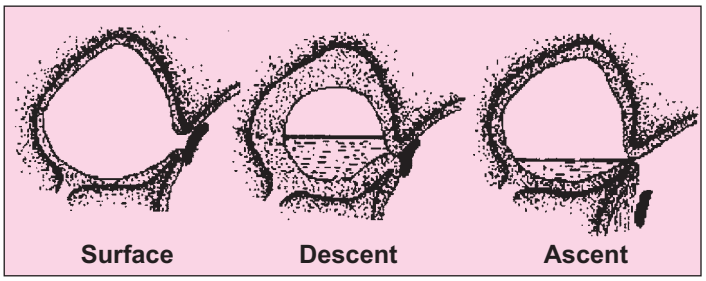
**Barotrauma**

Barotrauma is defined as tissue damage resulting from the expansion or contraction of enclosed gas spaces and is the direct effect of gas volume changes alterations with pressure, causing tissue distortion. It is the most common occupational disorder of divers, experienced to some degree by almost all. It must be realised that changes in volume caused by changes in pressure are greater near atmospheric pressure. Therefore, the effects of pressure changes in the body caused by changes in depth are more noticeable when the diver is near the surface and accidents are much more likely to happen there. Any spaces that are gas-filled viz. sinuses, ears, lungs will be affected by change of pressure in accordance with Boyle's Law.

(a) Sinus Barotrauma

The paranasal sinus cavities are lined with a mucous membrane similar to that in the nose. Bony canals add to provide means of equalisation of pressure between the cavities and the mouth. This means that normally, there is a free flow of air to the sinuses from the back of the nose and throat. However, if the canal through the bone becomes blocked by mucus or swelling of the tissues, the flow will not occur. In these circumstances, the volume of air in the sinuses contracts on increase in external pressure, causing pain and damage to the sinus mucosa, which may burst causing the cavities to fill with blood. If that should happen, there will be a decrease in pain and the diver will feel more comfortable. However, on ascent, the air in the sinuses will expand and, may force the blood out through the canal, resulting in a nose or mouth bleed. Prevention is achieved by avoiding diving when suffering from a cold, catarrh or throat infection (Fig - 3).

Fig - 3 : Sinus Barotrauma

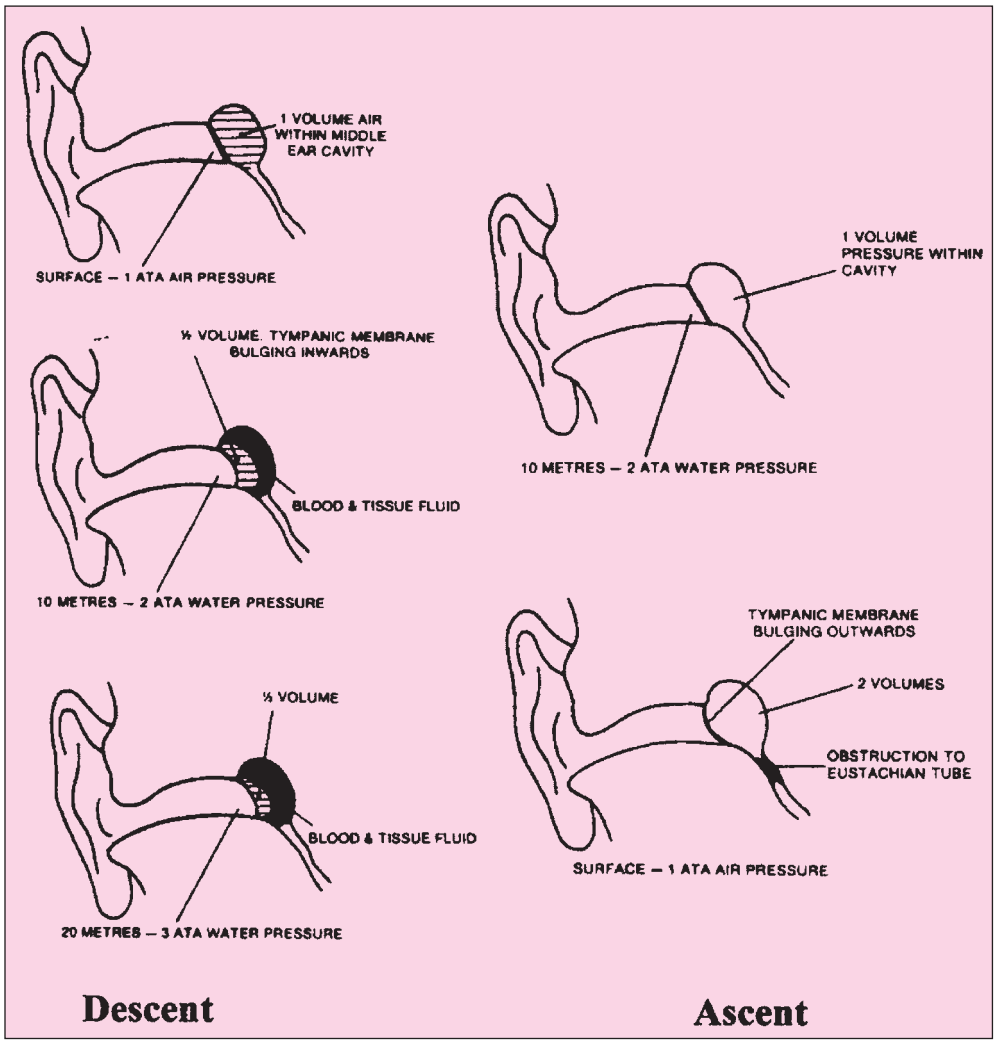


(b) Aural Barotrauma

The Eustachian tube is only lightly closed and usually opens in the healthy individual during the act of swallowing. Its function is to allow air in or out of the middle ear to maintain pressure. However under large pressure differences, the tube does not open freely and discomfort is felt as the drums are stretched inwards (Fig - 4).

This discomfort is overcome by opening the Eustachian tube and allowing air to pass into the middle ear to equalize the pressure on each side of the drum. This can usually be done by either swallowing or yawning, which opens the tube, or by blowing against a nose clip (valsalva maneuver), which forces air through the tube. The act of clearing is evident either as a feeling of relief or as an audible click in the ear. The clearing of ears is required at the pressure of 2.2, 4.4, 7.3, 10.8 m and so on. During ascent the air escapes by itself and clearing is not usually necessary. Middle ear barotrauma is the most common occupational disorder of divers. If the Eustachian tube is blocked by swelling or mucous as in the upper respiratory tract catarrh, the pressure equalisation between middle ear and external ambient atmosphere will not take place resulting in inward bulging of ear

Fig - 4 : Aural barotrauma



drum with stretching pain, haemorrhage and finally perforation. Treatment includes pain relief by use of analgesics, antibiotics if indicated. The diver is unfit to dive until the ear has recovered. Prevention includes pre dive ENT examination, avoidance of diving with nasal or ear symptoms and slowing of descent rate.

(c) Pulmonary Barotrauma

For an average person the maximum capacity of the lungs is about six litres. When a person has exhaled as much as possible, there is still an amount of air left known as the residual capacity. For the average man it is about 1.5 litres. The damage occurs to lungs due to contraction or expansion of gases in accordance with Boyle's law. This is the most serious form of the Barotrauma, and causes most concern in all types of diving operations. i.e. descent and burst lung associated with ascent.

**(i) Lung Squeeze**

When a diver descends, the increase in pressure of water column causes a decrease in volume of the air in the lungs. At about 30 metres the volume of air will have decreased to the residual capacity. On further descent the chest and lungs will not contract any more. So, as the external pressure on the tissues continues to rise, fluid and tissues will be forced into the chest and lung air spaces to equalize the pressure and, in extreme cases, the ribs will crack and the chest will cave in. This is known as lung squeeze and is prevented by supplying gas at the same pressure as the surrounding water.

**(ii) Burst Lung and Embolism**

The incidence of pulmonary barotrauma among naval divers is 1 in 3000 free ascents and fatality rate is 1 in 50,000 free ascents. Decreasing pressure on ascent will cause the gas in the lungs to expand. If the gas is not allowed to escape the alveoli will rupture. This requires only an excess of about 0.035 bar. Thus it is essential to breathe out on a free ascent or breathe normally when using breathing apparatus. Thus the causes are voluntary breath holding during ascent, inadequate exhalation caused by panic, sudden blow to the breathing bag resulting in back pressure, obstruction in the pulmonary airways viz. asthma, tuberculosis, cysts, lung infections etc. A 'burst lung' produces the following main effects:

- Pulmonary tissue damage due to the result of over distention and rupture of lung alveoli. The patient may have haemoptysis and chest pain on deep inspiration.
- Pneumomediastinum: Surgical emphysema and Pneumomediastinum occur due to tracking of respiratory gases along the air passages resulting in dyspnoea, dysphagia, left recurrent laryngeal nerve palsy and brassy tone due to compression on the voice box.
- Air Embolism: The ruptured alveoli may allow gas to enter the blood stream. These gas-bubbles will travel around the body; expanding as pressure decreases and blocking the blood supply to vital organs such as the brain and heart. If a large quantity of gas enters the bloodstream death is rapid
- Pneumothorax: Air will escape from the lungs into the chest cavity, causing partial collapse of the lungs resulting in dyspnoea and hypoxia.

The symptoms apparent are pain in the chest behind the sternum, difficulty in breathing, bloody froth around the lips from blood getting into the lungs after the alveoli are ruptured, rapid unconsciousness and death. The manifestations may be in the nature of acute pulmonary and CNS symptoms described in decompression sickness. Immediate treatment is by recompression to 50 meters for 30 min after which the patient is decompressed according to the under mentioned table. A doctor or a paramedical person should go with the patient in the chamber and continue resuscitation while repressurisation is going on. Ancillary measures such as treating a pneumothorax with needle drainage in fluid may be necessary.

**Prevention:** Its prevention is by observing the correct drill of keeping the airway during ascent and breathing freely

Table - 4 : Modified air recompression therapy

| Gauge Depth ascent (mtrs) | Stoppages Ascent (min) | Elapsed time (hours) | Rate of (metres/min) |
|---|---|---|---|
| 50 | 30 (Air) | 0000 0030 | -- |
| 50-18 | 4 (Air) | 0030 0034 | 8 m/min |
| 18 | 20 ($O_2$) | 0034 -0054 | -- |
| 18 | 5 (Air) | 0054 -0059 | -- |
| 18 | 20 ($O_2$) | 0059 - 0119 | -- |
| 18 | 5 (Air) | 0119 - 0124 | -- |
| 18 | 20 ($O_2$) | 0124 - 0144 | -- |
| 18 | 5 (Air) | 0144 - 0149 | -- |
| 18-9 | 30 ($O_2$) | 0149 - 0219 | 3 m in 10 min |
| 9 | 15 (Air) | 0219 - 0234 | -- |
| 9 | 60 ($O_2$) | 0234 - 0334 | -- |
| 9 | 15 (Air) | 0334 - 0349 | -- |
| 9 | 60 ($O_2$) | - 0449 | -- |
| 9-0 | 30 ($O_2$) | 0449 - 0519 | 3 m in 10 min |

in and out. No one with pulmonary disease should be allowed to dive.

**Breathing Gas Associated Disorders**

The problems associated with oxygen depend upon the partial pressure of oxygen in the breathing mixture. The less percentage of oxygen in the breathing air causes

hypoxia, whereas higher percentage of oxygen breathing causes toxicity. At higher partial pressure, the pollutants like carbon dioxide and carbon monoxide will exert their toxic effects. Breathing of air beyond 50 m depth causes narcotic effect. The medical problems associated with the breathing of improper gas are briefly discussed below.

(a) Hypoxia

Breathing of less than 17 % of oxygen in breathing gas; this can occur due to wrong preparation of gas mixture, empty air cylinder, malfunctioning of reducers or accumulation of foul gases in breathing bag. It is difficult to detect in early stages and the first symptoms are false sense of well being and over confidence. If $O_2$ % continuously falls, the diver may become unconscious. Prevention is to ensure correct flow of gas mixture and also to clear the counter lung (to prevent dilution hypoxia).

(b) Oxygen Toxicity

When breathing under pressure at greater depths deeper than 20 meters, oxygen becomes toxic and produces symptoms of acute oxygen poisoning. This maybe experienced by a diver as twitching of lip & other facial muscles, dizziness, vertigo, nausea, unusual tiredness, disturbances of breathing like hyperpnoea, apnoea or dyspnoea; euphoria, disturbances of sight like tunnel vision, unconsciousness and general convulsions similar to a grand mal seizure. By far the most dangerous symptoms to the diver are the unconsciousness and convulsions, since such conditions could easily lead to his losing the mouthpiece or mask and drowning. For this reason while using 100% $O_2$ in diving, depth is restricted to 8 meters for free swimming and 10m for light work. In normal practice, oxygen is not used for diving beyond these depths. Treatment is to remove the breathing apparatus and suit, place the patient in fresh air to recover. Restrain the patient during convulsions to prevent self-injury, and gag the patient's mouth with a piece of wood to prevent him from biting his tongue. The patient must be kept under observation for at least 12 hours, because loss of memory almost invariably occurs. Prevention is by limiting the partial pressure of oxygen in the mixture breathed to two bars absolute, i.e. 10 metres under light working conditions and eight metres when working hard.

(c) Hyperbaric Oxygen Therapy ($HBO_2T$)

Breathing 100% oxygen at more than one atmospheric pressure in a pressurized chamber is called hyperbaric oxygen therapy. Breathing of pure oxygen at 3 atmosphere absolute pressure carries 6 ml of oxygen in 100 ml of blood in the form of physical solution, which is adequate to meet the oxygen requirements of body without dissociating oxyhaemoglobin. This soluble oxygen readily diffuses into tissues and corrects hypoxia, reduces oedema, improves blood circulation through neovascularisation and enhances wound healing by collagen matrix formation. The oxygen radicals are powerful bactericidal and controls anaerobic and partly aerobic infections. The indications for HBOT are as follows:

**(i) Accepted Indications**

- Decompression sickness
- Gas embolism
- Gas gangrene
- Carbon monoxide poisoning
- Osteomyelitis and osteoradionecrosis
- Problem Wound healing

**(ii) Experimental Indications**

- Burn injury
- Cerebral oedema
- Vascular insufficiency
- Leprosy, Actinomycosis

**$HBO_2T$ protocol**

Giving of pure oxygen at 2.8 atmosphere absolute pressure for 60 min/day for 1-2 weeks is sufficient for the above indications. However severe infections viz. Gas gangrene requires two sessions on first 3 -4 days. When oxygen is used for treatment purposes in a hyperbaric chamber at a depth of 18 m, convulsions may occur. In such cases oxygen mask must be removed and the patient allowed to breathe chamber air. The pressure is to be reduced to 12m and therapy may be restarted. Breathing of oxygen under pressure in excess of 0.6 ATA for prolonged periods can produce chronic oxygen toxicity, which manifests as pulmonary oedema, hemorrhages and fibrosis.

(d) Inert Gas Narcosis

When gases like helium, neon, hydrogen, nitrogen, argon, krypton etc are breathed, they dissolve in the body and produce narcotic effect as that of anaesthetic gases. Helium, neon and hydrogen are least narcotic, whereas krypton and xenon are highly narcotic. Narcotic effect is depth related i.e. it occurs immediately on reaching the depth and independent of time. In fact the diver develops acclimatisation after prolonged stay. The signs and symptoms of nitrogen narcosis are similar to that of alcoholic intoxication. One atmospheric pressure of air produces the effect equivalent to intoxication of consuming of 1 oz of Martini. The symptoms that occur at shallow depth upto 50m are euphoria, talkativeness and laughter. Breathing of air at more than 50m depth results in delusions, stupefaction and unconsciousness. Prevention is by avoidance of using air as breathing medium beyond 50m depth.

(e) CO Poisoning

CO poisoning occurs due to breathing of gas which is contaminated with CO. This occurs due to charging of air bottles in polluted atmosphere or near engine exhausts. The symptoms are shown in Table - 5. The treatment of carbon monoxide poisoning is quick removal of the patient from further exposure to CO and breathing 100% $O_2$. Definitive treatment is hyperbaric oxygen therapy.

(f) Carbon Dioxide Toxicity

In diving, carbon dioxide retention occurs mainly because of the malfunctioning of the sets i.e. non-functioning of

Table - 5 : Symptoms of CO poisoning

| Carbon monoxide in air (as PPM) | % of Caboxy-haemoglobin | Symptoms |
|---|---|---|
| 400 | 7.2 | Nil |
| 800 | 14.4 | Headache, nausea, dizziness, breathlessness |
| 1600 | 29 | Confusion, visual disturbance, increased pulse rate & respiration, collapse |
| 3200 | 58 | Unconsciousness, intermittent convulsions |
| 4000 | 72 | Profound coma, cardiovascular |

valves of the air bottles, inefficient $CO_2$ removal or accumulation of foul gases in the breathing bag. Excess $CO_2$ also may be produced due to over exertion. In chronic form of poisoning there is a stage of compensation, which is followed by decompensation and ultimately failure; if the toxicity is sufficiently prolonged. In the acute form compensatory stage may be totally absent.

**(i) Clinical Picture**

The signs and symptoms during various stages are as under: -

- Latent Hypercapnia (0.2-0.5% of $CO_2$). Perception of smell improves. There may be euphoria and feeling of stiffness.
- Compensated Hypercapnia (0.5-3 % of $CO_2$). Memory and attention are affected. There is hyperventilation and acidic secretion. Peptic ulcer may get aggravated from increased gastric secretion. There is increase in secretion of acidic urine and sweat. Hypotension may develop after 3-4 days.
- Marked Hypercapnia (3-6% of $CO_2$). Sharp deterioration of general condition, lack of confidence and self-control. Lack of orientation of space and time. Euphoria and deterioration of critical judgement.
- Uncompensated Hypercapnia (6-10 % of $CO_2$). There may be drowsiness, loss of consciousness, constriction of Pupils, convulsions and depression of adrenal cortex leading to collapse.
- Narcotic Stage (>10% of $CO_2$). Deep narcosis with respiratory depression leading to death.

**(ii) Treatment**

Flush through the counterlung, breathe deeply or signal for more air, according to the equipment in use. If this brings no relief, the diver must surface. Give the diver fresh air or oxygen. Allow the diver to rest. Recovery should be rapid.

**(iii) Prevention**

Ensure that the $CO_2$ absorbent is fresh, dry, dust free and. correctly packed. Do not exceed the endurance of the canister. Ensure that breathing is correct, i.e. long, deep breaths with all equipments. Periodically, the stale air in the Bell / Chamber must be replaced with fresh air without causing a change of pressure.

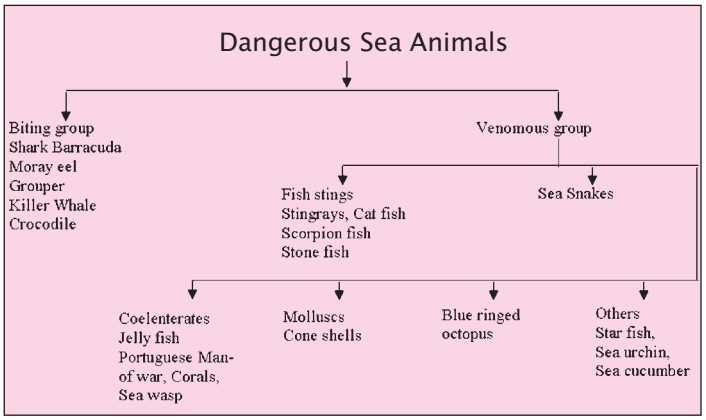
### Hypothermia

The Indian Navy personnel are not usually subjected to cold. They may sometimes suffer from hypothermic reactions following the diving operations in cold water with temperature below 15°C, as the body heat is lost very rapidly in the compressed cold atmosphere. The initial defensive response produces a constriction of blood vessels, increased heart rate and blood pressure and shivering. Generalised pathological hypothermia of adynamic phase occurs, when the core body temperature falls below 33°C resulting in hallucinations, delusions and cardiac arrythmias. When the core temperature falls below 30°C, paralytic phase sets in, which manifests as unconsciousness, stoppage of cardiac and respiratory activity. Most of the ship wreck victims die of hypothermia leading to drowning.

### Hazardous Marine Animals

Certain forms of marine life pose a threat to humans.

Table - 6 : Dangerous Sea Animals



Generally man gets hurt or killed by encountering the self-defence armament of the sea creatures or by trespassing on their property; only rarely he is threatened by unprovoked attacks. Dangerous sea animals are classified as shown in table 6.

(a) Biting Group

Sharks are the best known and most feared sea creatures. These predators are most vicious when a group is in the 'feeding frenzy' mood, usually when there is lot of flesh

and blood in the water. At such times they will attack and bite at any object in the vicinity. At other times unprovoked shark attacks are as frequent as commonly believed. Flesh blood, noise and irregular vibrations commonly attract sharks. Preventive measures include avoiding known shark infested water, avoiding water in which food and animal products has been thrown. Carry shark repellant while swimming and diving. If shark is spotted .do not panic, stay motionless or try to move away using slow strokes while watching the shark, which will probably go away. If it approaches too close hit it on the snout or eyes with any object. Emergency treatment is for hemorrhage and shock and secondary infection. Bites by Barracuda, Moray eel, crocodile, killer whales and grouper fish are rarely encountered in this part of the world.

(b) Venomous Group

The important venomous marine animals are:

**(i) Sea Snakes**

Out of the 40 species of sea snakes in Indian waters 39 species are poisonous. Sea snakes are 2-10 times as poisonous as that of cobra. But, because of its poorly developed fangs, they can deliver only 25% of the poison. The venom is neuro and myotoxic and usually causes acute tubular necrosis. In addition to first aid, treatment for shock, antihistamines and polyvalent anti snake serum are used.

**(ii) Fish**

Catfish stings are common and painful. Stingrays are found in mud and can deliver a fatal sting. Scorpion and stone fish stings can also be lethal but are uncommon. Numbness and respiratory paralysis, nausea and vomiting, dizziness may occur. Myonecrosis is common.

**(iii) Sea Wasp and Box Jelly Fish**

The sea wasp is the most venomous animals in the sea and its poison can kill within ten minutes. It has a balloon like float and long, very fine tentacles with the poison sacs. The sting causes a line of wheals on the skin and can cause local paralysis and respiratory paralysis if severe. The Jelly fishes normally cause painful pruritic local lesions. Cone shell sting and octopus bite may be lethal.

### Drowning

Drowning is asphyxia due to immersion in water and is the fatal termination of a sequence of preventable events. Among the many causes of drowning, the most common is hypothermia. The victim of immersion, both inhales and swallows water. However in the majority of cases comparatively little water enters the lungs due to spasm of larynx i.e. constricting the air passage (dry drowning). Whether it does or not, the result is the same: breathing stops. It is unimportant whether immersion occurs in fresh or salt water. Drowning causes lung damage and failure of oxygen transfer. Congestion of the lungs can occur very quickly, but may be not apparent for hours.

(a) Signs and Symptoms

The main clinical features are difficulty in breathing with increased rate and depth, noisy breathing, frothing from mouth, blueness of lips and finger tips, confusion, possible unconsciousness and death. Death usually occurs within about 8 minutes.

(b) First Aid

Remove any obstructions from the mouth of the casualty. It may be possible to start artificial respiration while still in the water. If in deeper water give the occasional breath of air while towing the casualty ashore. Place the casualty on a firm surface, check his pulse and respiration. Victims tend to swallow large quantities of water distending their stomach. No time should be wasted in trying to remove water from inside the casualty's body. Immediate Cardiopulmonary resuscitation is to be started and continued till the patient revives or medical help arrives or upto a minimum duration of 45 mins. If the casualty has been immersed in cold water for sometime there is also a danger of hypothermia. So he should be kept warm, wrapped in blankets. Occasionally survival may be prolonged by profound hypothermia. People have recovered after being totally immersed and without breathing for 40 minutes. Arrange to remove to hospital. Even though the survivor of near drowning may appear to have recovered, he should not be allowed home as complications may develop rapidly during the next day or so. No patient with Hypothermia is to be declared dead till fully warmed.

### Investigation of Diving Accidents

Diving accidents are not uncommon and almost all of them are preventable. There are various contributory factors, which may lead to a diving accident. Majority of diving accidents, however are due to human error or carelessness. Hence a high standard of physical fitness and good, continuous training of the diver are essential for the survival of the diver under water. All diving accidents, both fatal and non-fatal, should be investigated thoroughly to prevent their recurrence. When diving accident occurs, the diving set used by the diver should be inspected meticulously. The position of all the valves, pressure gauges and the external appearance of the set should be examined and noted down. None of the valves are to be operated. Gases filled in the cylinder/ breathing bag and $CO_2$ absorbent are to be sent for analysis. Statement of the diver, his buddy, the diving attendant and any other witness are to be taken as early as possible. All this information compiled together will lead to the cause of the accident. In cases of fatal accident, postmortem examination of the body is a must. The concerned Unit should render a report on a prescribed proforma (Diving Accident/ Incident Report) so that appropriate action is taken to prevent such accident in future.

Management of the casualty and investigation into the cause of the accident are both equally important steps in Diving accidents. Investigation of a fatal diving accident is a fact-finding mission. The intentions are to establish the cause of death and to take corrective steps to prevent recurrence of the event. Autopsy of a dive fatality includes the findings of a post-mortem examination and toxicology studies. A thorough external examination

including signs of trauma, animal bites and evidence of subcutaneous emphysema or envenomation should be carried out. Radiograms of the head, neck, thorax, and abdomen will reveal free air. An initial "I" shaped (modified "tent" incision) over the chest is made and this area filled with sterile water. A large bore needle is inserted into the second intercostal spaces bilaterally and escaping air can be captured in an inverted, water filled, graduated cylinder. As sternum is removed, any gas escaping from vessels should also be noted. The pericardial sac is opened under water to look for pneumopericardium. A needle is inserted into both the ventricles for capture of escaping gas. After an under water examination of the mediastinum, heart, and great vessels, the water may be evacuated and a standard autopsy is performed. The lungs are carefully examined for bullae, emphysematous blebs, and haemorrhage. Evidence of cardiovascular disease especially inter-atrial or inter-ventricular septal defects and any changes that would compromise cardiac function is looked for. Prior to opening the skull, all of the vessels in the neck are to be tied off. Once the skull is opened the vessels at the base of the brain are tied. Bubbles in the major vessels are significant. Carboxyhaemoglobin, $PO_2$, $PCO_2$ and electrolytes on aortic blood should be considered for toxicology. Investigation of a diving accident is a composite effort of specialist diver, marine medical specialist and pathologist. A study of circumstances leading to event, diving set analysis and autopsy findings contribute equally to indicate the probable cause.

### Survival at Sea

In case of shipwreck, the crewmembers who survive the initial impact should resort to abandonment (ditching) of vessel at sea. It is therefore necessary that prior training be imparted to the crew to familiarise with all procedures to safe and prolong life at sea. Forced immersion in water, after abandonment of vessel, is the primary hazard to life. In water there is increased heat loss leading to decrease in body temperature (i.e. generalised hypothermia) which can lead to abnormalities in heart rhythms or even cardiac arrest & death. This loss of body heat depends upon ambient water temperature and length of exposure in water.

(a) Warm clothing to be worn before ditching. If immersion suit is available it should be worn over the warm clothing. If immersion suit is unavailable, then put on a life jacket.

(b) It is always better to avoid jumping into the water from a height more than 5m as the sudden immersion in water can result in drowning or death. As far as possible climb on the life boat or life raft.

(c) After jumping it is important to orient oneself and try to locate ship, lifeboat or other survivors.

(d) In cold waters person will have violent shivering and feel great pain. While afloat, do not swim too much, as needless exercise will increase the rate of body heat loss. Hence it is important to remain as still as possible, however painful.

(e) In life boat/ life raft, shield yourself from the wind as wet clothes on the body causes a wind chill effect and further increase heat loss.

(f) It is very important to have a positive mental attitude and the will power to survive. There are many amazing cases of people who have survived with just will power.

(g) DO NOT CONSUME ALCOHOL before abandoning ship, as alcohol causes vasodilatation & thus heat loss.

(h) For further details refer to the Chapter on Survival at Sea

### Medico Legal Aspects of Death at Sea

In case of a sudden or unnatural death afloat, where circumstances do not permit the help of shore authorities for the postmortem of the body and the body cannot be preserved until arrival of the ship in harbour, the medical officer may under written orders from his Commanding officer, conduct the postmortem to ascertain the cause of death. If the dead body can not be preserved due to any reason, then it should be packed and sealed in the manner as to ensure its immediate sinking. In case of a natural death, the medical officer may, if he considers it necessary or advisable, conduct postmortem on the body with the prior consent of the commanding officer in the absence of consent from next-of-kin. Should there be any appearance of a suspicious case, he shall retain evidence in accordance with the normal medico-legal requirements. He shall also inform the Commanding officer of his suspicion. The commanding officer shall thereupon take appropriate steps to investigate the case and report the same to the senior officer present or the administrative authority who shall thereupon convene a board of inquiry .If the ship is near an Indian port, the commanding officer may, if considers it advisable, inform the coroner or other appropriate civil authority ashore so that an inquest may be carried out. Where, however, the body is to be cremated or buried ashore, the Commanding officer shall inform the coroner or other civil authority of the case. In case the death occurs at a place outside India, unless the local law requires otherwise, it is not necessary to inform the local civil police and the inquest may be held by the commanding officer of the ship to which the deceased belongs. If the death occurs during the day onboard a ship within port limits, the ensign and house flag if any, shall immediately be lowered to half mast and kept in that position from sunrise till sunset as long as the dead body remains onboard; and if death occurs between sunset and sunrise, one red light shall be hoisted at the peak, half mast high. Special provisions relating to the carriage of dead bodies and cremated remains: No person shall bring into India any dead body or human remains of persons who may have died of yellow fever, plague, Anthrax, glanders or such other diseases as may be notified by the Central government for this purpose.

## Health Problems in Naval Aviation

Health problems of aircrew and the supporting ground crew of Naval Air Arm are the same as for those of other naval personnel. Over and above, they also face the

problems encountered in aviation. The naval aviation is not limited to shore bases alone. The problems of take off and landing present different situations while flying from an aircraft carrier or another ship carrying different types of helicopters. It is very much essential that a Naval Medical Officer should acquaint himself with the aviation personnel so as to know the types of duties an aircrew has to perform. He should also know the types of aircraft flying in the Navy, their capabilities, and the types of jobs the ground supporting crew have to perform. He should establish himself as a member of the flying crew so that he develops a rapport with them and thus knows the problems faced by them in day to day life. The following conditions need close attention and medical evaluation for flying fitness: -

(a) Loss of flying efficiency.
(b) Physical and mental fatigue.
(c) Fear of flying or phobia during conversion.
(d) Increased indulgence in alcohol/tobacco.
(e) Frequent near miss, incidence and accidents.

## Water Supply

### Sources and Responsibilities

Safety of water supplies on naval vessels is very important for the prevention of waterborne diseases. Potable water must be provided for drinking and cooking purposes. As far as possible it should also be available for washing, bathing & laundering. However, due to storage difficulties afloat, it is not possible to supply water at the same liberal scale as on shore. The engineers are responsible for supply of water, and medical services advise on the treatment to render the water fit for human consumption. Constant vigilance by regular periodical examination of the water supply is essential to ensure that the quality of water on naval vessels conforms to the established standards. The source of potable water supply on naval vessels is mostly from potable water systems ashore or by distillation of seawater. Over board, sea water is normally utilised for fire fighting, flushing systems and cleaning of decks.

### From Shore

Before accepting any fresh water from shore, it is good to investigate the source of supply. If time permits, the bacteriological examination of the port water should also be carried out. Information regarding quality of the water is generally available from the local Port Health Authority. Water for ship's supplies is normally clarified and chlorinated, and the Port Health Authorities all over the world conform to the international requirements of the quality of water. Therefore, if proper precautions for transportation, storage and distribution are taken, there should be very little danger of dissemination of waterborne diseases. However, the fact that water has been purified earlier at port does not necessarily assure its continued safety. Rechlorination of water supply on board the ship ensures added safety, especially when water is of doubtful purity or when it is likely to get contaminated during the process of transportation. The following precautions while loading water should be taken: -

(a) Water should only be taken after the competent authority has determined and assured that the source of supply is safe.
(b) Generally, potable water is available from a common source of supply ashore for both domestic purposes as well as for fire fighting and flushing systems. In some ports there is a dual system and unfiltered water is supplied for fire fighting and in flushing system. The hydrant should be properly identified, specifically when they are not distinctly marked. This information must be passed to the individual who makes the connection between the shore supply and the ships system and operates the hydrants.
(c) The fresh water hose should always be kept separate from others. When taking it to shore for attachment to hydrants, precaution must be taken to ensure that no part of the hose falls into the harbour water. The hose should be thoroughly flushed with fresh water before it is connected with the water system of the ship.
(d) It is necessary to test the water for the residual free chlorine by the orthotoludine test.
(e) While filling the fresh water tanks, it should be ensured that no cross-connections exist between the fresh water system and fire-fighting or flushing systems.
(f) After the operation of loading is completed, the hose should be disconnected, drained and washed if necessary, and then stored away in the locker specially reserved for that purpose.
(g) If facilities are available, bacteriological examination of water from each tank may be carried out. This is not obligatory, specially when the water from the harbour is considered to be safe. As a further precaution the potability can be ensured by adequate rechlorination of the water.
(h) Sometimes the water is transferred to the vessel from a watership or a tanker. This water may have been purified before loading at the base or might have been distilled on board the ship. Arrangements for chlorination often exist in such vessels. If not, it will have to be carried out after receiving the delivery.
(j) Water barges are also sometimes used for transportation of shore water to the ship specially in harbour. The precautions mentioned above must be observed in transferring water from these vessels.

### Distilled Water

Distilling plants of various types for water supply to the fresh water system and boiler feed water system are provided on naval vessels. The distillation of sea water often leaves a considerable quantity of ammonia in the water, resulting in deviation of a considerable amount of chlorine. An adequate quantity of free chlorine is thus not available for sterilising purposes. Free chlorine in water should be estimated by the orthotoludine test. The 'flash

point' reading after 5 sec shows the free chlorine contents and the reading after 5 min indicates the combined chlorine.

### Overboard Water

The water in harbours or off-shore near habitations and around fleet concentrations is highly contaminated and should not be used for any purpose. When conservation of fresh water or fuel is important or when it is impracticable to provide fresh water for all purposes it may be necessary to use overboard water when away from contaminated areas. On naval vessels, seawater is ordinarily used out at sea for fire fighting and flushing purposes. At times overboard water has to be used in the laundry, showers, and washing of decks. This source should only be used when it is approved by the medical officer and when out at sea away from shore.

### Storage of Fresh Water

From water safety point of view, detached tanks for storage of fresh water are ideal; but in order to fully utilise the hull space, fresh water is often stored in the inner bottom and outer shell tanks. The ship's bottom is subjected to maximum external pressure and can also get damaged from under-water explosions or when grounded. Should the tank develop a leak, there is likelihood of the contamination of the fresh water in such tanks. Considerable care and regular maintenance are essential to keep the water free from contamination. Use of sounding rods for gauging the depth of water in storage tanks can be a source of contamination; therefore, their use should be strictly restricted. All tanks should have watertight covers, which are to be kept locked at all times. When it is absolutely necessary to enter the tanks for repair and maintenance, these should be properly disinfected before being taken into use. Only hose lines reserved for fresh water should be used and all cross connections to other systems eliminated while filling the tanks. Water tanks should be painted only with authorised paints; otherwise there will be a risk of unpleasant taste and odour or even poisoning by toxic chemicals. After treatment, the tanks should be cleaned, thoroughly flushed and decontaminated.

### Water Purification

Water on board the ship when obtained from shore should have been already treated. The medical officer should see that potable water on board the ship conforms to the bacteriological standards laid down for urban supplies. At least 0.2 ppm of free chlorine should be available in drinking water at all times. Sterilisation of water with chlorine may be carried out when necessary. In large ships chlorine gas in solution is sometimes used when automatic chloronome is available but in most of the smaller ships field methods have been employed. Every medical officer should be familiar with the use of case water sterilising (Horrocks' box). Free and combined chlorine can be estimated easily by the use of a chloroscope (Lovibond comparator).

### Distribution of Water

Naval vessels have two primary water systems which serve the entire ship; the fresh water storage and distribution system, and fire fighting and flushing system. An independent system of water supply is provided for special requirements of engine rooms. The fresh water distribution system delivers potable water to galleys, sculleries, pantries, sick bays, laundries, deck showers and to drinking water taps throughout the ship. The fresh water and salt water systems are generally independent of each other. Otherwise, precautions must be adopted to avoid danger of cross-connections and back siphonage between salt and fresh water systems. The fresh water system should be physically disconnected, preferably by removal of a section of the corresponding connection pipe, before installing a connection between the overboard water and the salt water system. The same precaution must be adopted in the case of the fresh water system. The following general rules should be observed as precautions for protection of fresh water on board the ship :

(a) The fresh water system should be kept entirely separate and disconnected from all other systems on board the ship.

(b) The fresh water tanks and all parts of the fresh water system must be disinfected at least annually or whenever there are reasons to suspect that it has been contaminated.

(c) Cross-connection between fire fighting and flushing systems on board and the potable water system ashore should not be permitted unless back flow preventers are used on the potable water outlets. If this is not done, there is risk of contaminating the drinking water on shore.

(d) It should be ensured that when there is a dual system ashore, the fresh water tanks aboard are filled from drinking water hydrants and not from the fire main.

(e) When fresh water is introduced into any piece of equipment that may contain contaminated water, it should only be admitted through a non-floodable air gap.

(f) Salt water for shower, laundry or flushing decks should not be used when the ship is anchored in polluted areas.

(g) As an added factor of safety, water stored in fresh water tanks should be re-chlorinated, especially when the ship is operating in polluted waters.

### Protection of Water

Cross-connection between two separate water supply systems causes water to leak or flow in either direction between the systems. The potable water to all tanks, pipes or other water connections likely to contain contaminated water should therefore be delivered through non-floodable air gaps. The air gap protection should be provided for galley and pantry sinks, scullery equipment, laundry machines, lavatories, hospital sterilisers and fixtures of all types. All drainage outlets to sewers, drains, or the bilge, should be protected from flooding by the use of air gaps. All fresh water pumps should be air tight and

should have air tight suction lines free from cross-connections. For priming of water pumps, only good quality water must be admitted to the pump casing through an air gap. All pumps after they have been dismantled for repair should be decontaminated after reassembly and before they are put into use. All faucets, hydrants, and other outlets on any system not carrying potable water should be clearly marked as "UNFIT TO DRINK". Hydrants and other connections used for loading water should also be stencilled for proper identification. In order to trace and identify the various water and other pipe systems and to prevent improper connections, all pipes are stencilled with the name of the fluid carried or are painted with distinguishing colours. The identification colours used are light blue for potable or drinking water, orange for sanitary water and red for fire services.

### Water Requirements

The normal minimum allowance of fresh water for all purposes on a naval vessel should be about 55 L / day, out of which about 1/5 is required for drinking and cooking. Economy in the use of water is essential but a liberal allowance is desirable as it helps in the prevention of diseases. At times drastic restrictions in the use of fresh water may have to be enforced, but even under these circumstances an allowance of 10 L / man / day for drinking and cooking purposes is considered to be the absolute minimum. Under such conditions sea water can be used after desalination and decontamination, in showers, waterclosets, laundries. The quantity of water required for drinking will depend upon the ambient temperature and physical activity.

### Use of Salt Water

Seawater on board ships is used primarily for fire-fighting and sanitary purposes (for flushing of toilets etc). Seawater is also used in condensers (Heat exchangers) for cooling of machinery, for anchor cleaning and for pumping out oil and grease bilge eductors. In the event of a NBCD fall out, certain types of ships have a sprinkling system on upper decks which form a "water curtain" to prevent against such biohazards from contaminating the ship. Now a days, most ships are fitted with reverse osmosis plants, the purpose of which is to convert sea water to fresh water thus drastically reducing the need for water storage on board during long sailings. The RO plant functions on the principles of reverse osmosis which prevents the free passage of solutes through a semi-permeable membrane thus letting out only fresh water which is checked for conductivity and salinity. If saline content is more then the permeate is recycled to further reduce the saline content till it reaches acceptable limits.

### Emergency Water Supplies

A 1000 L tank for vessels with a total complement of over 500, and a 500 L tank for vessels with a total complement of 300 to 500 should be provided at the forward and after battle dressing stations. Destroyers and other similar ships should have a 200 L tank. The mid ship battle dressing station should be equipped with a 500 L tank. Prior to action, buckets, tubs and other containers should be filled, and placed at the battle dressing station for use if connections to fresh water system tanks are damaged or destroyed. Arrangements for emergency drinking water should also be made in turrets and other action stations. Lifeboats and rafts must at all times carry a supply of drinking water. All emergency supplies should be regularly examined in order to ensure that safe water is available at all times.

### Cleaning of Storage Tank and Distribution System

On board the ship, in addition to thorough cleaning and disinfections of the tanks, the pipes, hose and pumps also require proper decontamination. For this purpose, after thorough cleaning by scrubbing and brushing, the tanks and the system are filled with water with a high chlorine concentration, which after an hour's contact is flushed through the system. All personnel employed for cleaning the tanks should be free from infectious diseases, and are required to bath and wear clean clothes before entering the tanks. After scrubbing and cleaning of the tanks, the pipes and other parts of the system are flushed with clean water. Tanks and pipes are then filled with water super chlorinated by adding 60 g of WSP / 1000 L of water. The capacity of the tank and system should be determined to know the quantity of water required to completely fill the system and the amount of WSP required. The total amount of WSP is first made into a thin paste, by mixing 1 kg in 10 L of water, and added to the tank when it is full and then filled. Circulation of water through the rump and back to the tank ensures proper contact with the superchlorinated water; taps and outlets nearest to the tank are allowed to flow until the highly chlorinated water appears in them. This process is continued outward from the tank until all outlets have been flushed. The outlets are then closed and after one hour's contact, the water is let out. The system is then washed and filled up with potable water.

## Food Supply and Food Inspection

The special problem encountered afloat is the preservation of fresh rations during prolonged sailing periods. Most ships of the fleet are equipped with cold rooms for preserving meat; but only some ships have a separate room for storage of fish. Fish should not be stored in the same room with meat as it imparts a fishy smell to the entire meat in store. Failure of power or a mechanical breakdown of the cooling plant may cause putrefaction of meat and fish. The thawing of the meat should be done gradually. Tinned milk is issued in lieu of fresh milk. Ships not having their own bakeries have to use bread baked many days before their consumption. There is a shortage of leafy vegetables during prolonged sailing. A daily inspection of fresh rations issued to the galleys is necessary during any prolonged sailing programme. Strict vigilance should be kept for detection of deficiency diseases amongst the ship's company. The medical officer serving afloat should ensure that the stored perishable foods are safe for consumption. He must inspect meat daily after it has been taken out of the cold room, particularly during prolonged sailing when frozen meat is often stored on board for over 2 months, as due to occasional power or mechanical failures it may become unfit for human consumption. The same applies to other

perishable foodstuffs stored in the cold room. Arrangement for cooking and serving of food should be on the same hygienic lines as on shore. Wastage of food should be avoided.

### Sewage Disposal

Ships, in most cases, discharge their sewage over the side without treatment. Disposal by this method presents no problem when a ship is underway, except that of providing adequate seawater to ensure flushing of the troughs and the effluent line, since sewage requires 1 to 40 dilution ratio. On some vessels, the construction is such that drainage from the plumbing fixtures cannot be discharged overboard by gravity flow because they are below the level of the waterline or because openings would weaken the armour of the ship. In such instances the liquid wastes flow into a sump tank equipped with a float-device which, when the sewage rises to a certain level, automatically starts a pump that lifts the sewage up and over the side. Inspections must be made to ensure that the pump is in working order and there is no leakage or overflow. The tanks should be cleaned, scraped and painted when the ship is in port for refit.

Disposal of all wastes from submarines when operating under water is achieved by forcing them out by use of compressed air. Some times the wastes are collected in a tank and ejected at specified intervals. This method requires special equipment and education of personnel in its use to avoid blowing the wastes back into the ship's compartment. Tanks require periodic cleaning, scraping and testing during dockyard refit periods to prevent fouling and leaking. Any cross-connection aboard presents a special problem due to the frequent variation of the water pressure and the subsequent back siphonage created, especially in the fresh water system. Because of necessity, fresh water, salt water, and flushing system lines are located in close proximity to one another. These conditions require special attention to prevent any accidental contamination of the fresh water supply by polluted harbour water or sewage wastes. Due to the problems involved in a ship's construction, it is often difficult or impossible to prevent sewage and other waste lines passing through food-service or food-storage areas. Under such conditions the lines must be marked distinctly, and frequent inspections should be made to determine their freedom from leaks that might contaminate food.

### Pest Control

Rodents, cockroaches and bed bugs are constant sources of nuisance on board. Rodents particularly pose a menacing problem by their wanton destruction of valuable stores and equipment. In modern ships burrowing from one compartment to another is impossible, but they can always find enough of hiding and nesting places, especially within panels between decks. They get on to the ships from the shore or from other ships alongside. Having gained access to the ship they multiply rapidly. It is, therefore, important that the medical officers should have adequate knowledge of rodent control to advise the executive officers. Knowledge of habits and characteristics of various species of rodents is helpful in instituting the control measures. In general, rodent control on ships is achieved by denying them access to the ship, denying food, water and shelter for them and active destruction by trapping, poisoning and fumigation.

#### Prevention of Access to Rodents

Rodents gain access to the ship over shorelines, gangways, cargo nets, electric and water lines and palletised cargo, which has been undisturbed for a month or so. Port health authorities normally enforce the regulations regarding the use of rat guards and these must be complied with. All lines connecting ship with decks should be protected with rat guards in such a manner as to prevent rats travelling from line to line. Bow, stern and spring lines should be illuminated during the hours of darkness. All landing ramps and gangways not in use should be removed and those in use should have adequate lighting between the hours of sunset and sunrise. Cargo nets should be lifted on board the ship when cargo is not being transferred. The following precautions should be observed when placing the rat guards :

(a) The lines should completely fill the central hole of guards so that no gap is left for rats to pass through.

(b) If several lines are enclosed by any one guard, they should be lashed together and the interstitial spaces stuffed with cloth.

(c) Guards should not be placed too close to the docks i.e. less than 1 m, as rats can jump from the dock to the rat guard or to the line beyond the guard.

(d) When the lines of different ships cross each other, the guards should be placed in such a way that they cannot be bypassed by the rodents.

(e) Rat guards should not be less than 1 m in diameter. There should be no sagging of the guards as this reduces their effective diameter.

(f) Guards with small central openings should not be placed on several lines as there is a tendency for the seams to gape and thus allow access to rats.

#### Rat Proofing

The object of rat proofing is to deny rats, by constructional fortifications, enclosed spaces for the purpose of hiding, nesting and breeding and also the opportunity of obtaining an adequate food supply. Being thus deprived of these biological necessities for existence and propagation even if rats manage to enter a rat-proof ship, it will be difficult for them to live and propagate for any considerable period of time on such a ship. Under conditions of food scarcity, rats even kill each other; and under conditions of semi-starvation and thirst it is easy to trap them and they also readily accept poison baits. The storerooms for provisions should invariably be made rat

proof by closing all openings around pipes and conduits with metal sheeting and by screening other openings. The proper turnover of the stores every month will reduce rat infestation. Food stuff should be stored in rat proof containers. Refuse and food scraps from galleys and mess decks must be deposited in raptor containers pending disposal. All cooked and left over food must be stored in proper rat proof lockers.

### Rodent Control

The most important place where active rodent control measures should be adopted are the docks and harbours. Destruction of rats ashore should be carried out. Trapping and poisoning can be practised on board the ships also.

(a) Trapping

This can be employed while ships are alongside or in dry dock or wet-basin. Rat traps are normally not authorised on board the service ships; these are obtained on loan from Station Health Organisation. Traps will be effective for the first three days, provided sufficient number of traps are laid on the rat runs which are usually along the borders of the cabin spaces and the air trunkings.

(b) Poisoning

This can be carried out even while the boat is on its run. The standard poison now used is Zinc Phosphide mixed in the proportion of 1 part to 19 parts of wheat flour. Bait can also be prepared with tinned fish.

### Control of Cockroaches

Good sanitation and housekeeping in kitchens, pantries and dining halls prevent cockroach breeding. The most effective aid to control them is by spraying of 1% Baygon or Malathion-pyrethrum mixture. These chemicals are not normally supplied on board the ships, and spraying is carried out by the staff of Station Health Organisations of the Navy. Newer agents like Goliath Gel are also useful.

## Prevention of Communicable Diseases

The scientific principles for prevention and control of infectious diseases afloat are in no way different from those on land. Ships, however may call at ports of the countries where specific infectious diseases may be prevalent. There is often a greater chance of spread of some of the communicable diseases on ships than on land due to overcrowding and adverse environmental conditions. Therefore, the medical officer has to be constantly on guard to prevent any importation of such diseases on board the ship and thereby to the country. The control of infectious diseases, disinfection and disinfestation are described in relevant chapters.

## International Health Regulations

International Health Regulations have been drawn up by the World Health Organisation with the object of maximum possible protection against infection while causing only minimum interference with international traffic. They seek to ensure this protection by preventing infection from countries where it exists and by containing it upon arrival. These regulations for the prevention of spread of diseases by ships and aircrafts are binding on all member states of WHO. The most important provisions of the regulations are notification; health organisation at the frontiers, particularly in ports and airports; and measures authorised with regard to individual goods and means of transport. The regulations cover plague, cholera and yellow fever now designated as "quarantinable diseases". The health measures prescribed are maximum measures applicable to international traffic, which a state requires for the protection of its territory against these diseases. It has also been laid down that sanitary measures and health formalities should be initiated forthwith, completed without delay and applied without discrimination. Disinfection, disinfestation, deratisation and other health operations should be carried out without causing any undue discomfort or injury to a person, damage to the ship and its cargo, and risk of fire.

### Bill of Health and Pratique

The health authorities of a port must take all practicable health measures to prevent the departure of any infected person or a person suspected to have been in contact with such a person and to prevent the introduction of a possible agent of infection or vectors of the diseases under the regulations on board the ship. A certificate completed by custom authorities in which, in addition to the routine details of the ship, it is certified that no such disease was present at the time of sailing from the port should be given to the Captain of the ship before leaving the port. This is called the 'Bill of Health'. Except when cruising in home waters, this certificate is necessary to be obtained before leaving from the homeport to any foreign country. Any vessel coming from an infected port or with an infectious case on board must fly the yellow quarantine flag. Such ships are directed to anchor at the quarantine anchorage and withhold communications with shore or other ships by boat until after all the instructions and regulations for the prevention of the particular disease have been complied with and the ship is declared by the port health authorities as free from a communicable disease: This certificate is called the 'pratique'. For obtaining a 'pratique' the 'Bill of Health' from the previous port of call has to be produced before the port official at the next port of call. However pratique can be granted by radio prior to the arrival of the ship, if the port health authority is satisfied on the basis of the information received from the ship prior to its arrival, that the arrival of a ship will not result in the introduction of an infection.

### Health Measures on Arrival at Port

The port health authority is empowered to carry out a medical examination of any ship or person on an international voyage on arrival and determine from the conditions, which exist on the ship at the time of the medical examination and any health measures, which may be applied. An infected person on board can be removed and isolated. Any person on an international voyage from an infected area can be placed under surveillance until the end of the incubation period of the disease. However, they are not quarantined unless the health authorities consider the risk of transmission of infection by the suspect to be exceptionally serious. Health measures other than medical examination are normally not repeated at a subsequent port unless, after the departure of the ship from the port where the measures were applied, an

incidence of epidemiological significance warranting the further applications of health measures has occurred, or when the health authority for the subsequent port considers, on the basis of definite evidence, that the measures applied at the previous port were not substantially effective. A ship is not prevented for health reasons from calling at any port. If a port is not equipped for applying these measures, permitted under regulations and which in the opinion of the health authority of the port are required, such ships can be ordered to proceed at their own risk to the nearest suitable and convenient port. The provisions of these International Health Regulations are equally applicable to aircrafts on international service.

### Special Preventive Measures

Prior to proceeding on a cruise, the incidence of infectious diseases at various ports of call should be studied (World Health Organisation 'Epidemiological and Vital Statistics Report' may be helpful in this respect). If information about the occurrence of diseases such as cholera, plague and influenza becomes available, it is better to avoid the infected port altogether. If an infectious disease is present in an epidemic form in a port of call, it might be necessary to place certain districts out of bounds or to stop all shore leave, according to the circumstances. Useful information can always be obtained on the subject from the port officer who comes on board to give 'pratique'.

If a member of the ship's company comes in contact with a person suffering from an infectious disease, while ashore or on leave, he is required in accordance with the naval regulations, to report this fact at once to his commanding officer. The measures for dealing with contacts of various communicable diseases have already been described. If the infectious disease assumes an epidemic proportion on board the ship, in addition to the routine preventive measures, the following special precautions may have to be recommended for the control of the disease :

(a) Stoppage of drafting or leave.

(b) Prohibition of the ship's company mixing with others while playing games ashore.

(c) Stoppage of visitors to the ship.

(d) Disinfection of outgoing correspondence and laundry.

(e) Disinfection of the ship as described in article 1106 clause 2 and article 1109 clauses 5 and 7 of the Regulations, I.N.

## Special Responsibilities of the Medical Officers

### Elimination of the Mentally Unfit

Medical officers afloat and ashore should be constantly on the alert to notice the appearance of nervous and mental disorders among naval personnel. Incipient cases can be detected if they acquaint themselves with the prodromal signs, and early symptoms and the diagnostic criteria of neuroses, psychoses, and psychosomatic conditions. The medical officer on board the ship can often spot those who are maladjusted and likely to breakdown, by paying particular attention to the frequent visitors to the sickbay and by checking the family background of the chronic offenders. They should gain the confidence of such personnel and investigate their personal problems. The divisional officers and the Chief Petty Officers in charge of such personnel may be of great help in such situations. Anyone showing a mental disorder should at once be evacuated to a hospital. Pending hospitalisation, sedation and guards should be arranged depending on the necessity of the particular case.

### Reports of Health

The medical officer to render a monthly report to a higher medical authority.

(a) In reporting on the health of the ship, the habitability of different living and working spaces should be reported in a methodical manner. When reporting on a section or a compartment, the following information should be included :

(i) Compartment name and number.

(ii) Approximate location.

(iii) Approximate dimensions.

(iv) Principal use of compartment.

(v) Average number of persons occupying the compartment.

(vi) Other relevant data, such as heat producing machinery within the compartment or adjacent hot spaces.

(b) The ventilation system of the compartment should then be described briefly. The climatic conditions should be reported by recording the physical measurements (see chapter II).

(c) The morbidity rate of diseases including effects of heat, prickly heat, boils, the physiological readings (pulse rate, blood pressure, weight, temperature etc.) and an opinion survey are also included in this report. However, investigations for research purposes can only be undertaken by a special team of workers. The type of work is only undertaken when the report from the medical officer indicates that the environmental conditions are having adverse effects on the efficiency and output of the personnel.

## Sea Sickness

This is an acute illness characterised by heaviness in the head, mild headache, nausea, dizziness, and vomiting. The psychological effects of this illness in the highly susceptible or neurotic personnel can be quite devastating and in rough seas can temporarily knock off a large percentage of the manpower. Severe cases are prone to vomit blood stained fluid leading to signs of collapse. Principal factors responsible for this syndrome are visual, kinesthetic, and psychological. Physiologically, the chemotactic trigger zone, vomiting centre and the vestibular apparatus are involved. Those who are prone to hypoglycaemia have a history of attack in an empty stomach. The preventive measures include acclimatisation, reassurance and administration of antihistamines. Preventive measures if instituted in time are quite effective; but once sea sickness sets in,

# Survival at Sea

## Introduction

A situation may arise during routine sailings, training exercises or operations warranting abandoning the ship. Shipwrecked mariners also need to fend for themselves for survival at sea. It requires qualities of leadership, courage and strong will to overcome adverse circumstances. If one has the understanding of the ocean's strength, commonsense and knowledge of the use of safety equipments, survival becomes easier.

## Incidence of Shipwrecks

In an analysis of incidence of shipwrecks, it has been found that 70 % ships were lost in Atlantic and most deaths of the crew were due to exposure to cold. In contrast 24% ships were lost in tropical waters and the main cause of death in them was dehydration. The remaining 6% ships were lost in arctic water. *Titanic*, a Passenger ship, sank on 15 Apr 1912 after colliding with a large iceberg. Out of a total of 2,200 passengers and crew only 700 survived. *HMS Glorious* was torpedoed in the World War - II. Out of 1,000 personnel on board, only 400 could board life-rafts. There were only 36 survivors. *INS Khukri* was sunk during Indo Pak war in 1971 in a torpedo attack. Out of 216 personnel borne on board, 149 died and 67 survived. In the peace time loss of INS Andaman in 1990, when the ship floundered in a tropical storm and sank off Visakhapatnam, 15 died and there were 92 survivors.

## Principles of Survival

Some terminologies used in this chapter are described below:

**(a) ABANDON** : The act of leaving a ship in distress.

**(b) SURVIVAL** : The ability to take to sea with the intention of getting rescued by external assistance.

**(c) RESCUE** : The act of providing assistance to shipwrecked mariners with the intention of saving their lives.

Successful survival depends on many conditions prevailing at the time of abandoning the ship viz. day or night, temperature of water, visibility, calm or stormy sea, presence or absence of enemy forces or friendly ships in the vicinity, the preparedness of the crew and their ability to lower the boats and rafts quickly. Three most important principles of survival are as under :

### (a) The will to Survive

God helps those who help themselves. A survivor should stay where he is. When the situation demands, one should help himself by taking following actions.

(i) Abolish all fears of mind

(ii) Decide on a course of action quickly

(iii) Check all safety equipments

(iv) Show leadership qualities

(v) Always avoid overexertion

(vi) Start rationing food and drinking water at once

### (b) The knowledge of expected hazards and use of commonsense

A person should acquire knowledge of the hazards expected and apply commonsense regarding the following: -

**(i) Protection**

Protection implies to application of first-aid, finding of suitable shelter and use of suitable clothing.

**(ii) Location**

One should do everything to assist search and rescue (SAR) organization to locate oneself by using the items in survival pack and the natural resources available.

**(iii) Water and Food**

Both water and food are vital for survival. Knowledge about what to drink and eat and in how much quantity is essential for survival.

### (c) Effective use of Safety and Survival Equipment.

(i) The Life Raft

The life raft is made from gas-tight, rubber proofed, high strength fabric. The various parts are rings, the floor, the arch or column supporting the canopy, and the canopy itself [Fig 95(a)]. The canopy will stay up even if one of the buoyancy rings is damaged or deflated. The following types of life rafts are available in Indian Navy:

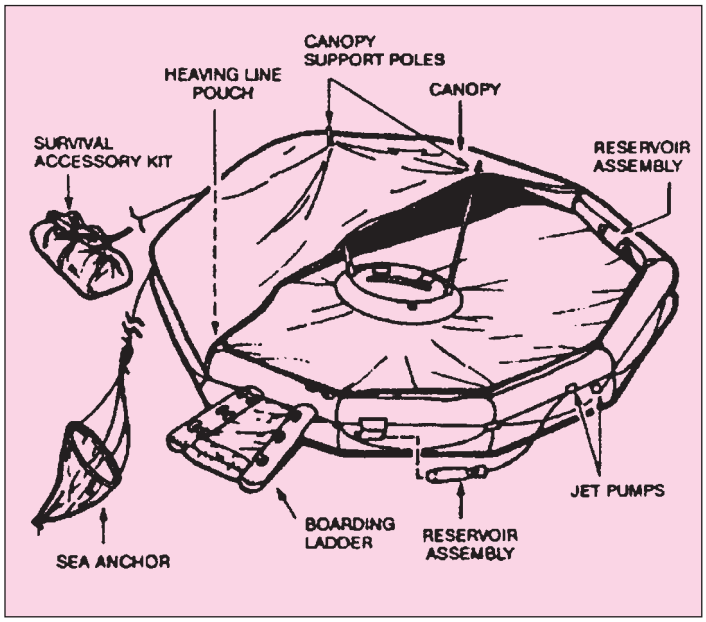
- Life-rafts (ships)
  - 25 men life-raft
  - 20 men life-raft
  - 10 men life-raft
- Life-rafts (air Crafts)
  - 12 men life-raft (TU)
  - 8 men life-raft (IL)
  - 4 men life-raft (Chetak & Sea King)
  - 1 men life-raft (Sea Harrier)

**The life raft should be handled as follows :**

**Charge of the Raft**

One person should be nominated to take charge of the safety responsibilities on the raft. All survivors must follow his directions without any reservation. The person-in-charge must maintain a log over the entire period spent in the raft. The first entry must include all details of the accident e.g. date, time and position of the wreck, names of survivors, weather conditions, details of rations

Fig - 1 : Twenty five men life raft



available etc. Later entries must over all details of stay in the raft, the physical condition and morale of the people on board, the rations issued, weather, sighting of ships and aeroplanes etc. The survival pack is likewise to be in the personal care of the person-in-charge and he should personally distribute water, rations, medicines etc.

**Topping up**

All parts of the raft must be checked regularly. From time to time the pressure in the buoyant rings, arches or column should be checked. DO NOT INTERFERE WITH THE DEFLATION VALVES.

**Leaks in the raft**

Any leaks in the raft that have been temporarily plugged with leak stoppers should be repaired properly at the first opportunity.

**Routine Duties**

Routine duties include checking of raft every hour or two, collection of rain water and care of the injured.

**Watcher**

A lookout must be kept throughout 24 hours without a break. The heliograph, Aldis or morse lamp and the distress signals should always be kept within reach. At least two men should be kept for each watch. One keeps a look out for rescue craft and the other is responsible for checking the collection of water in the raft.

**Weather Protection**

In cold weather, the floor of the raft must be kept inflated. In hot weather, the floor is to be kept deflated for cooling by seawater from below.

**Co-operation and Confidence**

The inmates of the raft should never lose hope. The raft offers excellent protection. It is important to keep the will to live and to maintain discipline.

(ii) Life Jackets

The following types of life jackets are available in the Indian Navy :

- Hazardous Duty Life Jacket
- General Service Life Jacket - supplied to all on board IN ships. It has to be orally inflated by means of the nylon mouth piece and inflation tube.
- MK 27-H (Sea Harrier)
- MK 6 & 6A (Other air crafts)
- KAPOK (In Sailing Boats)

**Care and maintenance** : Life jacket to be fully inflated and left for 24 hours to check for any leak. After submerging in sea, to be cleaned with fresh water, dried and preserved with chalk powder.

(iii) Life Buoy

Standard life buoy is made of polyurethane foam and covered by orange polyvinyl chloride. The ship's name should be written in 50 mm black letters.

(vi) Man over board smoke and light marker

It is attached to life buoy by a PP rope and secured on mounted bracket on the guard rail. It produces orange smoke for 15 minutes and white light for 2 hrs duration, when exposed to sea water.

(v) Survival Pack

The items described below are provided in Survival packs in rafts.

- **Drinking Water** : Water is supplied in cans or plastic bottles. If sufficient drinking water cannot be provided, desalination tablets may be provided for preparing drinking water from sea water.
- **Food** : Barley, sugar or glucose and rations in concentrated form providing a total of 2,500 calories food value per person is ideal for survival. A typical survival ration is rich in carbohydrate and contains only negligible amounts of fat and proteins.
- Calibrated mugs for measuring water rations for each person.
- Can openers for opening water and food cans.
- **Distress signals (Pyrotechnics) :** Two parachute rocket signals, hand held, rads. Six hand held flares red.
- **Signalling torch:** It has provision for signalling by morse code.
- Heliograph for signalling in daylight.
- Signalling whistle to attract the attention of people in water or on other rafts in the water or ships.
- Fishing tackle consisting of fishing line and hooks.
- First aid kit
- Anti sea sickness tablets.
- Deflation plugs
- Leak stoppers, Topping-up pump, repair kit
- Hand book for survivors
- Sponges, Baler

- Floating knives
- Drogue/ sea anchor
- Mittens, thermal protective aid
- Radar reflector
- Paddles

### Eating and Drinking

Drinking water is a more vital physiological need than food intake. One may tolerate hunger for three weeks whereas lack of water intake can be fatal in a few days.

Water

(a) No water should be given to healthy people in the first 24 hours; their bodies still have sufficient fluid. If time permits, drink as much water as possible before abandoning the ship Sick and injured may be given water in the first 24 hours, if they are thirsty. The daily ration of water must be given in several small portions soon after eating food.

(b) In drinking, the lips must be moistened, mouth and throat must be wetted by rolling the water around before swallowing; drinking should be slow and in sips.

(c) Rain Water

Do not overlook any chance of collecting rain water even if in very small quantities. Use plastic bags in the survival pack for this purpose. Empty water cans may also be used to collect rainwater. Even if abundant rain water is collected water is to be rationed prudently.

(d) Sea-Water

Seawater or even if diluted with fresh water should never be drunk even in small quantities as this leads to salt overload. The body will need large quantities of water to excrete the salt that is taken. DRINKING SEA WATER EVEN FOR A SHORT TIME IS FATAL

(e) Preserve water balance with proper sleep and rest, avoiding exertion, sweating, alcohol, smoking and highly proteinous food.

(f) Thirst can be allayed by increasing saliva e.g. by sucking on a piece of cloth or a button.

Food

(a) Food rations must be distributed sparingly. In the first twenty four hours no rations should be issued. The rations should be issued judiciously on subsequent days.

(b) Sea Weeds

Some types of sea weeds are edible. Fresh good sea weed is odourless and feels smooth and firm. Algae on the sea weed should be removed before it is eaten. Long sea weeds of a fibrous nature should not be eaten as they cause inflammation or irritation. Sea weeds contain salt and may be eaten only if sufficient water to dissolve or wash away the salt is available.

(c) Fish

Sea fish are generally edible and as much angling should be done as possible. Moreover, fishing is a good pastime, which keeps up morale. Fish contains some salt, hence if it is eaten, additional drinking water should be available. In temperate waters, all fish are edible. In tropics, fish caught in the open sea outside the sight of land are generally edible. In shallow tropical waters, however, there are some poisonous species. Fish with spikes and those which smell are poisonous. Fish with brushes or spikes but no scales SHOULD NOT EVEN BE TOUCHED, since there is danger of poisoning even in holding them. When handling such fish, hands must be protected, otherwise small injuries produced by handling them may lead to inflammation.

(d) Sea Birds

All sea birds may be eaten even raw if the oily taste can be overlooked.

### Preventive Measures

The following preventive measures are recommended:-

(a) Avoid perspiration as far as possible, as any loss of water from the body is dangerous. Cut down body movements to a minimum. It is very important to cut down sweating by protecting the body from sun and if necessary by wetting clothes with sea water.

**(b) Sea Sickness**

It can become dangerous if it continues over a long period as it causes loss of body fluids. Every one must be protected by taking the tablets provided in the survival pack.

**(c) Frost Bite**

It is caused by intense cold or icy wind and appears mostly on the face, hands and ears. Indications are numbness and intense pallor of the parts affected. The affected parts should be covered with protective clothing. These parts should never be rubbed or exposed to sudden heat.

**(d) Sea-Water Injuries**

If the skin is covered with salt and the pores are blocked, it is particularly sensitive and easily inflamed. Such inflammations should be covered with ointment and loosely wrapped in bandage.

**(e) Sun Burn**

Sunburns should be prevented by protecting the body from the direct rays of the sun which might result in boils and later in inflammation. Ointment is useful in treating the sunburns.

### Attracting Attention

Under normal conditions, a life-raft may be seen with the naked eye from a distance of 4 miles and in a good weather, it can be picked up by radar at more than 2 miles. In clear weather, pyrotechnic distress signals can be made out at a distance of 25 miles. The following instructions must particularly be observed when one is not sure whether rescue has been alerted and ships or planes are engaged in a search for survivors.

(a) Distress signals should be fired only when you are convinced that a distant ship whose attention is to be drawn is NOT coming any nearer. If it is seen

approaching, wait until you are sure that the distress signal can be seen from the ship before setting off the signal. For aeroplanes, the distress signals can be fired in the daytime only when you can actually see the plane. Generally fire the signal holding it out as far away as possible from the raft.

(b) The mirror heliograph is used to help search at sea and signals can be seen by ships and planes upto 20 miles depending on the sunshine and atmospheric conditions. It is a reflector with whose aid you can signal to search vessels and indicate your own position.

(c) At night the water proof signalling torch can be used to send blink signals or messages by morse code.

**Rescue**

The rescue teams should follow the guidelines as given below:

(a) If a life raft is sighted by a ship, rescue is immediate and the survivors are picked up by the ship. Even if the raft is sighted by a plane, rescue is absolutely certain. The plane will indicate by circling round, that the raft has been noticed, and call up a ship, sea plane or helicopter to pick up the survivors.

(b) Some search planes are equipped with a "Rescue-Supply" kit which is dropped into the sea near the life raft to keep the survivors supplied until final rescue. The kit consists of a number of containers connected to one another. One of these containers hold a life raft which inflates automatically on hitting the water and the other containers hold drinking water, food, clothes, medicines etc.

(c) To mark the life-raft and also ascertain wind direction, the search plane will first send out a smoke signal. The plane then flies at fixed height, obliquely to the wind in the lee over the raft and throws out the container. When the containers strike the water, a sea-anchor is released automatically from each one of them and the life-raft in the middle container inflates rapidly.

(d) The raft with survivors should then take in its sea-anchor and strike out towards the life-raft dropped from the plane. Some of the survivors should then board the air dropped raft, distribute the water, food, etc. and then wait for ship to come and pick them up.

(e) **Rescue by Ship:** The rescue ship will come as close as possible to the raft and make lee. As a result of the ship's height, which catches the wind, its drift is greater than that of the life-raft and it can therefore come quickly up to the raft. Take care that the sea-anchor of the raft does not tangle with any part of the ship e.g. the propellers. If necessary take the anchor in. Wait for a line to be thrown from the ship to the raft. When this is done and the line is caught, tie fast to the painter or the mooring of the life-raft. Thereafter, follow the instructions given by the rescue ship. If necessary, they will send a life boat and the rescue action will be directed from it.

(f) After the survivors have been rescued, the raft can be taken on board the rescuing vessel and deflated.

(g) Rescue by helicopter is easier than by sea-plane. The survivers are fished up from the water by a net. Naturally they must leave the raft and get into the water first, and care should be taken that not all the inmates of a raft leave at the same time. Generally the weakest ones should be sent first, as it will then be possible for the others to give them assistance. The survivors can also be picked up directly from the raft by a rescue sling. The sling is pulled over the body of the man and lies against the small of the back and under the armpits. The distance between the hoisting point and the chest of the person being lifted is adjusted by a safety slip-knot. If a survivor cannot help himself, a member of the helicopter crew may be let down and then the survivor can be helped into the sling for hoisting up.

## Glossary of events during survival at sea

**Boat stations**

(a) Muster all personnel as per their life-raft numbers.

(b) Ensure life-raft cord secured to strong point.

(c) Rig all, ropes & ladders, scramble nets to the ship side.

(d) If time permits, drink as much water as possible before abandoning ship.

**Abandon ship**

(a) Prior to abandon ship, all life-rafts must be manually launched.

(b) Put on life jacket and fully inflate.

(c) Board the life-raft with the help of ropes and ladders with out getting wet.

(d) Do not jump into life-raft. Avoid jumping from more than 3m height.

(e) If ship is drifting - jump from weather side.

(f) If ship is listed jump from bow or stern.

(g) If ASW weapon fired in the area swim back stroke, try and lift yourself clear of water line if any u/w explosion take place.

(h) Swim together.

(j) If oil burning on water:- Deflate life jacket, swim under water, come up, splash water, take breath and swim under water.

**Abandon ship: actions after boarding**

(a) Cut the painter line.

(b) Get away from sinking ship.

(c) Look for and rescue survivors.

(d) Stream the drogue.

(e) Open survival pack and read through survival instructions (INBR 1329).

(f) Close entrances in cold weather.

(g) Issue anti-seasickness tablets as soon as possible.

(h) Keep rescue rafts together.

(j) Appoint someone in charge.

(k) Familiarise yourself with the survival pack.

(l) Keep floor of rafts dry.

(m)Check raft lighting outside as well as inside.

(n) Attend to injured survivors.

(o) Appoint watch system and look outs.

(p) Ask survivors to pass urine within 2 hrs of boarding life-raft.

(q) Keep up the morale of the survivors.

(r) Never dangle limbs in the water, swim or bathe.

(s) Do not smoke in life-raft.

(t) Do not drink sea water.

(u) Do not refuse any dose of water or anti-seasickness tablet.

(v) Do not remove life jacket.

(w) Use only the safety knives which are provided in the rafts.

(x) Keep the rafts fully inflated at all times.

**Drinking water**

Allow 500 ml of water per person per day. Fortify with rain water, body fluids squeezed out of fishes, squids, crabs. Collect rain water in plastic bags. Daily water is rationed in three doses, issued soon after food intake.

**Food ration**

Allow one item/ person every 8 hrs (chew well).

Avoid salty or sweet foods taken from ship: both increase thirst and salty foods speed up the dehydration process in the body.

**Action in hot climate**

(a) Preserve body water: Do not spit. Deflate floor.

(b) Ventilate the raft. Keep out side canopy wet.

(c) Treat sunburn: apply ointment from first aid kit.

**Correcting an overturned liferaft**

(a) It is most unlikely that a life-raft will overturn.

(b) If it does, do not panic.

(c) Survivors are safe to come out through doorways.

(d) One man standing on the gas cylinder and pulling steadily on cross straps can correct the raft.

**Partial deflation of life-raft**

If already boarded

Close entrance securely as quickly possible to keep out of sea water.

If noticed before boarding the raft

Life-raft is still useful and should be boarded as quickly as possible. Do not abandon a life-raft that is swamped or being swamped; stay with it. Close both entrances immediately, even if the life-raft is full of water. Ensure drogue is streamed. Bale out life-raft.

**Rescue by helicopter**

Ascertain the wind direction. Do not use parachute/rocket flare in the presence of helicopter. All personnel except those assisting in the lifting operation should lie down keep still. Lifting strap must not be attached to any part of the raft. Ensure lifting device not entangled with any part of life-raft. Stretcher should be detached from lifting device during strapping procedure. Ground the lifting strap in seawater before taking it on board.

Wg Cdr (Ms) Renuka Kunte

# Medical and Other Aspects of Nuclear, Biological and Chemical (NBC) Warfare

## Nuclear, Biological and Chemical (NBC) Warfare

NBC warfare relates to both the employment of Nuclear Biological or Chemical munitions to cause large scale casualties, destruction and damage, as also the ability to fight in such an environment. The mass casualty/ damage producing effects of these weapons has given a new dimension to modern warfare. There is a possibility of these weapons being employed in future wars. NBC warfare is distinct from conventional weapons because of -

(a) Effect - The magnitude of the effect of NBC weapons is far more than that of conventional weapons.

(b) Mass casualties - The no of casualties is many times more than that in conventional warfare.

(c) Contamination - Large areas and casualties are likely to be contaminated with NBC agents making it necessary to decontaminate.

(d) Complex casualties - The casualties may suffer from conventional injuries and from the effects of different chemical agents, biological agents or from effects of radiation.

(e) NBC weapons have a marked psychological effect leading to severe stress.

(f) Unlike conventional weapons, these weapons have the potential to have a residual effect.

### NBC Defence - Constituents

NBC defence is central to fighting in a battle field wherein NBC weapons have been employed or there is a threat of such weapons being employed either by the enemy or by own forces. Survival in such a environment demands a capability to detect the presence of NBC agents and thereafter adopting protective measures. NBC defense thus includes -

**a) Detection**

The ability to detect any type of NBC contamination.

**b) Protection**

This is required when contamination cannot be avoided. It is broadly categorized as

(i) Individual protection

(ii) Collective protection

**c) Decontamination**

It includes all the measures adopted to remove, destroy or neutralize Nuclear, Biological or Chemical contamination.

**d) Damage control**

This includes mitigation, restoration activities and management of casualties due to effects of NBC weapons at different levels in the battlefield.

NBC weapons are weapons of mass destruction and the casualties caused to men and equipment will be colossal. In addition to the tremendous psychological effect on the personnel, the type of casualties would also pose a challenge to the medical personnel. It is important to elaborate the effects of Nuclear, Biological and Chemical weapons to understand the medical aspects of NBC warfare.

## Radiation

### Nature of Radiation and its Action on Living Cells

Transfer of energy from sun to earth by radiant heat and light is a well - known phenomenon. This radiant heat and light can be stopped by opaque objects, which are interposed in the path of these radiations. These radiations form only a small region of the whole spectrum of electromagnetic radiations - ultraviolet - visible light - infrared region.

The knowledge of the biological effects of ionizing radiation has been built over the past, through experience in the fields of early X-ray workers, luminous dial painters, patients who have been administered radium salts and high doses during radiation, uranium miners, atomic bomb survivors in Japan, victims of reactor accidents and children of mothers who received radiation exposure during pregnancy.

### Types of Radiation

Several kinds of ionizing radiations are known of which common types are the following :

**(a) Alpha Particles**

These nuclei of helium atom are swiftly moving particles of high energy, carrying a positive electric charge. They have little power of penetration, passing into soft tissue upto only fraction of a millimeter, and thus irradiation of the body from outside with alpha particles is of little significance. However, they may affect living tissues when released by radioisotopes within the body.

**(b) Beta Particles**

These are fast moving energy carrying particles (electrons) with a negative charge. The amount of energy carried varies and their penetrating power will also vary accordingly. In general beta particles are more penetrating than alpha particles and can traverse distances up to a centimeter or more in soft tissues. For this reason these are valuable therapeutically, and radioactive substances emitting beta radiations are used for the destruction of superficial tumours. However, heavy doses from outside the body can damage the superficial tissues, and if beta emitting substances are ingested, destructive effects within the body may be produced.

**(c) Gamma Rays**

These are electromagnetic radiations of high energy emitted by atomic nuclei. Like alpha and beta particles,

these are produced in the process of natural or artificially induced atomic disintegration. Gamma rays have great penetrating power in comparison with alpha & beta particles and the more energetic gamma rays can traverse the whole body with relatively little absorption. As a result, almost the whole thickness of the body may be irradiated by gamma radiation and this is the deciding factor in producing the general illness, which may follow this type of irradiation. The properties of gamma rays are essentially similar to those of X-rays but in general gamma rays have more energy and penetrating power compared to X-rays.

**(d) X-rays**

These are also electromagnetic radiations, which are usually produced artificially by electrical machines and their origin is from the electronic structure of the atom. These are widely used both diagnostically and therapeutically in medicine, varying considerably in their penetrating power according to the electrical potential used in their production. The biological effects of X-rays are brought about by high - energy electrons, which are liberated in the tissues during the passage of the rays, thus the biological action of X-rays and beta particles is essentially the same.

**(e) Neutrons**

These are primary constituents of atomic nuclei, and may be liberated with considerable energy. These carry no electrical charge and are therefore not repelled by the charged nuclei of atoms. These enter into the atomic nuclei to build up unstable structures, which often disintegrate with the production of artificial radioactivity. Fast neutrons act mainly by collision with the hydrogen of water and of other compounds which the tissues contain. The resultant recoiling hydrogen nuclei are called protons. The fast neutrons are gradually slowed down in the tissues and may then bring about biological effects by interaction particularly with nitrogen. They may also be captured by the hydrogen nuclei, thereby releasing energetic gamma radiation.

**Ionisation**

Ionizing radiation loses its energy in the medium by knocking out an electron and sharing part of its energy with the electrons. This results in a number of electrically charged atoms, molecules and electrons along the path of ionising radiation, which are called ions. For this reason this is called ionising radiation. Every radiation is characterised by the power of penetration as well as the ionizing capacity. It is the production of these electrically charged particles or ions, which is mainly responsible for initiating the physicochemical changes in the living tissue that lead to the production of radiation damage or biological effects.

The biological effects of radiation are closely related to its dose, the period of exposure and the type of radiation. The intensity of a beam of X-rays or gamma rays is simply the measure of quanta striking a particular area in a given time, the radiation being regarded as consisting of small units of energy called quanta. The radiation dose may be described as the energy, which is absorbed in the small mass of tissue upon which the radiation impinges. Living tissues are not inert. After damage by radiation, repair processes take place, and the rate at which the dose of radiation is given becomes an important factor in determining the biological effects. Thus, if a dose of radiation is spread out over many years, the response may be very much smaller than or even quite different from that which would occur if the same amount of radiation were given in a very short time. On the other hand with some forms of biological damage produced by radiation (like gene mutations) recovery does not occur.

**Measurement of Radioactivity**

Biological effects of radiation depend upon the amount of energy absorbed in the tissues. An atom emits certain amount of energy in the process of disintegration. The total rate at which the tissues are irradiated therefore depends upon the rate of disintegration. In assessing the effects of radioactive material within the tissue, the use of radioactivity units, which depend upon the number of atomic disintegration per second, is necessary. Based originally on the rate of atomic disintegration of radium, the unit of radioactivity is called the Curie and represents the amount of an element in which $3.7 \times 10^{10}$ disintegrations occur per second. This is too large an amount of radio - activity for most biological work and it is customary to measure the amount of radioactivity in the body in microcuries i. e. $3.7 \times 10^{4}$ disintegration per second. The present SI Unit is "Becquerel". The conversion factor from SI Unit to present unit is $2.703 \times 10^{-11}$ and present unit is 37 kilo Becquerel = 1 microcurie

The method of measuring the disintegration of a radioactive substance is in terms of half - life. The time taken for activity to decrease to half its original value is known as half - life, and is also called physical half - life (Tp). When isotope is administered into man, it is excreted out. The time required by the administered activity to excrete to half is termed as biological half - life (Tb). The effective half - life of radioactive substance in the body is as follows :

$$\frac{Teff}{Tp + Tb} = Tp \times Tb$$

## Measurement of Dose

### Roentgen

Roentgen is a unit of measure of exposure. It was only in 1951 that International Commission on Radiation Units (ICRU) clarified that Roentgen is the unit of exposure dose. Exposure at a point is a measure of the radiation at that point based upon its ability to produce the ionisation in air. Thus the unit Roentgen (R) is defined as the quantity of x or gamma radiation such that the associated corpuscular emission per 0. 001293 gram of air (i. e. 1 cc of air at NTP) produces ions carrying one electrostatic unit of quantity of electricity of either sign. In the matter of assessment of biological effects, the energy absorbed by the medium from the exposure of radiation is an important factor. One Roentgen corresponds to the absorption of 87. 7 ergs /gm of air. The Roentgen is unit

of exposure, which applies only to x - or gamma radiations with air as medium. SI Unit for exposure is measured in coulombs per kg.

**(a) Rad**

As mentioned earlier, Roentgen is a measure of exposure and is used in assessing the biological effects in tissues due to radiation exposure. The measurement of the energy absorbed in the tissue has become a necessity, which is called absorbed dose or simply dose. A measure of dose is called rad (radiation absorbed dose). This measure of dose includes all types of radiation irrespective of particulate or non particulate matter. The rad is defined as an energy deposition of 100 ergs per gram. This was first defined by ICRU in 1954. SI Unit for absorbed dose is Gray with 1 Gray equal to 100 rad.

**(b) Kerma**

Kerma (Kinetic Energy Released In Matter) is a unit just like Roentgen which is meant for all media and includes all indirect ionizing radiation (X-rays, gamma rays and neutrons). It is measured in energy / unit mass.

**(c) Rem**

Even though rad is a useful unit, it transpires that in biological system the same degree of damage is not necessarily produced by the same absorbed dose of different types of radiation. In order to account for this, a factor known as Relative Biological Effectiveness (R. B. E) or Quality factor (Q. F. ) has been introduced, which reflects the ability of the particular type of radiation to cause damage. The quantity obtained when absorbed dose is multiplied by R. B. E. or Q. F. is known as Dose equivalent, the unit of which is rem.

**(d) Relative Biological Effectiveness**

| Types of Radiation | QF or RBE |
|---|---|
| X-Ray, or B particles | 1 |
| Thermal neutrons | 3 |
| Fast neutron | 10 |

Relative Biological Effectiveness depends upon the density of ionisation caused by radiation. The values of RBE or QF for different types of radiation are given in the box:

In SI units of dose equivalent is measured in Sieverts (SV).

One Sv = 100 rem.

Certain measurements, which were preferred in exposure quantity and expressed in its special unit the roentgen, have now been replaced by air kerma measured in free air. An exposure of 1 roentgen is equivalent to an air kerma of 8. 7 milligray (mGy). Specific gamma ray constants are now replaced by air kerma rate constants, expressed in units such as wGy h - 1, GBq - 1. at 1m (Table - 1).

**Action on Living Tissues**

The radiation acts primarily upon the cell and its constituents, and upon the complex chemical processes occurring in these, rather than upon the fluids in which the cell is bathed. The processes associated with the formation of ions during the passage of radiation lead to changes in some of the highly organised molecular systems within the cell. These changes are probably brought about by highly reactive chemical intermediates liberated within the cell subsequent to the physical process of ionisation.

Table-1 : International system of units

| Radiation Quantity | SI Unit | Special unit |
|---|---|---|
| Adsorbed dose | 1 gray (Gy)<br>1 Centigray (Cgy) | 100 rad<br>1 rad |

All living tissues are killed when exposed to large doses of radiation. Different types of organisms, tissues and cells vary greatly on the amount of radiation, which they can withstand. Among the mammals, the dose of X-rays to the whole body, which will kill 50 % of an animal species varies from 200 - 1000 R (2 - 10Gy) depending on the species (for man it is thought to be between 400 and 500 R (4 - 5Gy). There is also a wide variation in sensitivity between different animal tissues. For instance, in man, the most sensitive tissues include the lymphatic glands, the epithelium of small intestines, and bone marrow, whereas adult nerve and muscle tissues are less sensitive. Variations in the sensitivity also occur at different stages in the life cycle of a cell; for example cells about to divide are often more sensitive than those in the resting stage.

**Repair Processes**

In case tissue damage is less, the situation is modified by a process of repair, but a distinction must be drawn between true recovery in which the damaged cells return to normal form and function, and the replacement of injured cells by those coming from outside the field of radiation. The latter is a more conspicuous form of repair after heavy radiation damage in the higher animals and leads to the original tissues being replaced by simpler and unspecialised material or scar tissue. Repair processes within the individual cell are not yet well understood and still a matter of speculation. An understanding of such repair processes plays an important role in low - level radiation effects.

**Effects of Radiation on Health**

The effects ionizing radiations on human beings are based on four main sources; uses of X-rays and radium in the treatment of disease, mainly concerning knowledge of occupational hazards of medical radiologists, workers in luminising industry and miners of radioactive ores; study

of the victims of atom bomb explosions and from animal experiments. Observation of patients receiving radiotherapy has yielded information on the general effects of radiation and on the effects produced in different tissues by external radiation, and the therapeutic use of radioactive isotopes has provided data on the effects of radioactivity within the body i. e. internal exposure. The second source of the radiation provided data on :

Radiological worker exposed to external radiation, by X-rays and gamma rays leading to skin cancer or bone marrow damage resulting in blood dyscrasias.

Luminising dial painters who used radium, mesothorium and radiothorium in paints, developed bone tumours. This is due to their ingestion and retention in the skeleton.

Miners who worked in an atmosphere containing high concentration of radon developed lung cancer. The study of different hazards has contributed to the knowledge of harmful effects of radiation and has helped to formulate safety standards. Atomic bomb explosions over Hiroshima and Nagasaki brought wide spread destruction to both the cities. About 15 to 20 % casualties were caused by the gamma and neutron radiation emitted during the explosion. The observations of these casualties regarding immediate and delayed effects of radiation have given baseline information on this subject.

Radiation hazards may be external or internal. The external hazards arise from the exposure of the whole body or its parts to penetrating radiations (like gamma ray or X-ray or neutrons) from sources outside the body. Alpha ray emitters are not an external hazard since alpha rays cannot penetrate even a fraction of a millimeter into the tissue. Beta rays will not normally be a significant external hazard either since clothing will act as a barrier but beta emitters in contact with the skin can produce some harmful effects like loss of hair and skin burns. Internal hazards originate through the incorporation into the body of radioactive materials. This may arise through inhalation of radioactive dusts and vapours, from ingestion of active material through eating and drinking or through cuts and wounds. Depending upon the nature of the isotope, the radiation it emits, its half - life - physical as well as biological, the critical organ in which the isotope concentrates etc. , even extremely minute amounts of internally deposited radioisotopes may be hazardous. The effects also depend upon the rate at which the radiation dose is received. 'Acute' exposure (received in a short period) is more injurious than protracted or chronic exposure. This is because cells have a certain capacity for repair and recovery from the radiation injury. Thus a whole body exposure to 600R(6Gy); would be lethal if received as a single exposure. The same dose spread over a period of 20 years should not cause appreciable clinical effects.

Biological effects can be classified as somatic and genetic. Somatic effects are manifested in the person exposed to radiation. These may be manifested soon after exposure (within a few days) while certain other effects exhibited after a latent period of several years. Genetic injury does not affect the exposed persons but their progeny. The exposure to radiation of sex cells of a person damages the genetic material causing "gene mutations. " During reproduction one of the damaged cells may take part in the fertilization process, the fertilized cell carrying the defect and repeating itself during successive divisions. This leads to a defective offspring. Biological effects can also be classified into immediate and delayed effects. Immediate effects are mainly due to acute exposure whereas the delayed effects are due to chronic low exposures. On the basis of mechanism of induction, radiation effects are broadly classified into Deterministic effects and Stochastic effects. Deterministic effects are sure to occur at high doses and do not occur below a particular threshold dose. Severity of the effects is proportional to the dose. Stochastic effects do not have a threshold dose and are probabilistic in nature and include induction of cancer, leukaemia and genetic effects. (1 - 6).

Immediate Effects of Radiation

A summary of the immediate effects in human beings related to radiation dose when the exposure is acute and to the whole body is given in Table - 2.

**Acute Radiation Effects on Individual Systems**

**(a) Central Nervous System**

An acute dose of 1600 R (16Gy) or more will cause brain damage with severe oedema causing unconsciousness within three to four days followed by certain death. The higher the dose, the more rapid is the onset of unconsciousness. Loss of sphincter control may be a sign of central nervous system involvement.

**(b) Gastrointestinal Tract**

A dose of 400 R and higher will cause radiation sickness with nausea, vomiting and diarrhoea. The higher the dose the more quickly the symptoms appear. Where vomiting comes on immediately and persists for several days without interruption, the dose received will probably prove lethal. Vomiting may also be induced by psychogenic factors. Denudation of gastro - intestinal tract with haemorrhages will follow doses of 900 -1000 R (9 - 10Gy) and is lethal within one or two weeks. The G-I tract is hyperactive initially but later on atony sets in.

**(c) Bone Marrow**

Depression of the haemopoietic activity of the marrow will be caused by doses as low as 200 R (2Gy). Even after 200 to 300 R (2 - 3Gy) improvement may occur without any symptoms, unless complications such as pre - existing illness, pregnancy, trauma and thermal burns are also present. Doses of 400 to 600 R (4 - 6Gy) may result in total aplasia of the bone marrow. Restoration may occur spontaneously by proliferation of primordial cells, provided the period of acute cellular depletion of the blood is tided over. Irreversible aplasia results from doses of 700 to 900 R (7 to 9Gy).

**(d) Lymph Nodes**

The lymph nodes become atrophic and depleted of cells after doses of 400 to 500R (4 - 5Gy). This condition becomes irreversible if 700 to 900R (7 - 9 Gy) have been

Table - 2 : Acute whole body exposure

| Acute Dose | Effects |
|---|---|
| 5,000R (50 Gy) | Immediate and persistent non-effective mass until death |
| 1,000 R(10 Gy) | Initial sickness appears in 1 hour or less. There may be no latent period. No survivors are expected. |
| 650R(6.5Gy) | Initial sickness appears in all personnel within 4 hours and lasts for about one day. The latent period is one week. Death ensues in about 2 weeks in about 95% of the cases. Survivors are non-effective for 6 months. |
| 450R (4.5Gy) | Initial sickness appears in all personnel during first day. The latent period is 2 weeks. About 50% deaths may be expected but can be reduced by giving adequate medical treatment. Survivors are non-effective for 6 months. |
| 300 R (3Gy) | Initial sickness during first day in all personnel. After about 3 weeks of latent period, about 25% deaths may be anticipated but this may be reduced by giving adequate medical treatment. Survivors are non-effective for 3 months. |
| 200 R (2Gy) | Initial sickness during first day in about 50% of personnel. Second period of sickness appears after about 3 weeks and lasts for 1 to 2 weeks. No deaths anticipated unless recovery is complicated by poor health, other injury, or infection. |
| | |

received.

(e) **Skin**

Following 400 to 500 R (4 - 5Gy) hair will usually be lost in bunches within 12 to 14 days. Alpha particles cause damage only if inhaled or ingested.

Delayed Effects of Radiation

Delayed effects of exposure to radiation may occur at any time after the end of the second month. Disorders of the skin and underlying soft tissues and bones may occur. There may be subsequent development of cancer. Cataracts, severe anaemia and leukemia have been caused. There is evidence from animal experiments that exposure to radiation may cause death at a prematurely early age. There may be inhibition of immune response. Radiation exposure may be harmful to the genetic material, which may be transferred from one generation to the other.

**Leukemia**

Leukemia is a disease in which there is an uncontrolled over production of white blood corpuscles. Experiments on animals have shown that the incidence of leukemia is increased by irradiation. Clear evidence that the same is true of the man, comes from two main sources; a study by the Atomic Bomb Casualty Commission of the incidence of leukemia in Hiroshima and Nagasaki, and a survey of the incidence of leukemia among patients treated by radiation for ankylosing spondylitis. The latent period, that is the average length of the period between exposure and the first appearance of symptoms of leukemia was about six years. The conditions of exposure to radiation in Hiroshima and Nagasaki and in the treatment of ankylosing spondylitis are not comparable with the irradiation in small doses over long periods which might be received by persons engaged in work with a possible radiation hazard i. e. in radiologists mainly. Some evidence has been presented suggesting an increased death rate due to leukemia among radiologists.

All evidence indicates that the incidence of certain types of leukemia increases in children as a result of prenatal irradiation at high dose rate of 5 - 50rads (5. 50cGy). Radiation induced leukemia's tend to occur most frequently within a few years (six years) after exposure, and, after 25 years, the frequency tends to return to levels expected in the absence of irradiation.

**Cancer**

Two characteristics of cancer induced by radiation are noteworthy:

(a) The tendency of tumours to arise in tissues already severely damaged by radiation

(b) The long latent period, 20 years or more, before they appear.

Studies of people exposed to internal irradiation include workers and patients contaminated with radium, mesothorium, plutonium and radioactive strontium and also miners exposed to radon gas. Radium, plutonium and strontium are accumulated and retained in the bone thereby irradiating bone - forming cells continuously at a decreasing rate for decades after being absorbed into the body and give rise to bone tumours.

Studies of pitchblende miners suggest that the inhalation of the radioactive gas radon may lead to cancer of the lung. The frequency appears to rise in proportion to the level and duration of exposure. The latent period has been about 20 years and the dosage to lungs over this period may be about 1000rads (10Gy) due to alpha radiation. Lung dosimetry is extremely difficult and the role of other carcinogenic factors such as smoking habits is very difficult to assess. In theory, the inhalation of radioactive particles in the fallout from atomic explosions or in the vicinity of nuclear reactors could also lead to cancer of lung. But the hazard due to fallout from atomic explosions in peacetime is extremely unlikely and steps are always taken to ensure that such incidents do not occur. Lung cancers appear to have been induced at Hiroshima by doses estimated on the basis of crude assumptions to be equivalent to some 30rads (30cGy) of external gamma

radiation and to have increased with dose upto about 100rads (1Gy). The data indicates that from 10 to 40 cases of cancer per rad (cGy) per million exposed (at 200 rad to 300 rad (2 - 3Gy) respectively) develop during the first 25 years after exposure to high dose rate gamma radiation.

Information is also available on the induction of thyroid and breast cancers. Breast cancer mortality at Hiroshima suggests a risk of 6 - 20 cases per million per rad (cGy) in the first 25 years after irradiation among women exposed to between 60 and 400rads (0. 6 and 4Gy). This is probably an underestimate of the situation. For thyroid cancers, an average of about 40 cases per million in the same range of irradiation over the same period of time is obtained. The estimate has large uncertainities due to small number of cases observed. Cancer of the thyroid gland in children has been a sequel to irradiation of neck for enlargement of the thymus gland. This form of cancer is distinguished by its short latent period (about 7 years) and comparatively low dosage of radiation required to induce it. There is a possibility of other factors also involved in addition to the direct effects of irradiation.

Cancer of the skin was the earliest form of radiation - induced tumour to be described in man. By 1911, before the adoption of proper safeguards, fifty four cases have been described among the pioneers of radiology. The doses of radiation which have led to the formation of skin cancers must have been high - - in the order 1000 rad (10Gy) and above (partial body exposure).

**Other Delayed Effects**

There may be other delayed effects like aplastic anaemia, cataract formation and temporary loss of hair. Miscarriage and stillbirth may be a consequence of irradiation during pregnancy. But they do not constitute a problem unless the dose of radiation is large. A number of different developmental abnormalities have been described in the children whose mothers were treated by irradiation during pregnancy, the most conspicuous defect being microcephaly, a partial failure of the development of the brain. Number of cases so classified are recorded in children with irradiation, before birth in Hiroshima and Nagasaki.

**Genetic Effects of Radiation**

The genetic material consists of chromosome (microscopically visible structures within cell nuclei) and genes (functional units being the chromosomes, which cannot be distinguished microscopically). These structures are present in all the body cells. But only those in the reproductive cells are transmitted to the fertilized ovum. Where the reproductive cells are irradiated, changes may be produced in the genes or in the chromosomes of these cells and subsequently transmitted to the descendents of the individual. These genetic changes are of different kinds:

(a) Gene - mutation i. e. alterations in the function of individual gene.

(b) Chromosomal aberrations resulting from breakage and reorganisation of chromosomes, and

(c) Changes in the number of chromosomes. Some of these changes result in offspring suffering from abnormalities, which may range from mildly detrimental to severely disabling lethal disorders.

Spermatogonia in the male and oocytes in the female are the two reproductive cell stages, which are most important for assessment of genetic risks. At high acute doses of radiation, the risk of mutation in females conceiving shortly after radiation exposure will be about twice as high as in males, whereas at low doses the risk will be reduced to one third and with chronic exposure to about one twentieth of that expected after acute exposure to high doses. If the human ovary responds to irradiation as it does in that of mouse, which is by no means certain, it can be expected that, if conception occurs after a sufficient interval following irradiation, the resulting frequency of mutations in the descendants of irradiated females might be zero. Dominant gene mutations are expressed in the first generation of an irradiated population.

Chromosomal Aberrations

Spontaneously occurring chromosome aberrations are a source of considerable hardship since they are responsible for a large fraction of all spontaneous miscarriages, congenital malformations and mental and physical defects. The possession of an additional chromosome (Number 21) leads to Down's syndrome which is associated with severe mental retardation.

Another type of aberration is known as translocation. This involves the exchange of parts between two different chromosomes. This may lead to malformations similar to those associated with the presence of additional chromosomes, or may lead to early pre - natal death. These effects are associated with the presence of translocation in the unbalanced form, in which there may be loss of one of the exchanged segments and gain of the other. In its balanced form, a translocation usually has no detrimental effect for the persons carrying it, but half of his or her offsprings are likely to have the translocation in unbalanced form. Many of these unbalanced zygotes will die at such an early stage in pregnancy that they will lead to a missed menstrual period. The proportion surviving will be abnormal babies. An estimation of such abnormal babies is very difficult.

There may be other forms of aberration in chromosomes. For instance there may be gain or loss in chromosomes in addition to translocation. Very few of these aberrations are transmitted to the next generations after irradiation of the male because the reproductive cells carrying them will be eliminated before they mature. In female, some are transmitted. Most of these cases will die before birth. Those surviving will be sterile and will have certain other symptoms (Turners' syndrome).

Genes on chromosomes form an important component of the human genetic burden. Gene mutations are induced at higher frequencies than chromosomal aberrations. Furthermore chromosome aberrations will be eliminated after a few generations whereas gene mutations may permeate through many more generations thereby

'affecting a larger number of individuals (3 - 7).

### Changes in Immune Response

Immune system provides the main defence mechanisms of the body against infective agents or their products. The system recognizes what is foreign to the body and responds by destroying or neutralizing it whereas it does not distinguish between "foreign good" and "foreign bad". It can stand in the way of medically desirable objectives, such as the acceptance of needed tissues or transplants. Some net effects of immune reaction are themselves undesirable, as in allergic and other immunological disorders where the system reacts to body's own components producing auto - immune diseases.

Because of the many values associated with the immune system, affecting it by irradiation has great human significance in numerous contexts. For example, depressing immune responsiveness by irradiation reduces the ability to acquire resistance to bacterial, rickettsial and parasitic infections or to neutralize bacterial toxins and is therefore an undesirable effect of radiation. This is the situation in atomic warfare.

Depressing immune responsiveness by some means is desirable, even necessary, if organ transplants are to be accomplished. Suppressing or controlling allergy, hypersensitivity, immunopathological disorders and autoimmune diseases are other important medical objectives.

In cancer, the malignant cells are recognised as foreign by the individual's own immune system and the lymphocytes in the host may be directed against tumour cells. The existence of specific serum factors, which react with cancer cells has also been recognised and in some instances these may protect cancer cells from the action of potentially lethal lymphocytes. In some situations, it is clearly observed that radiation induced immune depression permits an increased rate of growth of cancer. A more critical question arises as to whether immune suppression may be an important factor in radiation - induced cancer.

The immune system has large built - in factors of safety so that it can withstand substantial injury and recover from damage. Even then effects on human lymphocytes in culture have been noted at doses of 10rads (cGy). The observable damage to the immune systems such as changes in antibody formation resulting from the whole body dose of the order of tons of rads is unlikely to be the effect causing the greatest concern. A dose in the range of 100rads (1Gy) to the whole body and damage to the immune system leads to an increase in susceptibility to infection. When whole body doses approach and exceed 200rads (2Gy), it leads to increased risk of mortality from infection.

### Social and mental health aspect of radiation

The large - scale use of atomic power in the field of industry, medicine and agriculture is inevitable, and more people will have to live and work in intimate contact with ionizing radiation. The prospects of dangers to health of the people and genetic effects on their descendants would cause apprehension and since dangers of radiation cannot be seen or felt, emotional unrest and confusion are bound to occur in course of time. This new technological advance is therefore, bound to create a number of social and mental health problems involving the industrial and scientific workers and also the population in general. Added to these the real and imagined horrors of the nuclear bomb and weapons hang like the sword of Domocles'. A better understanding of these problems by the people, and more so by the medical profession, is necessary in order that they get a clear perspective of the real hazards, and know the efficient preventive and remedial measures that can be taken when need arises so that the people are confident of the preparedness of the medical profession to do so. The social and mental health problems can be divided into the ones that may occur among workers and the ones that may occur among the general population.

The mental health problems that may occur among workers in atomic reactors, chemical plants and allied nuclear industries are of immediate importance. Under vigilant management, the occupational hazards will not actually affect most workers; but a certain extent of fear and anxiety will be present in them. Radiophobia may arise in certain neurotic workers who may suffer from irrational and groundless fears of over exposure and may produce a serious mental derangement, which may also influence others around. The usual prevalence of anaemia, leukaemia, cancer, psychosexual aberrations such as impotency and male sterility, abortions, foetal abnormalities, sterility in women workers and so on, may all come to be ascribed to the occupational radiational exposure. In the event of an accident in the reactor, a few may be actually exposed to an overdose of radiation, although no immediate illness may occur, but some of the others actually not exposed to an overdose may constantly be haunted by the fear of development of late effects of radiation. A regular periodical medical examination is an excellent method of restoring confidence and removing anxiety and fear. Industrial Physicians will be able to remove and rationalise many of the apprehensions by explanation and assurance.

Concern, misgivings and anxiety may also arise in the minds of the people living in the vicinity of the reactors. The workers in the reactors knowingly and willingly submit themselves to the occupational nuclear hazards for vocational, financial or scientific interest. These factors, a correct knowledge of the real hazard, and observance of and confidence in precautionary measures help to maintain their mental balance and health. The people in the vicinity of a reactor on the other hand have no knowledge or interest in the reactor and have apprehensions. The usual incidence and outbreaks of disease may come to be attributed to radioactivity. A reactor accident, should it happen, may constitute a hazard to a wide area and may necessitate evacuation of people. This may lead to anxiety and tension in the population and resentment against the authority responsible for locating the factory in their vicinity. The education of the people regarding radiation, its hazards

and the observance of safety precautions may rationalize their attitude. An organisation to carry out monitoring of the surrounding areas of the reactor and to reassure the population regularly should be established and doctors and nurses will have to check the health of the surrounding population from time to time and inspire confidence.

**Food and water contamination by radioactive 'Fallout'**

Food and water are not spoiled by radiation, but contamination by radioactive material from accidents in a reactor or fallout from nuclear bursts makes them dangerous for consumption. The crops in areas highly contaminated with fallout build up radioactivity. The animals grazing on contaminated herbage pick up radioactivity. This when excessively absorbed, may cause hypothyroidism, or the bone seeking isotopes such as strontium - 90 may cause leukemia and anaemia. The edible parts of the animals do not concentrate radioactive materials to the same extent as the thyroid and ash bone, except that the milk may contain radioactivity. Consumption of such milk and its products will introduce strontium - 90 inside the human body resulting in the possibility of bone cancer and leukemia. Fish from water contaminated by a fall out, meat from exposed slaughter houses, fresh vegetables from fields contaminated with fallout, cereals from such crops, flour and bread from such cereals and also when directly exposed are dangerous for consumption. When water in lakes and reservoirs contaminated by a radioactive fallout is consumed, the gastrointestinal mucosa may be ulcerated and on absorption the contained radio - active material may get deposited in the bone, liver, muscle etc. and produce internal irradiation like strontium - 90, causing bone tumours and leukaemia. Casualties, however, may not result immediately from drinking moderately contaminated water.

**Monitoring techniques**

For ensuring that the precautions taken are adequate, monitoring should be done by ascertaining from time to time the total dosage to which workers have been exposed to in a given period. Personal monitoring with a pocket dosimeter or film badge gives better assessment of the total dose received by the workers than the routine six monthly blood examination. Because the minimum exposure of 25 rem (250 mSV) required before effects on the blood count are noted occurs only as a result of an accident or gross negligence, and rarely occurs in a radioisotope laboratory.

(a) For external radiation, monitoring is done by studying the TLD, dosimeter or the film badge, which is continuously worn on the front of the body, on the breast pocket, or attached to a finger ring or wrist by each person exposed to radiation. Intensity of radiation incident on the badge is shown by a proportionate blackening of film on its development. A fountain pen type dosimeter can be read by the wearer himself at any time but it requires expert maintenance. The developed film badge serves as a permanent record of the individual's exposure (physical monitoring).

(b) If an internal hazard is suspected, testing of urine, faeces, nasal smear, or sputum may be helpful depending upon the metabolism of the particular element involved (Biological monitoring).

(c) Measurements over the thyroid may be used to estimate the body burden of radioiodine where it is being used. A monthly thyroid count of the workers would show whether the radioisotopes have been inhaled or ingested.

(d) Hands and shoes, floors, tabletops, gloves and other items are checked for contamination by the Gieger - Muller portable survey instruments.

(e) For larger radioisotope units, a 'count rate' meter is also essential according to the nature of the radiation exposure.

(f) Intensity of radiation due to radioactive materials, which have entered the body by inhalation, ingestion or through skin can be estimated through Biological monitoring by a 'scintillating counter'.

(g) The total body burden can be estimated by assaying the amount of radioactivity excreted in the urine, faeces or exhaled air and by a direct measurement of radiation from the 'critical organ'.

**Protection of workers in industry**

In addition to the various measures described earlier, general protection is provided by measures described as under, the actual details varying with the nature of the hazard.

**(a) Protection Against External Radiation**

All techniques used for providing protection against the exposure to external sources aim at increasing the distance of the subject from the source of exposure, decreasing the exposure period, shielding from exposure and use of various remote control devices. The tissue - penetrating gamma - rays obey the inverse - square law just like light. Therefore, if the distance from the source is doubled, the intensity of radiation falls to a quarter. When it is necessary to work in fields of intense radiation, the dose received can be reduced by limiting the period of exposure and shielding the subject from exposure to radiation. The thickness of the shield is determined by types and intensities of radiations and the rate at which the shielding material attenuates the radiation. Alpha radiations are stopped even by a sheet of paper, clothes on the body and by horny layer of human skin. Beta rays penetrate into the tissues for about 3 mm and can be stopped by an aluminium foil, thick clothing or plastic overalls. For protection of hands, plastic or rubber gloves are enough. The use of protective clothing made of serial materials like plastics, aluminium, fabric or other synthetic fabric are important protective measures. Gamma rays are however, highly penetrating and can only be attenuated by lead and cement concrete. The shielding power against gamma rays is proportional to the specific gravity of the material. Therefore, 2. 5 cm

thickness of lead, which is about 4 times as dense as aluminium has the same shielding as 10 cm thickness of aluminium. In addition to shields of lead - bricks, a variety of 'remote control' implements are used while dealing with high intensity radio - active matter in industry and the working is reduced so that the permissible radiation exposure limit is not exceeded.

**(b) Protection Against Internal Radiation**

Smoking, drinking, chewing, taking snuff or eating in areas where there is a possibility of contamination, and pipetting of radioactive solutions by mouth is forbidden; rubber bulbs for aspiration are used for this purpose. Rubber or plastic gloves are worn for handling radioactive material. When a risk of air - borne contamination is present, appropriate devices to mechanically suck and carry the fumes, mists, dusts or vapours away from the worker, and respirators or special hoods are used. Fixed radioactive contamination is not a source of internal hazards as it cannot be inhaled or ingested, but loose contamination leads to hazards. The scrupulous cleanliness, protective clothing, washing of hands and mouth, prohibition of eating, drinking, smoking or application of cosmetics in work rooms will give considerable protection against internal radiation hazards. For ensuring that the precautions taken are adequate, monitoring should be done by ascertaining from time to time the total dosage to which workers have been exposed in a given period.

**(c) Prevention of Exposure to Radioactive Material**

In industries such as radium dial painters where the material comes in intimate contact is prevention of exposure affected by providing the workers with :

(i) Glass screen booths and efficient exhaust ventilation.

(ii) Adequate facilities for washing hands before meals.

(iii) Wearing of rubber aprons.

(iv) Use of paper handkerchiefs, which are collected daily and destroyed. Workers should not use their own handkerchiefs.

(v) Special separate rooms for eating and smoking. Food, tobacco, drinks and cosmetics must never be introduced into workrooms.

(vi) Special solvents to remove paints should be rubbed on the hands and removed with soap and water. The hands after drying thoroughly must be examined in a darkened room under ultraviolet light, which may reveal some residual luminescent material. Electroscope and Geiger - Muller counters can more accurately detect radioactive substances. A breath radon estimation may also be helpful, if facilities are available

(vii) Cleaning of floors must be done by employing the wet methods.

(viii) Mechanical painting process should be employed and brushes must not be licked for pointing.

(ix) Employees should be medically examined within seven days of employment and thereafter at monthly intervals. The first sign of finger damage is a reddened glazed appearance of the fingers tips commencing with the erasure of the finger impressions, followed by cracking of the nails. At this stage with complete stoppage of exposure, the fingers will revert to normal. A total WBC count below 4500 with reduction of polymorphs and relative lymphocytosis shows ingestion of large doses.

**(d) Medical Examination**

(i) A preplacement medical examination is necessary to eliminate individuals, physically and mentally or temperamentally unsuitable to work with radiation and also to get basic blood counts for future comparison during the employment. The preplacement medical standards are laid down in the ILO publication on 'Protection of Workers against Radiation'.

(ii) Periodical medical checks of persons who are continuously exposed to ionizing radiations are necessary. A complete medical record of such periodic or special examinations should be maintained. This should include information regarding preplacement state of health, the radiation hazards exposed to, details of clinical examination and any special investigations relating to the critical organs or tissues.

(iii) Examples of special investigations are: haematological examination in case of external whole body irradiation; skin examination in case of external irradiation or contamination; ophthalmological examination in case of exposure to neutrons and to heavy corpuscular radiations; examination of the 'body burden' in case of an internal radiation hazard; pulmonary examination in the case of inhalation of radioactive aerosols and gases.

(iv) Haematological examinations should include RBC, WBC and thrombocyte counts, a search for abnormal cells, haemoglobin estimation, and an assessment of the bleeding and the coagulation time. The skin examination should be carried out for detection of epilation, dermatitis, cancer and also slight changes such as the disappearance of the finger ridge details. The ophthalmological examination should be done for changes in the crystalline lens. The 'body burden' examination should define the nature and degree of the internal contamination assessed by means of measurement or analysis directly on the body or indirectly on the excreta, urine, faeces, inhaled air and so on. The pulmonary examination should be done for detection of the complex effects (mechanical, chemical and radioactive) of radioactive aerosols and gases.

**(e) Health Education**

(i) Health Education to Workers exposed to ionizing

radiations and internal changes should be watched for. Precautions should be taken where necessary as carelessness may lead to harm to themselves and others. They should immediately report to their doctor if any abnormal signs detected on the skin or any other unusual ailment develops, without becoming unduly alarmed. However, exposure beyond a permissible level can occur for a long time before any significant change in the blood count becomes evident. In planning protective measures, the emphasis should be much more on the instrument and film badge monitoring of radiation exposure than on blood counts (3, 4).

## Nuclear warfare

### Introduction

Conventional weapons contain chemical and high explosives and on detonation energy is released as a result of chemical changes. In chemical changes or reactions, only the outer electrons, which are revolving round the nucleus take part. The amount of energy released in a chemical reaction is of the order of few electron volts per atom. The atoms of carbon, hydrogen, oxygen and nitrogen originally combined in the high explosives are released uncharged but recombine with other partners to form the waste products of the explosion.

In the atomic weapons, the energy comes from the inner core or the nucleus of each atom. In nuclear explosions, measurable quantities of matter are converted into energy. This energy is of the order of few million electron volts. Only a few of the known elements have atoms capable of releasing large amounts of nuclear energy. Weight for weight nuclear explosives release greater amounts of energy than conventional explosives.

### Fission Weapons

Nuclei of heavy elements like uranium - 235 (naturally available), plutonium - 239 and uranium - 233 (made artificially in nuclear reactors) can be split into nearly equal parts in a process called fission by the addition of a neutron bringing an imbalance in the nucleus. This is the process that takes place when fission weapons are exploded.

### Fusion Weapons

Another process by which nuclear energy can be released is called fusion because isotopes of hydrogen can fuse together at high temperatures of the order of millions of degrees centigrade releasing large quantities of energy. Such hot atmosphere is available only at the centre of the sun and stars. But such temperatures can be obtained in the detonation of an atomic fission weapon. Fusion or hydrogen weapons therefore need a small atomic or fusion charge as an initiator and for this reason, these are some times known as 'fission - fusion' weapons. In fusion reaction, large number of fast neutrons of the order of 1014 are released and these can be utilized in fission of uranium - 238 in fast fission reactions. Such a bomb where a third stage is incorporated is called 'fission - fusion - fission' bomb or thermonuclear weapons. Conventional weapons explosive power is expressed in terms of tons of trinitro toluene (TNT). High explosives have maximum yield of the order of 1000 tons TNT explosion but atomic weapons exploded over Hiroshima and Nagasaki had yields of the order of 20,000 tons of TNT or 20 KT (TNT).

At present there are wide range of nuclear weapons ranging from sub kilo tons to few mega tons power i. e. mini nuclear weapons (Mini nukes), Nukes, tactical weapons, atomic weapons and thermonuclear weapons. There are also different varieties of weapons enhanced radiation weapons, another type of weapons where radiation is suppressed and blast effect is improved. The third type of radiological weapons where radioisotopes are used deny the enemy an area for certain period.

### Principles of Fission

The practical exploitation of nuclear energy becomes feasible with the discovery of nuclear fission in 1939. When $U^{235}$ (an isotope of uranium which occurs to the extent of 0. 7% in natural Uranium) is bombarded by a neutron, it splits into two nearly equal fragments with the release of a large amount of energy. In addition, 2 to 3 neutrons are also released, which under suitable conditions can be made to bombard further $U^{235}$ nuclei and sustain a chain reaction. In a nuclear reactor, the chain reaction takes place in a controlled fashion whereas in an atomic bomb, the chain reaction takes place in an uncontrolled fashion releasing all the energy in one millionth of a second in a confined space leading to an explosion. For an atomic bomb the elements required are:

(a) Uranium - 235

(b) Plutonium - 239 and Uranium - 233.

Uranium - 235 is naturally available whereas the other two are to be obtained from nuclear reactors. Ten to twenty kg of U - 235 (90% enriched in U235) is required for a 20 KT atomic weapon, which is of the same power as Hiroshima or Nagasaki bomb. The fuel must be kept in sub critical bits or in a sub critical shape before the explosion and suddenly made critical at the time of explosion. The other nuclear fuel, plutonium - 239 is a man - made element and obtained in a reactor by the absorption of a neutron by uranium - 238 nucleus. This is produced in a reactor after several months of operation. Since uranium and plutonium are chemically different these can be separated by chemical means.

### Chronological Development of An Atomic Burst in Air

The first indication of a nuclear burst is blinding flash of light (many times brighter than the sun). An intensely hot luminous sphere of compressed gases (containing vapourised fission products of the uranium or plutonium, bomb casing etc), called the ball of fire, is formed. It expands and rises like hot air balloon. At one second it reaches its maximum diameter of 300 M. By 10 seconds it cools to such an extent that it is no longer visible as a ball of fire. As the temperature falls, the smoke cloud rests on top of a column of dust and debris sucked from the surface of the earth by the force of the explosion. The smoke cloud rises to a height of about 8 Km in 10 minutes;

then the top spreads laterally for several kilometers giving the characteristic mushroom shape. About a thousandth of a second after the explosion, a high - pressure wave develops and moves out - ward from the ball of fire. This is the shock wave, which is the cause of the destructive blast. The high - pressure front of the shock wave initially travels at about 5 times the speed of sound (330 m/sec). When the shock wave strikes the earth it is reflected; the reflected and incident shock waves fuse at some distance from the explosion site to form the Mach Stem, which is extremely destructive to the structures. Gamma rays and neutrons are emitted from the ball of fire and smoke cloud. They are very intense for the first one - minute. The fission products that are formed during the explosion due to the fission of the uranium (i. e. the material used in the bomb) get mixed up with the dust sucked in and constitutes the radioactive cloud. This radioactive cloud travels down wind and settles down either in the immediate vicinity or over long distances in an area or circulates round the globe in stratosphere. Depending upon the height of the explosion, this fall of radioactive dust is called local fallout or global fall out. This radioactive fall out is responsible for the delayed radiation effects - high level as well as low level.

### Effects of Nuclear Weapons

The effects of nuclear weapons depend primarily on the

Fig. - 1

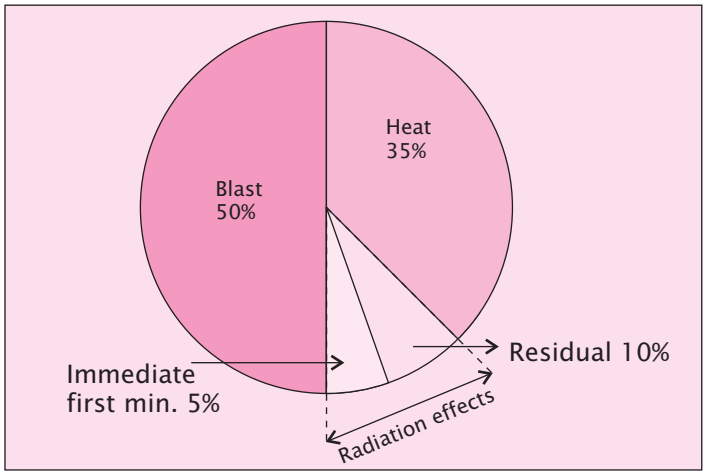

Table - 3 : Distribution of energy released 121012j by a nuclear bomb exploded in the troposphere

| Energy Form | Energy Released 12 1012j | % Total |
|---|---|---|
| Blast (Shock) | 41.9 | 50 |
| Heat | 29.3 | 35 |
| Nuclear Radiation 1st min | 4.2 | 5 |
| Nuclear Radiation Residual | 8.4 | 10 |

yield and type of the burst (high air, low air, surface, under ground and under water). For knowing the effects of any particular type of burst for a given yield (power) say for 20 KT, there are simple sealing laws which enable the effects from any other yield to be predicted. The effects are of two types (7 - 12) :

(a) **Immediate** (occurring within one minute of the explosion)

(b) **Delayed**

Immediate effects are of three categories - blast, heat and nuclear radiation. (Fig. - 1) Delayed effects are due to fall out. The distribution of energy released by a nuclear bomb of 20 KT yield exploded in the troposphere. (Table - 3)

### Effects of Thermal Radiation

Thermal radiation or heat flash consists of visible and invisible light rays - ultraviolet rays of shorter wave length and infrared rays of longer wave length. It is already mentioned that 35% of the energy released in the detonation is emitted in the form of light and heat radiation which will produce temporary or permanent blindness, burns on exposed parts of the body and set fire to combustible material. Substances will scorch, char or even burst into flames as a result of the heat radiation from the fireball. The intensity of the direct heat radiation received at any place may be enhanced, in a way similar to that of visible light, by reflection and scatter from clouds or from fog and dust particles in the atmosphere or it may be reduced by the absorption in passing through thick or heavy atmospheric pollution. Thermal radiation like visible light is reflected by light colours and absorbed by dark ones so that dark coloured objects are more likely to catch fire than the white ones. Paper, wood, rubber and dry grass are easily charred and may catch fire. Fortunately, wool and the material for the dress given to the soldiers are relatively resistant to heat. The primary inverse square law in determining the heat radiation at a point does not hold good, since the atmosphere consists of many pollutants like dust, fog, clouds etc.

Table - 4 : Range of heat effects on people exposed in the open : radii in km for ground burst weapons

| Weapon power | 20 KT | 1 MT | 10 MT |
|---|---|---|---|
| 3rd degree Burns | 2.25 | 13.0 | 35.5 |
| 2nd degree Burns | 2.8 | 14.5 | 40.25 |
| 1st degree Burns | 4.0 | 13.25 | 56.00 |

Table - 5 : Range of heat effects on people exposed in the open: radii in km for air burst weapons

| Weapon power | 20 Kt | MT | 10 MT |
|---|---|---|---|
| 3rd degree Burns | 1.4 | 6.5 | 21 |
| 2nd degree Burns | 1.6 | 8.85 | 23 |
| 1st degree Burns | 2.4 | 13.25 | 34 |

### Skin Burns

Skin burns can vary in severity from a mere reddening (first degree) or a more painful blistering (second degree) to a much more charring of the skin (third degree). But in considering the severity, it is necessary to keep in mind three important factors; total amount of heat; the area on which it falls and the duration of application of this quantity of heat to the surface.

Table - 4 gives ranges in Km at which people in the open would suffer various degrees of skin burns from the ground burst weapons of different power. Table - 5 gives similar data for airburst weapons.

### Personal Protection from Thermal Radiations

To protect oneself from the thermal radiation it is necessary to get out of the direct path of the rays from the fireball and any kind of shade will suffice to protect in an emergency. People caught in the open should dive far behind any available cover. While so doing one should cover one's body as far as possible so that the extent of the burns is kept to a minimum. Loose clothing offers some protection compared to tight clothing.

### Fire Protection and Precautions

Primary fires result from the heat flash through windows, open doors etc igniting the combustible contents in the houses, offices and stores. One precaution would be to rearrange the furnishings or equipment to remove all inflammable material out of the direct path of any heat rays that might enter through windows or other openings, Another precaution would be to white wash windows as this would keep about 80 % of the heat radiation.

Secondary fires might be the consequences of blast damage, scattering of domestic fires, rupture of gas pipes, or short - circuiting of electrical wirings. These risks could be reduced if ordinary common precautions were taken on receipt of warning such as shutting up stoves, covering open fires with sand or earth and turning off gas and electricity at the mains.

### Fire Storms

The chief feature of a fire - storm is the generation of high winds, which are drawn into the fire area to feed the flames. These inrushing winds prevent the spread of fire outwards but ensure almost complete destruction by fire of every thing within the affected area. A firestorm increases the number of causalities since it becomes impossible for people to escape by their own efforts and they succumb to the effects of suffocation and heat stroke. The 20 KT Hiroshima bomb caused a firestorm. A fire storm occurs in a heavily built up area of substantial size with plenty of combustible material and where at least every other building in the area had been set on fire by the heat flash.

### Effects of Damage From Air Blast

The enormous pressure produced in the detonation of a nuclear weapon gives a violent push to the surrounding air with the result that a wave of high pressure is transmitted outwards through the air; in addition, a strong wind is caused by the bulk movement of the air. The pressure wave is followed by suction wave that is a partial vacuum, which then causes a wind in a reverse direction towards ground zero. Initially the pressure wave is transmitted at a speed five times that of sound and then slows down to the speed of sound. The effect of a shock wave on any structure is an initial shock thrust and sustained push over it.

### Mach Wave and Mach Effect

When the shock strikes the earth, it is reflected. The reflected shock wave travels in a hot medium so it travels with a greater speed than the original shock front. After some time the two shock fronts (original and reflected) fuse together to form Mach wave. The effect due to this Mach wave is called Mach effect. The peak pressures in the Mach Wave are almost double that in the original wave.

### Relation Between the Blast Effects of Air and Ground Burst Weapons

The range of blast damage is substantially greater for an. air burst than for a ground burst weapon. For most practical purposes, the damage radii for the ground burst would be increased by as much as 30 % if the weapon were airburst at about the optimum height.

### Effects on Human Beings

Human beings run little risk of being killed outright if the static pressure is about 200 psi but ear drums may burst and lung damage may start at 35 Psi. For people in the open, the main risk (apart from other risks) is being blown over by the blast wind. A person standing in the open would be blown over at a distance of about 14 Km from a 10 MT ground burst. He would be moved bodily if lying prone in the direction of the blast at about 6. 5 km.

### Effects of Initial Nuclear Radiation

Nuclear radiations are emitted continuously from the moment of detonation of a nuclear weapon and for long periods thereafter. They are emitted from the fireball, from the radioactive particles in the cloud as it is dispersed by the winds, and finally from the radioactive fallout material deposited on the ground. The division between initial (some times called flash) nuclear radiations and residual radiations, therefore, has been chosen arbitrarily at one minute after detonation. Initial radiations consist of neutrons and gamma rays, followed by gamma radiation from the newly formed and intensely radioactive fission products in the fireball. Most of the neutrons are captured by the material of the weapon but some escape.

Neutrons being neutral particles, pose indirect problems by way of induced activity. In an airburst, these neutrons are absorbed by the atmospheric nitrogen and become radioactive emitting highly energetic gamma rays. This gamma radiation intensifies and extends the range of the initial gamma flash. For some distance around the point of detonation, the neutron dose may be higher than the gamma flash dose, but beyond a certain point the gamma hazard predominates. This point is always well within the zone in which storm blast and radiation protection are needed. Thus, it may happen that the neutron hazard is greater in shelters quite close to the detonation of tactical weapons with light cases, which permit a higher proportion of neutrons to escape. Otherwise a shelter, which gives reasonable protection from gamma radiation also gives good protection against neutrons.

### Initial Gamma Radiation

Gamma rays can penetrate considerable thickness of

Table - 6 : Radial distance (in km) of initial gamma effects on people exposed in the open to all ground burst weapon

| Weapon power | 20KT | 1MT | 10MT |
|---|---|---|---|
| 50 percent survival (450R) (4.5 Gy) | 1.2 | 2.5 | 3.5 |
| No appreciable risk of sickness (75R) (0.75 Gy) | | 1.6 | 2.8 |

matter for example the roof and walls of a building but they are attenuated in doing so. They can also be scattered back by the medium i. e. by the atoms of oxygen and nitrogen in the atmosphere causing an additional hazard even though one takes protection behind heavy obstacle. This is called invisible sky shine. So protection behind a heavy obstacle in the line of sight only will not be sufficient. One has to have a cover all around under a heavy shield for good protection.

**Weapon Power and Range of Effects**

Table - 6 shows the radial distance at which 50% lethal dose of 450R(4. 5 Gy) and a wartime emergency dose of 75R (0. 75 Gy) would be received by the people exposed in the open to initial radiation from a ground burst.

**Personal Protection from Initial Nuclear Radiation**

Inspite of extensive research in many parts of the world, no satisfactory drug is available yet for self injection or oral administration immediately after exposure to a lethal dose of radiation. Only protection against initial radiation is to remain under adequate shielding when the flash occurs (to escape both the direct and the scattered radiation). Protective clothing does not provide any protection against gamma radiation. It only prevents radioactive dust from getting on to the skin or into the body.

**Effect of Residual Radiation from Fall Out**

The radioactive fission products from a nuclear weapon, burst on or near the ground, would condense on debris and dust lifted by the explosion and would be deposited around the creator or dropped from the cloud, more or less slowly, as if swept over a broad area, the extent of which depends upon the power or yield of the nuclear explosion. Particles of size more than 20 microns would be deposited over a 'hide area' as a local fallout and particles less than 20 micron size would have been carried high into atmosphere or even into stratosphere in the case of air burst, and these would take more than weeks or even years to be deposited on the ground. This constitutes the global fallout.

**Residual Radiation**

Residual Radiations are those emitted later than one minute after the detonation of a nuclear weapon and come from the radioactive fission products. These fission products are deposited around the point of detonation of weapon. Depending on the prevailing winds at the time of detonation, the fall out pattern takes an oval shape extending in the down wind direction. Typically the region of severe fall out from a 20 KT low air burst may extend 5 km up wind, 8 km cross wind and 25 km down wind.

About 200 isotopes or different radioactive species of atoms of about 35 elements are released in a nuclear fission detonation. The half lives of these fission product isotopes vary from a fraction of a second to thousands of years. The rate of decay of the mixed fission products is very rapid. Starting from 1 hr after detonation to 200 days,

Table - 7 : Seven, Tenth rule

| Time after burst | Time factor | Dose rate per hrs | Dose rate factor |
|---|---|---|---|
| 1 hr | 1 | 100 | 1 |
| 7/4 hr | 7/4 | 50 | ½ |
| 7 hr | 7 | 10 | 1/10 |
| 2days (49hrs) | 7x7 | 1 | 1/100 |
| 2 weeks | 7x7x7 | 0.1 | 1/1000 |
| 14 weeks | 7x7x7x7 | 0.01 | 1/10000 |

the rate of decay follows the formula RT = R, t12 where RT is the activity at any time 't' and R is the activity at one hour after the detonation, t is time when RT is being assessed.

**Seven, Tenth Rule**

The use of this formula in the field conditions becomes a tedious process for fission product decay. For many civil defence purposes, the seven tenth rule enables one to make a quick approximate mental calculation of the radiation level at any time from a single measurement at a known time. This rule is that the intensity of radiation falls by a factor of 10 as the time lengthens by a factor of 7. Its application is illustrated in the Table - 7 for a dose rate of 100 Roentgens measured at one hour after a nuclear detonation at any point.

**Different Hazards Presented by Fall Out**

The radioactive fission products emit alpha, beta and gamma radiations. These have different penetrating and ionizing powers. The hazards due to these radiations can be assessed only when it is known as to what kind of problem the radioactive fallout possesses. There are three distinct situations in which radioactive fallout can be hazardous.

(a) The radioactive dust has already settled and personnel are to work in the area. In such a situation a person can have protective clothing so that the dust particles that

Table - 8 : Isotopes for critical organs

| | |
|---|---|
| 131 I | Thyroid |
| 239 Pu | Lungs, Bone and Bone Marrow |
| 90 Sn | Bone |
| 40 Ca | Bone |
| 137 Cs | Muscle (whole body) |

would be rising are not inhaled or contaminate the human body. This is an external hazard in which gamma rays irradiate the whole body and the other two radiations are not important.

(b) Fallout may contaminate the body, for example fallout on clothing, hair or skin.

(c) The fission products may get into the body through inhalation, through cuts or contaminated food and water.

131 I, 137Cs, 90Sr, 45 Ca and 239 PU are the more important isotopes as internal hazard. These are selectively absorbed in certain organs and irradiate the organs. This results in greatest damage to a particular organ or system in the human body called critical organ. Table - 8 gives the isotope and the critical organs.

Special protective clothing with a head gear and filters would protect a person from internal hazards and give temporary protection against the contact hazard. But these should be removed and decontaminated or replaced at the earliest opportunity. These do not provide any significant protection against gamma radiation. Personal cleanliness is essential to remove radioactive fallout from the clothing or skin and to prevent its entry into the body.

**Hazards to Food Stocks, Animals, Crops and Water Supplies**

Uncovered food, water, live stock and crops may be contaminated and through these they may find their entry into man via the food chain which will be harmful to human beings. Tolerance limits of contamination must be specified but their application requires advice of the radiological experts. The limits will depend upon how long it would be necessary to exist on the contaminated food or water supplies. ICRP had recommended maximum permissible concentrations (MPC) of various isotopes in water and air. These depend upon intake throughout lifetime. ICRP has also given guide lines to arrive at maximum permissible concentration in water, air and food when there are more than one radioactive isotopes present.

**Monitoring Organisations**

The first line of defence for the protection of the public and defence personnel would be the organisations for monitoring the degree of contamination and for controlling and distributing the available supplies of acceptably pure food and water. Civil defence personnel should co - operate with these organisations. So there should be teams even in civil defence organisation who have some knowledge of the problems involved and of possible protective measures.

These monitoring organisations should have a knowledge of the various fission products, solubility of these products, food chains, retention mechanisms in the body, critical organs in the body, significance of internal contamination, monitoring drinking water and decontaminating water to make it drinkable under emergency conditions, monitoring food stocks, crops and live stock for contamination. Milk consumption is associated with special problems. Iodine - 131 may get into the milk through the grazing of contaminated grass. This concentrates in the thyroid and consumption of this milk by children poses a problem in the long run.

**The Threat of Epidemics**

Post attack survivors suffering from exposure, malnutrition, heat, blast and radiation injuries are an ideal feeding ground for epidemics. Typhus, dysentery, tularemia and plague may appear in epidemic forms. Insects (especially flies, mosquitoes, ticks and mites which are of importance in transmitting diseases) are highly resistant to radiation. LD 50 for man is 400 - 600R (4 - 6 Gy) whereas LD 50 for insects is 10, 000 to 20, 000R (100 - 200 Gy). Their number increases enormously as there are uncleared human and animal carcasses with poor sanitation. This problem is enhanced in the poor tropical regions. Public Hygiene should be a part of the radiation hygiene. As in the event of a nuclear war these two cannot be separated, medical teams should educate in peace time the consequences of nuclear war.

**Protection Against Atomic Explosion**

(a) Against explosive blasts, flashes and fire

The distance from the point of explosion, reinforced concrete buildings, deep shelters, tunnels, caves and trenches afford protection to some extent. Inflammable material like wooden structures catch fire easily. Concrete brick and earth have greater protective value.

(b) Against ionizing radiations

The greater the thickness of the wall of the shelter the lesser are the chances of exposure to penetrating external radiation. To avoid internal radiation by inhalation of radioactive air and dust in the contaminated area or by ingestion of contaminated food or water, no person should enter a contaminated area without a respirator or touch food or water unless it has been declared safe by a monitoring team. To summarize, the protective measures are :

(i) Suitable underground shelters with thick non - inflammable walls and roofs.

(ii) Monitoring of all suspected areas and subjects

(iii) Avoidance of entry into the contaminated area

(iv) Use of suitable clothing i. e. respirators, overalls, gloves, gum - boots or strong leather boots

(v) Prohibition of the consumption of suspected food, water, fruits, milk and vegetables

(vi) Decontamination of personnel and equipment at decontamination centers

(vii) A periodical medical examination of rescue workers and cases likely to have been exposed to small doses of radiation

(c) Individual Protective Clothing and Equipment

Different types of protective equipment and clothing are available :

**Facelet**

The facelet mask affords marginal protection to personnel against low concentrations of chemical agents and protects personnel temporarily when threat is imminent. It also provides protection against radioactive dust being

inhaled. It can be worn for prolonged duration without physiological stress.

**Respirator NBC**

Respirator NBC provides protection against field concentration of most chemical agents, biological agents and radioactive dust in vapours and aerosol form. It does not provide protection against ammonia vapours and CO and must not be used for fire fighting. The respirators may be broadly classified based on the type of cannister being used viz; the filtering type and closed circuit types. The filtering type filters the contaminated air whereas the closed circuit type has compressed air/oxygen or oxygen which is regenerated within the system when desired. The respirator is also referred to as gas mask, protection mask or simply as mask also.

**Protective Clothing**

The protective Clothing Utility NBC, is the nomenclature of the more commonly used clothing items; the other is Clothing Isolating NBC. The clothing protects the wearer against effects of WMD including to some extent, from fire and incendiary. It causes physiological stress on the wearer and reduces his ability to operate. The clothing is of two types, namely the permeable and the non permeable. These may be further classified into disposable, reusable and non - reusable. The disposable, non, non - permeable are the plastic cape or over garment which provide the most immediate but temporary protection against liquid agents. The reusable permeable are those based on rubber and vinyl materials. The permeable layered cloth clothing cannot be reused in battle and has to be discarded.

**Gloves**

Gloves provide protection against liquid chemical agents and vapor hazards, as well as against radioactive dust and vectors. Each glove consists of an outer and an inner layer. The outer is usually made of butyl rubber or neoprene and the inner of cellulose fabric. If either glove is damaged, the glove set must be replaced.

**Boots and Overboots**

Exclusive boots for operating in NBC environmental are clumsy and difficult to use. An overboot may take a form of a boot or even fish tails and is used only when NBC threat is imminent.

**Haversack**

The haversack is designed to prevent contamination of items carried in them. Its usual contents include the respirator, face mask, liquid chemical agent detection paper, self aid kits etc. The haversack, when carried on man is anchored well to prevent damage to the respirator and the cannister.

**First Aid Treatment of Atomic Bomb Casualties**

(a) Multiple Injuries

Multiple injuries like fractures and wounds of different parts of the body will require conventional surgical and supportive treatment. In addition, decontamination of these patients should be borne in mind as they might have received sublethal doses of radiation.

(b) Treatment of Burns

Burns caused by 'flash' and 'fire' will always constitute a large %age of casualties. In order to reduce fatalities and disfiguring disabilities these cases will require special treatment. It is, therefore, important that special 'burn centres' with adequate accommodation, equipment, staff, laboratory and monitoring facilities are made available. Burns may also be produced by beta particles received in fallout; therefore, exposed patients should be thoroughly and quickly decontaminated under a shower with soap.

(c) Treatment of Radiation Injuries

Decontamination of all likely to have been exposed to radiation is the first essential procedure. Thorough training to make it a drill is necessary. A shower bath with soft soap is the initial requirement. Cases of actual radiation injuries may only constitute a small %age of total casualties. However, many of the wounded or burn cases will also be suffering from the effects of ionizing radiations. Early treatment of shock, maintenance of water, and an electrolyte and acid base equilibrium is essential. Later infection and anaemia will have to be combated.

(d) Prevention of Delayed Effects

This will need constant vigilance. Usually the central nervous system and gastro - intestinal denudation syndromes are lethal within two weeks. Patients who develop intractable nausea and persistent vomiting soon after exposure will probably have sustained a lethal dose in which case, medical care will not change the course. In others, however, these symptoms may well be of psychogenic origin and require only mild sedation and anti - emetic drugs, although sometimes fluid replacement may also become necessary. The major problems among the survivors will be those associated with bone marrow depression. The critical period will be within the 10th to 30th day after exposure. There is no specific form of therapy for severe bone marrow aplasia; treatment must therefore be largely symptomatic with good nursing care, maintenance of scrupulous cleanliness, an adequate fluid intake, and a high calorie and protein diet rich in vitamins. The leucopenia results in an increased susceptibility to infection. Therefore, the best nursing care possible should be provided. The mouth, nares, anus and vulva should be taken care of. Meticulous care should be taken of all minor cuts and abrasions of skin and mucous membranes. Antibiotics should not be used prophylactically but should be administered when signs of infection occur. Thrombocytopenia may result in haemorrhagic diathesis. Transfusion of fresh blood or platelet rich plasma will be needed. Since pooled and preserved whole blood does not contain platelets, it should be reserved for traumatic cases and for patients suffering later from persistent anaemia.

The chief difference between an atomic disaster and other heavy explosions are the suddenness and magnitude of the former event. 40, 000 to 50, 000 casualties, excluding the dead may occur as a result of one detonation. Most of the casualties may be similar to other type of explosions except that about 10 to 30 % of the wounded in an

explosion would have received ionizing radiations as well. Hence medical aid for sudden occurrence of a large number of casualties, their evacuation to safe areas and further special surgical and medical treatment needs to be planned, developed, and organized much earlier in the pre - strike period. Immediately following the incident, sufficient medical personnel and equipment enough to give minimum essential early treatment and preventive medical supervision would be required. As a practical consideration all casualties have to be regarded as radiation victims unless proved otherwise. In addition to attending to the wounded and sick there will be the enormous task of dealing with residual contamination. Monitoring and decontamination of the residual radioactive contamination and that of food and water supplies and of a substantial proportion of injured population is a task of such magnitude that cannot be relegated to a medical organization alone. Medical services may be able to deal with relatively easy procedures; monitoring and decontamination shall have to be done by a special team of monitors and decontamination centers and squads. Monitoring squads should be located near large cities and industrial areas. Their main duty is to assess the degree of contamination of any area, amongst uninjured population and that of stores and equipment.

Most people within a 15 km radius from the detonation of a megaton bomb will be killed by blast and heat, unless they are in a blast resistant shelter, where they should stay for at least 48 hours as it will probably be so hot from induced radiation and fallout that any efforts to reach survivors within this period would be risky or even fatal. Further out in the 15 to 30 km radius and beyond, it may be possible to remove patients with injuries and burns to sheltered areas for treatment, provided sufficient time is available before the expected arrival of fallout. Principal decontamination centres will have to be established outside the periphery of contaminated area and no individual should get in or out of the contaminated areas without passing through these centres. Decontamination of clothing and the bodies of casualties and refugees and workers who enter contaminated areas will have to be arranged. Washing and bathing arrangements and laundry facilities will have to be provided in these centres.

Additional medical support could be organised by the help of specialized medical units assigned on a regional basis as required, under centralized control. These will be casualty treatment units organised in advance and manned by a team of physicians, surgeons and trained para - medical staff. These units should also have decontamination staff. Such units must be capable of operating for short periods without communications. Each unit should be capable of caring for about 100 casualties. There will also be the need for airborne (helicopter) casualty treatment units to give medical help to isolated regions, where ground units may fail to approach. Airborne as well as ground evacuation units will have to work in close co - operation with the medical treatment units. Airborne units carrying dispensary, laboratory, preventive medical services, dental services, etc. , would also be needed. Special monitoring teams on the wings' to check the water, food and drug contamination need to be organised; so also ground monitoring at all levels of medical organisation. There is need for the organisation of decontamination units which should be able to take up the responsibility of personnel decontamination and laundry services for contaminated clothes.

Training of the general public and dissemination of information regarding atomic disaster must be carried out in peace time to create a sense of confidence in them. The dispersion of relief organisations and stores is absolutely necessary. The construction of shelters, protection of vital services and communications, training of monitoring teams and positioning of essential medical stores and

Effects of nuclear explosion

| Event | Effect | Protection |
|---|---|---|
| Flash | Flash blindness | Close eyes |
| | | Protective posture |
| Heat | Thermal burns | Protective clothing |
| | | Protective posture away from path of light |
| | | Shelter |
| Blast | Fractures and injuries Rupture of hollow viscera | Protective posture Appropriate shelter |
| Radiation | Acute and delayed effects | Protective clothing |
| | | Shelter |
| | | Avoiding entry in contaminated area |
| | | Avoiding eating / drinking in contaminated area |
| | | Decontamination |

equipment must be planned before the disaster. Medical and nursing officers and other staff shall have to be specially trained. Surgical teams and burn centres are essential medical units in any plan and should be raised in all civil and military hospitals. Fire fighting services must be fully organised. Emergency hospitals shall have to be opened in existing buildings or tents and located away from large towns and industrial areas. Large reserves of antibiotics, resuscitation fluids and medical stores will have to be arranged for dispersal over a wide area. Other relief organisations to evacuate and care for the victims, monitoring, emergency health services to deal with contamination of food and water supply and to decontaminate areas, stores and personnel are required. Similarly, the relief organisations for the supply of food, water, clothing and amenities of life to the victims of the exposure are also required (7, 12).

## Biological Warfare

### Definition

Biological warfare is the military use of living organism or their toxic products to cause death, disability or damage to man, his domestic animals or crops. As a conscious and planned form of waging war in an non - explosive but equally deadly manner, this form of warfare is still largely unknown and its true potential remains untested. However, there is ample evidence to show that active programmes of research have been in existence in various countries since 1930.

Biological weapons are fundamentally different from nuclear and chemical weapons for the following reasons

(a) Ability of the agents i. e. microorganisms to reproduce within the host after dissemination thereby causing infection.

(b) Ability of some of the agents to be transmissible from one person to another.

(c) Distribution of small quantities of agents in suitable wind currents could result in vast areas being affected.

(d) Difficult detection - it is virtually impossible to detect biological warfare agents until it is too late. There are no BWA detectors similar to the capabilities of CWA detectors now in use.

(e) Biological warfare agents can be produced quite easily and at low cost.

(f) Dissemination of these agents can be in many forms - aerosol form by bombs, release of vectors, covert methods.

(g) Delay factor - These agents take time varying from hours to days depending on the incubation period, to produce their effects.

(h) New disease agents i.e. genetically developed microorganisms or virulent variations of otherwise harmless microorganisms could be introduced almost any time.

(j) Potential weapons for terrorists.

### Types of Biological Agents

A biological warfare (BW) agent is any living organism which can be used to produce disease or death in an enemy, his animals or crops. An enemy would select an agent which is highly infectious, easily produced and stored, stable and suitable for use in the field and able to produce a disease for which there is minimum immunity in the target population.

According to the medical point of view, these are classified as under (Table - 9) :

(a) Bacteria : Cholera, anthrax, plague etc

(b) Rickettsia : Typhus, Rocky Mountain spotted fever etc

(c) Viruses : Small pox, Dengue, JE etc

(d) Fungi : Aspergillosis etc.

### Characteristics of BW agents

A majority of agents employ microorganisms which will only grow and reproduce under suitable conditions. The most important characteristics of micro - organism is that they are living. The essential characteristics are :

(a) Infectivity

(b) Virulence - This signifies severity of disease caused.

(c) Incubation period i. e. , time between the infective penetration of sufficient microorganism into the body and appearance of symptoms.

(d) Transmissibility

(e) Lethality

### Operational Classification

The classification of BW agents is in accordance with their operational effects :

(a) Lethal and transmissible (Small pox, Pneumonic plague)

(b) Lethal and non - transmissible (Anthrax, Epidemic Typhus)

(c) Incapacitating and transmissible(influenza, Typhoid)

(d) Incapacitating and non - transmissible (Tullaremia, Dengue Fever)

### Routes of Entry

To cause disease there are several routes of entry of BW agents into then human body.

#### (a) Respiratory route

This is the most important route and besides, in this way the infective dose required may be smaller and onset of symptoms more rapid than normal. The most effective delivery is by inhalation of an aerosol containing agent particles that are in the range 1 to 5 microns in size. Larger particles fall out of the aerosol or are trapped in the upper airway. Smaller particles are breathed into the lungs and expired out. In addition this route it has the following advantages :

(i) The delivery of BW agents by aerosol is one of the most practical methods.

(ii) The natural rhythm of breathing provides a continuing susceptibility.

(iii) Personnel are reluctant to wear respirator continuously.

#### (b) Skin

Penetration through damaged skin and mucous membrane may occur, particularly if the surface is damaged. Some protection will be afforded by the IPE (Individual Protective Equipment).

#### (c) Digestive Tract

This provides a route of entry of BW agents which have contaminated food and drink. This route, however, has some limitations :

(i) Many BW agents are destroyed by digestive process.

(ii) The drinking of deliberately contaminated water is a possible method but an unknown dilution factor, chlorination and boiling, all serve to reduce the

Table - 9 : Biological agents and their characteristics

| Disease | Symptoms | Incubation period infective dose | Man to Man txn |
|---|---|---|---|
| **Bacteria** | | | |
| Anthrax | Cutaneous form : Sores or blisters form on hands or forearms<br>Pulmonary form : Non specific respiratory symptoms followed by respirator distress, fever shock , lead to death.<br>Intestinal form : Intense stomach pain, bowel obstruction, dehydration, diarrhea, fever septicaemia and death. | 2 to 7 days(48 hrs)<br>8000 to 50,000 spores | No |
| Tularaemia | Sudden onset of fever with chills, headache, muscle pain, fatigue , dehydration, ulcers on skin, lymphadenopathy | 2 to 10 days<br>10 to 50 organisms | No |
| Plague | Bubonic plague- High fever headache, painful lymphadenopathy, haemorrhages on skin<br>Pneumonic plague High fever, cough, blood tinged sputum, respiratory distress ,death | 2 to 8 days<br>2 to 3 days | No<br>High |
| Cholera | Severe watery diarrhea with vomiting, muscular cramps, dehydration and death | Few hrs to 5 days | Rare |
| Diphtheria | Sore throat, low grade fever, respiratory obstruction | 2 to 5 days | |
| **Rickettsia** | | | |
| Q Fever | Sudden onset of fever, chills, weakness, profuse perspirstion, respiratory symptoms, muscle and joint pain | 2 to 3 weeks<br>1 to 10 organisms | Rare |
| Rocky Mountain spotted fever | Fever, chills headache, arthralgia, muscle pain, skin rash, neurological complications | 3 to 14 days | Rare |
| Typhus | Headache, high fever generalized bodyache, rash | 6 to 14 days | Rare |
| **Viruses** | | | |
| Encephalitis | Fever headache, drowsiness, stupor, convulsions, severe prostration, occasional paralysis | 2 to 15 days | |
| Dengue fever | Fever with severe headache, retro orbital pain joint pains, petechial rash, spontaneous bleeding, circulatory collapse and death | | 3 to 15 days<br>No |
| Yellow fever | Fever with chills, prostration, headache, backache, myalgia, nausea, vomiting, jaundice from liver damage. Bleeding from mucus membranes | | 3 to 6 days<br>No |
| Small pox | Fever with centrifugal rash, typically multilocular umbilicated with erythematous base, septicaemia, blindness and death. | 7 to 17 days<br>10 to 100 organisms | High |
| **Toxins** | | | |
| Botulinum toxin | Vomiting, Paralysis , muscle cramps | 1 to 5 days | No |
| Ricin | Fever, constipation, thirst and dizziness | 18 to 24h | No |
| | | | |

chances of success.

(iii) Cooking at high temperatures kills almost all microorganisms.

**Biological Agent Dissemination and Delivery Techniques**

**(a) Aerosols**

(i) Explosive bomblets

(ii) Generators

(iii) Spray tanks

**(b) Vectors**

**(c) Covert means**

These include direct placement of BW agents of liquids, powders or spray form into food chain at harvest, processing, distribution and preparation points, or by placement of BW agents into points of water reservoir /distribution chain.

**Techniques of biological attack**

**(a) Multiple point source**

Biological bomb lets or containers can be distributed over a large area as follows :

(i) Missile delivered warheads

(ii) Aircraft delivered bomblets

(iii) Aircraft released bombs containing clustered bomblets.

**(b) Line Source**

Biological munitions can be delivered in a linear fashion to disseminate the agent over a large area, downwind of release line :

(i) Elevated line source

Can be released from spray mounted on aircraft.

(ii) Ground line source

Can be released from bomblets that are ejected from dispensers of aircraft or missiles at a controlled rate. Agents can also be released along the ground from a vehicle - mounted generator.

**Medical Aspects of Biological Warfare**

There is nothing mysterious about the medical problems that would be created by a successful biological weapon attack. It would lead to an outbreak or epidemic of the disease with clinical features caused by the disseminated disease agent. The potential for causing devastating casualties is high for certain biological agents especially if genetically modified strains are used or if the disease is transmissible. In addition to affecting the general population, biological warfare agents also affect the healthcare system and cause mass panic ultimately affecting a nations' economy as a consequence.

The situation would require medical management on a mass basis rather than the administration of individual cover. But the basic principles of medical therapy would apply. Firstly every attempt should be made to make a definitive diagnosis by sending appropriate samples to appropriate laboratory facilities. While awaiting laboratory confirmation, a preliminary diagnosis must be made on clinical grounds. A firm diagnosis can only be made by a trained epidemiologist with good laboratory backup. Prompt treatment must be instituted Prompt treatment must be instituted based on preliminary diagnosis since it is in the initial phase of the diseases that therapy is most likely to be effective. Standard precautions for infection control for prevention against most diseases should be practiced, (14).

**Prevention & control measures for Biological Warfare.**

Prevention and control in case of Biological Warfare would include :

(a) Physical Protection.

(b) Chemo prophylaxis

(c) Immuno Prophylaxis

(d) Diagnosis

Physical Protection

It can be personal protection or collective protection for personnel. Simple measures to be adopted are - If out doors keep head covered. Wear a scarf or wrap a cloth/handkerchief around nose. Keep hands in pockets. If possible, take refuge in a closed shelter. Use personal (individual) protective equipment like:

**(a) Protective Mask**

The NBC mask offers protection against aerosol agents. The main functional part of the mask is the air filter which filters out particles of size 1 - 5 microns.

**(b) Protective Clothing.**

Protective clothing employed against chemical agents is also effective against biological agents. Even if this is not available standard uniform clothing of good quality affords a reasonable protection.

**(c) For Collective Protection**

(i) Personnel must be housed inside a shelter with an efficient air filtration system.

(ii) In case troops are in barracks at the time of attack, close all doors and windows of the barrack.

(iii) Reduce the ventilation rate as much as possible by shutting off any ventilation system (unless it contains a filtration unit) and by putting out the fire.

Chemoprophylaxis

Chemoprophylaxis should be used only under the conditions where an attack is known to have occurred and organisms identified.

Diagnosis

In an event of a biological attack, the all important factor in providing adequate medical management will be rapid establishment of an accurate specific aetiologic diagnosis.

In evaluating problems from a practical stand point one must assume that the enemy would employ an organism other than the ones commonly encountered in every day medical practice.

Plan for immediate movement of small number of representative cases to one or more previously designated

medical facilities.

How to recognise biological attacks? The number of people affected, the time relationships, the similarity of clinical picture, the sharply defined geographical boundaries will produce an epidemiological picture that can be explained only by an infection due to an artificially disseminated aetiological agent as in aerosols.

It must be remembered that success or failure in organising the medical defence may well depend on the rapidity and accuracy of diagnostic efforts.

Detection of Biological Warfare Agents

The detection of these agents in the environment is virtually impossible or difficult The first indication of a biological agent attack would be an increased no of patients showing up at hospitals with clinical features of the disease agent used. It is difficult to recognize the outbreak of an endemic disease from an outbreak stemming from a biological attack. The disease pattern that develops may be an important factor in differentiating between a natural and a terrorist or warfare attack. Some epidemiological clues of a biological warfare or terrorist attack are :

(a) The presence of a large epidemic with similar symptoms, especially in a discrete population.

(b) More severe symptoms than are usually expected for a specific disease, or failure to respond to standard therapy.

(c) A disease that is unusual for a given geographic area or transmission season.

(d) Multiple simultaneous or serial epidemics of different diseases in the same population.

(e) Unusual routes of exposure for a disease, such as the inhalational route for diseases that normally occur through other exposures like exposed skin.

(f) A single case of a disease by an uncommon agent (small pox, viral haemorrhagic fevers)

(g) Unusual strains or variants of organisms or diseases that resist normal treatment.

(h) Intelligence of a potential attack or claims by a terrorist of release (13).

Immune Prophylaxis

Most effective method against biological warfare would be the use of specific active immunoprophylaxis. Most of these vaccines are not available through commercial channels and have been developed mainly for protection of laboratory personnel or for possible protection of military personnel who might be required to operate in areas of the world in which specific diseases are endemic.

Problems associated with immunoprophylaxis are :

(a) Requirement of large amount of vaccine

(b) Development and production of vaccine against exotic diseases

(c) Logistic burden

(d) Requirement of multiple doses and limitations on the number of vaccines which can be administered at one time.

Single or polyvalent vaccines may be used. Polyvalent vaccines have the advantage of preventing multiple diseases by a single injection. For reducing time in mass vaccination programmes jet injectors can be used effectively. However active immunisation takes time for producing an immune response and is hence ineffective in a war like situation. Passive immunoprophylaxis might also be employed in biological operations situation when rapid protection is desired and agent used by enemy is known.

Public Health Aspects

A Biological attack can breakdown public health systems including disrupting of existing disease control programmes. Every precaution should be taken to prevent these consequences.

Medical aspects of biological warfare

| | |
|---|---|
| Epidemiological Indicators of biological warfare<br><br>diagnosis | Personal protection<br>Collective protection<br>Early detection and<br><br>based on features and lab diagnosis<br>Antibiotic stocks<br>Isolation<br>Prompt treatment<br>Infection control<br>Information to higher authorities |

The following measures may be instituted :

(a) Proper inspection and thorough cooking of food

(b) Institution of water surveillance, water chlorination/ superchlorination and/or boiling water for 15 mins.

(c) Frequent change of clothing, daily baths, washing of mouth by water/ normal saline.

(d) Strict control of rodents and insects is of immense importance following a biological attack as they may be a source of propagation of an epidemic (21, 28).

## Toxins as Warfare Agents

### Introduction

Toxins are poisonous substances usually produced by living organisms or extracted from the cells of these organisms. Toxin warfare agents or toxic weapons are toxins used for hostile purposes. Toxins are faster acting than biological agents, they are of potentially greater military utility.

Types of Toxins

**(a) Bacterial Toxins**

These can be broadly divided into exotoxins and

endotoxins. Few important bacterial toxins which are of military interest are :

(i) Botulinium toxin
(ii) Staphylococcal toxin
(iii) Tetanus toxin

**(b) Mycotoxins**

Mycotoxins are toxic compounds produced by moulds. Some of the important mycotoxins which are of military interest are :

(i) Alphatoxins
(ii) Trichothecenes
(iii) HT 2 toxins
(iv) T 2 toxins

**(c) Snake Toxins**

Out of many toxic components in snake venom the following are important :

(i) Neurotoxins
(ii) Necrotic toxins
(iii) Haemorrhagic toxins

**(d) Ricin**

Effects

Toxins, depending upon their type, can cause death or incapacitation in human beings and animals and are thus classified as :

(a) Lethal
(b) Incapacitating

Dissemination Techniques

Toxins can be delivered on the target area by all available means similar to those used for delivering chemical agents. In Laos, Cambodia and Afghanistan wars, the following means were reported to have been used for dissemination of mycotoxins :

(a) Aircraft
(b) Bombs
(c) Rockets, artillery
(d) Mines

Conclusion

Many toxins have turned out to be more toxic than orgonophosphorous compounds and other chemical poisons e. g. Ricin. Progress achieved in the field of microencapsulation might make aerosol distribution of toxin warfare agents more feasible technically. Modern method of genetic engineering, cell techniques, protein engineering and immune techniques makes it possible to produce large amounts of toxins.

## Chemical Agents and Chemical Warfare

### Definition

Deliberate use of chemicals against humans, animals or crops with the primary intention of inflicting casualties or to decrease combat efficiency of the enemy during war is called as chemical warfare. A weapon that owes its destructive power entirely to the toxicity of one or more of its constituent chemicals rather than the energy of the chemical interaction between them is called as a chemical weapon. A chemical agent is a compound which when suitably disseminated produces incapacitating, lethal or damaging effect on men, animals, plants or materials.

**Salient features of Chemical agents are**

(a) Most chemical agents are powerful organic solvents and able to penetrate into polymeric materials.
(b) Depending upon its physical properties and the method of application chemical warfare agent may present itself as liquid, aerosol or vapour.
(c) Chemical warfare agents may be thickened to increase their persistency.
(d) Chemical warfare agents present a dangerous contact risk and are difficult to decontaminate.
(e) These agents have a much more immediate effect than biological agents when used on the battlefield.

### Methods of Dissemination of a Chemical Agent

Chemical agents may be disseminated in one of the following ways :

(a) Liquid droplets or spray like rain
(b) Liquid aerosols like fine mist small enough to be inhaled
(c) Solid aerosols like smoke
(d) Vapour or true gas.

Chemical Warfare agents may be delivered in many different ways from aircrafts, spray tanks, containers, aerial bombs, artillery shells, rockets, grenades, missiles from air or ground or from aerosol generators.

### Classification

Chemical agents may be classified in one of the following ways

(a) Classification based on their military use

The chemical agents are further classified as:

**(i) Lethal agents**

Also called as killing agents, they are delivered with the primary aim of killing maximum number of men e. g. , nerve agents.

**(ii) Incapacitating agents**

Make an individual temporarily unable to perform his duties.

**(iii)Riot control agents**

They are selected and approved for use while giving aid to civil authorities.

(b) Classification based on Duration of Effectiveness:

This is based on the duration for which the agents are effective over a target. They are classified as follows :

**(i) Non - persistent agents**

Such agents disperse rapidly as they are highly volatile. They affect the body through respiratory route. Examples include Phosgene and G. agent.

**(ii) Persistent agents**

Such agents continue to present a hazard over the target for considerable period after delivery. Example V agent.

(c) Classification based on Effect of the agent on the body:

**(i) Nerve agents**

Interfere with the working of the nervous system e. g. , Tabun (GA), Soman (GD), Sarin (GB).

**(ii) Blister agents**

Also called as vesicants, they cause inflammation, blistering and superficial destruction of contaminated tissues such as lining of breathing passages. Examples include distilled mustard, nitrogen mustard and lewisite.

**(iii)Blood agents**

They prevent body tissues from using oxygen e. g. , hydrogen cyanide (AC), cynogen chloride (CK), arsine (SA).

**(iv)Choking agents**

Phosgene, diphosgene, chloropicrin.

**(v) Vomiting agents**

Diphenylchloro arsine, adamsite.

**(vi)Mental incapacitators**

These are further classified as

- CNS depressants e. g. , marijuana
- CNS stimulant e. g. , LSD

Chemical weapons have been tried out and their effects are known more or less thoroughly (22 - 27). General and medical defences against these agents are well developed and if instituted early can save large number of lives. Effects, sign and symptoms and the treatment of a few important chemical agents is given below:

**Effects of Nerve Agents**

These are a group of highly toxic organophosphorus compounds and constitute one of the deadliest chemical agents. High exposure may lead to death without any reaction time. Broadly they are divided into G group agents such as GA (tabum) GB (sarin), and GD (soman).

**Absorption**

Entry is through respiratory route usually. They can act through the eyes, skin and penetrate ordinary clothing rapidly. They can be easily removed from the skin using Fuller's earth or soap water. They act by inhibiting cholinesterase enzyme. Signs and symptoms resemble Organophosporous poisoning. Treatment consists of termination of exposure, and decontamination. Atropine and oximes are used whereever indicated, severe cases may require ventilatory support. NAPS or nerve agent pre - treatment set consisting of 30 mg pyridostigmine bromide is available. NAPS can be used 8 hourly before an anticipated attack. Self - aid consists of use of protective mask and hood. Eyes should be irrigated. Combopen auto injector with 2 mg of atropine and 220 mg of oxime can be used every 15 minutes. In case of soman, diazepam can be added with combopen.

**Effects of Blister Agents**

These are absorbed through the skin, conjunctiva and respiratory tract. They are rapidly absorbed if they are ingested. Repeated exposure leads to cumulative effect. These agents are cytotoxic and mutagenic. Their effect resembles that produced by ionizing radiations. They interfere with DNA synthesis and cellular division process. Eyes are blistered after a heavy exposure and may lead to blindness. Mild exposure leads to lacrimation and foreign body sensation. Self aid consists of washing the area exposed with normal saline or water. Antibiotic eye drops may be used. Exposure of the skin leads to erythema, vesication and necrosis, depending on the dose. Treatment consists of decontamination with Fuller's earth and use of bland lotions. Beclomethasone can be used on blisters and erythema. Analgesics can be used when required. Four to six hours of exposure leads to effects on the respiratory system. These include nasal secretion, burning pain in the throat, hoarseness of the voice and aphonia. Repeated exposure leads to pulmonary fibrosis and chronic bronchitis. Secondary infection may lead to pneumonia. Treatment consists of cough syrup, steam inhalation and antibiotics. Exposure to the GIT leads to vomiting, bloody diarrhoea, prostration and shock. Large number of similar cases with GIT symptoms should lead to a suspicion of exposure to blister agents. In such a case close examination of food should be done. Treatment consists of use of atropine, analgesics and IV fluids.

**Effects of Choking Agents**

These agents affect the lung tissue leading to pulmonary oedema. Best known example is phosgene. This is a colourless gas with suffocating odour reminiscent of mouldy hay. Maximum oedema occurs after 92 hours of exposure. The gas may be inhaled in vapour or aerosol form. Exposure to the eyes leads to lacrimation. Irrigation of the respiratory passages leads to cough and choking along with feeling of tightness in the chest, nausea and vomiting. Increasing quantity of frothy white or yellow sputum is expectorated which later may become blood tinged. Circulatory collapse and cardiac failure may occur. Death may occur within 48 hours of exposure. Diagnosis is ascertained by history of exposure and a large number of cases occurring at a particular time. The initial symptoms of choking, coughing and lacrimation disappear to reappear after one to six hours. Treatment consists of use of mask, protection from exposure, bronchodialators and antibiotics. Decontamination is not required.

**Effects of Blood Agents**

These include hydrocyanic acid and cyanogen chloride. These are absorbed by inhalation. These agents act by combining with cytochrome oxidase enzyme and lead to death due to respiratory failure. Cyanogen chloride leads to symptoms of upper respiratory system. Acute poisoning is characterized by dizziness, headache, palpitation, anxiety, dyspnoea, ataxia, paralysis and coma. Severe cases may show collapse, convulsions and respiratory arrest. History of exposure, typical signs and symptoms and peculiar odour, like bitter almonds, point to the diagnosis. Treatment consists of use of mask, and smelling amylnitrite. Crush 2 ampoules close to the nose.

In case the individual is in a contaminated atmosphere, crushed ampoules are inserted inside the protective mask. Two crushed ampoules can be used every 4 to 5 minutes to a maximum of 8 ampoules. Ventilatory support may be required.

**Detection of chemical warfare agents**

Detection and identification of chemical agents is extremely important for taking protective action since chemical agents have different mechanisms of action. The detection of chemical agent (compound) is defined as the determination of its presence in a qualitative and often In a quantitative way. Sometimes especially if the agent is highly toxic, it is also important to determine the hazard which a combination of its presence, its concentration its form and its toxicological properties.

Detection can be carried out on site and off - site both by detection in its vapour or liquid form by using physical and other automated techniques. Some of the Detection methods are

(a) Residual vapour detection kit
(b) Detector tubes
(c) Three colour detector paper forliquid blister and nerve agents
(d) CAM (Chemical agent monitor) for mustard and nerve agents
(e) Portable gas chromatography
(f) Mass spectrometry

**Protection against chemical agents**

In a situation of chemical warfare agent use, physical protection of the individual is the most important measures to counteract the toxicity of the agent. Physical protection for an individual is known as individual protection and if for a group of individuals is known as collective protection. In either of the cases the twin aspect of physical protection are creation of an artificial barrier between the chemical warfare agent and the 'subject' and the provision of breathable air.

Individual Protection

Protective equipment which is used by an individual to achieve protection is termed as Individual Protective Equipment. This includes protective clothing such as trousers, jacket with hood, overboots and mask or respirator. Respirable air is provided through a source connected to thr face piece which can be a pure air cylinder or a canister which detoxifies the contaminated air.

Collective Protection

In case of collective protection, locations such as shelters, tanks, ships buildings, vehicles etc are suitably modified e. g. by a ventilation system to protect against the chemical environment. Collective protection reduces the discomfort of wearing the individual protective equipment.

Medical management of chemical casualties

Chemical warfare agents are weapons of mass casualties, with casualties having features specific to the toxic effect of the agent.

(a) The effects of chemical agents are known.
(b) Chemical casualties have features specific to the toxic effect of the agent.
(c) The general defensive measures, NBC suit and face mask were primarily developed against chemical agents and are efficient in preventing the effects provided the troops are well trained in their use.
(d) Medical protection in the form of pre treatment, self aid and treatment is well developed and if instituted early can save lives.

**Medical management of Nerve agent poisoning**

Principles of treatment

(a) Termination of exposure
(b) Decontamination
(c) Assisted ventilation
(d) Anticholinergic agents eg atropine which competitively blocks acetyl choline
(e) To reactivate he inhibited acetylcholine esterase enzyme by an oxime
(f) To use adjuncts eg carbamates to augment the effects of cholinolytic agents. The carbamates bind with a portion of the body's AchE forming a weak complex thus saving this from the effects of nerve agents. Thus carbamtes eg pyridostigmine reserves upto 30 % of the body's AchE for later release. This release is facilitated by oximes. Use of pyridostigmine allow the body to tolerate larger doses of nerve agents provided post exposure treatment is given.

Management

**Pre treatment**

Pyridostigmine bromide 30 mg, also known as Nerve Agent Pre Treatment Set(NAPS) tablets are taken 8 hourly before an anticipated chemical attack. The set consists of 21 tablets.

**Self aid and First aid**

(a) The protective mask and hood must be put on immediately if any of the symptoms of nerve agent poisoning are noticed eg
  (i) Feeling of tightness in the chest.
  (ii) Unexplained running nose
  (iii) Unexplained dimness of vision
(b) The eyes must be washed with water if a splash of liquid agent gets into the eye.
(c) Atropine must be taken immediately in the form of autoinjectors. These contain 2mg of atropine and are to be injected in the outer aspect of the thigh by self or buddy every 15 minutes till a maximum of three injections are taken. Oxime injections are also to be taken in the same way in the other thigh for a maximum of three injections. The auto injectors contain 220 mg of atropine. The two can

be combined in one injection known as combopen injection.

(d) 5 mg of diazepam taken orally is also a useful adjunct in the treatment of nerve agent due to its central anti convulsant properties.

**Treatment**

The casualty must be evacuated to the hospital if there is no improvement after 3 injections of combopen. Here treatment can be continued with oxygen inhalation, artificial respiration, intravenous atropine and supportive care.

**Medical management of blister agent poisoning**

Self aid and first aid

(a) Remove the casualty from the source of the blister agents.

(b) Clothing should be removed.

(c) Wash the eyes preferably with normal saline otherwise with clean water.

(d) Decontaminate the skin with fullers earth i. e. DKP I and 2

(e) Local anaesthetic eye drops may be instilled in the eyes e. g. amethocaine hydrochloride may be instilled in the eyes.

(f) Topical antibiotics e. g. chloromycetin should be used to prevent secondary infection.

(g) For areas of erythema and minor blistering bland calamine lotion may be used.

(h) Beclomethasone dipropionate cream may be used for minor blistering.

(j) Pain relief by using analgesics, (Paracetamol).

(k) Application of antibiotic ointment and covering the area with sterile bandage.

Treatment

Blister agents require long period of hospitalization and skin care depending on the area involved. Broad spectrum antibiotics, pain relief and dressings form the mainstay of treatment. In case of GIT symptoms, atropine and IV fluids may be required.

**Medical management of choking agents**

Self Aid and first aid

(a) Protective mask should be worn immediately on suspicion of exposure to the toxic agent eg odour of cut grass, irritation of eyes or choking feeling with cough.

(b) Casualty must be removed from the source by buddy wearing protective mask.

(c) Personnel must be made to rest and provided with warmth.

(d) Decontamination is not necessary.

(e) Bronchodilators e. g. beclate in metered doses must be inhaled every 15 min.

Treatment

Rest, oxygen, bronchodilators e. g. aminophylline is helpful. Antibiotics are required to check infection and ventilatory support may be required.

**Medical management of blood agents**

Self aid and first aid

(a) Mask must be put on immediately as soon as suspicious odour is detected. Breath should be held till mask is worn.

(b) Crush two ampoules of amyl nitrate immediately and hold close to the nose. If individual is still in contaminated environment, two crushed ampoules are inserted inside the protective mask. This treatment of crushed ampoules is repeated every 4 - 5 minutes till breathing returns to normal or a maximum of 8 ampoules are used.

Treatment

(a) Oxygen inhalation and artificial respiration if breathing difficulty persists.

(b) 600 mg of dicobalt edetate is given IV over one minute. If there is no recovery, another 300 or 600 mg is repeated iv over two min

(c) Sodium thiosulphate and Sodium nitrite are given in combination as an alternative treatment. Three % sodium nitrite 10 ml along with 50 % sodium thiosulphate 25 ml.

## Principles of NBC Defense

Protection from NBC agents involves the following components

(a) Avoidance

(b) Detection

(c) Protection (individual and collective)

(d) Decontamination

(e) Medical management

**General**

An enemy may use its NBC capabilities in direct support of its attack to cause maximum casualties. He may also attempt to contaminate ground and equipment so that our troops are forced to take precautions, which may degrade their operational performance. The operations may also be hindered because of :

(a) NBC casualties.

(b) Reduction of efficiency of troops who wear protective clothing and equipment.

(c) Loss of time in performing decontamination operations.

(d) Lack of logistical support required to perform decontamination

In spite of taking measures for avoidance of contamination, and individual and protective measures, it is likely that troops, terrain and equipment will get contaminated while fulfilling the mission. It is therefore essential that the decontamination operations be carried out at the earliest to restore the combat potential in order to fight and win.

### Nature of NBC Contamination

NBC contamination will generally take the following forms :

**(a) Chemical Contamination**

Chemical agents, either free standing or absorbed, will gradually evaporate posing residual vapour hazards.

**(b) Biological contamination**

Existing in solid or liquid forms as spores, powders or live micro - organisms, may persist for long periods, posing a potential hazard.

**(c) Nuclear Contamination**

Gamma rays and neutrons are very penetrative. These cannot be destroyed and decontamination must be aimed at removal of contamination or separation of personnel from the source of radiation.

**(d) Secondary Hazards**

Fall out of military activities in areas of NBC contamination may cause a secondary local and down wind hazard areas.

### Reasons for Decontamination

(a) Contamination can be lethal to unprotected troops.

(b) It degrades performance. Contamination forces soldiers into Mission Oriented Protective Posture or MOPP - 4. This reduces efficiency.

(c) Limitations of MOPP gear will begin to reduce effectiveness of the gear as well as the soldier. MOPP also provides only minimal protection from radiological contamination.

(d) Contamination also tends to spread to the shelters and along the supply routes due to spread of troops.

### Contamination Hazards

Contaminations may take the form of solids, liquids or gases. These can take place by :

**(a) Transfer**

Anything that touches a contamination tends to pick it up and then transfer it. The aim is to limit such a transfer.

**(b) Vapour**

Vapours have the potential of being inhaled. Also they tend to settle out of the air and coat the surface they touch.

**(c) Desorption**

Any absorbed contaminant is let out as vapour. This poses a vapour and transfer hazard.

**(d) Radiation**

For decontamination purposes radiation can be thought of as solids and removing a contaminated equipment will remove the hazard.

### Locating Contamination

**(a) Radiological**

Survey meters / Radiation meters.

**(b) Biological**

Only non specific contamination can be detected in the field. For specific detection, laboratory help is required.

**(c) Chemical**

Chemical detector papers, field detectors and alarms.

### Decontamination

It is the normal removal, neutralization or reduction of hazardous level of NBC contamination from personnel and material. Its aims are :

(a) To remove the free liquid or solid agents or radioactive dust from surface.

(b) To reduce the residual vapour hazard levels to permit relaxation of full personal protection.

(c) To hasten the rate of weathering and decay.

Types of Decontamination

**(a) Emergency Decontamination**

Any thing that immediately neutralises or removes contamination from exposed skin. The technique uses DKP1 and DKP 2 kits. It should be started within a minute of exposure.

**(b) Partial Decontamination**

Neutralisation of visible contamination from individual clothing and equipment that the crew must touch to perform its mission. Techniques used are :

(i) Personal wipe down.

(ii) Operator spray down.

(iii) MOPP gear exchange.

(iv) Vehicle wash down.

**(c) Complete Decontamination:**

This aims to reduce all or most of the contamination hazards.

Principles of Decontamination

(a) Decontaminate as soon as possible.

(b) Decontaminate only what is necessary

(c) Decontaminate as far forward as possible.

(d) Decontaminate by priority.

Chemical Decontaminants

They work by destroying the specific structure of toxic chemical agents. Some commonly used chemical decontaminants are :

**(a) Super Tropical Bleach (STB)**

It is a mixture of chlorinated lime and calcium oxide. It contains 30% active chlorine. Decontaminates mustard, lewisite and nerve agents.

**(b) Decontaminating Solution (DS - 2)**

Clear solution consisting 70% active chlorine, triamine, ethylene, glycol, monomethyl ether and sodium hydroxide.

**(c) High test hypochlorite (HTH)**

Bleaching powder similar to STB and contains a higher

%age of active chlorine.

**(d) Caustic soda or sodium hydroxide**

Neutralises a nerve agent and hastens hydrolysis of lewisite.

**(e) Sodium hypochlorite (house hold bleach)**

Effective against blister and V agents.

**(f) C - 8 calcium hypochlorite.**

Acts as a universal decontaminant.

**(g) Miscellaneous decontaminants.**

Organic solvents such as gasoline, kerosene, alcohol can dissolve toxic chemicals. Absorbant materials such as earth, charcoal, coal dust, saw dust, fuller's earth or clay.

Decontamination Equipment

These are used at individual, unit or formation level. These are:

**(a) Personal Decontamination Kit - PDK No. 1**

(i) Characteristics.

- It effectively decontaminates all types of chemical warfare agents.
- It is for immediate decontamination of human skin exposed to a chemical attack.

(ii) Description

It consists of pads filled with an inert, non - irritating strong absorbent powder. Each pad is sealed in polythene laminated aluminium paper bag to protect it from moisture and contamination.

(iii) Procedure

Quickly blot affected parts of skin with the pad then dap the pad lightly on the skin so as to cover the area liberally with powder. Remove excess powder with a fine towel to be thrown away or destroyed.

(vi) Packing

- It consists of four bags (containing powder pads) wrapped and sealed in polythene coated paper folder.
- Instructions are printed on package.

(v) Precautions

- It should be stored in a dry place.
- It is used as survival kit in an emergency to be followed by medical treatment.
- Always be alert to the development of symptom even after decontamination.

**(b) Personnel Decontamination Kit - PDK No. 2**

(i) Characteristics

- PDK No. 2 effectively decontaminates all types of chemical warfare agents.
- It is used for the decontamination of clothing, equipment and small arms.

(ii) Description

- It is puff bottle with a mixture of absorbent powder and chlorinated lime.
- Presence of chlorine helps in fast neutralization of mustard and VX agents in addition to the absorption properties.

(iii) Procedure

Press puff bottle repeatedly. Spray powder to spread all over the contaminated surface, dab the surface briskly and then wipe off the excess powder.

(iv) Packing

- Its puff bottle contains 80 gms of powder.
- Instructions are printed on the package.

(v) Precautions

- It should be stored in a dry place.
- It should be used for decontamination of skin.
- It is for use as field kit by the individual in an emergency.

**(c) Radiological Decontaminant Personnel Rdp**

(i) Characterstics

- It is intended for decontamination of dry/oily skin contaminated with radiological dust particles.
- It is a dilute aqueous solution with PH value of 7. This solution is adsorbed on special paper handkerchief.
- Fine handkerchiefs are packed in aluminium coated polythene bags.

(ii) Procedure

- Contaminated skin surface is cleaned thoroughly by wiping of the dust particles with the help of handkerchiefs provided.

(iii) Packing

- Hundred polythene bags (5 handkerchief in each bag) are packed in cardboard box.
- Instructions for use are printed on each bag.

(iv) Disposal

- These handkerchiefs should be collected in container to be buried under the earth.

(v) Precautions

- This handkerchief is for single use and repeated use of the handkerchief is strictly prohibited.

**(d) Portable Decontamination Apparatus - PDC 1**

(i) Technical Description

- This is used to decontaminate surfaces of materials and equipments.
- This is designed for spraying all liquid decontaminating agents.
- PDA - 1 assembly consists of a steel container capacity 10 litres, spray gun equipped with adjustable nozzles to obtain desired spray angles, brush for rubbing the surface, hose

pipes 2 metres in length, small size air cylinder for pressurizing liquid inside the container upto 3 Kg/sqcm pressure guage and safety valve.

- Spraying range is 10 m (max).
- Total height of apparatus is 565 mm.
- Weight of filled apparatus is 20 Kg.
- Generally 9 litres of decontaminant is filled into container.

(ii) Operating Instructions

- PDA - 1 container is filled to volume of 9 litres and stoppered. Air is slowly released to get desired pressure. The spray gun is operated and directed towards contaminated area.
- In case of slurry, higher pressure would be required for its delivery.
- Maximum pressure of air in the steel container should not be more than 3 Kg/sqcm.
- Slurry is slowly rubbed over contaminated surface to ensure complete decontamination of thickened agents.
- Maximum pressure of compressed air in the air cylinder is 130 - 150 Kg/sqcm.

(iii) Maintenance of Apparatus

- After each operation the steel container should be cleaned thoroughly with water.
- Spray gun should also be thoroughly cleaned with water.
- Threadings of stopper should be greased properly.
- Safety valve should be checked periodically for its correct setting.

**Various types of first aid kits used in Chemical Warfare are described below :**

**(a) First Aid Kit CW Type 'A'**

(i) First Aid Kit CW Type 'A' is intended to be used primarily to augment first aid resources available with a small body of troops when speedy evacuation of casuality is not possible. Kit can also be used at MAP.

(ii) Contents

| | |
|---|---|
| Combopen autoinjectors | 6 |
| Beclomethasone inhaler with metered dose | 1 |
| Personal decontamination kit | 1 |
| Detector paper chemical agent | 1 |
| Sterile gauze dressing | 2 |
| Antibiotic skin ointment | 1 |
| Dimercaprol eye ointment | 1 |
| Ampicillin 250 mg capsules | 25 |
| Paracetamol 500 mg tablets | 25 |
| Codine phosphate 30 mg tablets | 15 |

**(b) First Aid Kit CW Type 'B'**

(i) First Aid Kit CW Type'B' is intended to be used primarily at RAP for management of chemical casualities flowing in from FDL by trained medical personnel. It can also be used at ADS by pooling more number of such kits for treatment of casualities after decontamination has been carried out. Kit can also be used at MAP Cl 'I'.

(ii) Contents of the kit are attached as: Appx 'A'

**Emergency and Partial Decontamination**

One must decontaminate just enough to keep fighting rather than enough to make contamination free environment. Decontamination can be:

(a) Emergency or individual survival decontamination

(b) Partial

(c) Complete / deliberate

**Individual Survival Decontamination**

**(a) Chemical**

The skin decontamination kit DKPI provides the best means of decontamination. If it is not available, then chemical contamination may be pinch - bottled from the skin with any cloth and then area flushed with water from canteen.

**(b) Biological**

No decontamination is required immediately. The best biological defence is to take action before you are attacked. Keep immunization up to date, observe basic sanitary precautions and keep skin breaks covered. Treat minor cuts or abrasions by ordinary first aid measures. A 1. 5 % sodium hypochlorite (household bleach) solution is also an effective biological decontaminant.

**(c) Radiological**

Because no immediate life threatening hazard is caused by radiological contamination, no immediate skin decon is required. If your skin is contaminated by radiological contamination, use the individual sustainment techniques as soon as possible.

**Partial Decontamination**

Unit sustenance Decontamination Technique

It is a company sized operation that consists of three techniques:

(a) The MOPP gear exchange. This removes all liquid or solid contamination from the soldier and his equipment.

(b) Equipment decontamination

(c) Vehicle wash down: The last two techniques reduce the transfer hazard. Unit sustenance should be done as soon as possible.

**Individual Decontamination Equipment**

Decontamination is done at different level. It implies degassing, deradiation and disinfection. As part of an individual's kit there are individual decontamination kits, one based on the principles of absorption and the other on neutralization. Both are needed to tackle different types of contamination of different surfaces to be encountered on

an individual. The most popular one is the Fuller's Earth using a special technique to absorb maximum toxic chemical agent from such surface. However when the surface is skin, it must be decontaminated immediately. For this, chemical which neutralize most toxic chemical agents are used. Some kits can be used to remove radiological contamination also. Both contamination and decontaminating agent must be prevented from contacting eyes, mouth and open wounds. If contamination does occur, it must be flushed with water and if symptoms appear then they require medical attention. If a soldier is incapacitated, then his buddy must perform the decontamination.

**Special Equipment**

'Special' is the term used to express the range of equipment which are not personal equipment but are unit or subunit equipment. Every individual must know how to use since any person may be required to use them. This range of equipment includes

Residual Vapour Detection Kit (RVD)

It is also known as Field Chemical Agent Detection Kit. This kit consists of different sets of detection tubes, a mechanical pump and detection papers. The detector tube will detect harmful concentration of agent in field and the extent to which the changes in the colours indicate the approximate concentration of the sample. With the detection kit, it is also confirmed that the concentration of the agent is below hazardous level and therefore unmasking may be done. It also helps in collecting samples of any novel and unknown agent used by the enemy.

Direct - Reading Personal Dosimeter

It helps in reading total radiation dose and also gives a total gamma/neutron cumulative dose. Thus it enables commanders to determine the single exposure dose and the total dose at the end of the day and maintain the Radiation Exposure State of the Unit.

Hand - Held Decontamination Apparatus

It is used to decontaminate small areas that individuals come in contact with during the perusal of the mission. It reduces the levels of hazard of such mission. It has a pressurised can, a nozzle and a handle and looks like a fire extinguisher. Examples of situations where this apparatus can be used are: steering wheel and the wind screen, the door and its handles, the foot rests and the dashboard of a vehicle, laying and siting parts of an artillery gun and mortar and the like.

Casualty Bag

It used for evacuation of casualties through contaminated areas and to control contamination while transporting contaminated casualties through clean areas. Its of two types:

(a) Whole casualty bag. Its employed for evacuation of stretcher borne cases.

(b) Half casualty bag. Its used for walking wounded cases.

**Individual Self Aid Kits**

(a) Nerve Agent Poisoning

(i) Pre treatment Set of pyridostigmine bromide tablets (20 gm), commonly known as NAPS (Nerve agent pre - treatment set). These tablets are taken every eight hours and the set consists of 21 tablets. It therefore caters for 7 days. These tablets bind about 30 - 40% of body enzyme in a reversible reaction which then is not available for reaction with nerve agent. There is however a need to administer the autoinjector after attack if symptoms are observed.

(ii) **Autoinjectors :** Should be administered as soon as possible in case of nerve agent poisoning. A set of these autoinjectors contain a mixture of atropine (2mg) and an oxime (150 mg). A set consists of three auto injectors.

(b) Vesicants

These are hazardous whether they enter the respiratory system, come in contact with skin or are ingested. Mustard will also get through the clothing, given time. Immediate emergency decontamination, hence is ideal. If vesicants have gone into the eyes, it is best treated by using distilled water provided in self aid kits

(c) Miscellaneous

Amyl nitrite (smelling salt) can be used to relieve respiratory congestion against choking agents.

**Individual Detection Equipment**

Instruments needed to help the soldier to measure radiation and detect chemical agents encountered on the battlefield, help in survival of the man in NBC environment.

(a) Personal Dosimeter

It enables to record the radiation to which the person is exposed. These are of two types:

(i) Direct reading

These provide the commanders with information on single exposure doses and daily exposure doses.

(ii) Indirect reading.

This records cumulative gamma and neutron dose received by the person.

(b) Chemical Agent Detector

In case of vapour or aeresol this is provided by the detector alarms and monitors. But they do not give indication of absence of the hazard. The detection of liquid chemical agent is achieved by single colour and three colour detector paper. Immediate self aid or buddy aid is essential to survive in case an individual has been subjected to chemical attack. Each soldier is issued a set consisting of three autoinjectors, nerve agent pretreatment tablets, oxime tablets and some anti

## Policies and Procedures for Medical Classification of Personnel Affected by Important Conditions

Tertiary prevention constitutes the final level of prevention. Theoretically it appears to be a different stage from secondary level of prevention but in practice both run concurrently. As soon as a disease is confirmed, effort of medical & health fraternity is to cure it and thereby prevent loss of tissue / function which may result in disability necessitating rehabilitation. In diseases where early / timely intervention results in complete recovery / regeneration of tissue without any loss of function the disease process halts at secondary level, in others it progresses further. The modality of practice of tertiary prevention entails (a) disability limitation and (b) rehabilitation as applied to various diseases (1).

**(a) Disability limitation**

Early identification of disease and prompt treatment remains cornerstone of disability limitation. A delay in either will lead to instituting subsequent modalities of rehabilitation. During the treatment an appreciation of complications of disease helps in preventing them. Therefore, it will now be appreciated that secondary and tertiary level are inherently interlinked and run concurrent to each other.

**(b) Rehabilitation**

As far as it is concerned main thrust of all the activities under this head are directed to make the individual a useful member of society besides maintaining the pride and dignity of a human being. A holistic approach is adopted for this purpose. Main components of rehabilitation are (i) physical, (ii) vocational (iii) emotional/ psychological and (iv) social.

(i) **Physical** : It involves measures like reconstructive surgery or artificial limbs or wheel chairs, training of other group of muscle whereby endeavor is made to compensate the individual physically for loss of Function.

(ii) **Vocational** : Individual specific jobs are identified & created to make the individual self reliant in finances so to support himself & his family. Various financial rehabilitation schemes also come under this head.

(iii) **Emotional / psychological rehabilitation** : It should start immediately as soon as illness / loss of body part / function is realized. Besides the immediate treating team, the family support plays a crucial role in over coming the physical loss by individual. An aggressive management in secondary level will reduce subsequent effects for disability limitation & rehabilitation. However, when a patient reports late in pathogenesis of disease then disability limitation follows the cycle of function impairment leading to disability and ultimately becoming a handicap.

In Armed Forces a very dynamic and robust system follows disability limitation and rehabilitation of affected individuals and the modalities are laid down in concerned Army/Navy/ Air Force orders on the subject. This is applied in the form of various medical categories, SHAPE - 1 being the highest category denoting fitness of individual for all duties any where. The SHAPE factors then increase in number to denote various restrictions being put on individual as far as his / her employment, postings, dietary habits, periodic monitoring by medical authorities are concerned. The highest number i. e. 5 in any factor of SHAPE denotes unfitness for ARMED FORCES service and individual is invalided out of Service. An individual after being downgraded can be upgraded to his / her original medical category provided during periodic reviews the medical condition commensurate with laid down standards for particular disease.

Each SHAPE factors has a corresponding employment index and it is mentioned in each individual's medical documents at the time of categorization. The guidelines for administrative authorities are in the form of these employment indices. At the time of discharge a detailed counseling of patient is conducted to explain the various restrictions being put on the patient and periodicity of follow-up to be observed by the patient.

### Disposal of cases of important diseases in the armed forces

**Diabetes mellitus**

Diabetes mellitus like many other chronic diseases, leads to systemic complications if treatment is inadequate (poor compliance) or delayed. Tertiary prevention revolves around motivating intensely the patient by health education for self-care and early identification of complications by virtue of sign & symptoms Importance of maintaining euglycaemic state with proper diet, weight control and adequate physical activity.

In Armed Forces after an initial period of three months of diagnosis and after initiating the treatment if a patient develops unstable serious complication or requires insulin for routine control or any one developing serious complications is invalided out.

All diabetic retained in service will be placed in med category P3 (T-24) following which, officers requiring insulin, will be placed in P3(P) while JCOs/OR achieving control with diet / oral drugs will be followed to check the grade of control achieved. Grade III control patient will be placed in P3 for further period of 24 weeks whereas, Grade II control patients will be upgraded to P2 (Temp). Finally if a patient maintains grade II control without drugs and without complications for a year than he / she will be upgraded to P1 with instruction to be on follow up every 3 years by Endocrinologist / Senior Advisor (Med).

Remaining cases of impaired fasting and glucose tolerance (IFG & IGT) with obesity will be placed in P3 (T-

24) with instr to reduce to normal range of ideal body weight and subject to Oral GTT being normal will be upgraded to P1 otherwise will be disposed as above. However, if Impaired Fasting Glucose(IFG) & Impaired Glucose Tolerance(IGT) incl obesity persists then they will be placed in P3 (P).

**Non obese patients of IFG & IGT :** These patients will be observed in P2 (T-24) and following an Oral GTT (in normal limits) after 24 weeks can be upgraded to P1 otherwise they will continue to be in P2 (T-24). If glucose profile continue is unchanged after a year they will be placed in P2. (2).

### Hypertension

Besides emphasizing the importance of good control with / without medicines, diet, body weight and physical activity, tertiary prevention of hypertension involves extensive patient education about early recognition of likely complications which can be Ischaemic heart disease, Cerebro vascular accident, renal insufficiency, retinopathy etc. Management in case a complication occurs, will entail huge system specific rehabilitation.

In Armed Forces all individuals with high normal blood pressure without target organ, damage will be in SHAPE 1 but will be regularly followed up by AMA. All stage 1 hypertensives without target organ damage will be placed in P2(T-24) with final disposal in P2. Stage II & III hypertensives will be initially placed in P3 (T-24) following which those displaying well controlled hypertension with grade 2 retinopathy will be upgraded to P2 (T-24) and if blood pressure remains well controlled finally will be placed in P2.

All remaining patients will be observed initially in P3 (T-24) and those with well controlled Blood Pressure incl static complications finally will be placed in P2. Rest all patient will be invalided out.

Any up-gradation to P1 will be for patient showing good control without target organ damage without medicines for at least one year. This can only be done be by Senior Advisor (Med)/ Cardiology (3).

### Problems of high altitude

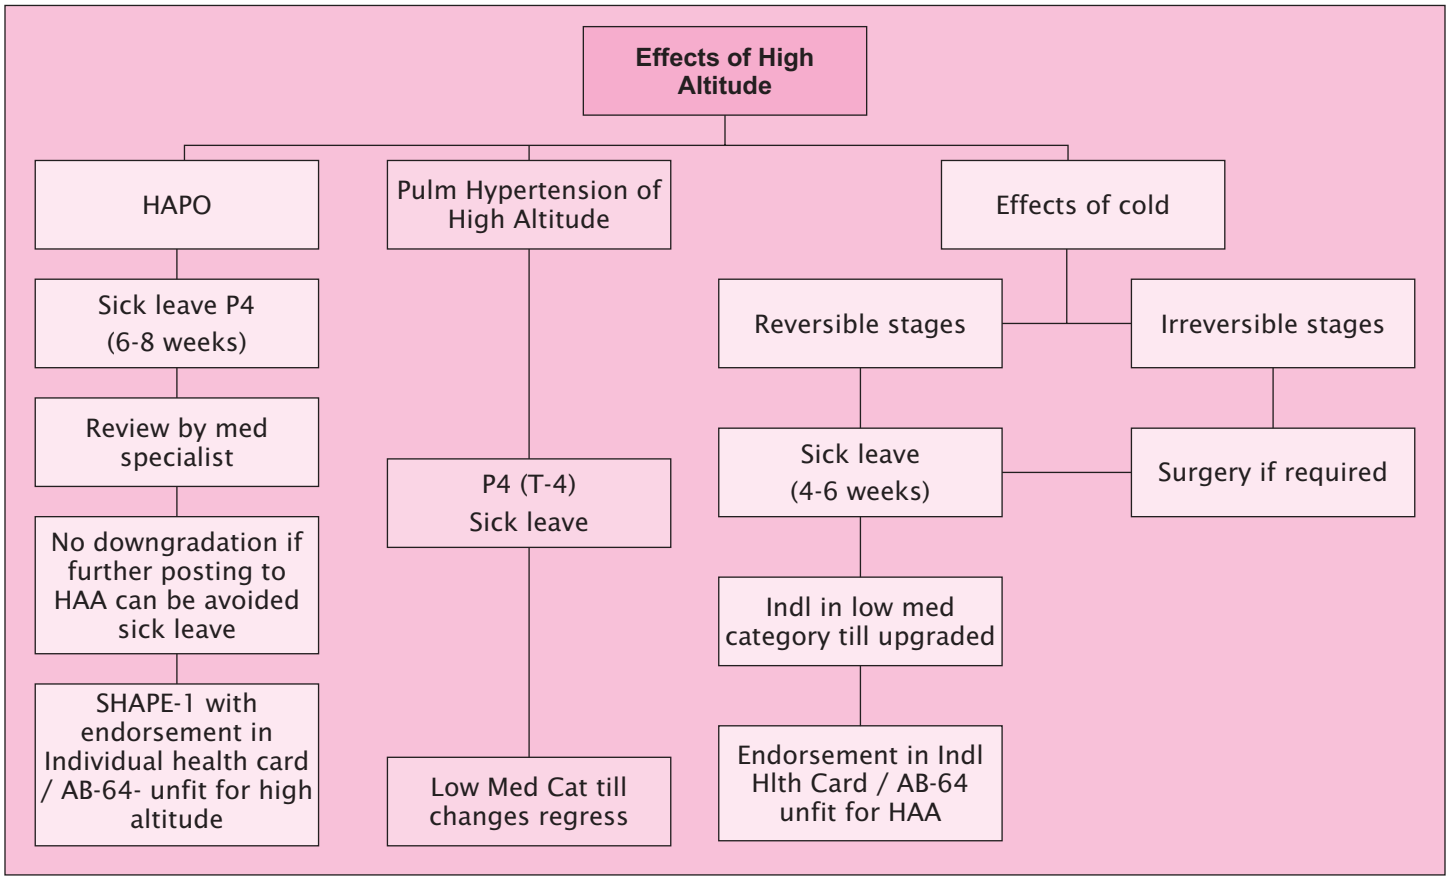
Tertiary prevention of HAPO has to take in account the possibility of recurrence in old patients of HAPO on subsequent reentry to High altitude (4).

In Armed Forces the patient is immediately brought to lower altitude so that other associated complications do not develop. Once an individual has recovered, then action in taken as per Table - 1.

### Ischaemic Heart Disease (IHD)

Disability limitation has a very imp role in IHD and an aggressive, active management of cases ensures that maximum possible individuals return to their normal duties. Armed Forces follow the protocol for tertiary prevention of IHD as given Table - 2. (5)

Table - 1



**Viral hepatitis**

Armed forces lay special emphasis on viral hepatitis especially water food borne viral hepatitis (Type A & E). All such cases are treated as indoor patients and after screening for other types of hepatitis are provided bed rest, High glucose, and low fat diet. Once the liver enzymes regress and there is improvement in general condition of patient, he is dispatched for four weeks of sick leave. Following the sick leave, if liver enzymes & general condition are found to be in normal ranges the patient is placed in low med cat for six months and is upgraded to SHAPE-1 provided liver condition is healthy otherwise low med cat continues.

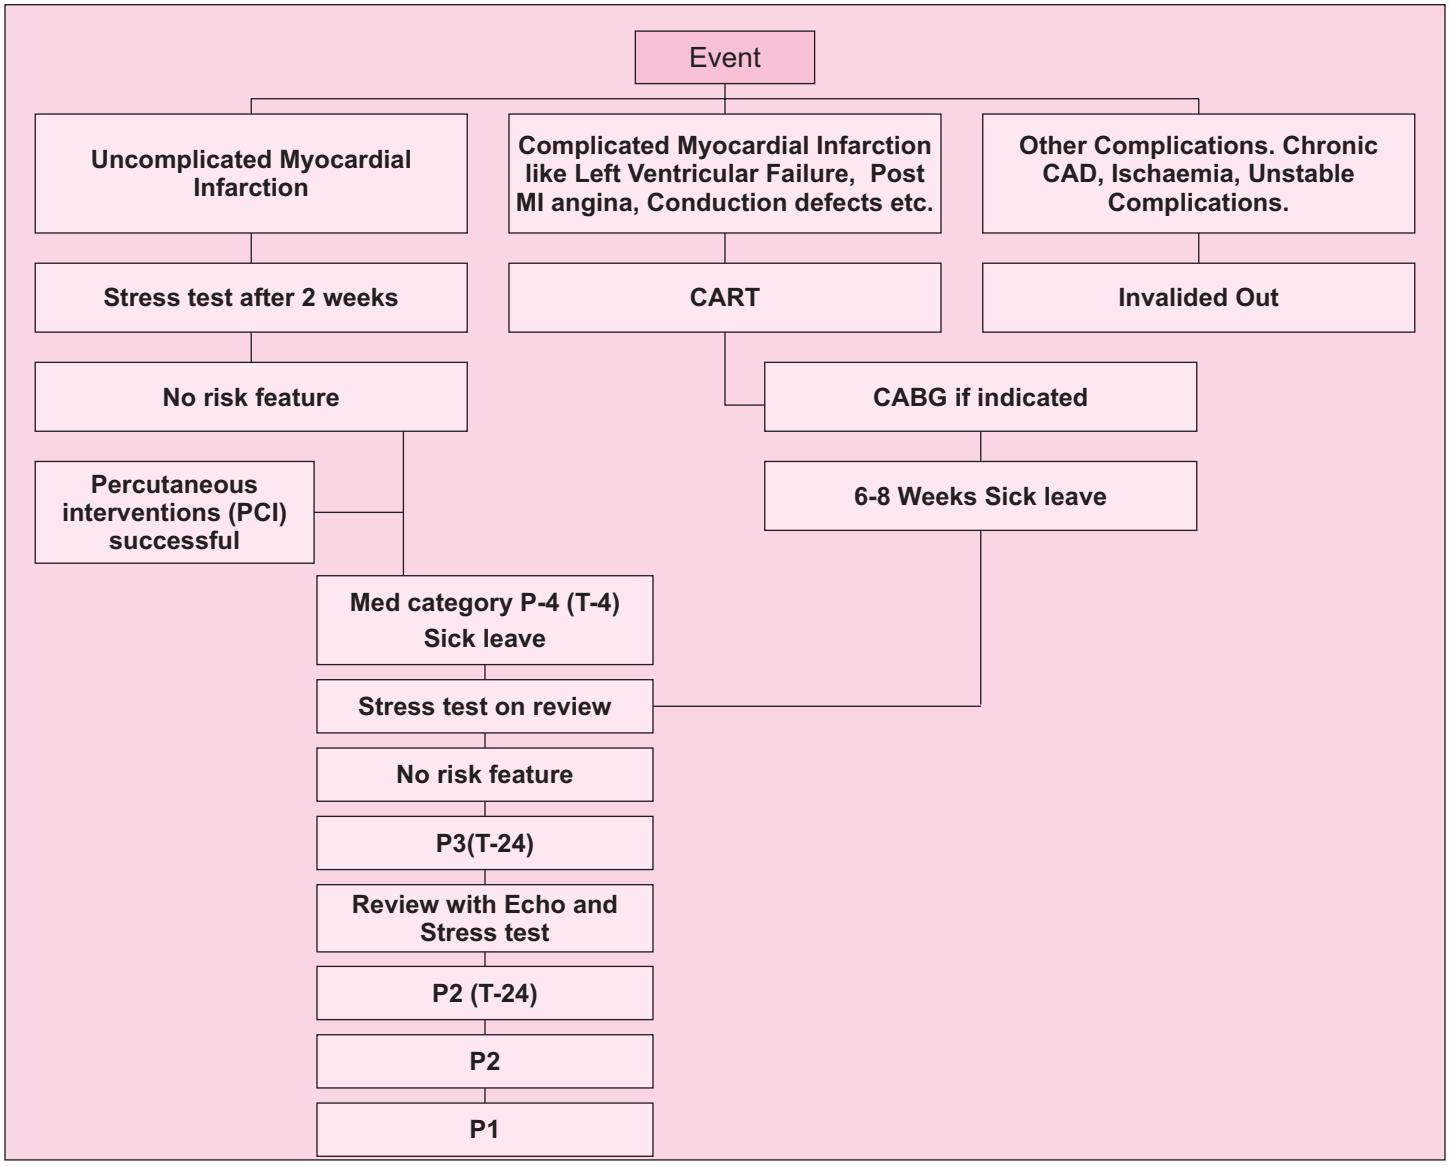
**Psychiatric disorders**

An entitled person would be referred for Psychiatric evaluation and care when he or she reports with symptoms which might be considered to be due to Psychiatric illnesses, by the authorised medical attendant, OC of unit, MCO, Military Police or Civil Police or even the relatives and friends of the individual. The examining Psychiatrist may ask for additional information, relevant backgrounds or circumstances suggesting the possibility of the illness in AFMSF – 10, from the OC of the unit.

All relevant history and clinical findings should be simply described by the AMA while referring the patient. AMA should also make possible efforts so that a person does not harm self or others. No patient will be held back from medical attention for want of AFMSF – 10.

All recovered cases of Psychotic disorders would be observed in temporary low medical category for 2 years/96 weeks with maintenance medication. Thereafter subject to satisfactory remission, they will be placed in medical category S2 permanent for 2 years without medication. At the end of this period, provided the clinical

Table - 2



condition is well stabilised and fresh AFMSF – 10 report is favourable, upgradation to S1 may be considered after review by Senior Adviser in Psychiatry.

Cases of bipolar/recurrent depressive disorders who require long term prophylactic therapy may be considered for retention in service in S2 permanent for longer periods on the recommendation of Senior Adviser (Psychiatry).

All cases recommended retention in service on account of their disease being unlikely to interfere in the performance of duty and in all instances of initial downgradation of medical category in S factor and upgradation to S1 for Officers would need to be concurred by Senior Adviser in Psychiatry. The medical board proceedings in such instances would be approved by DDMS Area/ Corps/Command for JCOs/OR and DGMS of respective service for Officers.

Individuals who are unlikely to be reasonably productive in the discharge of their duties on account of their illnesses would be invalided out of service. These would generally include cases of dementia, alcohol and drug dependence showing relapse, major Psychiatric disorders, neurotic and somatiform disorders, other mental disorders due to brain damage, dysfunction and physical disease which have taken a chronic course and are not responding well to treatment (6)

### Cancer

All medical officers must develop a strong sense of suspicion to the possibility of cancer and whenever suspected, must record a detailed history and conduct a thorough clinical examination of the patient. While transferring the patient, the medical officer should explain regarding the possibility of prolonged treatment in the oncology centre and arrange necessary administrative support.

The medical officers should constantly make efforts to educate the troops and families about cancer and try to dispel the widely prevalent myths regarding this disease. With the availability of highly advanced and modern methods of investigation and treatment in military hospitals, cancer could be detected at an early stage and treatment could help in remitting the disease and improving the quality of life of an individual.

All serving persons with cancer are placed in low medical category 2 or 3 in factor P with advice for follow up at regular intervals at the nearest service oncology centre. An individual who is incapable of discharging his/her duties effectively due to illness is recommended invalidment from service on medical grounds (7)

### Tuberculosis

All serving personnel suspected to be suffering from Pulmonary tuberculosis are hospitalised at authorised respiratory centres till the condition has stabilised and the patient is considered non-infectious. The patient is put in low medical category P3 temporary, till such time he/she is on medication, for a maximum duration of one year.

Once the patient is off-medication and minimum observation period of 24 weeks has been completed, he/she could be considered for upgradation to category P2 by medical specialist at the nearest service hospital.

All cases of pulmonary tuberculosis, where there are chances of drug resistance, are transferred to Military Hospital (Cardio thoracic Centre) Pune. Cases of multi drug resistant tuberculosis (combined resistance to rifampicin and isoniazid with or without resistance to any other drug) would be candidates for invalidment out of service. However patients showing clinical and radiological improvement and bacteriological quiescence within six months of start of anti TB treatment may be considered for retention in service at the advice of Senior Adviser in TB and Respiratory Disease or Consultant in Medicine.

Patients with single drug resistance or polyresistance (to more than one drug other than combined resistance to rifampicin and isoniazid) may be considered for retention in service (8)

### HIV/AIDS

A serving personnel found to be positive for HIV on ELISA/Rapid/Spot test at any testing centre is admitted and transferred to the nearest Immunodeficiency Centre with a diagnosis of Immunosurveillance (Inv). Their diagnosis is confirmed at this Centre based on three E/R/S tests using HIV kits with different antigens. In all indeterminate/discrepant HIV test results, the serum sample is tested by Western Blot/ Line Immunoassay.

The Immunodeficiency Centre confirming the diagnosis forwards a report regarding the positive test to AIDS Control Organisation in the Department of Community Medicine, AFMC, Office of DGAFMS/DG-3A and to the Commanding Officer of the individual by a confidential DO letter. The individual detected to be HIV positive is evaluated monthly by the Authorised Medical Attendant and advised yearly follow-up at the nearest Immunodeficiency Centre.

**Follow up** - In all newly diagnosed cases of HIV, the Immunodeficiency Centre prepares a HIV Surveillance Card (AFMSF 6B) in duplicate, of which one is kept with the individual and the copy is sent to ACO. The card records the follow up of the individual. When the individual is posted to a new unit, the records in the surveillance card is required to be monitored by the new AMA and the card would be presented by the individual at the time of follow up at MI Room or the nearest ID Centre.

Monthly and yearly follow up of HIV positive family members of a service personnel, whenever living with the family, is also carried out by the AMA and the local service hospital and all records maintained and notified to ACO. If the family member is not living with the service personnel, the latter will be counselled to get yearly follow up at the nearest civil HIV surveillance centre.

**Anti retroviral therapy** - The HIV persons on follow up, are put on Anti retroviral therapy on the basis of WHO criteria for initiating ART based on CD 4/8 counts, viral load and WHO stage of the disease. ART is provided to all service personnel, their families and to Ex-service pensioners under the ECHS.

**Medical Classification** – Asymptomatic HIV positive persons not on anti retroviral drugs are placed in low medical classification P2 (temp) for maximum 48 weeks with appropriate employability restrictions and regular monitoring of CD 4 counts or total lymphocyte counts. Those who are put on ART are placed in low medical classification P3 (temp) with employability restrictions for a period of one year, and thereafter they are placed in classification P3, if the CD4 count is above 200 or total lymphocyte count is above 1200 cells/cu mm and disease stage corresponds to WHO stage I, II or III. If the CD4 or lymphocyte counts are below this limit, and individual shows unsatisfactory response to therapy, he/she is considered for invalidment.

**Invalidment** – The guiding factor for invalidment is functional disability of the individual. However, disabling manifestations of the disease corresponding to WHO stage IV who have shown unsatisfactory response to therapy, such as HIV wasting syndrome, disabling neurological/psychiatric illness, disseminated tuberculosis, malignancies are considered for invalidment (9)

### Sexually transmitted diseases

All suspected cases of Sexually Transmitted Diseases (STDs) are to be referred for further management at the nearest STD Treatment Centre (STDTC). At the STD Centre, an etiological diagnosis is made after relevant investigations and AFMSF-18 (reporting of an STD case) is raised and dispatched to the Centre Disease Registry at AFMC, Pune for allotment of CDR Number. Simultaneously, AFMSF-6 (STD Treatment & Surveillance Card) is also raised in duplicate documenting the history, examination findings, investigations and treatment given. At discharge, the patient is placed on STD Surveillance and instructions for the given in AFMSF-6. The Original AFMSF-6 is dispatched to the patient's unit and duplicate retained at the original STDTC.

Surveillance protocol in various STDs :

(a) **Syphilis** : The patient is placed on 30 months STD surveillance with investigations as under :

(i) VDRL at 3, 6, 9, 12, 18, 24 & 30 months.

(ii) HIV antibodies at 3 & 6 months. 10

(iii) CSF studies (VDRL, Cytology and Biochemistry) at 6 & 30 months

FTC (Final Test of Cure) certificate is issued at 30 months, if all relevant investigations are normal.

(b) **Gonorrhoea** : The patient is placed on 06 months STD surveillance as under :

(i) VDRL at 3 & 6 months.

(ii) HIV antibodies at 3 & 6 months.

(iii) Urine 2 Glass test at 3 months.

(iv) Prostatic massage & smear at 3 months.

FTC certificate is issued at 6 months.

(c) **Chancroid and all other STDs** : The patient is placed on 6 months STD Surveillance as under :

(i) VDRL at 3 & 6 months.

(ii) HIV antibodies at 3 & 6 months.

FTC certificate is issued at 6 months.

The STD Surveillance Card (AFMSF-6) is held with the unit, preferably under the care of the RMO and it is the Unit's responsibility to direct the individual for periodical tests as advised and completion of STD surveillance.

On completion of FTC at the nearest STDTC, the AFMSF-6 (Original copy) is dispatched to the original STDTC, where the AFMSF-6 (both copies) is closed, dispatched to the individual's Record office and CDR informed.

If the original STDTC does not get intimation of an individual's completion of STD Surveillance as per the records held by them, they issue a Tracing Proforma (TP) to the individual's unit to direct the individual to report to the nearest STDTC for completion of STD Surveillance.

If the individual does not report for STD surveillance for 5 years from the date of FTC, his AFMSF-6 will be closed and dispatched to his Record office.

If the individual is proceeding on release during the period of surveillance, he has to be given pre-release treatment for syphilis and his AFMSF-6 closed and dispatched to his Record office (10)

It the individual is proceeding on release during the period of surveillance, he has to be given pre-released treatment for Syphillis and his AFMSF-6 closed and despatched to his record office.

# Medical Examinations, Medical Boards and Medical Documents : Policies and Procedures

The objective of Medical Examination is to detect disease at an early state when it may be latent (without producing any ill effect) and institute timely preventive and curative measures promoting positive health. It is, thus, the individual who is responsible to get his/her medical examination (ME) carried out. ME will only be carried out by the Authorised Medical Attendant (AMA) of the unit. A MO will be deputed by CO of the hospital for annual medical examinations of officers upto 55 years of age. After 55 years of age, AME will be carried out by a Medical Specialist deputed by the CO of the hospital. For routine investigations and treatment, the individual will be dependent on the nearest field ambulance/hospital.

### Initial Medical Examination

Initial medical examination on AFMSF – 2 will be conducted for the following :

(a) The medical examination of candidates for commission in the Armed Forces and for admission into the Rashtriya Indian Military College, Dehradun as cadets will be conducted by a medical board.

(b) Recruits for the Armed Forces will be examined by a Medical Officer of the Armed Forces in accordance with current standards of physical fitness and findings. Recruiting officers are responsible for the measurements, apparent age, intelligence and mental suitability of the candidates selected by them. Medical Officers are responsible for the health, physical fitness for service, likely extent of development and identification marks.

(c) Short service Officers applying for permanent commission

(d) Candidates for admission to NDA, IMA, AFMC, schools for probationer Nurses and Engineering cadets of various Armed Forces Institutes.

### Medical boards

Medical Boards will be held on candidates for commission in the Armed Forces, officers selected for Permanent Regular Commissions and on Armed Forces personnel in the following circumstances :

(a) Officers/Cadets of the Armed Forces recommended sick leave and on return there-from and officers recommended change of climate on medical grounds.

(b) Officers on the expiry of a period of six months spent continuously in hospital.

(c) All ranks of the Armed Forces considered unfit for further service or claiming a disability pension or gratuity.

(d) All ranks of the Armed Forces, who are to be placed in lower medical category.

(e) All ranks of the Armed Forces permanently placed in a low medical category who are proposed to be discharged, because no suitable employment compatible with their low medical category can be found for them.

(f) Officers/Cadets of the Armed Forces for upgrading their medical category.

(g) Individuals placed permanently in a low medical category applying for a fresh medical board.

(h) Persons (before the age of superannuation) serving under Civil Service Regulations, proposed for invaliding from service or claiming pension.

(j) Candidates for admission to the National Defence Academy, Indian Military Academy, Rashtriya Indian Military College, AFMC, and Schools for Probationer Nurses.

(k) All pensioners and ex - service personnel for assessment/reassessment of the percentage of their disability.

(l) In such other cases as may be ordered by service HQ.

Medical Boards will ordinarily be composed of a President and two members. If this number is not available, a board may consist of two medical officers only. The President of the Medical Board will ordinarily be of the rank of Major or above or equivalent rank of the Navy or Air Force. The medical officer in charge of a patient or who gives a specialist opinion on the case will not, as far as possible be a member of the Board which considers it, and in no instance may act as President of the board.

### Annual Medical Examination (AME)

A complete clinical examination and investigations as per AO 1/2004 and as considered necessary by the Authorised Medical Attendant (AMA) will be carried out for officers. The details and findings including medical advice, if any, will be entered in the officer's Health Record Card (HRC) for Officers below 35 years of age, while for those above 35 years, AFMSF - 3B will be filled up, in addition to HRC. In case during the AME, the AMA finds that the officer requires specialized investigations / treatment, reference will be made to the nearest hospital where such medical facilities are available. The AMA will suitably advise the officer, if a minor disability is noted during ME and record it on AFMSF - 3B/HRC para 4, 6 and 7.

The dates of AME and Annual Confidential Report (ACR) have been delinked in case of all officers. Medical classification recorded in AME immediately preceding the ACR will remain valid unless, due to disease or injury during the interim period, it has been changed by

appropriate Medical Categorisation Board.

AME for JCOs/OR will be carried out once a year, two months before the initiation of ACR and in the months of Mar to Jun for those individuals for whom there is no ACR. A complete medical examination and relevant investigations as considered necessary by the AMA will be carried out. Body weight will be checked as per age, height and weight chart. The details of findings including medical advice, if any, will be entered in the individual's health record card. Urine for sugar and proteins will be carried out for OR at the time of AME during 26th year of age, 36th year and thereafter every five years. For JCOs this should be carried out every year.

## Periodic Medical Examination (PME)/Periodic Medical Board (PMB)

The aim of carrying out PME is to ensure an individual is periodically examined in detail by all relevant specialists for early detection and cure of any disease. The PME will be recorded in AFMSF - 3A and the individual will be brought before a medical board. The composition of Medical Board will be as per para 419 of RMSAF – 1983.

AMA and OC/Comdt of nearest service hospital will provide necessary guidance to the officers for PME. The officers are required to be examined by all the specialists including Dental, Eye and ENT. The lady officers will be examined by Gynaecologist. USG of abdomen will be carried out for ladies. Findings of the PME are to be noted in AFMSF - 3A. It is the responsibility of the officer as well as the CO of the unit to which he/she is posted to ensure that the PMB is held on time when due. However, if for any reason the officer fails to undergo PME during scheduled time, he/she will take up a case for delayed PME. Dispensation shall be based on the merits of the case. Any deliberate omissions shall be administratively dealt with. All the periodic Medical Boards shall be approved and perused by the Medical Authorities.

An age - wise schedule and venue of PME is given at Appendix 'A' to AO 1/2004. It shall be mandatory for an officer to undergo Periodic Medical Board (PMB) at the prescribed age, ie, during 36th, 41st, 46th, 51st, 54th, and 58th year of age. Officers who are abroad during the schedule of PMB, will undergo the same within three months of arrival in India. No sanction will be required for the same.

The PMB as well as all Medical examination / boards will be held at the duty station of the officer, if a service hospital with requisite facilities is located at the station. Otherwise, it will be carried out at the nearest station where such facilities exist

Periodic medical board will be held for JCOs during 41st year of age i. e. on completion of 40 years of age or within 1 year of promotion to the Rank of Nb Sub, whichever is earlier at the nearest hospital. The board proceedings will be recorded on AFMSF - 3A and will be approved by ADMS Div/DDMS Area/Corps.

## Medical classification

The Army has a unique system of medical classification which is based on functional capacity of individual to perform military duties with a view to enable better cadre management especially of LMC individuals as regard their treatment, employment, promotion and financial emoluments. The SHAPE classification is based on fitness includes following five factors :

(a) **'S' Factors (Psychological)** : This factor denotes psychological aspect and covers personality, mental acuity, emotional stability and psychiatric disease.

(b) **'H' Factor (Hearing) :** This factor covers auditory ability to hear spoken voice or audible signals often against considerable back ground noise and its important in certain trades and Military situations.

(c) **'A' Factor (Appendages)** : This covers the functional efficiency of upper and lower limbs (including amputees, loss of fingers and toes), shoulder girdle, pelvic girdle and associated joints and muscles

(d) **'P' Factor (Physical Capacity)** : This covers general physical capacity or stamina as may be affected by medical/surgical conditions not covered by other factors.

(e) **'E' Factor (Eye sight) :** This covers visual acuity and good eye sight.

Classification is further divided into 5 Grades based on functional capability of the individual. The grades are as under

**IA** Fit for all duties anywhere

**IB** Fit for all duties anywhere, under medical observation and has no employability restrictions. Disabilities for which an officer needs to be placed in SHAPE 1B are asymptomatic dyslipidemia, asymptomatic hyperuricemia, impaired glucose tolerance, simple obesity, asymptomatic ECG abnormality, supraventricular or ventricular ectopics, cervical spondylosis, low backache, cholelithiasis, benign prostate hyperplasis, varicose veins, cataract (operated) with corrected vision upto 6/9 both eyes and fracture of non weight bearing bones / sprains / stress fractures

**2** Fit for all duties but may have limitations as to type of duties and areas of employability.

**3** Except 'S' factors, fit for routine or sedentary duties but may have limitations of employability as spelt out in the Employment Management Index

**4** Temporarily unfit for Military duties on account of hospitalization /sick leave

**5** Permanently unfit for Military duties.

To ensure that administrators are properly guided about utilization of officers who have been downgraded in medical category an employment management index has been formalized. Medical board may add medical advice in various cases as thought necessary by it. This also permits low med cat officers to be posted to locations where their disease will not be aggravated due to service conditions. Employment management index which are recommended

are as follows :

(a) **F 1A** : Fit for military duties anywhere.

(b) **F1B** : Fit for military duties anywhere, under medical observation and has no employability restrictions.

(c) **F2** : Fit for military duties anywhere. However at the discretion of Medical board may state :

(i) Unfit for posting to HAA (above 2700 meters) OR

(ii) Places that have sub - zero temperature for more than three months in a year.

(d) **F3** : Fit for normal military duties with restrictions as advised by medical authorities.

(e) **F4 :** Fit for normal military duties not involving strenuous exertions.

(f) **F5** : Unfit for military duties.

If AMA is of the view that the existing medical classification of an individual needs to be changed, he/she will refer the officer to appropriate specialist in that discipline. After clinical examination and investigations, the concerned specialist will write his/her opinion and recommendations about the medical classification of the officer on AFMSF - 15 and request CO of the hospital for holding Medical Board.

The individual will be communicated about the disability and medical classification awarded. It will be explained to him/her that it is subject to approval from higher medical authorities. The medical classification awarded to the officer will be communicated to the officers' unit by the approving/perusing authority at the earliest but not later than thirty days from the date of holding the board.

While placing an officer in a classification below SHAPE – I, Medical Board must clearly state in the Board proceedings whether or not the disease / disability of the officer is attributable to service and will also bring out aggravation, if any. In formulating opinion about attributability or non – attributability, all medical officers comprising the Medical Boards and the approving authorities must follow the guidelines given in the publication "Guide To Medical Officers (Military Pensions) 2002".

In case one or more factors of the medical classification is required to be lowered temporarily on account of disablement, the grade assessed should be that from which no further deterioration is expected.

Temporary classification in any grade factor will be permissible for a maximum period of 24 weeks. Then the officer will be upgraded/downgraded/placed in Permanent LMC in the same grade factor depending on the clinical response. Opinions given by Specialist officers for classification/ reclassification purposes will be valid for a period of three months. If an officer requires observation beyond the permissible period, he/she will be placed in permanent LMC, except in "S" factor where provisions of para 36 of AO 1/2004 will be applicable.

All personnel in 'S3' factor can be observed on a temporary basis for a maximum period of 48 weeks. He/She will not be placed in S3 permanent. In case, after 48 weeks, the officer cannot be upgraded to S2 temporary, he/she will be downgraded to S5.

There are certain diseases or group of diseases which are not amenable to short term therapy or quick cure. Some such diseases are, viz, Ischemic Heart Diseases, Hypertension, Diabetes Mellitus, Peptic Ulcer and Malignant diseases. Medical experience has shown that a large number of officers suffering from these diseases require prolonged medical treatment and surveillance. It is thus appropriate for officers placed in temporary LMC P3 for diseases such as above, to be placed in appropriate permanent LMC (P2 or P3) after the initial observation of 24 weeks depending on their clinical condition.

Classification med boards of PBOR does not require approval (RMSAF 425 (a) (v)). Classification boards of officers (other than S Category) are to be approved by CO Hospital. Medical boards of officers placed in 'S' category are to be approved in Office of DGMS (Army). Upgradation of IHD and Malignant cases are to be approved by DGMS (Army).

### Follow up LMC Personnel

All LMC individuals are required to be followed up and may require specialist care and change of treatment from time to time. Follow up system for LMC individuals will be as follows :

(a) The AMA will maintain a register for all LMC personnel on posted strength of the Unit. Necessary information will be obtained from the unit HQ. Units who have no RMO, will forward the names of the LMC individuals to the Staff Surgeon/MO i/c, Central MI Room to enable the AMA to maintain the requisite register.

(b) The AMA will call such individuals for examination and enter their personal particulars, nature of disability, medical category and date of the next review in a register and also any investigation, treatment or any follow up action required to be taken. All LMC individual are to be seen by the AMA at least once a month and cases may be referred to the concerned Specialist, if required.

(c) Necessary investigations will be carried out well in advance of the date of the next Medical Board and Specialist opinion obtained in time.

(d) When an individual in LMC is posted out from a unit, all medical documents will be forwarded by the Officer Commanding, Unit to the next unit with a request that these documents be handed over to the RMO/AMA of the new unit.

(e) A similar system as above will be followed for officers who are observed in SHAPE - 1B.

When an individual is placed in a classification lower then SHAPE - 1, whether temporary or permanent, it is obligatory for him/her to appear before a Reclassification Medical Board on due date. It will be ensured by the OC Unit of the indl that if Reclassification Medical Board of an individual is due, he/She will not be sent on annual leave/long casual leave and will be detailed on a course

only after taking prior permission for postponing the Medical Board from DDMS Corps/Area well in advance. OC unit will forward a Statement of the Case whenever delay in holding Reclassification Medical Board is anticipated by more than two weeks from the due date. Permission will be obtained for holding Reclassification Medical Board at the next station, if indl is to be attached on a long course.

Whenever an officer is in Permanent LMC for two or more disabilities and where the Reclassification Medical Boards are due for different disabilities within 12 weeks of each other, the officer will be assessed for both the disabilities simultaneously and awarded the necessary classification. This will be done with review of the classification for the disability which falls earlier. Where an officer, already in LMC, develops another disablement within 12 weeks of being reviewed for the former, he/she may be recommended observation for the second disability for a period proportionate to the unexpired period of the former disability, so that he/she can be reviewed simultaneously for both the disabilities during net review.

Posting/job assignment by Military Secretary's Branch of Low Medical Category officers will be guided by a matrix based on

(a) Medical Advice as given in Medical Board Proceedings.

(b) Job content

(c) Endorsement in the ACR as given by IO/RO/SRO regarding officer's demonstrated physical capacity.

Where sick leave has been recommended by the Medical Board to an officer, the approval will be accorded as under :

(a) Upto six weeks - No approval is required.

(b) More that six weeks - DDMS Command except where the Medical Board is held at AH, Delhi Cantt, when Approving Authority will be the Commandant, Army Hospital.

(c) 2nd spell of Sick Leave - Will be approved by DGMS (Army)

An officer who is not satisfied with the opinion of a Medical Board may submit a representation against the findings of the Board to the CO, medical unit, where the Board was held. This appeal will be submitted within one week of the Medical Board being held. A copy of the appeal will be sent directly to DGMS (Army) - 5A. Copies of the appeal will also be sent to the ADMS Div/DDsMS Area/Corps/Command simultaneously.

Early review of low medical classification

For individuals placed in temporary Low Medical Classification (LMC), it is obligatory to appear before the Re - classification Medical Board at the stipulated time and venue as given in the previous Medical board proceedings. In case of permanent low med classification, the individual will be reviewed after two years. However, for officers early review can be asked at any time if the Authorised Medical Attendant (AMA) certifies that the officer's condition has improved materially. The requisite application will be recommended by the OC unit certifying the performance of the officers and will be forwarded through the immediate superior formation Commander to DDsMS Corps/Area/Command for granting an early review. The competent authority to grant such a review will be MG (Med) Command. In case of PBOR review of permt category is permitted only after one year with requisite certificates from AMA. The competent authority for grant of such review is ADMS Div/DDMS Corps.

Condonation of Delay

Officers should undergo AME/PME as per schedule given in Appx 'A' to AO 1/2004/DGMS. If an officer fails to undergo AME during the schedule period of Apr to Sep and Oct to Mar he/she will take up case for delayed AME. In case he/she has not undergone AME for the year he/she will seek dispension of AME for the year and will undergo AME/PME for the next year. The authority for sanctioning delayed AME/PME is the respective formation commander and for the officers posted at Delhi the competent authority is MP Branch. Detailed guidelines are mentioned in letter No 76086/DGMS - 5A dt 16 Sep 2004.

If an officer fails to report for recategorisation when due, condonation of delay can be asked from MG (Med) Command. The offr concerned will fwd a Statement of case duly recommended by his CO and Fmn Cdr to medical authorities. In case of lapse by officer requisite counseling/administrative action will be taken.

Condonation of delay in undergoing AME/PME and Re - cat med board of PBOR will be carried out by Fmn Cdrs. Units will fwd statement of case through administrative channels for obtaining requisite sanctions. Guidelines for the same are contained in DGMS letter No 76086/DGMS - 5A dt 11 Feb 2005.

**Obesity**

During AME/PME the AMA will check height and weight of individual and also carry out requisite investigations. Guidelines for disposal of over - weight officers are as follows :

(a) If body weight is more than 10% but less than 20% over and above the Ideal Body Weight (IBW) and the individual has no symptoms/signs of any diseases and no abnormality is detected after investigation, the individual will be advised in writing to reduce body weight to within 10% over and above his IBW within 10 weeks for officers and 12 weeks for PBOR, with copies to his CO and SEMO. If the individual fails to reduce his/her weight to the acceptable level even after the specified period he/she will be down graded to Medical Classification P2(T - 24).

(b) If the body weight is in excess of the IBW by more than 20%, investigations will be carried out to exclude any metabolic abnormality. If no abnormality is detected the PBOR will be placed in category P2 (T - 24). In case of officer he/she will be disposed of as under :

(i) If the officer has no metabolic abnormality

and ECG is normal, The medical specialist should decide whether over weight is due to obesity or due to increased muscle, mass/bone thickness by measuring the following parameters :

- Body Mass Index (BMI) = Normal range : 20 - 25 A person is definitely obese if it is more that 27.
- Waist and Hip ratio :Normal range – 0. 6 to 0. 9. A person has definite central obesity if it is more than 0. 9.
- Skin fold thickness measurement with the help of caliper.
  - Normal range of Tricep skin fold – 12 - 15 mm.
  - Normal range of sub scapular skin fold - 18 - 20 mm.

(c) All the above measurements will decidedly determine whether over weight is due to obesity or due to increased muscle mass/bone thickness. If the over weight is due to obesity, the officer should be down graded to Medical Classification P2 (T - 24).

(d) Individual downgraded for obesity will have no restrictions of employment.

**Management of Individuals in LMC for Alcohol Dependence / drug abuse**

Alcohol Dependence and Drug Abuse are incompatible with Military Service/ethos and all such cases should be invalided out of service unless they show an unequivocal determination to give up the use of Alcohol/Drug for good in the shortest time span. There is a well laid down procedure for disposal of such cases, which has been mentioned in revised DGAFMS memorandum No 111.

**Army Aviators**

On completion of the medical examination, the medical classification in respect of Army Aviators will be indicated as follows :

(a) SHAPE – 1 FLYING FIT

(b) SHAPE – 1 AND FLYING UNFIT

(c) SHAPE – 1 AND FLYING RESTRICTED* "Flying restricted" status will not be acceptable for initial entry into Army Aviation.

AME in respect of Army Aviators will be carried out on the scheduled time as per AO 1/2004/DGMS by medical officers trained in Aviation Medicine. In case aviation trained medical officers is not present in the station the Army Aviator may be directed to the SMO of the nearest AF Wing (Flying station).

(a) If any Army Aviator is declared as 'Flying unfit' at the time of AME it will be recorded on AFMSF 15 and his category will be down graded to ensure that the officer is not allowed to resume flying duties.

(b) AME which is scheduled to be held at MH on the specified age will be carried out as in vogue, which is in addition, to that conducted by a specialist in aviation medicine.

(c) ECG during AME will be carried out on alternate years up to 30 years of age and there after it will be carried out each year. TMT (Max) will be carried out on all air crew provided no medical contraindication exists at the age of 40 and every five years thereafter.

Army Aviators will acclimatize for high altitude area for a minimum period of 36 hours before under taking flying in high altitude area. After 36 hours of acclimatization, Army Aviators will be cleared for flying by the MO of the Aviation unit. A record of such medical examination and clearance for flying will be maintained by the concerned medical authority as well as the Aviation unit. Similarly a post flight check will be conducted on return from the high altitude area and a record will be maintained.

**Special Medical Examinations**

All ranks of the Armed Forces including civilians employed therein will be medically examined by a medical officer on the following occasions :

(a) Prior to proceeding on active service.

(b) Prior to release, retirement, discharge or dismissal, re - employment, except in the case of civilians.

(c) To assess physical fitness for special duty.

(d) Prior to being tried by a Court Martial or when committed to prison.

(e) To take up a policy with LIC at stations where there are no civil doctors.

(f) Other occasions when medical examination is considered necessary.

JCOs and OR of the Army and their equivalents in the Navy and Air Force will also be examined on occasions mentioned below

(a) Prior to their re - mustering/change of branch/trade when a higher medical standard is required.

(b) Prior to regular engagement/reengagement or extension of the term of engagement.

(c) On transfer from one unit to another (Medical inspection only)

(d) When proceeding to or returning from leave (Medical inspection only)

Personnel before proceeding to HAA on permanent posting will be subjected to ME to detect any disease/disability which might be aggravated in HAA. Similarly, Personnel will be subjected to ME within two months of their return from HAA. Their medical examination will be carried out by AMA and record maintained in HRC.

**Unscheduled Medical Examination**

Any officer wishing to have a medical examination at anytime of the year may request for such an examination at his/her convenience not more than once in a year, provided he is not asking for review of his/her disease/disability for which he/she is downgraded to low medical category temporarily. Permanently placed low medical category officers can ask for a review at any time, if the AMA certifies that the officers' condition has improved materially.

#### Medical Examination – Individuals Proceeding Abroad

All ranks and families proceeding abroad at Government expense on duty/deputation/study leave or any other form of official duty will on all cases be examined by the authorized medical attendant and obtain a certificate of medical fitness. When a body of men are moving overseas, findings of the medical examination will be recorded on a nominal roll in the case of officers and in AB - 64 in the case of JCOs and OR. Within a week of return from overseas, similar medical examination will be carried out of all service personnel

### Release Medical Examination / Board

All ranks are required to be medically examined by a medical officer prior to release, retirement, discharge, completion of tenure or service limit or release/discharge at their own request vide paras 391 (a) and 418 (e) of RMSAF, 1983. Such medical examination will be conducted by the authorized medical attendant (RMO/Staff surgeon) and the report will be recorded on the form AFMSF - 18 in quadruplicate. The OC unit will ensure that the individual is medically examined by the medical officer or brought before a medical board prior to release. If an individual is proceeding on Leave Pending Release this may be conducted before he proceeds on such leave. The individuals who are in SHAPE - 1 will be required to undergo only a Release Medical Examination.

In the event of the individual being in low medical category or any disability being found, or claimed by the individual at the time of release, he will be brought before a medical board well in time so that the board proceedings are completed prior to his release from service. A Release Medical Board can be held, in advance by eight months to the date of release from service. The proceedings of the medical board will be recorded on form AFMSF - 16. The medical board will also render a certificate in the prescribed proforma to be attached with the AFMSF - 16 (for those released in low medical category), making an annotation about the individual's longevity, which will be accepted by competent authority for the purpose of commutation of pension.

The Release Medical Examination Report (AFMSF - 18) in respect of personnel released in medical category SHAPE - 1 do not require approval by ADMS concerned and will be disposed of directly by the OC unit of the individual. A Release Medical Examination can be held in advance by eight month from the date of release from service.

Release Medical Board Proceedings (AFMSF - 16) in respect of personnel released in low medical category will however, be approved by the ADMS/DDMS of the Area / Div / Corps / Command, who will in turn forward the medical board proceedings to MG (Med) Command for approval /confirmation and disposal. One copy of Release medical Examination (AFMSF - 18) will be given to individual by the authorized medical attendant to be attached with his application for commutation. In case of individuals released in low medical category, an extract of board proceedings and also of the annotation made by the Release Medical Board about the individual's longevity will also be given to him. He can attach this when he applies for commutation of pension to CDA (Pension).

### Attributability / Aggravation

Before an award can be made for a disability or death claimed to be related to service, a causal connection between disability or death and military service has to be established by evidence.

Disablement or death shall be accepted as due to military service provided it is certified by appropriate medical authority that :

(a) The disablement/death is due to a wound, injury or disease which :
  (i) Is attributable to military service, or
  (ii) Existed before or arose during military service and has been and remains aggravated thereby. This will also include the precipitating/hastening of the onset of a disability.

Attributability / aggravation shall be conceded if causal connection between death/disablement and military service is certified by appropriate medical authority. In respect of diseases, the following rules will be observed

(a) For acceptance of a disease as attributable to military service, the following two conditions must be satisfied simultaneously.
  (i) That the disease has arisen during the period of military service
  (ii) That the disease has been caused by the conditions of employment in military service.

(b) If medical authority holds, for reasons to be stated, that the diseases although present at the time of enrolment could not have been detected on medical examination prior to acceptance for service, the disease, will not be deemed to have arisen during service. In case where it is established that the conditions of military service did not contribute to the onset or adversely affect the course of disease, entitlement for causal pensionary award will not be conceded, even if the disease has arisen during service.

(c) Cases in which it is established that conditions of military service did not determine or contribute to the onset of the disease but influenced the subsequent course of the disease, will fall for acceptance on the basis of aggravation.

(d) In case of congenital, hereditary, degenerative and constitutional diseases which are detected after

the individual has joined service, entitlement to disability pension shall not be conceded unless it is clearly established that the course of such disease was adversely affected due to factors related to conditions of military service.

If it is established that the disability was not caused by service, attributability shall not be conceded. However if service conditions result in worsening of the disease aggravation by service is to be accepted unless any worsening in his condition was not due to his service or worsening did no persist on the date of discharge/claim.

The onset and progress of some diseases are affected by environment factors related to service conditions, dietic compulsions, exposure to noise, physical and mental stress and strain. Disease due to infection arising in service, will merit an entitlement of attributability. The diseases affected by environmental factors in service is as follows :

(a) Diseases known to be affected by exposure to weather like Bronchitis, Rheumatism and Nephritis

(b) Diseases know to be affected by stress and strain of service.

(c) Disease endemic to certain areas like Malaria, Kalazar, Filariasis, Dysentery, Cholera.

(d) Diseases due to infections in service.

(e) Disease known to be affected by dietary compulsions like Gastritis, Gastric and Duodenal Ulcers.

(f) Diseases know to be affected by service in the submarine arm of the Navy.

(g) Diseases which run their course independently of external circumstances like Malignant disease, cancer etc.

(h) Sexually transmitted diseases are not accepted as attributable to/aggravated by service.

**Injuries**

In respect of accidents or injuries the following rules shall be observed :

(a) Injuries sustained when the man in "on duty" as defined, shall be deemed to have resulted from military service, but in cases of injuries due to serious negligence/misconduct the question of reducing the disability pension will be considered.

(b) In cases of self inflicted injuries whilst on duty, attributability shall not be conceded unless it is established that service factors were responsible for such action; in cases where attributability is conceded, the question of grant of disability pension at full or at reduced rate will be considered.

(c) In all injury cases, Board should ask for injury report (IAFY - 2006) and Court of Inquiry proceedings. While deciding attributability, Board should rely on directions of Fmn Cdr given on Injury Report and findings of Court of Inquiry.

(d) In cases where there is no record in official documents or other verification, date, place, circumstances etc should be carefully recorded in the individual's statement and board should say whether the disability claimed resulted from the injury. They should leave the question of entitlement open for decision by Pension Sanctioning Authority.

Right to appeal

Where entitlement is denied by the Pension sanctioning authority on initial consideration of the claim, the claimant has a right of appeal against decision on entitlement and assessment. For decision on entitlement all concerned authorities have to give opinion. Assessment of degree of disablement is entirely a matter of medical judgement and is responsibility of medical authorities.

## Medical Case Documents

**Non fatal cases**

Presently all medical documents are being dealt with as per procedures laid down in paras 79 (b), 94, 95, 96, 422 and 760 of RMSAF 1983 and the relevant regulations laid down for Navy and Air Force.

The consumer protection act (CPA) 1986 provides for the legal right of the patient to be informed about the quality, quantity, potency, purity and standard of services provided to the consumer. Further the Right to Information Act also provides for right to medical information.

The policy to be followed by all medical establishments in the Armed Forces will be as under :

(a) Various provisions in the RMSAF - 83 relating to handing over of medical documents to patients/NOKs will continue to be enforced as hitherto. However medical documents can be produced in a court of law under the instructions of competent legal authorities.

(b) Patients/NOKs will be informed verbally about the medical status and management of a case on a daily basis, particularly when a request is made. A Medical summary of the case alongwith results of investigations undertaken and treatment provided will be handed over to the patients/NOKs in addition to the info being endorsed on the discharge slip, as and when requested by the patients/NOKs. This is aimed at satisfying the needs of the patients/NOKs as well as facilitate subsequent management at a different medical facility. The fact that a summary has been handed over to the patient/NOK will be prominently endorsed on the case sheet.

On transfer of a patient from one hospital to another, the medical case sheets and connected medical documents pertaining to the case will be handed over to the patient, or an attendant, if detailed, to accompany the patient, in a sealed envelope, for delivering them to the receiving hospital. Before sending the documents, OC of the forwarding hospital will satisfy himself that the documents are up - to - date and the word "TRANSFERRED"

is inserted in the columns provided for in the medical case sheets, admission card, Field Medical card and clinical chart.

Medical case sheets of all non - fatal cases of professional interest particularly those relating to disease which the OC hospital considers as uncommon, may be submitted to Office of DGMS in the first Instance before final disposal as instructed in 23 above. These cases should be sent through the same channel as laid down for submission of Original fatal case documents and must be perused by the Adviser concerned and the Adviser in Pathology for their comments, which should be recorded on separate sheets of paper

In all other cases medical case sheets and connected hosp documents will be disposed off to AG/Org9/MPRS(O) in case of officers and Records concerned in case of PBOR. Documents of families are to be retained by OC hosp and destroyed as per ruling laid down.

**Fatal case documents**

The responsibility of preparing and processing the fatal case documents is of the hospital where the death occurs irrespective of the fact whether the patient was originally admitted there or received as a sick transfer from another hospital. If, however, a patient died enroute during sick transfer, he will be taken to the nearest service hospital, who will accept him as a Found Dead case and, after carrying he Postmortem/histopathological examination, (if required), will complete fatal case documents and process them in accordance with the instructions contained in this lesson.

Fatal case documents will be prepared in duplicate as follows :

(a) Original set will comprise of hand written medical case sheets. Investigation forms and other relevant documents.

(b) Duplicate set will comprise of typed copies of all the documents of the original set.

Only original fatal case documents will be prepared in case of :

(a) NCC Officers and cadets

(b) Police Battalions, Assam Rifles, Indo - Tibetan Border Police and BSF

(c) Coast Guard Personnel

(d) Documents will be submitted to Office of DGMS direct by the OC hospital in respect of Foreign Nationals who die while undergoing treatment in a Military Hospital, for perusal and onward transmission to Govt of the Country concerned, through the Min of Def/D (Med) and Min of External Affairs.

(e) Medical case sheets and connected medical documents of pensioners, will be perused and disposed of by the DDMS Command concerned to the respective Records holding Offices.

In case of unnatural deaths, i. e. deaths due to suicide, violence, accident, under suspicious circumstances and so on, OC hospital will ensure that civil police is informed in writing about the incident and their clearance obtained, in writing, before handing over the dead body to the relatives of the deceased. Confirmation that this requirement has been complied with will be incorporated in clear terms in the remarks endorsed by the OC hospital on the fatal case documents.

In cases of unnatural and unattended deaths, the main interest of the civil authorities in performing the postmortem examination is to find out whether death was due to foul play or not and, as such, they carry out few, if any, histopathological examinations on the tissues. In case a pathological death is suspected liaison will be maintained with civil authorities so that pathologist/MO of hospital attends the postmortem.

Fatal case documents in respect of service personnel who are transferred to civil hospitals and die there while under treatment. The following action will be taken :

(a) The OC hospital who transfers the case to civil should liaise with the civil medical authorities regarding progress of the case and treatment given to the individual.

(b) On the basis of the above information, he will complete the case sheets and other hospitalization documents and initiate fatal documents.

In cases classified as BCs/BCs for which no Injury reports are required to be prepared (except in cases of gross negligence or misconduct as specified in orders) and which end fatally after admission to hospital, duplicate copy of the case sheets and attributability certificate need NOT be prepared. In such cases, death certificate and case sheets in original, alongwith injury Report, if prepared, should be forwarded to Record Office concerned. These documents should clearly indicate that the death was on account of Battle Casualty/Accident.

Fatal case documents will be initially sent to Adviser in Pathology who in turn will forward them to the other Advisers concerned. In “Brought - in - dead” cases, documents need to be routed only through Adviser in Pathology.

DDsMS Command/Corps and ADsMS Area/Division will ensure that comments endorsed by various Advisers are communicated to the concerned unit/hospital and specialists concerned. DDsMS Commands, in their forwarding letters will indicate that :

(a) The comments of the Advisers have been communicated to the treating clinician, and

(b) A warning (where considered necessary) has been issued to the concerned officer for his lapse. A

Lt Col A Hazra

# Health Guidelines for UN Missions and International Travel

## Introduction

A large and increasing number of Armed Forces Personnel are being deployed as a part of United Nations peacekeeping forces in various countries across the world. In most of these countries of deployment, the governments or armed groups have been engaged in armed conflict for several years, a collateral impact of which is the forced migration or displacement of large numbers of people from their war-ravaged homes and the destruction or weakening of health systems with a diminished capacity to detect, prevent and respond to infectious disease outbreaks. The refugees or internally displaced persons (IDPs) are often compelled to live in cramped, congested living conditions, without access to safe water, sanitation, safe food or decent shelter which, in turn, heighten the risk of infectious disease epidemics. This was the cause of the cholera epidemic in the Democratic Republic of the Congo, in the aftermath of the crisis in Rwanda in 1994. In July of that year, between 500,000 and 800,000 people crossed the border to seek refuge in the outskirts of the Congolese city of Goma. During the first month after their arrival, close to 50,000 refugees died (1).

The contingent of troops assigned to a UN Peacekeeping Operation are deployed in unfamiliar environments and, apart from the vulnerability to the epidemic-prone diseases, are also exposed to a variety of emerging or locally endemic infectious diseases (against which they have no previous immunity); adverse environmental conditions, physical threats to health, as well as a variety of specific, operation-related health hazards. However, most such health risks can be minimized by taking suitable precautions before, during and after deployment, and it is the purpose of this chapter to provide guidelines on measures to prevent or reduce any adverse consequences to the health of our Armed Forces personnel proceeding abroad.

The current country/ continent-specific epidemiological intelligence and counter measures are available through the Armed Forces Central Epidemiological Surveillance Centre (AFCESC), Department of Community Medicine (PSM), Armed Forces Medical College, Pune, and through the latest publications of UN/ WHO. Medical Officers are also advised to acquaint themselves with the recent instructions and guidelines issued by Army Headquarters, regarding medical examinations for troops and families proceeding abroad (2), as well as the epidemiological descriptions, based on first-hand mission experiences, forwarded to the o/o DGAFMS/ DG-3A, o/o DGMS (Army)/ DGMS-5B and DGMS-3E, respectively by Senior Medical Officer (SMO) of the contingent of a particular UN mission.

## General considerations

The conceptual framework for assessing the potential health risks to troop contingents assigned to a UN peacekeeping mission, and integration of preventive medicine recommendations into the deployment planning process is outlined in the succeeding paragraphs. Taking into account that all situations are different, the primary objective of these guidelines is to supplement the country-specific summaries, describe several aspects where advanced planning is recommended/ needed and enable medical officers to provide valuable inputs and recommendations to Commanders in order to safeguard the health of troops before, within and after the mission. The following aspects must be taken into consideration :

(a) Medical screening.
(b) Vaccine-preventable diseases and immunization policy.
(c) HIV/ AIDS and sexually transmitted infections.
(d) Malaria prévention and chemoprophylaxis.
(e) Environmental health risks
  (i) Adverse climatic conditions (e.g., excessive heat and humidity, cold, high terrestrial altitude and UV radiation from the sun).
  (ii) Infectious diseases (e.g. insect/ arthropod borne diseases, food and water-borne health risks, water-contact diseases, soil-transmitted diseases, acute respiratory diseases etc.).
  (iii) Physical threats (including those associated with animals and bites/ stings).
(f) Waste disposal in mission area.
(g) Personal hygiene.
(h) Oral health.
(j) Jet lag.
(k) Stress management .
(l) Road safety measures.
(m) Epidemiological surveillance.
(n) Notification and reporting.

A brief review of the medical support structure in UN peacekeeping missions has been included at the end of these guidelines.

## Medical screening

### Medical category

All personnel are required to undergo a pre-deployment medical examination and should be in SHAPE-1 or equivalent medical category. Women candidates should not be pregnant at the time of departure. This examination must have taken place within the preceding three months and shall be completed and recorded on UN form MS-2 (Entry Medical Examination: United Nations and specialized agencies) for a mission assignment with the United Nations.

### HIV screening

HIV screening will be done before departure as well as three months after return from foreign assignments as per guidelines mentioned in DGAFMS letter No 5496/DGAFMS/DG 3A dated 13 Nov 92, and even number

dated 10 Nov 95, and letter No 5496/Policy/DGAFMS dated 27 Sep 96. Details are also available in the handbook on HIV / AIDS for Medical Officers, developed by Armed Forces AIDS Control organization (3) as well as instructions issued by Army headquarters (2). As per existing policy, persons who are detected to have HIV infection during the initial screening are excluded from proceeding on the assignment abroad.

## Vaccine preventable diseases & immunization policy

### Vaccination requirements

There is no single schedule for the administration of immunizing agents. The schedule depends on the past immunization history of the individual, the amount of time available before departure and the intended area of deployment of troops in a particular UN Mission. These requirements are divided into those that are mandatory (e.g. Diphtheria, Pertussis, Tetanus, Typhoid, Yellow fever if indicated, Hepatitis B for medical staff, Poliomyelitis etc.) and those that are recommended (e.g. Meningococcus, Rabies, Hepatitis A, MMR etc.) (4). The United Nations Department of Peacekeeping Operations immunization requirements by Mission are given in **Appendix 'A'**. In case of a first-time deployment of troops to any UN Mission, Medical Officers are also advised to acquaint themselves with the recent WHO guidelines on International Travel and Health (an Internet version is available on the web-site http://www.who.int/ith) as well as the mission-specific immunization requirements from the Force Medical Officer (FMedO)/ Chief Medical Officer of the particular UN Mission. In case of a turnover deployment of troops in an ongoing UN Mission, the epidemiological situation reviews and recommendations for individual vaccines submitted by SMO of the contingent to the o/o DGAFMS/ DG-3A, o/o DGMS (Army)/ DGMS-5B and DGMS-3E, respectively as well as the Armed Forces Central Epidemiological Surveillance Centre (AFCESC), Dept of Community Medicine (PSM), AFMC, Pune should be consulted for determining the additional vaccination requirements for troops prior to deployment in Mission area.

### Immunisation policy

As per current UN policy, it is the responsibility of the Troop Contributing Country (TCC) to ensure that all personnel have received at least the initial dose of mandatory vaccinations before deployment into the Mission area, at national expense. The vaccines should be procured through the Office of DGAFMS/ DG-2 along with the requirements of various other prophylactics and drugs. The immunization status of each individual is to be properly documented in the WHO International Certificate of Vaccination. Should a multiple dose immunization regimen not be completed prior to deployment, the same may be completed in the Mission area and the TCC Hospitals should make provisions for administration of subsequent vaccinations including booster doses to members of the contingent. If the troops are deployed into a Mission area without the required vaccinations, these are provided by the UN, but all costs incurred are deducted from the reimbursement due to the troop contributing country. Failure to follow UN-recommended immunization policies may result in the denial of entry into the host country, as well as rejection of any resulting medical claims and compensation (4).

### Vaccine-preventable diseases and vaccines

The recommendations for vaccination against certain infectious diseases of potential risk for troops proceeding on mission abroad are summarised below :

(a) Yellow Fever Vaccine

Yellow fever occurs in Africa and South America. The World Health Organization (WHO) estimates that a total of 200,000 cases of yellow fever occur each year (5). A valid international certificate of immunization against yellow fever is required by many countries for entry of persons coming from or going to recognized yellow fever zones of Africa and South America; otherwise quarantine measures are applicable for up to 6 days. Persons aged >9 months who are travelling to or living in areas of South America and Africa where yellow fever infection is officially reported should be vaccinated. Information concerning known or probable infected areas is also available from WHO (http://www.who.int). For persons of all ages for whom vaccination is indicated, a single subcutaneous injection of 0.5 ml of reconstituted vaccine is used (6). The International Health Regulations require revaccination at intervals of 10 years. The International Certificate of Vaccination against Yellow Fever is valid from 10 days after date of immunization for 10 years; if re-immunized within that period, it is valid from the date of re-immunization. Yellow Fever Vaccination centres in India are as follows :

(i) National Institute of Communicable Diseases, New Delhi.

(ii) All India Institute of Hygiene and Public Health, Kolkata.

(iii) All major Airport Health Organizations.

(iv) All Port Health Organizations.

(v) Armed Forces Clinic, New Delhi (this is the designated centre for Armed Forces) (2).

(b) Hepatitis B vaccine

There is a heightened risk of acquiring Hepatitis B infection in unvaccinated persons deployed in UN Mission areas as they are frequently engaged in humanitarian relief activities and may be exposed to infected blood or other body fluids in health-care settings or due to sexual contact with potentially infected persons. All non-immune persons proceeding on a mission abroad should receive a 3-dose series of either plasma-derived or recombinant-DNA (yeast-derived) vaccine; 1 ml IM (deltoid) at months 0, 1 and 6. The complete series should be given prior to deployment if possible; otherwise remaining doses can be given in the country of deployment. A booster dose may be given for those who have taken the complete immunisation regime earlier.

(c) Meningococcal Vaccine

Sporadic cases are found worldwide. In temperate zones, most cases occur in the winter months. Localized

outbreaks occur in enclosed crowded spaces (e.g. dormitories, military barracks). In sub-Saharan Africa, in a zone stretching across the continent from Senegal to Ethiopia (the African "meningitis belt"), large outbreaks and epidemics take place during the dry season (November-June) (7). The current recommendation is to vaccinate all Hajj pilgrims, travellers to areas with current outbreaks and travellers to the sub-Saharan meningitis belt (8). The persons being deployed to countries where outbreaks of meningococcal disease are known to occur should be vaccinated with a single dose, 0.5 ml, SC, quadrivalent (A,C,Y,W-135) vaccine, at least 10 days prior to deployment.

(d) Typhoid Vaccine

Typhoid fever occurs in all parts of the world where water supplies and sanitation are sub-standard. Risk is greatest for travelers to developing countries (e.g., countries in Latin America, Asia, and Africa) who have prolonged exposure to potentially contaminated food and drink. It is recommended that all personnel proceeding on UN Missions abroad are vaccinated with either the Vi capsular polysaccharide (ViCPS) vaccine in a single dose of 0.5 ml, IM with a booster dose every 2 years, or in case the individual has been previously immunized with the TA (Heat-phenol inactivated) parenteral vaccine, then a sub-cutaneous, booster dose of the same (due once every 3 years). Medical Officers are advised to caution all personnel that typhoid vaccination is not a substitute for careful selection of safe food and drink. Typhoid vaccines are not 100% effective, and the vaccine's protection can be overwhelmed by large inocula of S. typhi. (9, 10).

(e) Japanese Encephalitis Vaccine

Approximately 50,000 sporadic and epidemic cases of JE are reported annually from the People's Republic of China (PRC), Korea, Japan, South-east Asia, the Indian subcontinent, and parts of Oceania. Viral transmission occurs across a much broader area of the region than is recognized by epidemiologic surveillance. In temperate regions, JE virus is transmitted during the summer and early fall, approximately from May to September. In subtropical and tropical areas, seasonal patterns of viral transmission are correlated with the abundance of vector mosquitoes and of vertebrate-amplifying hosts. These, in turn, fluctuate with rainfall, with the rainy season, and with migratory patterns of avian-amplifying hosts. In some tropical locations, however, irrigation associated with agricultural practices is a more important factor affecting vector abundance, and transmission may occur year-round. Patterns of JE viral transmission vary regionally, within individual countries, and from year to year (11).

Immunisation should be considered for persons deployed for extended periods of time in rural areas where JE is endemic or epidemic. Primary series of three 1.0 ml doses SC at days 0, 7, and 30. Alternate schedule on days 0, 7, 14, is slightly less immunogenic. Single dose booster indicated 3 years after basic series. Last dose should be given 10 days before departure. Use with caution in persons with multiple allergies, especially history of urticaria or angioedema (11).

(f) Tetanus Toxoid (TT)

This should be given to all persons as and when due/ required as booster.

(g) Other Vaccines

As dictated by mission and the individual situation, consideration for the usage of other vaccines may be appropriate.

Lapsed vaccination schedule

Vaccines should be administered as close to the recommended intervals as possible. However, longer-than-recommended intervals between doses do not reduce final antibody concentrations, although protection might not be attained until the recommended number of doses has been administered. With the exception of oral typhoid vaccine, an interruption in the vaccination schedule does not require restarting the entire series of a vaccine or toxoid or addition of extra doses (12).

Unknown or uncertain vaccination status

Medical Officers frequently encounter persons who do not have adequate documentation of previous vaccinations. Only written, dated records should be accepted as evidence of vaccination. Although vaccinations should not be postponed if records cannot be found, an attempt to locate missing records should be made by contacting previous unit of the individual and searching for a personally held record. If records cannot be located, these persons should be considered susceptible and should be started on the appropriate vaccination schedule (12).

## HIV/ AIDS and sexually transmitted infections

### Risk factors in UN peacekeeping operations

Throughout the world, military personnel, including United Nations Peacekeepers, are uniquely at risk for infection with HIV and other STIs. Military duty often puts soldiers in stressful situations and can also take them away from home for extended periods of time. The need to relieve stress, loneliness, and boredom can lead to risky behavior. The factors which further increase the likelihood of high-risk behaviour amongst UN peacekeepers are the use of alcohol and drugs to cope with stress, less inhibitions and restrictions in a new country and the ready access to sex workers near campsites and frequented off-duty areas (13). It must also be borne in mind that UN peacekeepers are deployed in active conflict zones or in the immediate post-conflict scenario. There is a likelihood of significantly elevated prevalence rates of HIV/ AIDS and Sexually Transmitted Infections (STIs) amongst certain vulnerable population groups in these regions (such as Internally Displaced Persons (IDPs), Refugees, Commercial Sex Workers etc.). The main factors contributing to the vulnerability and favouring the spread of HIV/AIDS and STIs amongst these population groups are mobility across borders, armed conflict, poverty and economic disparities, drought, high-female illiteracy, local cultural and ethnic practices, low access to Voluntary Confidential Counseling and Testing (VCCT) services, taboos around sexuality, denial, silence, stigma,

discrimination and fear.

### Pre-induction training

Medical Officers accompanying troop contingents on United Nations peacekeeping operations must impart "Pre-Induction Training" to all ranks such that they are fully aware of the risks of contracting HIV/ STIs and learn effective prevention strategies, so they can protect their health and the health of civilian populations in the locales they work, and maintain the integrity of their missions. The key approach to prevention of HIV/ AIDS and sexually transmitted diseases is abstinence or responsible sexual behaviour. Details are also available in the handbook on HIV / AIDS for Medical Officers, developed by Armed Forces AIDS Control organization (3).

### The UN policy of "Zero Tolerance"

It must also be emphasized that the United Nations has a policy of "Zero Tolerance" in fraternization with local population in the country of deployment and any allegation of sexual exploitation and abuse (SEA) on the part of UN peace-keepers may constitute a criminal offence regardless of whether there is involvement of money or material in exchange of sex.

### Hospital-based control measures

All Troop Contributing Country (TCC) hospitals in the Mission area must exercise universal precautions, adequate sterilization practices, blood and injection safety procedures and pay special attention to proper handling/ disposal of biomedical wastes including use of incinerators.

### Post Exposure Prophylaxis kits

Post Exposure Prophylaxis (PEP) kits must be available in the TCC Level 2 and Level 3 hospitals, respectively to ensure administration within 2-72 hours to all personnel who have been exposed to the HIV virus due to either accidental needle stick injuries or as a result of sexual violence.

### Blood safety

In all UN Missions, blood and blood products are provided from sources that meet WHO standards and are monitored by the Chief Medical Officer of the mission. Blood for transfusion is provided only from a known source (abroad procurement).

## Malaria prevention and chemoprophylaxis regimens

### Magnitude of the problem

Malaria is endemic in most tropical countries, particularly in Africa, South America and South Asia, with 400 million individuals infected and 1.5 million dying from the disease each year. It is one of the major diseases affecting peacekeepers and an important cause of morbidity and mortality. In 1995, health statistics from UNAVEM (Angola) showed that 970 out of 7,005 UN peacekeepers had malaria. This indicates a general lack of awareness of the disease among peacekeepers, as well as inadequate or incorrect use of environmental and personal protection measures. Prevention of malaria is further hampered by delays in diagnosis, development of Anopheles mosquitoes resistant to standard insecticides and resistant-strains of Plasmodia (**4).** Chemoprophylaxis and treatment of falciparum malaria are becoming more complex because *P. falciparum* is increasingly resistant to various antimalarial drugs. Chloroquine resistance of *P. vivax* is rare and was first reported in the late 1980s in Indonesia and Papua New Guinea. Focal "true" chloroquine resistance (i.e. in patients with adequate blood levels at day of failure) or prophylactic and/or treatment failure have since also been observed in Brazil, Colombia, Ethiopia, Guyana, India, Myanmar, Peru, the Republic of Korea, Solomon Islands, Thailand and Turkey. Chloroquine-resistant *P. malariae* has been reported from Indonesia (14).

### Malaria prevention

Physical protection, including environmental prevention, impregnated bed nets, the possibility to treat uniforms and use of repellants must be provided to all troops. Due to the operational needs of a peacekeeping mission, troops must use chemoprophylaxis against malaria. Thick and thin smears are the gold standards for diagnosing malaria. All Troop Contributing Country (TCC) medical facilities in endemic areas must have the capability of diagnosing malaria, including microscopy, appropriate staining supplies and adequately trained laboratory personnel. Rapid diagnostic tests should only be used in conjunction with microscopy, and only tests to identify *P. falciparum* should be used.

### ABCD of malaria protection

Medical Officers should note the following four basic principles of protection against malaria and advise troops accordingly (14) :

(a) Be Aware of the risk, the incubation period, and the main symptoms.

(b) Avoid being Bitten by mosquitoes, especially between dusk and dawn.

(c) Take antimalarial drugs (Chemoprophylaxis) when appropriate, to prevent infection from developing into clinical disease.

(d) Immediately seek Diagnosis and treatment if a fever develops one week or more after entering an area where there is a malaria risk and up to 3 months (or, rarely, later) after departure from a risk area.

### Malaria risk-stratification

Depending on the malaria risk in the country of deployment (see "Country list" for details concerning the malaria risk situation and recommended prevention available on the web-site http://www.who.int/ith), the recommended prevention method may be mosquito bite prevention only, or mosquito bite prevention in combination with chemoprophylaxis, as given in Table - 1.

### Use of antimalarial drugs for chemoprophylaxis

The choice of antimalarial drug for chemoprophylaxis will depend upon the malaria risk situation and the reported resistance pattern of the malarial parasite to these drugs in the country of deployment of troops. Alternate chemoprophylaxis may have to be considered for those

Table - 1 : Malaria risk and recommendations for prevention

| | Malaria risk | Type of prevention |
|---|---|---|
| **Type I** | Very limited risk of malaria transmission | Mosquito bite prevention only |
| **Type II** | Risk of *P. vivax* malaria only; or fully chloroquine-sensitive *P. falciparum* | Mosquito bite prevention plus chloroquine chemoprophylaxis |
| **Type III** chloroquine+proguanil | Risk of *P. vivax* and *P. falciparum* malaria transmission, combined with emerging chloroquine resistance | Mosquito bite prevention plus chemoprophylaxis |
| **Type IV** | (1) High risk of *P. falciparum* malaria, in combination with reported antimalarial drug resistance; or (2) Moderate/low risk of *P. falciparum* malaria, in | Mosquito bite prevention plus mefloquine, doxycycline or atovaquone-proguanil chemophylaxis (select according to reported |

Source: WHO (Ref 14)

individuals with history of known hypersensitivity to the recommended drug and/or other specific contraindications. The antimalarial drugs commonly used for chemoprophylaxis, dosage regimens, contraindications and special precautions for use are listed in Table - 2.

**Implementation of malaria prevention and control measures**

A SOP should be formulated which should include all aspects of prevention of malaria, including the drugs to be used for chemoprophylaxis, environmental management measures, personal protective measures to be used, insecticides and spraying equipment, manpower training, supervision and command support. This should be incorporated in the administrative instructions issued by the National Senior of the Contingent in the mission area. Adequate stocks of second and third line antimalarial drugs should be ensured. Also provision for synthetic pyrethroids such as deltamethrin/ permethrin for impregnating mosquito nets/ uniforms should be catered for and impregnation of mosquito nets/ uniforms implemented preferably before deployment and monitored.

## Environmental health risks

The deployed military contingent in any UN Mission is subject to a variety of environmental health risks other than those resulting from combatant operations.

Types of environmental health risks

The various environmental health hazards in the area of deployment may include :

(a) Adverse climatic conditions (e.g., excessive heat and humidity, cold, high terrestrial altitude and UV radiation from the sun).

(b) Infectious diseases (e.g. insect/ arthropod borne diseases, food and water-borne health risks, water-contact diseases, soil-transmitted diseases, acute respiratory diseases etc.).

(c) Physical threats (including those associated with accidents, explosions, animals and bites/ stings, and certain forms of ionizing radiation).

(d) Ambient chemical and radiological contaminants in air, water, food, and soil.

Troops will inevitably be exposed to these hazards, and exposures may or may not occur intermittently, continuously, or simultaneously, but they will occur. In some situations, environmental health risks may be present for only a short time, but at high exposure levels. These may have detrimental effects on individual health and well-being or even degrade the mission. In other situations; continuous, but less extreme levels in the environment, may put military personnel at increased risk of delayed, permanent health problems (15, 16).

**Environmental health and safety planning considerations**

The following aspects must also be taken in consideration by medical officers/ specialists in PSM, when evaluating environmental health and safety considerations during the planning process to ensure valuable and effective input to commanders (15) :

**(a) Accommodation**

Type, adequate ratio to be determined and all other related general health aspects to be addressed.

**(b) Ablution**

Type, adequate ratio, hot & cold water supply, drainage, etc to be determined and addressed in appropriate SOPs.

**(c) Mess facilities**

Ensure adequate, placement, equipment, personnel, etc.

**(d) Immunizations**

Ensure that all personnel are administered all necessary and required inoculations as per international requirements, as well as requirements imposed by legislation and endemic diseases in the country of deployment.

**(e) Prophylactic medicines**

Ensure that all personnel are supplied with necessary chemo-prophylactic drugs as required and properly educated on use. Registers to be instituted and maintained throughout the period of deployment.

**(f) Quarantine/ isolation**

Table - 2 - Antimalarial drugs for use as prophylaxis

| Recommended Drug | Adult Dose & Duration of Prophylaxis | Main Contraindications | Special Precautions |
|---|---|---|---|
| Chloroquine | (1 tablet = 150 mg chloroquine base) 300mg base (2 tablets) once every 7 days, starting 1 week before entering the area, once weekly while in the area, and once weekly for 4 weeks | Hypersensitivity to chloroquine; history of epilepsy; psoriasis. | (i) Concurrent use of chloroquine can reduce the antibody response to intradermally administered HDCC rabies vaccine.<br>(ii) Extended use of chloroquine can cause retinal damage, 6 monthly eye checkups are recommended |
| Chloroquine + Proguanil | Chloroquine as above, plus Proguanil (1 tablet = 100 mg) 200mg (2 tablets) daily starting one day before entering the area, continuing daily while in the area and daily for 4 weeks after | Hypersensitivity to chloroquine and/or proguanil; liver or renal insufficiency; history of epilepsy; psoriasis. | (i) Concurrent use of chloroquine can reduce the antibody response to intradermally administered HDCC rabies vaccine.<br>(ii) Proguanil can interfere with live, oral typhoid vaccine |
| Mefloquine | (1 tablet = 250 mg mefloquine) 250mg (1 tablet) every 7 days, starting at least 1 week (preferably 2-3 weeks) before entering the area, once weekly while in the area, and once weekly for 4 weeks after leaving the area. | Hypersensitivity to Mefloquine; psychiatric or convulsive disorders; not recommended for persons performing activities requiring fine coordination and spatial discrimination e.g. pilots, machine operators. | (i) Restrict use to 1 year.<br>(ii) Do not give Mefloquine within 12 hours of quinine treatment. |
| Atovaquone-Proguanil combination | (1 adult tablet =250 mg Atovaquone plus 100 mg Proguanil)<br>1 tablet daily, starting 1 day before entering the area, continuing daily while in the area, and daily for 7 days after return | Hypersensitivity to atovaquone and/or proguanil; severe renal insufficiency. | Proguanil can interfere with live, oral typhoid vaccine |
| Doxycycline | (1tablet = 100 mg doxycycline)<br>(1 capsule = 50mg , 100 mg or 200 mg doxycycline)<br>100mg once daily starting 1 - 2 days before entering the area, continuing daily while in the area, and daily for 4 weeks after leaving the area. | Hypersensitivity to tetracyclines; liver dysfunction. | (i) Doxycycline should only be used if other drugs are unsuitable. It is an option to consider for epileptic patients who have to enter a high-risk chloroquine-resistant malaria area.<br>(ii) Restrict use to 3 months (due to lack of safety data for long-term use of daily 100 mg administration).<br>(iii) Doxycycline makes the skin more susceptible to sunburn. People with sensitive skin should use a highly protective (UVA) sunscreen and avoid prolonged direct sunlight, or switch to another drug.<br>(iv) Doxycycline should be taken on a full stomach with plenty of water to prevent oesophageal irritation.<br>(v) Doxycycline may increase the risk of |

Ensure capability at the TCC medical facility in case of emergency requirements.

**(g) Camp-site layout/ planning/ construction**

Close inter-sectoral collaboration with engineers in the context of water supply, drainage, structural requirements, refuse disposal, etc.

**(h) Occupational health monitoring**

Ensure monitoring of possible chemical, biological and physical influences on personnel.

**(j) Health education/ briefing.**

Proper briefing of all personnel during the pre-deployment phase (mobilization) about environmental health risks and their prevention; health education throughout the deployment as well as follow-up medication/ investigations to be done during the post-deployment phase (de-mobilization).

**(k) Disease outbreak investigations**

All cases to be investigated recorded and followed up. Detailed reports to be archived for future reference. Necessary notifications as per International legislation to be adhered to.

**(l) Personal protective gear**

All personnel utilised in activities where protective gear is essential such as vector control, de-contamination, barrier nursing, etc.

**(m) Disease vector and pest control**

Ensure adequate routine disease vector/ pest control activities including residual spraying, fumigation, ULV fogging, rodent control and proper storage/ handling of hygiene chemicals.

**(n) Office accommodation**

Inputs with respect to floor space, ventilation, lighting (natural as well as artificial), etc.

**Prevention of effects of heat**

It is the "greatest overall threat" to military personnel deployed in areas with a hot and humid climate. The important components of a heat-injury prevention programme include "heat acclimatization", which may take 10-14 days; proper work-rest cycles, scheduling work during the coolest times of the day, adequate hydration, consumption of salt-containing foods/ drinks and command emphasis on the strict implementation of preventive measures.

**Prevention of adverse effects of cold**

Loss of body heat to the environment causes cold injury. Cold injuries can occur in any environment. Air temperatures between 32-55$^0$ F can lead to a general lowering of body temperature (hypothermia, a life-threatening condition) and local non-freezing injuries (chilblains and trench foot). Air temperatures below freezing can result in hypothermia and local freezing of body tissues (frostbite). Risk of cold injuries is increased for persons who are in poor physical condition, dehydrated, or wet.

**Counter-measures include :**

**(a) Clothing and cover**

Exposed skin is more likely to develop frostbite. Ensure full provision of ECC clothing. Clothing should be clean, loose, multi-layered and dry. Remove layers of clothing, as needed to avoid sweating. Change socks 2-3 times per day, if wet. Cover the head to conserve heat.

**(b) Hydration and nutrition**

Provide warm food and beverages, especially at night. Increase water intake and avoid alcohol.

**(c) Physical activity**

Plan for shortened periods of sentry/guard duty. Shivering is a warning sign of impending cold injury; increase activity, add clothing, or seek warm shelter. Use the buddy system; observe all personnel for early warning signs/ symptoms.

**Ultraviolet radiation from the sun**

The ultraviolet (UV) radiation from the sun includes UVA (wavelength 315-400 nm) and UVB (280-315 nm) radiation, both of which are damaging to human skin and eyes. The intensity of UV radiation is indicated by the Global Solar UV Index, which is a measure of skin-damaging radiation. The Index describes the level of solar UV radiation at the Earth's surface and is often reported as the maximum 10-30 minute average for the day. The values of the Index range from zero upwards the higher the Index value, the greater the potential for damage to the skin and eyes, and the less time it takes for harm to occur. The Index values are grouped into exposure categories, with values greater than 10 being "extreme". In general, the closer to the equator the higher the Index. UVB radiation is particularly intense in summer and in the 4-hour period around solar noon (16).

Adverse effects of UV radiation

**(a) Short-term effects**

(i) Exposure to UV radiation, particularly UVB, can produce severe debilitating sunburn and sunstroke, particularly in light-skinned people.

(ii) Exposure of the eyes may result in acute keratitis ("snow blindness"), and long-term damage leads to the development of cataracts.

(iii) Persons on prophylactic/ therapeutic drugs (e.g. oral contraceptives, doxycycline, etc.) develop adverse dermatological reactions on exposure to sunlight.

(iv) Phototoxic contact reactions are caused by topical application of products, including perfumes, containing oil of bergamot or other citrus oils.

(v) Exposure may suppress the immune system, increase the risk of infectious disease, and limit the efficacy of vaccinations.

**(b) Long-term adverse effects on the skin include :**

(i) Development of skin cancers (carcinomas and malignant melanoma), mainly due to UVB radiation.

(ii) Accelerated ageing of the skin, mainly due to UVA radiation, which penetrates more deeply into the skin.

Precautions to reduce exposure to UV rays

(a) Avoid exposure to the sun in the middle of the day, when the UV intensity is greatest.

(b) Wear clothing that covers arms and legs (summer clothing is UV-protective and generally more effective than even good-quality sunscreen).

(c) Wear UV-protective sunglasses of wrap-around design and a wide-brimmed sun hat.

(d) Apply a broad-spectrum sunscreen of sun protection factor (SPF) 15+ liberally on areas of the body not protected by clothing and reapply frequently.

(e) Take precautions against excessive exposure on or in water.

(f) Check that medication being taken will not affect sensitivity to UV radiation.

(g) If adverse skin reactions have occurred previously, avoid any exposure to the sun and avoid any products that have previously caused the adverse reactions.

**High terrestrial altitude**

Adverse health effects will most likely occur at elevations of about 2,500 meters and higher. Acute mountain sickness, high altitude pulmonary edema, and high altitude cerebral edema are the most serious types of altitude illness. Symptoms may be delayed for several days after ascent. Pulmonary edema and cerebral edema are life-threatening emergencies that require immediate descent to lower elevation. Risk of cold injury, heat injury, and solar UV radiation are all increased at higher terrestrial altitudes.

Counter-measures include :

(a) Acclimatization schedule as per Advance Army Order on prevention of adverse effects of high altitude and cold, issued in 2002.

(b) Avoid alcohol and barbiturates.

(c) Remain well hydrated; individual water requirements are greater at high altitude.

(d) Protect skin (sunscreen), lips (lip balm), and eyes (sunglasses) from UV radiation.

**Protection against insect / arthropod-borne diseases**

The key to preventing vector-borne diseases is to avoid being bitten by disease-carrying insects and other arthropods. For some diseases, it is the only means of protection. Arthropod vectors of disease can pose a threat at any time, day or night. A comprehensive vector-borne disease prevention program will include (17) :

(a) Emphasizing prevention of disease by ensuring appropriate supplies, educating personnel about diseases and preventive measures, and soliciting command support at all levels.

(b) Proper camp site selection.

(c) Ensuring command emphasis on compliance with malaria chemoprophylaxis.

(d) Issuing adequate tubes of 33% DEET or other suitable insect/arthropod repellent lotion per person. Personnel should be instructed in its proper use. While at risk (during periods of vector biting activity), all personnel should apply the repellant to all exposed skin surfaces.

(e) Requiring all personnel to sleep under mosquito nets both during day and night. The mosquito nets should be treated with synthetic pyrethroids to increase their efficacy.

(f) Wire-mesh screening of all doors/ windows.

(g) Applying insecticides (camp area treatments) by properly trained personnel.

(h) Applying rodent control measures if needed (fleas must be eradicated before rodents are killed to prevent transmission of flea-borne diseases, such as plague).

(j) Chemoprophylaxis against Onchocerciasis (River Blindness) : The African Programme for Onchocerciasis Control (APOC), which includes Sudan and other 18 African countries recommends once-a-year administration of oral Ivermectin in the dosage of 150 µg/kg of body weight.

**Food and water-borne health risks**

Food-borne diseases

Food safety is a subject of great concern today, generated and fuelled by the ever increasing cases of food-borne diseases and the appearance of major food safety hazards involving beef, poultry, eggs, fish and sea products etc. Whilst bacteria cause the majority of cases, the most numerous being Campylobacter and Salmonella species, others like Clostridium, Staphylococcus, Botulism as well as chemical contaminants also play a major role in outbreaks. Investigations have identified the commonest factors, exclusive of above-mentioned bacteria, associated with outbreaks of food-borne diseases are (18) :

(a) Preparation of food too far in advance from the likely time of consumption.

(b) Inadequate storage temperatures/facilities.

(c) Inadequate cooking or re-heating.

(d) Inadequate cooling and holding.

(e) Contamination of cooked food (due to handling with "dirty" hands or exposure to dust/ flies).

(f) Consumption of raw food (not properly washed or peeled)

Food safety standards

Catering operations are an integral part of United Nations peacekeeping operations, consequently high and uniform standards of food safety are essential and must be maintained at all UN-provided or military contingent

provided catering facilities. Military contingent members may be required to dine in UN-provided catering establishments during travel in the mission area and on the other hand, apart from own troops, military members from other contingents as well as visiting UN international staff may require partaking food from TCC 'team-sites' or hospitals, on several occasions. It is the responsibility of medical officers to carry out routine inspections of all catering operations to monitor food safety management systems for compliance with these generic standards (18).

Precautions for avoiding unsafe food and drink during travel

Medical officers must educate all personnel on the following (16, 19) :

(a) Consume food from mission approved sources only and completely avoid food bought from street vendors.

(b) Wash hands with soap and water before eating, handling food or kitchen utensils, and after using latrines.

(c) Avoid cooked food that has been kept at room temperature for several hours.

(d) Eat only food that has been cooked thoroughly and is still hot.

(e) Avoid uncooked food, apart from fruit and vegetables that can be peeled or shelled, and avoid fruits with damaged skins.

(f) Avoid dishes containing raw or undercooked eggs.

(g) Avoid ice cream from unreliable sources, including street vendors.

(h) In countries where poisonous biotoxins may be present in fish and shellfish, obtain advice locally.

(j) Boil unpasteurized (raw) milk before consumption.

(k) Boil drinking-water if its safety is doubtful; if boiling is not possible, a disinfectant agent can be used.

(l) Avoid ice unless it has been made from safe water.

(m) Avoid brushing the teeth with unsafe water.

(n) Bottled or packaged cold drinks are usually safe provided that they are sealed; hot beverages are usually safe.

Safe drinking water

UN Missions are usually deployed in areas where locally available water sources are unsafe for human consumption and diseases like cholera, enteric fever, viral hepatitis, etc. are endemic amongst the local population. In most UN Missions, the Memorandum of Understanding (MoU) between the Troop Contributing Country (TCC) and the United Nations (as per the wet-lease agreement) lays down that providing the source of water is the responsibility of the UN whereas, the purification and further distribution of drinking water to troops is the responsibility of the TCC. Hence, the water purification plants, reverse osmosis plants and chemicals for treatment of water have to be provisioned by the troop contributing country and carried to the mission area by all units of the contingent.

**Role of medical authorities**

Medical Officers need to pay special attention to the following aspects during the various phases of deployment :

(a) Pre-deployment phase

(i) Make recommendations to commanders while planning for procurement of equipment/ stores and chemicals for setting up water treatment, distribution and storage systems in the mission area.

(ii) Provision for laboratory reagents and test kits for free chlorine estimation as well as bacteriological examination of drinking water in the mission area. A rapid and sensitive test kit to detect microbial contamination of water such as "$H_2S$ method" is recommended under field conditions in the mission area.

(b) During deployment and immediate post-deployment phase

This is a crucial phase during which the troops are vulnerable to traveller's diarrhoea. Safe drinking water supplies in the form of bottled/ packaged water supply which is either UN-provided or from the Contingent's own resources, as the case maybe, must be ensured for all personnel. In case the same is not available, then individual water sterilising outfits or Aquatabs must be used to make water potable.

(c) Post-deployment phase

(i) Medical Officers must advise the Unit Commander and Engineers in selecting an appropriate source of water and monitor the establishment of drinking water supply systems.

(ii) Establish a drinking water quality surveillance system (including regular free chlorine estimation as well as bacteriological examination of samples).

(iii) Offer timely and appropriate advice to commanders in the event of reported contamination of drinking water supplies to troops. Measures like supply of bottled / packaged water or boiling of water must invariably be resorted to under such circumstances.

**Drinking water safety precautions in mission area**

(a) Ensure bulk water containers remain properly sanitized. Maintain adequate chlorine residual level (minimum of 2.0 ppm) in all bulk water.

(b) If local water must be used, proper chlorination or even superchlorination, depending on the risk, should be carried out after calculating the chlorine demand by Horrock's test. If reagents for Horrock's test are not readily available, 'fixed dose' chlorination may be resorted to by adding 4 scoopfuls of WSP to 500 litres of water and confirming adequate chlorination after 60 minutes contact period by OT reagent, before

(c) When detachments are separated from the main bodies, all personnel on such detachments should carry either bottled/ packaged water supply or possess individual water sterilising outfits or Aquatabs.

**Acute respiratory diseases**

Acute respiratory diseases such as influenza, cold, sore throat, and meningococcal disease and more recently SARS and avian influenza, can be highly contagious particularly in crowded conditions. Additionally, tuberculosis infections are increasing rapidly in many areas of the world and can be a significant threat to personnel in close contact with indigenous populations. Preventive measures include providing living areas with adequate space/ ventilation and head-to-foot sleeping arrangements to reduce droplet and aerosol spread of these diseases. Encourage all personnel to practice cough etiquettes and hygienic hand washing.

**Diseases spread by contact with soil**

Hookworm, strongyloides, and various diseases can be contracted by contact of skin with contaminated soil. Minimize direct skin contact with soil (such as walking barefoot and sleeping on bare ground). Wash hands frequently.

**Diseases spread by contact with water**

Diseases like schistosomiasis, leptospirosis, etc, are spread by direct contact with fresh water lakes, ponds, and streams (see Fig. 1). Counter-measures include :

(a) Avoid/ minimize swimming, wading, or bathing in fresh water that may be contaminated. All recreational swimming areas must be inspected and cleared by the medical authority.

(b) Wear shoes when walking on shores, riverbanks and muddy terrain.

(c) Leptospirosis prophylaxis: Prophylaxis should be considered when personnel are in a high-risk area and they have prolonged contact with mud or standing water. Doxycycline, 200 mg once a week,

Fig. 1 : Children bathing in the highly contaminated waters of a stream in South Sudan(UNMIS)

Fig. 2 : Intense water logging following rains in a settlement in South Sudan(UNMIS)

can provide protection.

**Animals**

Animals can spread disease through close contact (e.g. anthrax, Q fever) or bites and scratches (e.g. rabies). Animals with these diseases, including rabies, may not exhibit any obvious signs of illness. Educate all personnel to :

(a) Avoid all unnecessary contact with local animals. Commanders must insist that stray or wild local animals will not be fed or kept as pets or mascots.

(b) Conduct proper food storage and waste disposal inspections to prevent attracting stray animals. Water containers should be protected or raised high enough from the ground to prevent animals from contaminating the water.

(c) If bitten or scratched, immediately wash the wound with soap and water and seek medical evaluation.

**Protection against bites and stings**

Educate all personnel to take adequate precautions to adopt measures to protect themselves from being bitten by snakes, centipedes, scorpions and spiders. Personnel should not go bare foot, sleep directly on the ground and put their hands or feet in crevices or holes. Boots, clothing and bedding should be checked and shaken out before use. In the event of stings or bites, should report immediately to the nearest medical facility. First-aid measures may be taken as appropriate while evacuating/moving to the medical facility.

**Specific anti-venom requirements in mission area**

Medical Officers must gather information on the varieties of poisonous/ non-poisonous snakes and scorpions found in the mission area, prior to deployment and make provisions for specific anti-venom requirements (e.g. anti-venom to African varieties of poisonous snakes).

Scorpion control

Scorpion control is difficult and requires patience but is

not impossible.

**(a) Outdoor control measures**

(i) The first and most important step in control is to eliminate the scorpions' habitat. Wood, large stones, vegetation, garbage and other debris should be removed from the vicinity of tents/ living areas. Gloves and protective clothing should be worn when cleaning up areas where scorpions may hide.

(ii) Outdoor applications of hygiene chemicals (insecticides) are aimed at eliminating scorpions from the immediate area (before they gain entry into the living area). Most hygiene chemical sprays will also reduce insect populations that serve as food and will have some effect on reducing the number of scorpions. The following hygiene chemicals should be sprayed :

- Hit (Propoxur)-once a week
- Deltamethrin 2.5% WP-once a month

(iii) Use a compression sprayer to spray the hygiene chemicals at the following places :

- On the ground upto a distance of 6 feet around the tents/ pre-fabricated shelters. This "treated turf" will not only deter scorpions from re-entering but also keep ants, spiders and crawling insects from entering the living areas.
- Also spray upto a height of 3 feet, on the outside surfaces of tents / pre-fabricated shelters.
- Then spray around all entry points such as windows, doors, openings in tents.
- Hiding places should be located and treated, and any scorpions that are observed can be treated directly. Repeated applications may be necessary for effective control since scorpions may hide for two to three months after feeding.

(b) Indoor control measures

(i) Keep the insides of tents/ shelters clutter-free. Good housekeeping is a key measure to deny indoor hiding places for scorpions.

(ii) Place steel boxes, cupboards and other equipment on bricks to provide adequate ground clearance for cleaning and brooming on a daily basis.

(iii) Use the hygiene chemical, Cresol Black liquid for wet mopping of flooring, wherever feasible.

(iv) Indoor sprays upto a height of 3 feet on tents and walls with Hit/ Propoxur.

(v) Impregnation of lower portion of tent inner-fly with Deltamethrin 2.5% SC.

(c) Personal protective measures

(i) Always wear adequate footwear when walking around at night to minimize the possibility of being stung by a scorpion.

(ii) Always use a torch when you walk around at night.

(iii) Vigorously shake your clothes, bed sheets, blankets, sleeping bags, socks and footwear (by turning upside down) before using them.

(iv) Sleep inside Deltamethrin impregnated bednets.

(v) Apply the repellent 33% DEET over hands and feet at night.

(vi) Impregnation of cuffs, collars and lower portion of trousers with the hygiene chemicals Permethrin or Deltamethrin 2.5% SC.

## Waste disposal in mission area (15)

### Sewage Disposal

A waste management system that deals with the collection, storage, treatment and disposal must be developed early in the planning process. The selection of the method used is dependent on local facilities and services available as well as the local geology. Placement of the facilities requires special consideration to minimize potential impacts to the environment and prevent contamination of the water supply for deployed forces and local inhabitants.

Solid waste management

The method of choice for the disposal of solid waste must take into account the sensitivities of the local population. If existing landfills are not available, burial of waste should employ the characteristics typical of landfill operations. Landfill operations will not be conducted in the vicinity of watercourses or in areas of high water tables. Burning of solid waste may be an acceptable alternative.

Fig. 3 : UN-provided ablution units deployed under field conditions in the UN Mission in Sudan

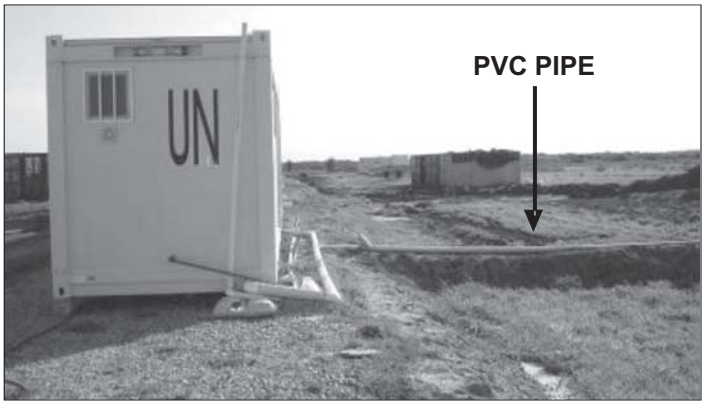

Fig. 4 : Sewage is carried through PVC pipes from ablution unit to an oxidation pond (UNMIS)

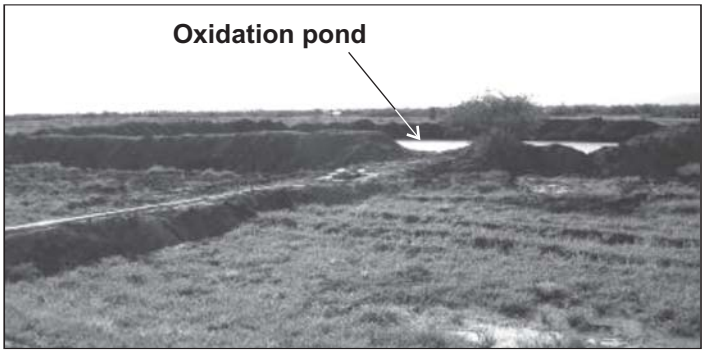

Bio-medical waste management

Bio-medical waste generated by medical facilities in the mission area should be disposed off either by incineration or other suitable methods. Medical authorities should ensure the disposal method does not present any immediate or future danger to personnel or the local population. Ashes should be disposed of by burial in an appropriate landfill site.

Sullage disposal

Effluent from showers/ bathing facilities must be located downstream of any military or civilian water sources. Construction should ensure proper drainage of sullage water runoff to preclude pooling. All measures will be taken to prevent creation of pest (e.g. mosquito, etc) breeding sites. Planning must be done in collaboration with Engineers.

Storm water management

Storm water management will reduce pooling within the camp area. Storm water is best managed during the base camp design process, where proper site preparation and maintenance will minimize these risks.

Personal hygiene

Maintenance of good personal hygiene includes frequent hand-washing, proper dental care, maintenance of clean, dry clothing (especially socks, underwear, and boots), and bathing with water from an approved source. If bathing facilities are not readily available at any given point in time, sites of perspiration must invariably be wiped clean with a washcloth daily. Change socks as frequently as practical. Foot powder will help prevent fungal infections.

## Oral health

Neglecting essential oral hygiene practices during deployment can result in periodontal disease and increase the risk of tooth decay. All personnel should undergo periodic dental inspection and take prompt treatment for problems, if any.

## Jet lag

Rapidly crossing several time zones may result in fatigue, irritability, reduced efficiency, and early morning wakefulness within the first 24 hours, lasting up to five days after landing. Preventive measures to reduce jet-lag include re-scheduling sleep hours to coincide with the destination time-zone before embarking upon the journey, and in-flight measures like avoidance of alcohol/caffeinated beverages, maintaining adequate hydration and refraining from overeating.

## Stress management

During the tenure of deployment to any UN Mission, the members of the peacekeeping contingent are frequently confronted with various situations which result in significant and often prolonged levels of stress on them. It is important for the Medical Officers to be able to recognize different types of stress reactions in individuals and be familiar with measures that can be taken to deal with them.

### Factors contributing to stress among peacekeepers (4)

(a) Not professionally trained for the task at hand as well as lack of influence (e.g. Military Observers, who can only monitor and report, and cannot directly intervene in the situations they are observing).

(b) Need to show impartiality to different parties in a conflict, despite personal beliefs and convictions.

(c) Lack of security and concerns about personal safety.

(d) Need to suppress emotions.

(e) Uncomfortable living conditions and lack of privacy.

(f) Separation from home, family and friends.

(g) Cultural differences, language difficulties and dietary changes.

(h) Lack of recreation facilities.

(j) Traumatic stress (e.g. witnessing violence or death, experiencing intimidation or threat, serious accident or life-threatening illness).

### Recognising mission-related stress in individuals

The following behavioral changes are likely to occur in individuals in response to undue stress :

(a) Changes in behaviour.

(b) Changes in eating habits.

(c) Sleep disturbances.

(d) Psycho-somatic complaints.

(e) Decrease in personal hygiene.

(f) Withdrawal from others.

(g) Prolonged periods of silence.

Medical officers should be able to identify persons having serious problems adjusting to deployment as they may be at risk for suicide. Recognition and early referral of personnel at risk is an important aspect of preventing suicides.

### Managing mission - related Stress

It is important to recognize the emotional, functional and physical changes in individuals accompanying stress-related reactions. While these cannot be totally prevented, awareness of such problems by an individual or his colleagues, openness in discussing such problems and the availability of professional help should this be required, are key factors to successfully managing stress.

Some of the measures to combat mission-related stress are as follows :

(a) Before deployment, commanders should ensure that all personnel have secured a current will, made arrangements for childcare, arranged for bills to be paid in absentia, and provided in advance for possible family separation.

(b) Pre-deployment training on stress-management techniques and giving adequate information on what to expect and what not to expect in the mission area.

(c) Making provisions for organized sports, recreational activities and social gatherings (such as Barakhana, screening of movies etc.) at the HQ or unit or sub-unit level.

(d) Keep personnel regularly informed about the mission situation and likely tasks in the days to come.

(e) Debriefing of personnel following exposure to traumatic events, to be conducted in group sessions, and preferably with participation of trained counsellors.

(f) Training of medical personnel to recognize signs and symptoms of stress and to manage such conditions.

(g) Access to professional counselling should this be required. This is generally available at TCC Level 2 or Level 3 hospitals.

## Road safety

### Introduction

It is important to note that road traffic accidents are the main cause of serious injury and fatalities in peacekeeping missions. In a study conducted in 1997, it was shown that out of a total of 876 accidents reviewed, 64% comprised road traffic accidents. Most resulted from human error on the part of the peacekeeper, or of another party. Although not directly responsible for accident prevention, the Medical Officer in the field has a duty to advice the contingent commander if road safety measures are not being adopted. Strict enforcement of such measures will lead to reduction in loss of human life and limb (4).

### Road safety programme

Basic components of a road safety programme in the mission area include (4, 20) :

(a) Commander's emphasis on road and vehicular safety.

(b) Clearly documented safety regulations and Standard Operating Procedures (SOPs) which are understood by all drivers and vehicle occupants. These measures have to be strictly enforced (e.g. speed limits, use of seat-belts, alcohol control, vehicle breakdown drill, restrictions on night driving and under no circumstances should any individual drive alone).

(c) Certified driving standards for military and heavy vehicles, and orientation drives for new drivers.

### Re-orientation and training of drivers

It is advised to gather prior information on the driving norms in the country to which troops are proposed to be deployed. If the situation so warrants, then special training must be conducted for all drivers on left-hand drive vehicle as well as driving on the right side of the road before leaving for the mission area. All drivers must know the informal rules of the road; in some countries, for example, it is customary to sound the horn or flash the headlights before overtaking (20). Drivers must be advised to give right of way to pedestrians, cyclists and maintain a safe driving distance from local vehicles. Medical Officers must also conduct basic first-aid training courses for all contingent members.

UN driver's permit

It is also important to note that a national driving license issued by the Troop Contributing Country to its contingent members does not suffice to drive vehicles in the mission area. In addition, a UN driving license is an essential pre-requisite for driving either the contingent-owned or UN-owned vehicles. It is the responsibility of the Transport Section of the UN Mission to conduct driving tests, assess the suitability of individuals and issue driver's permits.

### Special precautions

While travelling in conflict-prone areas of the mission, it is advisable to wear bullet proof jackets and UN helmets; keep car doors locked and windows shut and not to pick up strangers.

### First-aid kits and blood safety

All vehicles must carry adequate first-aid kits including splints, IV fluids and plasma expanders, as safety of local blood supplies cannot be guaranteed.

### Land-mines

In many UN peacekeeping missions there is a significant threat from large-scale and indiscriminate deployment of land mines. All contingent members are advised to use only those roads or tracks that have been de-mined and clearance to this effect issued by the Mine Action Service of the UN mission.

## Health education

During the pre-deployment phase, Medical Officers should endeavour to collect the relevant health intelligence on the country/ region of intended deployment and based on this impart relevant health education and training to the troops which should continue during the period of deployment at regular intervals. It is important for troops to have a high level of awareness about the anticipated health risks in the mission area and learn how to minimize the risks of acquiring these diseases in order to maintain optimal levels of health, reduce the likelihood of repatriation due to prolonged periods of illness/ convalescence and carry out the mission-mandated tasks effectively.

## Epidemiological surveillance

Senior Medical Officer/ Medical Officers in the Contingent should develop and employ a plan for epidemiological surveillance for the entire period of deployment, including during the moves, for early diagnosis and treatment of diseases/ health-related conditions which may adversely affect the troops and take appropriate containment measures, both medical and administrative, to control any outbreak. SMO of the Contingent should formulate SOPs on medical care and health of troops, in consultation with the specialist in Preventive and Social Medicine (if accompanying the Contingent), as per existing policies.

The SOPs should be issued as administrative instructions through the National Senior of the contingent.

## Notification and reporting

The SMO of the contingent is required to compile information from all contingent medical facilities and submit reports on the out-patient attendance, in-patient treatment details, disease outbreak investigation reports (on occurrence), medical aid to civilians, etc. to the following :

(a) Force HQ : Daily/ weekly/ monthly reports (as per mission policy)

(b) DGMS (Army)/ DGMS-3E (UN Cell): Weekly reports (or, as per instructions)

(c) o/o DGAFMS / DG-3A; DGMS (Army)/ DGMS-5B and AFCESC, Dept of Community Medicine (PSM), AFMC, Pune: Six-monthly reports as per format (including the conditions prevalent in the area of deployment, morbidity/ mortality reports, epidemiological investigation reports of disease outbreaks and specific recommendations (if any) on chemoprophylaxis, additional immunisation requirements, etc.).

(d) Notification about diseases governed by the International Health Regulations to the medical authorities at the Force HQ of the Mission.

All contingents that are deployed/ return from UN/ foreign assignments should send a health intelligence feedback to the Armed Forces Central Epidemiological Surveillance Centre (AFCESC), so that the information can be used to update these guidelines.

## Medical support structure in UN missions

There is a clear command structure within a peacekeeping force. The Force Medical Officer (FMedO), subordinated directly to the Force Commander (FC) (or the designated Head of Mission), plans, directs, advises and supervises all activities related to the Mission's medical support plan. He/ she is the senior medical adviser to the Force Commander (FC), and supervises all contingent medical officers in the Mission and exercises functional control of all medical assets provided for the Mission (4).

The Senior Medical Officer (SMedO) of the national contingent is the medical adviser to the National Senior in mission area as well as the FMedO's point of contact on medical matters. He/ she implements the Medical Support Plan for the Mission in accordance with UN medical policies and the FMedO's directions and oversees health-care, hygiene and implementation of preventive measures in contingent's area of operations.

### Levels of medical support

The levels of Troop Contributing County (TCC) medical support for UN peacekeeping missions are as follows :

(a) Basic Level

This effectively refers to basic first-aid and preventive medicine practised at the smallest sub-unit level. As there is no medical officer present, care is provided by the peacekeeper, or by a trained paramedic or nurse, using basic medical equipment and supplies.

(b) Level one medical support

This is the first level where a medical officer is available. The Level 1 Hospitals are usually attached to Infantry Battalions, Engineer Company, De-mining Company and other sub-units at various team-sites in the area of operations of a contingent. It provides first-line primary health care, emergency resuscitation, stabilization and evacuation of casualties to the next level of medical care within a peacekeeping mission.

(c) Level two medical support

This is the next level of medical care and the first level where surgical expertise and specialist medical facilities are available. The task of a Level Two medical facility is to provide second-line health care, in-patient treatment emergency resuscitation and stabilization, limb and life-saving surgical interventions, hygiene control and preventive medicine, basic dental care, basic laboratory support and diagnostic radiography, and casualty evacuation to the next echelon.

(d) Level three medical support

This is the highest level of medical care provided by a deployed UN medical unit. It combines the capabilities of Level One and Two units, with the additional capability of providing specialized in-patient treatment and surgery, as well as extensive diagnostic services. It is important to note that a Level Three unit is only deployed in missions with a large number of personnel, and in smaller UN missions, this level of support is generally obtained from existing civilian hospitals within the Mission area or in a neighbouring country.

(e) level four medical support

A Level Four medical facility provides definitive medical care and specialist medical treatment unavailable or impractical to provide for within a Mission area. This includes specialist surgical and medical procedures, reconstruction, rehabilitation and convalescence. Such treatment is highly specialized and costly, and may be required for a long duration. It is neither practical nor cost-effective for the UN to deploy such a unit within the Mission area. Such services are generally sought in the host country, a neighbouring country, or in the troop contributing country itself. The UN arranges for transfer of a patient or casualty to such a facility and continues to monitor the patient's progress.

### Primary role of TCC medical facilities

Military contingents are normally self-sufficient with respect to medical care, and often bring with them what appear to local populations to be large medical structures and resources. They are generally not deployed for humanitarian purposes, but rather for the care of their own and associated personnel. Where populations are medically at risk, lack of access to these facilities may generate local resentment. However, TCC medical units often receive requests from the Sector / Force Headquarters of the UN mission to provide emergency medical support to the local population on humanitarian grounds. In such instances, after providing emergency medical care at the TCC medical facility, the patient(s)

should be transferred to civilian or NGO-aided medical facilities in the mission area.

While the mandate of medical components of military forces may not allow direct assistance to local populations in a humanitarian basis, contingent medical officers can make meaningful contributions by assisting other UN agencies and International NGOs in programme development and technical assistance with the concurrence of the contingent commander. The role of

## Additional Information

### Units and Measures

#### Systeme International d'Unites

The use in medicine of the Systeme International d'Unites (SI) was endorsed by the 30th World Health Assembly in May 1977. The SI is universally acceptable system of units of measurement. It is essentially an expanded version of the 'metric system' and comprises units like base units and derived units.

(a) Base Units

Seven units have been selected to serve as the basis of the system. These SI base units are mentioned below together with their symbols and the quantities they measure (Table - 1) :

Table - 1 : Base Unit

| Quantity | Name of the unit | Symbol for unit |
|---|---|---|
| Length | Meter | m |
| Mass | Kilogram | kg |
| Time | Second | s |
| Electric current | Ampere | A |
| Thermodynamic | Kelvin | K |
| Luminous intensity | Candela | cd |
| Amount of substance | Mole | mol |

(b) Derived Units

By multiplying a base unit by itself or by combining two or more base units by simple multiplication or division, it is possible to form a large group of units known as 'SI derived units'. Examples of a few simple derived units are given below (Table - 2) :

Table - 2 : Desired Units

| Quantity | Name of derived units | Symbol for unit |
|---|---|---|
| Area | Square metre | $m^2$ |
| Volume | Cubic metre | $m^3$ |
| Speed | Metre per second | m/s (or $m.s.^{-1}$) |
| Acceleration | Metre per second square | $m/s^2$ (or $m.s.^{-2}$) |
| Substance concentration | Mole per cubic metre | $Mol/m^3$ (or $mol.\ m^{-3}$) |

(c) A number of SI derived units have been given special names, most of which are the names of scientists who made an outstanding contribution to the field of study concerned. Out of 18 SI derived units given special names, some are mentioned below (Table - 3) :

Table - 3 : Desired units with special names

| Quantity | Name of unit | Symbol for unit | Derivation of unit |
|---|---|---|---|
| Frequency | Hertz | Hz | $s^{-1}$ |
| Force | Newton | H | $m.\ kg.\ s^{-2}$ |
| Pressure | Pascal | pa | $n/m^2$ |
| Work; energy; quantity of heat | Joule | j | N. m |
| Power; radiant flux | Watt | w | j/s |

#### Useful Factors for Conversion

| To convert | Multiply by |
|---|---|
| Inches to metres | 0.0254 |
| Metres to inches | 39.37 |
| Inches to centimetres | 2.539 |
| Centimeters to inches | 0.3937 |
| Metres to feet | 3.28 |
| Feet to metres | 0.3047 |
| Kilometers to mile | 0.6214 |
| Grams to pounds (a voirdupois) | 0.0022 |
| Pounds to grams | 453.592 |
| Kilograms to pounds | 2.204 |
| Pounds to kilogram | 0.4537 |
| Grams to grains | 15.432 |
| Grains to grams | 0.0648 |
| Ounces to grams | 28.35 |
| Grams to ounces | 0.0353 |
| Litres to gallons | 0.22 |
| Gallons to litre | 4.546 |
| Litres to pints | 1.76 |
| Pints to litres (British) | 0.5681 |
| Litres to fluid ounces | 35.2 |
| Cubic centimeters to fluid ounces | 0.0352 |
| Fluid ounces to cubic centimeters | 28.57 |
| Gallons to cubic feet | 0.1605 |
| Cubic inches to gallons | 0.003607 |
| Cubic inches to cubic metres | 16.386 |
| Cubic feet to cubic metres | 0.0283 |
| Cubic centimeters to cubic inches | 0.061 |
| Cubic metres to cubic feet | 35.316 |
| Pints to cubic centimeters | 568.182 |
| Square feet to square yards | 0.111 |

| | |
|---|---|
| Parts per 100,000 into grains per gallon | 0.7 |
| Grains per gallon to parts per 100,000 | 1.43 |
| 1 Joule(J) to K cal | 0.0239 |
| 1 K cal to Joule | 4184 |
| 1 roentgen to Coulomb | $2.58 \times 10^{-4}$ |
| 1 rad to Grey | 0.01 |
| 1 rem to Sievert | 0.01 |
| 1 mEq/l of hardness producing ion to mg of $CaCO_3$ | 50 |
| lb per cubic feet to KG per cubic metre | 16.023 |

**Physical Data**

(a) Air

(i) **Weight :** 1 Cu ft of air at 62˚F and pressure of 14 lb weighs 0.076097 lb.

(ii) **Volume** : 1 lb of air at 62˚F and pressure of 14.7 lb, is 13.141 cft in volume.

(iii) **Mean atmospheric pressure** : 14.7 lb per square inch at sea level.

(b) Heat

(i) **Thermometer Scales**

Fahrenheit and centigrade conversion formula

(F-32) x 5/9 = C

(C x 9/5) +32 = F

(ii) **The Calorie**

It is the amount of heat required to raise 1 gram of water through 1˚C (i.e. to change the temperature of 1 g of water from 3.5˚C to 4.5˚C). The large or major calorie (sometimes spelt with a 'K' or a capital 'C' or Kilogram calorie is the amount of heat required to raise 1 Kilogram of water through 1˚C.

(C) Water

(i) **Specific gravity** : 1.0

(ii) **Standard temperature** : 62˚F or 16.6˚C

(iii) **Boiling point** : 212˚F or 100˚C

(iv) **Freezing point** : 32˚F or 0˚C

(v) 1 gallon of water weighs 10 lb at 62˚F

(vi) 1 gallon salt water weighs 10.272 lb.

(vii) 1 cu ft contains 6 ¼ gallons of water & weighs 62.5 lbs.

(viii) 1 cu ft salt water weighs 63.5 lbs.

**Measurement of light**

(a) Candela of candle power

It is the intensity of light at a point placed at a distance of one foot from a light source of a standard candle.

(b) Lumen

It is the total quantity of light, which falls on one square foot of surface, all points of which are one foot from a light source of one standard candle.

(c) Lux

It is the amount of light reaching a surface measured per unit area.

(d) Lambert

It is the amount of light reflected from a surface area.

Measurement of Daylight

Daylight factor is the ratio of illumination at a given point to illumination at a point exposed simultaneously to the whole hemisphere of the sky (taken as 500 foot candles) excluding direct sunlight. The day light factor may be summarised as follows :

**Measurement of Noise**

(a) Loudness is measured by decibel, which is a ratio of the sound in question to the smallest distinguishable sound, which is 0.0002 dynes/$cm^2$.

(b) Frequency is determined by number of cycles per second (CPS of C/S) or in Hertz (Hz). One HZ is equal to one wave per second.

$$\text{Daylight factor} = \frac{\text{Instantaneous illumination indoors}}{\text{Simultaneous occurring illumination outdoors}} \times 100$$

**Hygiene Chemicals Provisioning Scale**

The provisioning scales of certain hygiene chemicals are given in Table - 6. These scales are for the guidance of the provisioning organization only and not the scales for demand, which should be based on the local requirement under medical advice.

Contd. . . . .

## Prevention and control of diseases and important orders on health matters

### Army Orders

Some of the important Army Orders on various health matters are :

| | |
|---|---|
| Cerebrospinal fever | AO 426/64 |
| Dispensation, commutation med bd | AO 153/79 |
| Med bd: Grant of PC to SSC Offr | AO 121/79 as amended |
| Re-survey med bd(RSMB) | AO 121/79 as amended |
| Avoidance of delay in finalisation of C of I proceedings in death cases | AO 123/81 |
| Disposal of low medical category personnel other than officers | AO 46/80 as amended |
| Introduction of medical treatment entitlement certificate for ex-service personnel & widows | AO 10/97 |
| Issue of indl water sterilising outfit to Army pers travelling by train on leave/duty | AO 393/68 |
| Med exam of Armed Forces pers and families proceeding abroad at Govt expense on duty/deputation/study leave | AO 299/77 & AO 5/79 |
| Entitlement of medical treatment in civ/pvt hosps and procedures for re-imbursement of med exp | AO 32/81 |
| Precautionary measures to be undertaken while travelling by rail | AO 117/76, 56/77 |
| Malaria and other mosquito borne diseases 27/2004, | SAO 25/5/71, AO AO 6/79 & 16/86 |
| Immunization | AO 337/71 |
| Effects of cold and prevention | SAO 23/S/72 |
| Sanitary rules for cook houses | AO 515/72 |
| Scrub typhus | AO 550/72 |
| Food poisoning | AO 35/73 |
| Food handler's examination | AO 36/73 |
| Prevention of heat stroke and heat exhaustion | AO 57/73 And AO 7/80 |
| Medical care and reclassification of diseases | AO 11/2001 |
| Infectious intestinal disorders | AO 209/73 |
| Barber's shop cleanliness | AO 247/73 |
| Disposal of personnel (other than officers) on discharge from hospitals (IMB) | AO 482/73 |
| Medical treatment and disposal of Armed Forces personnel and their families suffering from pulmonary tuberculosis and leprosy | AO 150/75 |
| Accn for relatives and patients who are on DI/SI list in MHs | AO 84/77 |
| Medical treatment in civil / pvt hospitals | AO 163/77 AO 32/81 & AO 38/84 |
| Control of sexually transmitted diseases (STD) | AO 164/77 |
| Supply of spectacles to Armed Forces personnel | AO 69/79 |
| Prevention of carbon mono-oxide poisoning | AO 101/79 |
| Swimming pool sanitation | AO 149/79 |
| Control of housefly | AO 163/79 |
| Infectious hepatitis | AO 164/79 |
| Prevention of food and water borne diseases | AO 25/2004 |
| Duties and responsibilities in relation to health of service personnel and families | AO 165/79 |

| | |
|---|---|
| Prevention of rabies | AO 182/79 AO 111/80 |
| Relapsing fever | AO 202/79 |
| BPET | AO 7/80 |
| Appeal medical board | AO 14/80 |
| Dental inspection | AO 36/80, AO 71/81 & AO 39/83 |
| Effects of high altitude and prevention | AO 110/80 & AO 55/85 |
| Introduction of entitlement certificate for non service beneficiaries entitled to medical/dental treatment from service institutions | AO 120/80 And AO 16/91 |
| Medical documentation | SAO 8/S/83 |
| Medical and psychiatric examination of personnel recommended trials by court martials | AO 37/83 |
| Sick leave (officers) | AI 10/83 and para 426 of RMSAF 1983 |
| Sick leave (JCOs / OR) | Para 427 of RMSAF 1983 |
| Medical treatment and disposal of leprosy | AO 36/87 |
| Medical cat for courses of instruction | SAO 6/S/89 |
| Release medical board | AO 3/89 |
| First Aid snake bite | AO 4/89 |
| Disability Compensation Medical Board | AO 17/89 |
| Health care system in the Army- Instructions for Medical Examination and classification of serving officers | AO 11 /2001 |
| Biological hazards of micro wave radiation and Preservation | AO 269/69 |
| Boiling of milk before consumption | AO 19/65 |
| Disposal of dead body died of infectious disease | AO 428/69 |
| DDT sprays | AO 341/65 & 203/67 |
| First Aid Snake bite | AO 4/89 |
| Food inspection zones | AO 814/64 |
| Infection/intestinal diseases | AO 209/73 |
| Infectious/Serum hepatitis-prevention and control of | AO 164/79 |
| Supply of spectacles to Armed Forces Personnel | AO 69/79 |
| Prevention of Carbon Monoxide poisoning | AO 181/79 |
| Relapsing fever | AO 202/79 |
| Heath care system in the Army Instr for medical examination and classification of serving officers | AO 01/2004/DGMS |
| Health care system in the Army : Instrs for medical examination and Categorisation of serving JCOs/OR. | AO 3/2001 |

**Note** : Army Orders related to food hygiene and sanitation eg., AO 185/53, 19/65, 313/65, 515/72, 35/73, & 36/73 are under revision.

DGAFMS Office Guidelines

**Sub: Preparedness for Biological and Chemical Warfare.**

Guidelines issued by office of DGAFMS vide letter no. 3048/DGAFMS/DG 3A dt. 24 Dec 2001.

## Navy Orders

Some of the important Navy Orders on various health matters are

| | |
|---|---|
| Medical Check-up of Ex-servicemen boarded out due to T.B. | NO 31/79 |
| Medical attendance in Ships and Establishment | NO 40/79 |
| Medical Standard (Officers/Sailors) | NO 3(S)/85 |
| Mosquito Borne Diseases | NO 36/86 |
| Control of Rabies | NO 26/99 |
| Sick List Concession Officers | NO 5/87 |
| Morbidity and mortality return | NO 6/99 |
| Annual Health Return | NO 16/87 |
| Alcohol and Drug Abuse | NO 4/90 |
| Control of Meningococcal Meningitis | NO 1/91 |
| Hosp Stoppage Sick Attendant | NO 4/94 |
| Medical Treatment in quarters : Service Officers | NO 12/94 |
| Medical Treatment of dependent parents | NO 27/94 |
| Posting of personnel in low med cat to remote areas | NO 31/94 |
| Immunization | NO 34/94 |
| Naval Medical Research Advisory Panel | NO 38/94 |
| Procedure for disposal of naval personnel on discharge from hospitals | NO 45/94 |
| Refusal to undergo medical examination, treatment, operation, immunization and to appear before medical board | NO 51/94 |
| Protection of ears from high intensity noise | NO 54/94 |
| Mouth to Mouth breathing | NO 59/94 |
| Entitlement of medical treatment in civil/private hospital and procedure for re-imbursement | NO 6/95 |
| Medical Board-Assessment of Dental disability of Officers and Sailors | NO 11/95 |
| Medical examination of Naval personnel before release, retirement and discharge | NO 15/95 |
| Naval Health Committee in Shore Command/Establishments | NO 21/95 |
| Dental Returns | NO 22 & 23/95 |
| Medical and Dental Treatment of Ex-Service personnel and families | NO 24/95 |
| Notification of Communicable Diseases | NO 25/95 |
| Pest Control on Ships and Aircrafts | NO 31/95 |
| Dental Inspections | NO 32/95 |
| Sanitary Rules of Food handlers | NO 34/95 |
| Hospital and Blood Bank | NO 35/95 |
| Provision of beds for crisis expansion - Naval Hospitals | NO 36/95 |
| Food Poisoning | NO 38/95 |
| Annual Medical Examination Officers | NO 2/96 |
| Psychiatric examination, treatment and disposal of naval personnel and families | NO 3/96 |
| OPD treatment to naval personnel and families from Govt Civil hospitals where service facilities are not available | NO 21/96 |
| Reporting of casualties | NO (Spl) 3/99 |
| Maintenance of STD Register | CNO 1/2000 |
| Preventive measures against effects of Heat | NO 3/99 |

### Air Force Orders

Some of the important Air Force Orders on various health matters are given below: -

| | |
|---|---|
| Arsene poisoning | AFO 147/70 |
| Air craft noise and preservation of hearing | AFO 239/70 |
| CO Poisoning | AFO 460/70 |
| Relapsing fever | AFO 473/70 |
| Responsibilities of AF Health | AFO 162/75 |
| Prevention of scrub typhus | AFO 277/76 |
| Aircraft noise and preservation of hearing | AFO 326/76 |
| Effects of cold and high altitude and their prevention | AFO 462/76 |
| International certificate of vaccination and inoculation | AFO 461/76 |
| Malaria eradication | AFO 1091/76 |
| Prevention of epidemic typhus (louse borne) | AFO 163/76 |
| Prevention of diseases conveyed by infected food and drinks | AFO 414/76 |
| Prevention of viral hepatitis | AFO 113/80 |

**Themes for World Health Day :** Themes for the World Health Day since 1950 are given below:

1950 Know your own health services
1951 Health of your child and world's children
1952 Healthy surroundings make healthy people
1953 Health is wealth
1954 Nurse, pioneer of health
1955 Clean water means better health
1957 Food and health
1958 Ten years of health progress
1959 Mental illness & mental health in the world of today
1960 Malaria eradication a world challenge
1961 Accidents and their prevention
1962 Preserve sight Prevent blindness
1963 Hunger Disease for millions
1964 No truce for tuberculosis
1965 Eradication of small pox
1966 Man and his cities
1967 Partners in health
1968 Health in the world of tomorrow
1969 Health, labour and productivity
1970 Early detection of cancer saves life
1971 A full life despite diabetes
1972 Your heart is your health
1973 Health begins at home
1974 Better food for a healthier world
1975 Small pox; point of no return
1976 Foresight prevents blindness
1977 Immunize and protect your child
1978 Down with high blood pressure
1979 A healthy child a sure future
1980 Smoking or health; choice is yours
1981 Health for all by the year 2000
1982 Add life to years
1983 Health for all the countdown has begun
1984 Children's health tomorrow's wealth
1985 Healthy youth our best resource
1986 Healthy living every one a winner
1987 Immunization a chance for every child
1988 Health for all all for health
1989 Let's talk health
1990 Our planet, our health think globally, act locally
1991 Should disaster strike, be prepared
1992 Heart beat the rhythm of health
1993 Handle life with care prevent violence and negligence
1994 Oral health for a healthy life
1995 Target 2000 A world without polio
1996 Healthy cities for a better life
1997 Emerging infectious diseases. Global response. Global alert
1998 Pregnancy is special, let us make it safe
1999 Active aging makes the difference
2000 Safe blood starts with me
2001 Mental Health Stop exclusion Dare to care
2002 Move for Health
2003 Shape the Future of LifeHealthy Environment for Children
2004 Road Safety is No Accident
2005 Make Every Mother and Child Count
2006 Working Together for Health
2007 Invest in Health , Build a Safer Future
2008 Protecting Health from Climate Change

## Important Health Related Days

| | |
|---|---|
| **January** | |
| 01 Jan | Anti smoking Day |
| 12 Jan | National youth Day |
| 30 Jan | Leprosy Eradication Day |
| 30 Jan | Martyr's Day |
| **February** | |
| 05 Feb | Oral Health Day |
| **March** | |
| 06 March | National Science Day |
| 08 March | International Women' Day |
| 15 March | National Environmental Day |
| 22 March | World Water Day |
| 24 March | World Tuberculosis Control Day |
| **April** | |
| 06 April | Pulse Polio Immunisation Day |
| 07 April | World Health Day |
| 18 April | World Heritage Day |
| 22 April | World Earth Day |
| **May** | |
| 01 May | Labour Day |
| 03 May | International Energy Day |
| 11 May | National Technology Day |
| 12 May | World Nursing Day |
| 14 May | Mother's Day |
| 17 May | World Telecommunication Day |
| 21 May | Anti- Terrorism Day |
| 29 May | Commonwealth Day |
| 31 May | No Tobacco Day |
| **June** | |
| 05 June | World Environmental Day |
| 26 June | International Anti-Drug Day |
| **July** | |
| 01 July | Doctor's Day |
| 10 July | Safe Motherhood Day |
| 11 July | World population Day |
| 27 July | WHO ORS Day |
| **August** | |
| 01 August | World Breast feeding Day |
| 01-07 August | World Breast Feeding week |
| 05 August | Filaria Control Day |
| **September** | |
| 01-07 September | National nutrition Week |
| 08 September | International Literacy Day |
| 25 September | World Heart Day |
| 27 September | World Tourism Day |
| **October** | |
| 01 October | Voluntary Blood Donation Day |
| 01 October | World Habitat Day |
| 06 October | World Wildlife Day |
| 07 October | World Housing Day |
| 11 October | World Sight Day |
| 12 October | Mental Health Day |
| 14 October | World Disaster Control Day |
| 16 October | World Food Day |
| 21 October | Iodine Deficiency Disease Control day |
| 31 October | National Integration Day |
| **November** | |
| 01 November | World Ecology Day |
| 11 November | Anti- Poverty Day |
| 15-21 November | National Newborn Week |
| **December** | |
| 01 December | World AIDS Day |
| 02 December | National Population Prevention Day |
| 03 December | World Disability Day |
| 10 December | World Human Right Day |
| 11 December | UNICEF Day |
| 23 December | Farmer's Day |

## Indicators for Obesity

**(a) Body Mass Index (BMI)**

= Weight in Kg/Height in (metre)$^2$

Normal range = 20-25

A person is definitely obese if it is more than 27

**(b) Waist Hip ratio**

Waist is measured with a tape at a point mid way between 12$^{th}$ rib and upper border of iliac crest on both sides.

Hip is measured with a tape at upper point of greater trochanter of femur on both the sides.

Normal range 0.6 0.9

A person has definite central obesity if it is more than 0.9.

**(c) Skin fold thickness measured with the help of a caliper**

Normal ranges

(i) Triceps skin fold = 12-15 mm

(ii) subscapular skin fold = 18-20 mm

**(d) Broca index**

=Height (cm) minus 100

## Ideal Weight as per age and Height (AO -01 /2004)

Table - 4 : Male average nude weights in kilograms for different age groups and heights
(10% variations on either side of average acceptable)

| Height in Cms | AGE IN YEARS | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| | 15-17 | 18-22 | 23-27 | 28-32 | 33-37 | 38-42 | 43-47 | 48+ |
| 156 | 48 | 49 | 51 | 52.5 | 53.5 | 54 | 54.5 | 55 |
| 158 | 49 | 50 | 52 | 54 | 55 | 55.5 | 56 | 56.5 |
| 160 | 50 | 51 | 53 | 55 | 56 | 56.5 | 57 | 57.5 |
| 162 | 51 | 52.5 | 54.5 | 56 | 57.5 | 58 | 58.5 | 59 |
| 164 | 52.5 | 53.5 | 55.5 | 57.5 | 59 | 59.5 | 60 | 60.5 |
| 166 | 53.5 | 55 | 57 | 59 | 60.5 | 61 | 61.5 | 62 |
| 168 | 55 | 56.5 | 58.5 | 60.5 | 62 | 63 | 63.5 | 64 |
| 170 | 56.5 | 58 | 60 | 62 | 64 | 64.5 | 65 | 65.5 |
| 172 | 58 | 60 | 61.5 | 63.5 | 65.5 | 66 | 66.5 | 67.5 |
| 174 | 59.5 | 61 | 63.5 | 65.5 | 67.5 | 68 | 68.5 | 69 |
| 176 | 61 | 62.5 | 65 | 67 | 69 | 69.5 | 70 | 71 |
| 178 | 62.5 | 64 | 66.5 | 68.5 | 70.5 | 71.5 | 72 | 72.5 |
| 180 | 64 | 65.5 | 68 | 70.5 | 72.5 | 73 | 74 | 74.5 |
| 182 | 66 | 67.5 | 69.5 | 72 | 74 | 75 | 75.5 | 76.5 |
| 184 | 67 | 70 | 71.5 | 74 | 76 | 76.5 | 77.5 | 78 |
| 186 | 69 | 70.5 | 73 | 75.5 | 78 | 78.5 | 79 | 80 |
| 188 | 70.5 | 72 | 75 | 77.5 | 79.5 | 80 | 81 | 82 |
| 190 | 72 | 73.5 | 76 | 78.5 | 80.5 | 81 | 82 | 83 |
| | | | | | | | | |

The body weights are given in this chart corresponding to heights (in cms) on even numbers only. In respect of the heights (in cms), in between, the principle of "average" will be utilized for calculating body weights.

Table - 5 : Female average weight in kilograms for different age groups and heights
(10% variations on either side of average acceptable)

| Height in Cms | AGE IN YEARS | | | | | | |
|---|---|---|---|---|---|---|---|
| Cm | 20 | 25 | 30 | 35 | 40 | 45 | 50 |
| 148 | 38.5 | 41.0 | 42.5 | 44.0 | 45.0 | 46.5 | 47.0 |
| 150 | 40.5 | 41.5 | 43.5 | 45.0 | 46.0 | 47.0 | 48.0 |
| 153 | 42.0 | 43.5 | 45.5 | 46.5 | 48.0 | 48.5 | 49.5 |
| 155 | 43.0 | 44.5 | 46.0 | 47.5 | 49.0 | 49.5 | 50.0 |
| 158 | 45.0 | 46.5 | 48.0 | 49.5 | 50.5 | 51.5 | 52.0 |
| 160 | 46.0 | 47.5 | 49.0 | 50.5 | 51.5 | 52.5 | 53.0 |
| 163 | 47.5 | 49.0 | 51.0 | 52.0 | 52.0 | 54.0 | 55.0 |
| 165 | 49.0 | 50.5 | 52.5 | 54.0 | 55.5 | 56.0 | 57.5 |
| 168 | 50.0 | 52.0 | 54.0 | 55.5 | 57.0 | 58.0 | 59 |

Authy : DGAFMS letter No.25114/DGAFMS/DG-3A dated 14 May 2004

Table - 6 (C) : List of hygiene chemicals

| S. No. | Item | Use | Method of preparation | Remarks |
|---|---|---|---|---|
| **ADULTICIDES : As residual insecticides (for spray on walls as per stn pgme)** | | | | |
| 1. and | Deltamethrin 2.5% WP Synthetic pyrethroid with rapid knock down effect and long residual life. | Used as a residual spray against mosquitoes. Effect lasts up to 3 months. No. of spray rounds required 2/annum. | Mix 400 gm in 10 litres of water and spray over 500 Sq. m area @ 20 mg a.i. per Sq.m. | A broad spectrum insecticide can be used against other vectors pests also. |
| 2. m area | Cyfluthrin 10% WP Synthetic pryethroid with rapid knock down effect and long residual life. | Used as a residual spray Effect lasts up to 3 months. No. of spray rounds required 2/annum. | Mix 125gm in 10 liters of water against mosquitoes. @ 25 mg a. i. per Sq. m. | -do- and spray over 500 Sq. |
| 3. | Lambdacyhaloithrin 10% WP Synthetic pyrethroid with rapid knock down effect and long residual life. | Used as a residual spray Effect lasts up to 3 months. No. of spray rounds required 2/annum. | -do- against mosquitoes. | -do- |
| 4. | Bifenthrin | -do- | -do- | -do- |

| S. No. | Item | Use | Method of preparation | Remarks |
|---|---|---|---|---|
| 5. | Malathion 50% EC | Used as a residual insecticide. | | Mix 1 Litre in 10 Litres |
| of water | To be used in Malathion Organophosphorus Insecticide. | Effect lasts up to 2 months. | (5%) spray over 250 Sq m. @ | susceptible areas. 02 |
| coats | Available as amber coloured liquid. | No. of spray rounds required | 2gm a.i. per Sq m. | of spray are required to |
| be | | 3/annum. | | done to get the right dose. |
| 6. | DDT (50%) WP | Insecticide used for killing | Mix 1 Kg in 10 Litres of water | |
| and | To be used in DDT Organochlorine Insecticide supplied in powder form | adult mosquitoes. Residual effect up to one month. No. of spray round 2/annum | spray over 500 Sq. m area @ 1 gm a.i. per Sq.m. | susceptible areas. To be gradually phased out by 2007. |
| **FOR IMPREGNATION OF BEDNETS/MOSQUITO NETS** | | | | |
| 1. | Deltamethrin 2.5% SC Synthetic pyrethroid to be used specifically for | To be used as personal | Steps of impregnation of nets | Re-treatment required |
| absorption | treatment of bed nets. | every six months. It is | protective measure against | (a) Estimate water |
| | treated bed nets | mosquitoes. | capacity of net mosquito. | advisable not to wash |
| | | | (b) Add 11 ml of insecticide in the above qty of water. | frequently. |
| | | | (c) Dip net mosquito in solution till completely soaked and entire solution absorbed. | |
| | | | (d) Rub and squeeze net to ensure equal distribution in the net. | |
| | | | (e) Dry nets by laying them on ground. Once semi-dry hang on a wire in shaded area for complete drying. | |
| 2. | Cyfluthrin 5% EW Synthetic pyrethroid to be used for treatment of bed nets. | To be used as personnel protective measure against mosquitoes. | 1 ml per 1 sq.m. area in the required quantity of water @ 50 mg a.i. per Sq.m. Method of trearment as followed for deltamethrin. | Re-treatment required every six months. It is advisable not to wash treated bed nets frequently. |
| **SPACE SPRAY (To be sprayed after closing all doors and windows and open after ½ hr)** | | | | |
| 1. | Pyrethrum 2% | Used for indoor space spray. | Mix 1 litre with 19 litres of K-Oil | |
| or | To be used for quick knock | | | |
| | Natural insecticide used for space | | Diesel and spray 400 | |

| S. No. | Item | Use | Method of preparation | Remarks |
|---|---|---|---|---|
| gm hectare. | pyrethroid used during outbreaks or impending epidemics of vector borne diseases on advice of health auth. | be used during dawn or dusk. Windows and doors should be kept down of vectors. | | or K-Oil and spray @ 0.5 a.i. per open during the fogging operation. The speed of the vehicle should be about 06 Km/hr. |
| 2. | Malathion 95% Technical used for outdoor thermal fogging. | Fogging to be done during dawn or dusk when the wind velocity is low. | Mix 5 litres in 95 litres of diesel or K-Oil. | -do- |
| **LARVICIDE (For killing mosquito larvae-in water collections where breeding occurs)** | | | | |
| 1. water and when water | Fenthion 1000 EC Organophosphorus insecticide available as a brown liquid with a garlic smell. | 1. Not to be used in drinking/potable water Reapply every week. | Used as a mosquito larvicide in polluted water collections. depth is upto 10 cm. Mix 25 ml in 10 litres of water and spray over 500 Sq.m. when water depth is upto 50 cm. | Mix 5 ml in 10 litres of spray over 500 Sq.m. collections. 2. For adult mosquitoes and flies in outdoor locations mix 15 ml in litres of water and spray over 1000 sq.m. area. |
| 20 2. with stagnant/polluted | Fenthion Granules 2% | Used for mosquito larval control in water with organic pollution and weed growth. | Use 5 Kg per hectare in water upto 10 cm depth. Use 25 Kg per hectare in water upto 50 cm depth. | Is thrown (broadcast) hand in water. |
| 3. and meters. Do when used | Temephos 50% EC it is an organophosphorus insecticide available as a brown coloured viscous liquid. | Used for mosquito larval control in potable water. It has other aquatic vectors like black fly. Reapply every week. | Mix 25 ml in 10 litres of water a high mammalian safety. in potable water. | spray over 500 linear not increase the dose |
| 4. of water | Bacillus Thuringiensis var israelensis It can also be used against (Bti) 12 AS it is a Biocide that kills mosquito larval stages on ingestion | Should not be used in potable water. Available in 1200 ITU/mg potency. Repeat | (2.5%) and spray @ 1 litre per 50 linear metre. | Mix 250 gm in 10 litres larval stages of black flies. |

| S. No. | Item | Use | Method of preparation | Remarks |
|---|---|---|---|---|
| | as a ready to use bait. | required. | It is placed in the evenings and multiple dose consumption results in death of rodents. | |
| 2. with | Bromadialone 0.005% bait. It is a single dose anticoagulant. | Available as a ready to use bait. | A single dose consumption by rodents results in death. Single dose of 50 mg/Kg bait kills rats and mice. | To be used in rotation Coumatetralyl. |
| **COCKROACHES** | | | | |
| 1. | Propoxur 20% EC. It is a carbamate insecticide. Available as white to brown colour liquid | To be used for cockroaches It has rapid knock down. | Mix 100 ml in 1 litre of water and spray over 100 sq.m. area. | It is also used for debugging |
| 2. crevices of | Fipronil 0.05% Gel. It is an insecticide and of the Phenyl Pyrazole group. where cockroach infestation is present. | It can be used anywhere treatment against cockroaches. It is a safe, non-staining, odourless and extremely effective product. | To be used in crack and crevice cockroaches in kitchen and dining areas. To be reapplied when the gel is consumed by the cockroaches. | Apply in cracks and common harbourages |
| **ANTI FLY** | | | | |
| 1. is a against | Dichlorvos (DDVP) 76% EC It is an organophosphorous insecticide available as a light blue coloured liquid with high vapour pressure. | It is used as a house fly larvicide. It has a rapid knock down effect and a long residual life. | Mix 10 ml in 1 litre of water and spray over 50 sq.m. area (0.5%) | Spraying should be done under supervision as it highly toxic insecticide. It can also be used bedbugs, cockroaches, mosquitoes, fleas etc. |
| 2. water and | Diflubenzuron 25% WP. It is an insect growth regulator. | Can be used as a larvicide. It inhibits the synthesis of chitin. | It is used as a house fly spray over 10 sq.m. area @ 1 gm a.i. per sq.m. | Mix 10 gm in 5 litres of mosquito larvicide also. |
| **PURIFICATION OF WATER** | | | | |
| 1. requirement | Water Sterilising Powder White powder with strong smell of chlorine. Potency maintained only by | Used by Engrs for disinfecting For disinfecting water. It is water before issue to tps. | est by Horrock's test. Make paste Used for disinfecting vegetable | For disinfecting water- issued only to Engr Regt. and add in water |

| S. No. | Item | Use | Method of preparation | Remarks |
|---|---|---|---|---|
| 2. Engr of water | PAC (Polyvinyl Aluminium Chloride) Supplied in liquid form. potable water in | It is used to quicken the settling down of suspended impurities in water, before it is chlorinated. | It is added to water in canvas tank and stored water. if slightly turbid. ~~Add 18 ml per 1000 litres of~~ water if highly turbid. | Only to be issued to Regt/MES for supply of Add 9 ml per 1000 litres field/peace. |
| 3. till tablet | Aquatabs Available as tablets in blister packs. | For sterlising water in individual water bottle, drivers on convoy duties, patrol parties, etc. Also be issued to tps on leave/TD passing through areas of impending epidemics on advise of ~~med auth.~~ | Add one tablet in 1 litre water dissolves. | bottle. Shake the bottle |
| **OTHER ITEMS** | | | | |
| 1. face, lips. | Lip Salve ~~Issued to tps at high~~ Supplied in tubes. altitude. | A cream for prevention of cracking of lips/cheeks in cold weather. | Apply by finger or cotton on | |
| 2. | Foot Powder ~~Supplied in plastic containers.~~ Contains boric acid 6%, Starch 10%, Salicylic Acid 2%, Zinc stearate 3%, Talc 78% and Excucated Alum 1%. | It is a fungicide. Also used to ~~prevent fungal infection.~~ | Wash and dry toes, groin and ~~axilla to remove sweat and~~ moisture. Sprinkle between toes/other parts of body. | |
| 3. black water and drains/floors/ latrines. | Cresoli Liquid Black. A dark brown, oily, emulsifiable liquid. Turns white on dilution with water. | Used as disinfectant for to enter into septic tanks latrines/bath rooms/ hospitals as it damages the night etc. | For Drains- sputum mug/linen/drains in For Hospitals- Add 50 ml in 1ltr of water and steep linen/for 4 hrs before washing. Also used to disinfect | Do not allow Cresoli Add 25 ml in 1 ltr of spray along soil digesting bacteria. |

# Military Preventive Medicine

## Introduction

Mathematician philosopher Bertrand Russell had stated that man is continuously engaged in three kinds of conflicts - **Man and Nature; Man and Man; and Man and Himself** - in that order. A study of history of mankind confirms this view. Men come closer to each other when pitted against nature, be it natural calamities like earthquakes, floods, etc or day to day individual struggles against nature in finding food, clothing and shelter. Once he has conquered nature, he turns his aggression against fellow human beings the extreme spectrum of which is war. Once he has vanquished his mortal enemy he turns to self-indulgence in an attempt to avoid boredom giving rise to the modern life style diseases of overindulgence.

What took mankind centuries to experience is experienced by a soldier in a single lifetime, either in combat or preparing for combat. Deployments in alien and hostile environments, be it the Siachen glacier, the deserts of Rajasthan, or the jungles of North-East, take their toll in form of injuries and diseases due to hostile environment manifesting in cold injuries and effects of high altitude in the glacier, effects of heat in the desert and arthropod- borne diseases like malaria in the forests of North-East outnumber battle casualties. Once he survives these vagaries of nature and the uncertainties of battle, he faces periods of inactivity and perhaps loneliness, leading to ennui under stress of which some men loose their morale leading to psychiatric morbidity and incidence of sexually transmitted infections including HIV (1).

Among all the three adversaries, nature still reigns supreme. Deserts, jungles, severe cold, severe heat, and other unhealthy environments still account for most of the morbidity and mortality among the Armed Forces personnel. Any terrain is strategically and tactically disadvantageous if disease conditions are harmful to the troops operating in it.

Unit effectiveness is greatly dependent upon the health of its soldiers. Military units are unable to carry out their missions when the soldiers are weakened by disease. The success or failure of an Army, the outcome of a war, and the fate of a Nation may, therefore, rest upon how well diseases are prevented through effective preventive medicine practices in the units. For example, historical records of Armies in the field are replete with accounts of failures for which disease was a major contributing factor. This was true of Napoleon in his retreat from Moscow in 1812. Confronted with cold weather and louse borne typhus, his elite Army was almost completely decimated (2).

Napoleon's loss is understandable in view of his lack of knowledge concerning the medical threat. But, modern armies have also experienced great losses from preventable diseases. Arthropod- borne diseases alone were responsible for the loss of 16,576,100 man- days among United States Armed Forces during World War II. The entire Asia - Pacific campaign in World War II was seriously threatened by the debilitating effects of malaria (3).

During the talk of strategy of the South East Asian Campaign, Admiral Mountbatten stated, "More serious than the monsoon, however, was the incidence of tropical diseases. The jungles of Burma are infested with malaria mosquitoes, the scrub typhus mites, and the bacteria and amoebae of dysentery. Between them they presented a more redoubtable enemy than the Japanese themselves. I, therefore, set up at once an inter-service, inter-Allied medical advisory division to help the research and to organize an offensive drive against disease to be waged by the medical services. In 1943, for every man who was admitted to hospital with wounds, there had been 120 who were casualties from the tropical diseases. By 1944, these 120 men had been reduced to 20, although hospital admission still reached between 14 to 15 per thousand per week in peak periods. By 1945, the rate had dropped to ten men sick for one battle casualty and during the last six weeks of the war, these ten had been reduced to six. The enemy had no medical advisory division and appears to have made no advance in medical research. As our troops became more immune from circumstances against which the Japanese had no remedy, I was determined to enlist disease as an additional weapon on our side and deliberately chose unhealthy areas in which to fight" (4).

## Factors affecting health of troops

The impact of casualties caused by preventable diseases upon military campaigns has been a prominent and a continuous feature of military operations. From the beginning of recorded history up to the present time, Armies have had immense problems with heat, cold, and communicable diseases. It was realized in the past, as it is universally agreed today that losses of men in war from sickness far exceed the losses due to battle wounds. Frederick of Prussia said, "Fever cost me as many men as seven battles" and that saying was as true in the SE Asia Campaign during the Second World War as when uttered almost 150 years ago. The ultimate objective of a military force, success in battle, demands that troops be maintained in a constant state of good health. Among the many health hazards, there are four major components of the health threat to field forces:

(a) Heat

During the 1967 Arab- Israeli conflict, the Israelis enveloped the Egyptians, severing their lines of support. The Egyptians suffered a total of 20,000 deaths, mostly due to heat while the Israelis had no deaths due to heat and only 128 cases of heat injury. The Israelis demonstrated that health hazards, such as heat, could be as effective as tactical weapons in securing success on the battlefield. Our troops operating in the deserts of Rajasthan, also need to be protected from the ill effects of extreme heat.

(b) Cold

In World War II, during the winter of 1944- 45 in the European theatre, over 54,000 US soldiers were admitted to hospitals with cold injuries. Over 90, 000 US soldiers were admitted with cold injuries throughout the war (5). In the twenty four days the British were in combat on the Falkland Islands, they sustained 777 total casualties, 109 (or 14%) were cold injuries. When the British had the Argentinians surrounded at Port Stanley, they could have waited until the Argentinians exhausted their food and water. But they were forced by the adverse environment to attack, thus sustaining additional combat casualties. Our troops deployed in the Siachen glacier, are engaged more in the day to day battle against a bitterly cold, high altitude environment rather than frequent engagements with the enemy. The respiratory group of ailments has also increased due to these adverse environmental conditions.

(c) Arthropods

There are many species of arthropods that transmit diseases, which seriously affect military operations. Napoleon's Le Grand Armee numbered over 600,000 when it crossed the Russian border in June of 1812. Although he succeeded in taking Moscow, guerrillas, disease, and cold injury decimated his troops, forcing his retreat. Only 100,000 men returned to France. There were 70, 000 combat losses versus 430,000 losses due to disease. Of these, over 100,000 of Napoleon's soldiers were lost to louse borne typhus (6). In our conflicts with China and Pakistan, the same experience was repeated. The areas were infested with malaria mosquitoes and scrub typhus mites, and the latter disease caused at least 500 casualties in a vital combat sector . It is extremely unfortunate that valuable lessons learnt during wars are so quickly forgotten after the combat is over.

(d) Diarrhoeal diseases

These can be contracted from contaminated water or food, but in either case it can have a catastrophic impact on a fighting force as illustrated by Rommel's predicament in North Africa. Not one of Rommel's original highly successful generals was available to help him when he needed them most- at El Alamein. They had all, over time, been medically evacuated for illness. Rommel himself was not present when the battle began, he was in Germany recovering from hepatitis. His Chief of Staff and his Intelligence Officer were evacuated just prior to the battle and his Operations Officer was evacuated during the battle, all three for amoebic dysentery. In 1980, during Operation Bright Star, the US commander rewarded his troops for a job well done by allowing them to go into town the evening prior to redeployment. Thirty percent of his command contracted shigellosis and were sick with gastroenteritis on the flight back to the States.

In the field our soldiers have increased vulnerability to preventable diseases because of :

(a) The harshness of the environment, and the tactical situation, often requiring them to go into places good sense tells one to avoid. The environment may be mosquito- infested jungles; sandfly infested villages; hot, dusty deserts; or cold windy plains and high altitudes. Our soldiers and their leaders must be prepared to live and fight in such places.

(b) The disruption of the body's natural defenses. The human body has an excellent capacity to protect itself against disease and climatic injury. But the efficiency of these mechanisms is dependent upon one's overall well being. If soldiers are deployed around the world (as in UN Peace Keeping Missions), there may be disruption in their circadian rhythms. Added to this, exposure to extremes of heat or cold, meals at irregular hours, and deprivation of sleep, will result in troops who are more susceptible to illness and combat stress.

(c) Breakdowns in basic sanitation. Potable water and proper waste disposal are examples of things taken for granted in a garrison. But even using the latrine or changing socks becomes a challenge for the soldier when living in a muddy foxhole.

The Individual in a Field Environment Ordinarily, a soldier maintains a high standard of personal hygiene in a peacetime environment with convenient facilities. In the field, however, where proper sanitation requires coping with the elements of nature, problems arise; the soldier is suddenly faced with inconveniences. In a peacetime garrison, an individual follows a set course after rising in the morning. Routine acts of personal hygiene are performed in a conveniently located toilet and bathroom that is warm and has hot and cold water. However, upon arising in the field, one may feel too cold to change into clean underwear. There may be insufficient water to enable every soldier to have a daily bath and wash his undergarments. The toilet in the field is not as convenient and hygienic as the one in the garrison. An ordinarily well groomed individual may become dirty and unkempt in such an environment. Filth and disease go hand in hand. Dirty, sweaty socks may cause the feet to be more susceptible to disease. Dirty clothing worn for a prolonged period of time and unwashed hair are open invitations to lice. The problems entailed in reducing preventable diseases, therefore, pertain not only to the existing elements of nature but also to the reactions of soldiers brought into that environment. Inadequate individual personal hygiene in the field is one of the most difficult problems to overcome, because it requires a sense of responsibility on the part of each individual to try to maintain his health regardless of the difficulties encountered. This also includes the difficulty of ensuring personal prophylactic measures such as use of mosquito repellants for prevention of malaria so vital during night operations / exercises particularly when most vectors may be resting outdoors as is common in forested areas.

Reference in respect of camp sanitation are found in Susruta's works, where it was enjoined on medical men that they should be aware of the possible harmful effects to the health of troops and animals through shelter, water, food, fuel and fodder and to constantly protect the commander and his forces by taking all possible preventive measures against any harm to their health. In Chapter 7 of Mahabharata (600 BC) Karna, the

Commander-in-Chief of Kauravas warned that prevalence of fly nuisance, appearance of swarms of crows and vultures, and epidemics of intestinal diseases were sure precursors of defeat. In respect of establishment of camps for troops, it is stated in Kautilya's "Artha Shastra' (350 BC) Chapter 129, section 10, that camps should be sited by a survey party comprising of a surveyor, a combatant officer, an engineer and a meteorologist. The duties of the survey party consisted in the selection of a site with due consideration to the nature of the terrain, character of the soil, meteorological conditions such as the temperature and humidity variations, shelter from strong wind and sun to ensure its suitability appropriate to the arm or service whether at rest or in action. In the Mahabharata, in Chapter 7, instructions were issued on mobilization of Army, in respect of selection, establishment and siting of water points at such places not liable to contamination. Kautilya warned that in the field, where water is likely to be scarce, importance of pure water carried in a water cart or by each soldier on his person was not to be forgotten (7, 8, 9).

Caesar paid the utmost attention to physical fitness of his men, particularly to their bathing and to camp sanitation. Marlborough concentrated on clothing and feeding, and his Army was the best fed and clothed of its day in Europe. In Mahabharata, reference exists in respect of large stocks of provisions made available for sale to troops at controlled rates e.g., honey and ghee, in order to maintain the nutrition of the soldier. Parkes, Professor of Hygiene at the British Army Medical School, later R.A.M. College, was the first scientific military hygienist. He lived from 1819 to 1876, and his efforts to improve the living conditions of the soldier had such a remarkable and world-wide effect that, when he died, Von Moltke said; 'Every Regiment in Europe ought to parade on the day of Dr. Parkes' funeral and present arms in honour of one of the greatest friends a soldier ever had'.

Reference in respect of naval hygiene also exists. Capt Cooke, the Commander of Ships scanning the South Pacific, found the good effects of citrus fruits especially lemon in the health of the sailors. In fact, the first vitamin to be described i.e. vit C has been named after the first alphabet of his name. Nelson interested himself in the prevention of scurvy and introduced the issue of lemon in the Royal Navy, which caused the Royal Mariner (and later all British sailors) to be nicknamed "LIMEY". James Lind, a naval surgeon, who lived from 1716 to 1765, had ideas a century and half ahead of his time. He recommended the delousing of sailors and baking of their infested clothing as a means of preventing typhus; he knew as much about scurvy as we do today and his recommendation for the introduction of lemon juice in the Navy as a daily issue contributed materially to naval victories during the time of Nelson. He introduced the sand filtration of water and the production of drinking water by distillation from seawater.

### Changing pattern of morbidity in the Armed Forces

Admissions to hospitals per 1000 of strength at present in Indian Armed Forces are approximately one eighth of what they were 100 years ago. In 1870, when there was no military operational activity in India, the admission rate per 1000 of strength was 1650; in 1976 the rate dropped down to 200.77; and in 2005 it was 105.87 per 1000 (10). Besides the rate, changes in morbidity pattern in the Armed Forces over the last 100 years or so is interesting to study as it reflects changes occurring throughout the world, both in developed and developing nations, during the last century.

For the developed nations, the evolution of patterns of disease spanned more than a century and fell into three fairly distinct stages. The first, marked by infectious diseases associated with poverty, malnutrition, and poor environmental sanitation and personal hygiene, gradually gave way thanks to better housing and sanitation, greater availability to safe drinking water, and vaccination services. In the second stage, degenerative diseases such as heart disease, cerebrovascular accidents, and cancer gradually began to replace infectious diseases as the leading causes of morbidity and mortality. Finally, the third stage reflects a growing concern with health problems caused by rapid urbanization and to changing social conditions in families, communities, and the workplace which foster stress manifested by increasing violence, alcohol abuse, and drug addiction.

One of the distinguishing features of the health situation in developing countries is that, whereas developed nations went through all three stages in more than a century, developing nations must face all three at once-consequently health conditions in these countries have become a veritable "epidemiological mosaic." The man in uniform is not insulated from these developments. Changes have been observed in the Armed Forces as well, where on one hand communicable diseases are still a priority (particularly in the field and operational areas) and on the other hand there is increasing trend in non-communicable diseases and injuries.

Overall morbidity rate per 1000 of strength decreased from 1322 to 123 during the last 130 years. Incidence of communicable diseases came down from 989 to 26 per 1000 of strength and made a major contribution towards the improvement of overall morbidity incidence; non-communicable diseases also decreased but as compared with the spectacular fall in the incidence of communicable diseases, the incidence of non-communicable diseases showed a more modest fall during the same period. Similarly, the proportionate morbidity due to communicable disease decreased from 75 to 19 percent of the overall morbidity but that due to non-communicable disease increased from 25 to 81 per cent during the past 130 years. Non-communicable diseases have been less sensitive than the communicable diseases to the socio-environmental improvements or perhaps these very socio-environmental changes have promoted them by encouraging life styles involving lesser physical activities coupled with the stress of modern living and increasing aspirations. Increased motorized transport also contributes to increasing incidence of Injuries NEA which heads the list for causes of morbidity and mortality in the Armed Forces today.

Reduction in incidence of communicable disease through general improvement in the environment by exogenous methods may reach its limit in near future. Further improvement in morbidity due to both communicable and non-communicable diseases will need conscious efforts on the part of the people themselves. Health education of service personnel and their families is, therefore, of utmost importance in addition to continuance of assiduous efforts to further improve their environmental condition.

Of the non-communicable diseases, 'Injuries' (non-enemy action) is one single cause of high morbidity (23.55 per 1000 in 2005). The other group, which has been causing concern, is the group called 'stress diseases'. Effects of hot climate have been with us for a considerable long time but effects of cold climate and high attitude are the new invaders consequent to the necessity of deployment of troops in the Himalayan ranges. Among the communicable diseases, sexually transmitted diseases including HIV/AIDS have assumed major significance in view of the global pandemic of HIV/AIDS, and increasing commitment of our troops both in stressful internal security duties and overseas deployments for UN Peace Keeping Missions. Moreover, routine health education may not adequately control these diseases. They require application of behavioural sciences and enlightened military leadership.

**Important causes of morbidity and their countermeasures**

(a) Dysentery and Diarrhoea

These are essentially the diseases of active service and have been present in every campaign, often with devastating results. Experience obtained during the two World Wars indicates that the only way to reduce the incidence is by the application of the principles of general sanitation. Over the years, because of better awareness among the rank and file, the incidence of diarrhoea and dysentery has declined in the Armed Forces. The incidence of admission due to intestinal infectious diseases (excluding cholera and food poisoning) in the year 2005 was 3.44 per 1000 in the Army, 1.18 per 1000 in the Navy and 0.36 per 1000 in the Air Force. (10). However, sporadic outbreaks of food poisoning among troops are reported from time to time. This calls for continuous efforts to maintain high degree of food and water hygiene.

(b) Malaria

In addition to its specific role as a major global public health problem, malaria as a military medical problem goes back into antiquity. Malaria has the potential of incapacitating such a large number of troops that military operations may be jeopardized. In India, the Vedic medical literature recognized it as the “King of Diseases”. The incidence of malaria in Army was 4.62 per 1000, in the Navy 7.16 per 1000 and in the Air Force 1.99 per 1000 in 2005.(10)

With increasing deployment of our troops overseas in UN Peace Keeping Missions, particularly in some of the worst malaria affected regions of the world such as the African Continent, it is important that global intelligence not only of the prevalence of various parasites and vectors of malaria be known to our medical officers but also the different drug resistance patterns including recommendations for treatment and prophylaxis in different parts of the world. These should be ascertained before deployment and adequate provisions of hygiene chemicals (including repellants and synthetic pyrethroids for impregnation of mosquito nets) and appropriate antimalarial drugs should be catered for. Then only such mishaps such as an Indian officer with the UN Peace Keeping Forces at Sierra Leone succumbing to cerebral malaria in the year 1999 could be avoided.

Enforcement of the use of countermeasures is a command function. The appearance in a unit of cases of a specific disease that should have been prevented by the application of the command directed countermeasures (e.g. cases of malaria that should have been prevented with the prescribed chemoprophylaxis) should bring about an epidemiological investigation to determine if the outbreak is due to failure of the prescribed countermeasures to prevent the cases (e.g. the malaria parasites are resistant to the prescribed chemoprophylaxis) or the result of command failure to enforce the countermeasures (e.g., the soldiers are not taking the drug). If the investigation shows that the cases are due to failure of the prescribed countermeasures, then better methods must be decided upon and put in place quickly. If due to the latter, disciplinary action may be warranted. In this connection, Field Marshall Sir William Slim, commander of the British Army in Burma in World War II, in his personal diary of the period, stated: “Good doctors are no use without discipline. More than half the battle against disease is fought, not by doctors, but by the regimental officers....When mepacrine was first introduced....often the little tablet was not swallowed. An individual medical test in almost all cases will show whether it has been taken or not....I, therefore, had surprise checks of whole units, every man being examined. If the overall result was less then ninety-five percent positive I sacked the commanding officer. I only had to sack three; by then the rest got my meaning.”(11)

(c) The Rickettsial Group of Fevers

Two common forms of typhus fever have been associated with the morbidity amongst troops and these are epidemic and the scrub typhus.

(i) **Epidemic Typhus Fever :** It was a scourge of armies and the navies upto and including World War 1. Known as 'Jail Fever', 'Ship Fever', “Camp Fever' and Barrack Fever'. This was associated with louse infestation and overcrowding concomitant with wars and famines. During the World War II, outbreaks were recorded at Naples among captured German and Italian troops in 1943 and in Middle East amongst Polish refugees. The epidemiology and aetiology was studied. It made their control easier and added a great deal of knowledge for the classification of fevers in this group. With improved knowledge in the dynamics of disease process, better experience of

organization of refugee and POW camps, and better methods of disinfestation, this disease should not become a major problem again.

(ii) **Scrub Typhus :** During the Second World War there were large outbreaks of this disease with a high mortality rate in the Eastern theatre. The problems became so serious that special research teams were established to elucidate the epidemiology. With the institution of rational preventive measures e.g. use of mite repellents and avoidance of mite infested areas along with large scale use of modern insecticides, the hazard of this disease was reduced to a great extent. However, the lessons learnt were soon forgotten and during and after the operations in J&K from 1947 to 1953 there were serious outbreaks. In 1965, Indian troops occupying the Pakistan territory adjacent to Jammu and Amritsar suffered heavy casualties due to scrub typhus which could have been averted. It is observed that the incidence shoots up whenever troops are deployed for operational purposes and they fail to observe preventive measures. The incidence in 1971 and 1972 during and after Indo-Pak War was 0.12 and 0.04 per 1000 respectively. However, scrub typhus need not always be associated with operations. Time and again there have been focal outbreaks during peacetime including in a training academy where after outdoor training few officer cadets contracted scrub typhus.

(d) Plague

Homer, 3000 years ago, described the first outbreak among the Greeks at the siege of Troy. The relationship between what is now known as epizootic plague and the human plague had been appreciated in Bhagavata Purana written sometime between 700 to 500 BC. The people were warned to 'desert their homes when rats fall from the roof above, jump about and die'. The earliest official record of plague was made by Emperor Jehangir in 1612. The first serious outbreak was in Bombay in 1896 having probably been imported from Hongkong, and thence it spread to Kolkata and subsequently throughout India. A plague commission appointed to investigate into the various factors involved in the epidemiology of plague completed the report in 1904 and rationally established the role played by the rat and the rat flea in its transmission. Plague accompanied armies all over Europe from Norman days to the end of the 17th century. It was essentially a disease of the base and Comm Z area, of besieged cities and towns but not of troops on the move. With the present knowledge of its epidemiology and control measures based on rodent and flea control, judicious use of residual insecticides and efficient vaccine in prevention, drugs and antibiotics for its treatment, it is extremely unlikely that our troops will ever be seriously menaced by plague. In any case, plague has never been a disease of military camps, even when the Cantonments were too close to the infested towns. The disease made a comeback in India in September1994 after a gap of almost 30-years (after 1966), when 4 persons tested positive for bubonic plague in Beed (Maharashtra) followed by an outbreak of pneumonic plague in Surat (Gujarat). Cases were also reported from Delhi, Mumbai, Kolkata and some other places. 4780 suspected cases were reported, out of which 167 tested positive for plague and 53 deaths were reported.

(e) The Enteric Group of Fevers

These played havoc amongst the armies in the past. It is difficult to know its true incidence in the earlier wars of history but its incidence was 100 per 1000 in the S. African war of 1899-1902. In India, between the years 1890-1898, the incidence rose from 18.5 per 1000 per annum in 1890 to 36.9 per 1000 per annum in 1898. Due to its rising incidence a medical organization was set up with two objectives in view, firstly to institute bacteriological inquiries in connection with enteric fevers and secondly to undertake detailed inspection of sanitary conditions existing in unit lines. In July 1899 the importance of examining water supplies and ensuring their purity and protection was realized.

Prophylactic inoculation first invented by Prof. Arlmoth Wright of St. Mary's Hospital London was introduced for mass immunization of troops. Later, bleaching powder was introduced for purification of water by Horrocks. These preventive measures resulted in an appreciable decline. In 1907 the incidence came down to 13 per 1000 per annum and during the World War I, the incidence did not go higher than 5 per 1000 in the various theatres of operations.

The incidence of enteric fever in the Indian Army during the post-war period of 1919-33 remained between 3 and 4 per 1000. At about that period, the quality of TAB vaccine which hitherto had been prepared from the old classical strains of bacilli, was further improved by ensuring that only virulent organisms which had fulfilled certain tests, were employed in its preparation. Since the introduction of this more potent vaccine, the incidence of enteric fever in the Army 1941 came down to approximately 1 per 1000, 0.13 per 1000 in 1950 and less than 0.10 per 1000 thereafter.

The superiority of this improved vaccine was clearly demonstrated during the N.African campaign of the last world war. The incidence of enteric fever among Axis troops who were still being protected with the old type of vaccine prepared from classical strains of doubtful virulence, was much higher than that among allied troops, and assumed almost epidemic proportions among the large number of prisoners of war taken at El Alamein. Re-inoculation with stocks of captured vaccine, failed to check the spread of the diseases, but as soon as stocks of the potent vaccine became available the epidemic was quickly brought under control. On the other hand, although ideal conditions existed for the spread of enteric fever among the British and Indian prisoners of war in enemy hands, to the great surprise of the Axis medical

authorities, very few cases of enteric fever were encountered, inspite of the fact that the sanitary conditions of these prison camps were primitive. Improved sanitation, control of water supplies and care of food, both in Cantonments and in the field, had also contributed to the lowering of incidence of enteric fever. But from the mentioned facts it seems obvious that this remarkable reduction in its incidence had been mainly achieved by enforcement of the routine practice of prophylactic inoculation with the potent TAB vaccine. This fact is also corroborated with the study of the morbidity tables of Burma campaign during the last war when malaria, dysentery, viral hepatitis and typhus were responsible for high sick rate but enteric groups of fevers was at no time a serious problem.

In recent years there has been a slow but steadily increasing trend in the incidence of enteric fever in the Armed Forces. In the Army it has risen from a rate of 0.40 per 1000 in 1991 to 1.58 per thousand in 2005; in the Navy from 0.50 per 1000 in 1991 to 1.04 per 1000 in 2005; and in the Air Force form 0.30 per 1000 in 1991 to 0.67 in 2005.(10) This indicates some deficiency in the food and water sanitation as well as probable effect of advent of drug resistant strains of S typhi. Another reason may be that our troops are now less insulated from the civil environment and eateries. It also raises doubts about the complete efficacy/coverage by vaccination. The problem is compounded by the fact that the production of the vaccine (TA), by the laboratories of Government of India has stopped, but some laboratories of the State Governments are producing the same. Hence its administration and availability must be closely monitored. The feasibility of introducing the newer oral vaccines against enteric fever and monitoring their efficacy in military setting also needs to be explored.

(f) Cholera

In the past cholera has always been present among the troops both in the field and in the barracks. Cholera had been endemic in certain parts of India for a long time and had assumed epidemic proportions from time to time due to well-known causes. Troops were thus liable to contract infection in the field and in garrison towns. High mortality and ignorance of its causation created scare. Considerable research on cholera has been carried out in India and its epidemiology has been understood to a great extent. It used to be said 'you can eat cholera, you can drink cholera but you cannot catch cholera'. Outbreaks of cholera occurred in the war 1914-18 in Austria, Germany, Russia, Turkey, Palestine and Mesopotamia. Localized outbreaks have occurred in the Army from time to time.

Cholera is now commonly due to El Tor biotype. The majority of the cases nowadays are mild or asymptomatic. Epidemiological studies have shown that cholera is responsible for about 5-10% of all acute diarrhoea cases in a non-epidemic situation. Global experience of the current pandemic has shown that cholera can get introduced into any country, but can create problem only in areas where other acute enteric diseases are endemic signifying defective sanitation and unsafe water supply (12).

A new strain of cholera, code named O139, emerged in India in 1992. It spread westwardly to Pakistan and in the East to Bangladesh. In the early months of 1993, cholera caused estimated one-lakh cases and 10,000 deaths in southern Bangladesh. Although it has not spread that rapidly since then, it still remains a threat.

(g) Small pox (Obituary)

There was a time when the prevalence of the disease was very high. As a result of successful vaccination drive, surveillance and containment, it has been possible to achieve global eradication of the disease on 29 Oct 1979 with the active support of WHO. India reached the goal of smallpox eradication in April 1977.

(h) Brucellosis

Undulant fever was responsible for causing a high sick rate amongst the naval and military garrisons in Malta. David Bruce discovered the causal organism in 1884 but it was not until 1905 that a committee under the chairmanship of Bruce found goat as the reservoir of infection. The knowledge of aetiology of this disease helped in its elimination from the Army and Navy. Sporadic cases of brucellosis, both Malta fever and abortus fever, have been reported amongst the troops in India. Improved management of dairy farms under veterinary and medical supervision, pasteurization and the popular custom of boiling milk are responsible for the low incidence of brucellosis amongst our troops.

(j) Malnutrition

The task of feeding sailors and soldiers in war has always been a difficult one. Scurvy was for centuries the dread of mariners. In planning military nutrition in India one must bear in mind two facts viz., the supply of food to large bodies of troops in the field may pose a logistic problem and secondly the nutritional state of recruits on enrolment. It should be our endeavour that the troops are supplied with rations not only to subsist but also for promotion of positive health. Sometimes, however, it is not possible to deliver these rations and as a result, the nutrition of the troops may suffer. Ration scales now cater for different requirements e.g. at high attitude and for the edentulous. Vitamin C and compound vitamin tablets can be issued to the troops in emergency to prevent deficiency diseases whenever they have to subsist on freeze dried rations. Morbidity due to malnutrition has been negligible in recent years.

(k) Sexually Transmitted diseases (STD)

In 1898, incidence of sexually transmitted diseases was 30.5 per thousand per annum in the Army, which rose to 60.5 per 1000 per annum in 1920. However, it dropped to 7.5 per 1000 in 1938. During World War II there was a steep rise in the incidence of STD and reached its peak in 1943 with a rate of 49.3 per thousand. As mentioned earlier stress of war affects people in different ways; for some there is breakdown in morale leading to war psychosis, while in others it is the loosening of morals - leading to increased incidence of STDs. Both call for effective military leadership.

The post war decline in STDs began in 1946, when the admission rate was 46.6 per thousand, further coming down to 10.5 per thousand in 1951. Since 1956, the incidence has been below 4, and this downward trend continues to date as shown in Figure 6. Comparative data of the three services, in recent times show that this fall is most marked in the Navy as shown in the graph. In the year 2005, the incidence of hospital admission for STD's in the Army was 0.13 per 1000, in the Navy 0.39 per 1000 and in the Air Force 0.04 per 1000.(10)

(l) HIV infection and AIDS

There has been a gradual increase in the incidence of HIV infection in the Armed Forces since the first case of HIV was detected in the services in the year 1986. In the year 2005, the rate per 1000 for the Army was 0.13, for the Navy 0.09, and 0.03 in the Air Force. (10). Most of those infected (45%) have acquired infection from exposure to commercial sex workers (CSW) (13).

Besides, the problem in the Armed Forces has to be seen in the context of the Global and National Scenario since with increasing commitments of our forces both within the country and internationally (UN Peace Keeping Missions), there is increasing interface between the civil and military populations. Globally there are over 30 million HIV positive persons in the world, and some of the worst affected continents are Africa and Asia (these are the very places our troops are deployed during peace keeping missions). In India there are over 5 million infected with HIV. Most of the big cities such as Mumbai, Chennai, Pune, Delhi, Kolkata, Goa , and the North East are pockets of intense HIV transmission (14, 15).

Military service provides a disciplined highly organised environment in which HIV/AIDS prevention and education can be provided to a large “captive audience”. In some ways, such efforts fit perfectly well with the ethos of a profession that places a high value on loyalty to comrades and the tradition of officers looking after the welfare of troops under their command. From this perspective, HIV prevention and education is every bit as important to life and health as rescuing a wounded colleague on the battlefield or securing a position once taken.

(m) Stress Diseases

The group of illnesses called 'stress diseases' is gradually emerging in the list of important diseases. Modern civilization with its accelerated tempo of life has brought in its wake stimuli which hitherto were absent or were of such low impact that they did not stimulate the chain of psycho-physical reactions enough to cause manifest effects. Age of 'infections' is gradually passing to an age of 'stress'. Stress constitutes a chain of psycho-physical reactions which, when generated in excess of or for longer periods than necessary for physiological functions, creates manifestations of 'stress diseases'. This group broadly includes psychiatric diseases, hypertension and ischemic heart disease. Stress diseases has shown a steady incidence in the past three decades and unlike communicable diseases seems refractory to preventive measures.

About 20% of the total manpower wastage caused by invalidments and deaths can be attributed to this group of diseases. All these diseases are multifactorial in origin and have complex aetiology; but the fact that the incidence of these diseases in the western countries has been steadily increasing, indicates that the impact of modern living has definitely a bearing in the genesis of these diseases.

Even in peacetime, the occupation of the soldier exposes him to certain stressful conditions peculiar to military service. Increasing demands made on the military for internal security duties, Low-Intensity-Conflicts (LIC), aid to civil authorities, etc together with the nomadic existence of the soldier unsettling family life may increase stress among servicemen.

(n) Injuries (non-enemy action)

Like the stress diseases, the incidence of injuries (non-enemy action) also has maintained a steady trend in the past three decades and appears refractory to control measures. Injuries cause great wastage of man-days and manpower. Moreover, the money spent on their treatment and rehabilitation has increased the importance of prevention of injuries. Injuries may be sustained on roads by mechanical transport accidents, in factories or workshops, during training, during operational and tactical maneuvers, in daily routine tasks due to poor training, unsafe and careless working methods, at homes, during organized games and sports. All have their definite epidemiology and preventive aspects. It was also the leading cause of death in all the three services in the year 2005.

**The Past and the Present**

A study of the past campaigns shows that more men are lost by sickness than by enemy action and that the majority of the diseases are preventable even during active warfare. Diseases have decimated armies even before reaching the scene of operations, and expeditions have been abandoned owing to the ravages of diseases in camps. Injuries (NEA), malaria, hepatitis, psychiatric illnesses and tuberculosis are the major causes of morbidity.

**Future challenges**

The end of the cold war has substantially altered the nature of the threat to global security, and along with it the military strategic responses of the nations of the world. Military forces were formerly preoccupied with the potential for large scale, high intensity armed conflicts. The primary strategic concern now seems to have shifted to the containment of various regional ethnic and religious conflicts and to the prevention of terrorist attacks against national interests, both at home and abroad. The use of weapons of mass destruction (biological, chemical and nuclear) among warring factions or by terrorists against national targets is regarded as a distinct possibility. The effect of these trends has been to increase the mission diversity of our Armed Forces to include not only fighting war, but also peacekeeping, humanitarian assistance, and disaster relief missions, which, in turn, require the medical capacity to provide highly flexible and mobile support over long distances and in widely diverse environments. To meet these

challenges, Military medical officers, besides being well-versed in general preventive medicine, should also be conversant with the following subspeciality areas of military preventive medicine.

## Conclusion

Preparedness of Armed Forces for war depends largely on its training, equipment and its physical fitness. Physical fitness is largely the outcome of good nutrition, physical training, and absence of illness. Therefore, prevention of illness and injuries occupy a prominent position in the life and efficiency of the Armed Forces in a country. It is amply proved from the campaigns described earlier that
