## Definition and Uses of Epidemiology

The roots of "Epidemiology" can be traced back to somewhere around 400 BC, when Hippocrates had related the occurrence of human diseases to the environment in his treatise "On Airs, Waters and Places". (1). After a long lull for almost 2000 years John Graunt in 1662 and William Farr in the nineteenth century (2,3), revived the interest and laid the seeds of the modern epidemiological surveillance systems. These efforts were boosted by John Snow's field investigations of cholera epidemic in London in 1850s (4). However, it is only after 1940 that Epidemiology really expanded as a modern science, with the initiation of cohort studies at Framingham, the clinical trials of anti-tubercular drugs, the preventive trial of injectable polio vaccine, the community intervention trials of fluoridation of water supplies, and the advent of Case-Control studies on smoking and lung cancer, by Sir Richard Doll and Sir AB Hill (5-7).

In this regards, epidemiology seems to be a special field, for she has expanded very fast. Today almost every standard medical text book, be it Medicine, Surgery, Obstetrics & Gynaecology, or Paediatrics, would give a paragraph on "Epidemiology" of almost every disease. Epidemiology is therefore an all pervasive science and a basic tool for understanding and practice of all specialities of medicine (8). In fact, the understanding of epidemiology involves two things - firstly, the knowledge of the principles of Medicine; and, secondly, the knowledge of certain basic "principles" of epidemiology, which we shall endeavor to explain in this chapter.

For instance, if we, as medical person, or for that matter even an undergraduate medical student were asked to write a short essay on a common disease like malaria, the essay would read something like : " …….. Malaria is caused by a parasite called plasmodium. It is transmitted by the bite of female anopheles mosquito. It manifests as an acute febrile illness with chills and rigors. If untreated, many cases recover after a few febrile attacks but, in some, the disease may take a serious course and even some of those who recover may get a relapse. In our country out of every 1000 people, 2 to 3 are likely to get malaria every year. The disease is more common among the children, the poor people, among foreigner tourists, immuno-compromised persons, and among the agriculturists. It is commoner in North-Eastern states of our country, in rural areas and in urban slums but is not seen in highland areas. It is also much more common during and immediately after monsoons. Malaria can be prevented by spraying insecticides on water collections and on the walls of our dwellings. It can be diagnosed by a simple blood test and can be treated effectively by oral chloroquin and primaquin ……. ".

If we examine the above essay, we would appreciate that we have systematically covered certain facets, which are summarized in Table - 1. We would have covered up an essay in the same way for any other disease - IHD, HIV, Road Accidents or Neurosis.

The above facets according to which we consider any disease are, put together, nothing but what we call

Table - 1

| Facet | Example in our essay |
|---|---|
| What is the disease (Identification) | Malaria, which presents with fever & chills |
| How much is the disease (frequency) | 2 to 3 out of every 1000 people in our country |
| **How is the disease distributed according to** | |
| Person characteristics (who) | Children, poor people |
| Place characteristics (where) | Rural areas, slums, NOT in highlands |
| Time characteristics (when) | During & immediately after monsoons |
| **Why and How does it occur? (what are it's determinants)** | |
| What is the cause (etiology) | Plasmodium |
| What are "risk factors" | Foreigner, agriculturist |
| What is it's natural history | Many recover, some relapse |
| What is it's prognosis | Untreated cases may turn serious, some die |
| **What can be done about it? (How can it be prevented or mitigated?)** | |
| How can it be diagnosed | Blood test |
| How can it be treated | Chloroquin, Primaquin |
| How can it be prevented | Insectide spray, mosquito nets |
| | |

"EPIDEMIOLOGY". Epidemiology is that branch of medicine which answers the issues related to all human health problems and diseases, the magnitude that they pose, their distribution according to persons, place and time, and the various factors which determine the causation, risk, prognosis, management and prevention of the diseases.

## Definition

With the above background, we can define epidemiology as "The study of the frequency, distribution and determinants of diseases and health related states and events in human populations" and the application of this knowledge in prevention, control and mitigation of these problems ( 9-12 ). (Greek; Epi = upon, Demos = populations, logos = scientific study).

## How does Epidemiology differ from Clinical practice

Epidemiology uses the same tools and techniques as clinical medicine; however there are two major differences

(a) In clinical practice the focus is on an individual, the patient; however, in epidemiology, the focus is on a group of human beings (patients or healthy people) which we refer as "population" (13).

(b) In clinical practice there is no effort at "quantifying" by converting the findings into numbers, but epidemiology is essentially a "quantitative" science, in which the findings are analysed after converting them into "frequencies" which are numerical figures that "summarise" our findings.

## Uses of Epidemiology

There are a large number of uses of epidemiology (14), which can be broadly classified into 4 headings

### Uses in Health Care Management

Table 2 : Principal Uses of Epidemiology

| |
|---|
| In Health Care Management |
| In Understanding the disease process |
| In Public Health Practice |
| In Clinical and preventive practice |

(a) Making a Community Diagnosis

In clinical settings, the clinician makes a clinical diagnosis before proceeding to manage the case. In health care of large community, the health provider must make a Community Diagnosis" by epidemiological methods to obtain information on the important health problems and their associated socio-demographic characteristics, quantifying and summarizing them (15, 16 ). Only thereafter relevant health care for the community can be organized.

(b) Planning and Evaluation of Health Services

Any planning process will need accurate information about the socio-demographic profile, the diseases, the facilities, communications etc. Similarly, while evaluating a health programme, we will again need current information about various diseases and compare it with the "baseline" state that existed when we started the programme. This quantified and summarized information is available only through epidemiological steps (17).

(c) Developing Health Policies

Since Epidemiology is indispensable for making assessment of community "diagnosis" and "needs" and the fact that it provides " evidence based" decisions about the risks for the individuals and communities, due to various exposures, makes it a key discipline for developing Public Health Policies (18).

### Uses in Understanding the Disease Process

(a) Study of the Natural History of Diseases

what we know today of the natural course of HIV or pulmonary TB or any human disease has been possible due to systematic observations on hundreds and thousands of patients and describing the summarized findings from the observations on these large number of patients, which is only possible by epidemiological methods.

(b) Searching for the Causes and Risk Factors of Diseases

How do we say that smoking is a cause of IHD? Or, obesity is a risk factor for diabetes? It is by observing thousands of obese and non-obese people and following them forward to see what percentage in each group develops diabetes (cohort epidemiologic approach) or else by asking hundreds of IHD people compared to hundreds of healthy people about smoking history (case-control epidemiologic approach) (19, 20).

(c) Historic study of rise and fall of diseases

Small pox rose to its peak, killed millions and was finally eradicated; plague almost vanished after killing huge proportions of humanity and then again reappeared. Epidemiological studies of such rise and fall of diseases are essential to understand the various factors which can be effectively utilized in preventing the occurrence or re-emergence of other diseases.

(d) To Identify Syndromes

The idea of "syndrome" is that two or more different medical phenomena (constellation of signs / symptoms) occur more frequently together than can be accounted for by simply a "chance" association. It is only after obtaining data on hundreds of patients from various countries about signs & symptoms of a related nature, through epidemiological methods, that we are able to put the pieces of information together and identify "syndromes" and their etiological factors. For instance, till 1920s, peptic ulcer was thought to be a single entity. Based on collection of large scale epidemiological data (from death certificates and surgical records) and its analysis according to sex, social class, anatomical site and time-related trends the two entities, viz, duodenal and gastric ulcer were clearly distinguished (22, 23). More recently, obesity, central obesity, raised blood pressure, impaired glucose tolerance and raised triglycerides / low HDL-Cholesterol were all identified individually as CHD risk factors; however, only after studying the data from large number of subjects, in a consolidated manner, it was observed that these tend to cluster together more

frequently than can be expected simply due to chance, as "Metabolic Syndrome X" (24, 25).

**Uses in Public Health practice**

(a) Investigations of Epidemics and Other Field Investigations

While epidemiology, today, is involved in practically all aspects of medicine and health care, the fact remains that it originally started as the science dealing with investigations of epidemics (26) and even today, this remains one of the most important duties of the epidemiologists.

(b) Surveillance for Diseases

In addition to investigations of epidemics, disease surveillance was another important function for which epidemiology came into being. Today, we have huge national & international surveillance systems which all essentially involve epidemiological principles of information generation, consolidation, analysis and interpretation.

(c) Making Projections

Quite often we hear that there will be so many million cases of IHD in our country by 2025 and so on! How are these projections made? They are actually mathematical models developed by epidemiologists after collecting data from large populations for the past many years and then developing the mathematical models to calculate what is likely to occur in future.

(d) Assessing the Programmes for Mass Screening for Diseases

Based on epidemiological principles of "diagnostic test assessment", the mass screening programmes are planned and subsequently evaluated for their effectiveness in large population groups.

**Uses in Clinical and Individualized Preventive Practice**

(a) Assessing the effectiveness of treatment and preventive modalities

Any treatment modality, be it a drug, surgical intervention, or else any preventive modality (vaccine, immunoglobulin preparation, chemoprophylactic drug, lifestyle change, personal protective measure, etc.) has to be evaluated through the epidemiological approach of "Randomized Controlled Blinded Trial" (RCT or Clinical trial) before it can be taken up in clinical usage.

(b) Assessing Prognosis

Epidemiological studies on a large sample of patients, using the "cohort" approach are essential for evaluating the role of a prognostic factor in predicting the outcome of a disease.

(c) Assessing the effectiveness of diagnostic procedures

Any new diagnostic procedure, as a new laboratory test or a radiological test or even a clinical algorithm has to be evaluated for its diagnostic accuracy as well as utility, by studying it on a adequately large sample of patients who are all also subjected to the gold-standard test, based on epidemiological principles of "diagnostic test evaluation studies".

(d) Assisting in Clinical decision making

Modern epidemiological methods as "clinical decision trees" are being increasingly used in clinical practice for taking decisions regarding optimum clinical management of individual patients. Summary of definition and uses of Epidemiology is given in Table - 3.

Table-3 : Summary Box (Definition & Uses)

## Making Measurements in Epidemiology

### Identifying the Disease and "Case Definition"

As we have seen in the previous chapter, the first step in epidemiology is "identifying" the disease or a health event or state. Hence at the very outset, the epidemiologist must clearly give a "case definition" of the disease or health related phenomena that she is going to study. It may appear too simple but is not so in reality. If our interest is to study "tobacco use", how do we define a tobacco user? - Anybody who has even once put tobacco inside the mouth in the lifetime? Or those who smoke at least one cigarette a week? Or, who smoke at least one cigarette a day for at least three days in a week? Or, how do we say that a given child is a case of Dengue fever or not?

Apparently, one has to give some definition. This, in epidemiology, is known as "case definition". Naturally, we should have a case definition which identifies each and every person who has the disease (sensitive) and at the same time, exclude every person who does not have the disease (specific). In practice, getting a definition which is 100% sensitive as well as 100% specific is never possible, for pragmatic reasons. Hence, we draw an optimum trade-off between sensitivity and specificity, and quite often, make case definitions according to two or three levels of certainty, as "suspected", "probable" and "confirmed" (27), e.g., we may define the three levels for dengue as shown in Box above.

**Case Definition : Dengue Fever**

**Suspected**

Fever of at least two days duration with myalgia, arthralgia, retro-orbital pain and severe backache, occurring between July to October in an area where at least one confirmed case of dengue had occurred during past 3 years.

**Probable**

A clinically compatible case with a single convalescent phase serum IgG titre of 1280 or above or positive IgM.

**Confirmed**

4 fold rise in dengue antibody titre in paired sera taken at least 10 days apart, or detection of dengue virus.

Now, having defined the various diseases or health related phenomena that we are interested in studying, we need to make accurate measurements. Two essential requirements come up in epidemiologic practice when we talk of making measurements. Firstly, we should be accurately measuring what we intend to measure, i.e., the measurement process should be "valid". Secondly, since in epidemiology, we study a large number of subjects, the method of measurement should give consistent results when repeated applications are made (i.e., measurement process should be reliable or repeatable) (28).

Thirdly, in the process, we would decide the various headings on which we will make measurements on our subjects. For example, in a trial of the efficacy of a new lipid lowering drug, we would note down the age, sex, blood pressure, blood glucose, total / LDL / HDL cholesterol, whether given the standard lipid lowering drug or else the new drug, final level of various lipids after, say, 6 months and so on. In epidemiology, these various "headings" are called "Variables". Thus, Age, Sex, name of the drug administered, LDL level and so on are all "variables". A variable is thus any quality, or constituent of a subject which 'varies', i.e., likely to have a different value from one subject to another. We will enter these findings initially on individual forms for each patient and later transfer the information to a chart (manual or computerized) wherein the "value" of each of these "variables" will be entered for each patient. This chart, duly completed with all details for the required sample of patients / subjects is what is known as 'DATA'. Data can thus be defined as an organised collection of information, containing the 'values' of the various variables, which would be used to derive conclusions through analysis and reasoning. As an example, a 'Data-set' of an epidemiological study on IHD and its determinants, would look something as shown in Table - 1

In Epidemiology, depending on the manner in which the values of various variables have been measured and recorded, the data that we collect can, broadly, be either of the following types (29)

(a) Quantitative Data

It is the data which is collected in terms of mathematical figures; eg, Blood Pressure, Serum lipids, Body Weight, No. of Carious teeth etc. Since such data is recorded in

Table - 1

| Sr. No. | Name | Dyspnea grade | Waist (cms) | Hip (cms) | Body Mass Index | Tobacco smoking | SBP | DBP | Physical exercise | IHD | Blood Group |
|---|---|---|---|---|---|---|---|---|---|---|---|
| 1. | XX | 3 | 90 | 100 | 27.5 | Yes | 146 | 92 | None | Yes | A |
| 2. | AC | 1 | 84 | 96 | 23.2 | No | 132 | 78 | Regular | No | B |
| 3. | XB | 1 | 76 | 84 | 21.2 | Yes | 128 | 82 | Irregular | Yes | O |
| 5. | XY | 0 | 88 | 97 | 25.1 | Yes | 138 | 86 | Irregular | No | AB |
| 400. | AX | 2 | 92 | 96 | 26.7 | No | 148 | 94 | Regular | Yes | O |

form of numerals, one can also call it as 'Numerical data'.

(b) Qualitative Data

When information is not recorded in form of numbers but according to certain defined qualities or attributes; e.g. "Sex - Male/Female"; Outcome of treatment - Recovered/ Dead; Blood group A, B, AB or O; "Satisfied with treatment - Yes or No" etc. Both quantitative & qualitative data have 3 scales of measurement

## Quantitative

The 3 types of scales that can be used to collect such data are -

### (a) Discrete (Numerical) scale

Also called as "count" data. Information recorded on this scale has the following characteristics

(i) They correspond with a count of some sort

(ii) They are recorded as integer numbers

(iii) They can not take any decimal value

(iv) The numbers have a definite mathematical relationship.

A number of variables in epidemiology are measured on discrete scale; e.g., number of DMF teeth; no. of abortions; no. of spells of a given disease for individual subjects; no. of doses of a vaccine taken; no. of visits to the hospital and so on.

### (b) Numerical, Continuous Scale

Also known as "measured" data. Like the numerical 'discrete' scale, numerical continuous scale, also records the observations as quantities which have mathematical relationship; however the major difference is that the observations can take any value (theoretically at least) along a 'continuum' between 2 integers (and not necessarily restricted to integers as in a discrete scale). Take, for example, systolic BP. While we would generally measure systolic BP as 118, 120, 122 etc., this is only because we have calibrated the instruments accordingly. Theoretically at least, SBP can be recorded as 199, 121 etc; and can also be measured as 119.5 or 121.7, or even, for that matter, as 119.5397501 or 121.7039267 ! A large number of measurements in clinical practice are made on this scale - eg. various biochemical parameters, Body weight, height, BMI, Stroke Volume, CSF pressure and so on.

### (c) Numerical ordinal Scale

The ordinal scale uses numerical symbols for recording the data, but these numbers do not have any meaningful mathematical relationship. For example, to record the variable '"fever", we can record it as numerical values (no fever =0, Mild fever =1, Moderate = 2, High = 3). In fact epidemiologic practice is full of such examples (grades of dysponea, , grades of murmur, levels of satisfaction, grades of cancer, APGAR score, degree of relief from pain and so on). With this type of data, we would instantly think of working out the 'means of fever score'. However, it is here that the catch point lies. The numbers 0,1, 2 and 3 are not real mathematical numbers - high grade fever is not really equal to 3 times mild grade nor will a patient each of nil, mild and moderate fever added together will give a clinical state equal to high fever ! The point is important to understand because the statistical tests to be used in such situations (non-parametric) are very different from the usual parametric tests used for discrete or continuous scales.

## Qualitative Data

The peculiarity of qualitative data is that the recording of observations is not made in form of numbers as in quantitative data, but in form of words; thus it records "qualities" and not "quantities". The major 'scale' for recording the qualitative data is a "Categorical", also called a "nominal", scale in which two or more categories are made and depending on whether there are only 2 categories or else more than 2 categories, the scales are called as "nominal dichotomous" and "nominal polychotomous" respectively.

### (a) Nominal dichotomous

In nominal dichotomous there are only 2 possible alternative answers to the information being recorded; e.g. Hypertensive - Yes/No; Status - Dead /Alive; Response to treatment - Recovered/ Not recovered; Tobacco user - Yes/No; and so on. In other words, the response will be recorded as "either" - "or" of the 2 alternatives, in words, not numbers. (At this point it should be noted that the response may be recorded as '0' for No and '1' for Yes; however, in such cases, even if the response is recorded as 0 (for No) and 1 (for Yes), the scale remains dichotomous.

### (b) Nominal polychotomous

In a nominal polychotomous scale, there are more than two alternative answers or possibilities for which the information is being recorded; and the information is recorded in words, not in numbers. In addition, the categories in a nominal polychotomous scale do not have any ordered relationship, in contrast to the ordinal scale (see below) where there is a definite ordered relationship. A number of variables in medical research are recorded on a nominal polychotomous scale; eg., Blood groups (A,B, O, AB), race, religion, place of residence, hospital where treated etc.

### (c) Polychotomous ordinal scale

Sometimes, the investigator may not give numerical scores to his ordinal variables but treat them on a polychotomous (ordinal) scale. While doing so, he may not record the fever grade in numbers (0, 1, 2, 3) but in words (nil, mild, moderate, severe). The essential difference between a "polychotomous nominal" and a "polychotomous ordinal" scale is that while in the nominal scale there is no "natural" ordering of various categories, on the other hand in a polychotomous ordinal scale, the various categories have a very logical / natural ordering which cannot be overlooked. E.g., blood groups ,A, B, AB and O can be written in any sequence without any disruption in natural ordering, but grade of dyspnoea has to be written in either ascending or else, descending order. The issue is important since the statistical tests are

different for polychotomous nominal and polychotomous ordinal variables. Summary of scale of measurement is given in Table - 2.

Table - 2 : Summary (Scales of Measurement)

**Quantitative (records numbers)**
- (a) Numerical Discrete (counts)
- (b) Numerical continuous (Measures)
- (c) Numerical Ordinal (Grades)

**Qualitative (records qualities in words)**
- (a) Dichotomous (two categories)
- (b) Polychotomous (more than two categories

**Nominal (no natural ordering of categories)**

**Ordinal (natural ordering among categories)**

Col RajVir Bhalwar

## Quantitatively Summarizing the Findings

As said in the previous section, measurements in epidemiology are made in respect of 'variables' like age, sex, presence or absence of a disease (e.g. MI) and so on. For making measurements in respect of each variable, we have to specify certain 'scales' of measurement (i.e. numerical continuous, numerical discrete, ordinal, nominal dichotomous or nominal polychotomous). An organised collection of the 'values' of each and every 'variable', according to the specified scale of measurement is called 'data'. Now, this 'data-set' has a lot of scientific information but does not convey much sense. The epidemiologist should, therefore, reduce these 'values' of the 'variables' to certain 'summary' figures which convey the state of affairs and also enable him to make the desired comparisons. Depending on the type of 'Scale', the summary figures can be of the following types :

(a) For variables which are measured on a numerical-continuous or numerical-discrete scale

we would calculate the arithmetic 'mean' and make interpretations based on a single mean or on 2 or more means (see chapter on Biostatistics).

(b) For variables which are measured on ordinal scale

Here we would work out the 'median' values for making comparisons, as covered in the section on biostatistics.

(c) For variables measured on 'nominal' scale

Most of the times, we are interested in such outcomes which are dichotomous (eg, improved / not improved with a given therapy; survived / died; etc.) In such cases we work out the percentages.

Once we are dealing with dichotomous type of data, the first question that comes to us is whether we should count only the numbers or work out some frequency measure? An epidemiologist must remember that she should not go by the numbers, but proceed with some form of frequency, by relating these numbers to a denominator. See the following hypothetical example.

A study collected the total number of cases of oral cancer which occurred in a defined state in a calender year. Of the 300 such cases, all were asked about the history of tobacco chewing. The results were as shown in Table - 1

The comparison based solely on numbers would give a fallacious impression that oral cancer is two times more

Table - 1

| | Tobacco Chewers | Non Chewers | Total |
|---|---|---|---|
| Cases of Oral CA | 100 | 200 | 300 |
| Total population | 100000 | 2000000 | 2100000 |
| Rate per lakh | 100 | 10 | 14.29 |

common among those who do not use tobacco. However, when we relate the above numbers to a denominator, i.e., the total population in the same state who were tobacco users or non users, we would get the correct picture as shown in adjacent table. The correct picture that emerges is that oral CA is 10 times more common among tobacco users, since the frequency (rate) of oral Ca is 100 per lakh population among users vis-a-vis 10 among non-users.

### Second question

Which denominator to relate with? Now that we have clarified that numbers 'counted' in epidemiology must be related to a denominator for converting them into frequency, the question arises as to which denominator to use. We can have 3 types of frequency measures, depending on the denominator used (9).

**Ratio**

Where the numerator is not a part of denominator e.g. Female : Male ratio in collection of cases of Primary hypothyroidism as 8:1 is a ratio, wherein the numerator (females) are not included in the denominator (males).

**Proportion**

A proportion also has a numerator and a denominator, but in contrast to ratio, the numerator is a part of denominator. Eg, when we say that 80% of the patients of Buerger's disease are smokers, it actually means that the numerator (a) is included in the denominator (b) and hence it is a proportion. In fact, a proportion is recorded on a scale of 0 to 1. If we multiply it by 100, we get a 'percentage'.

**Rate**

The rate is a summary expression in which, in addition to

$$\frac{\text{No. of patients of Buerger's disease who are smokers (a)}}{\text{Total no. of patients of Buerger's disease (b)}} \times 100$$

the numerator being a part of denominator, there is also a relation with time. For example,

The above will be a rate in which a clear relationship to time (of one year) is also implied, i.e., "% per year"; thus,

$$\frac{\text{No. of previously healthy smokers who develop Buerger's disease in one year}}{} \times 100$$

this expression is rate.

The two most commonly used measures in epidemiological / clinical research are Incidence and Prevalence

**Prevalence**

Prevalence (often, though erroneously, called prevalence "rate") is the number of subjects having a given condition of interest out of the total subjects who were examined.

Apparently prevalence is a proportion (because the numerator is also included in the denominator) and not a

$$\text{Prevalence} = \frac{\text{No. of subjects having the condition of interest at a given time}}{\text{Total No. of subjects examined}} \times 100$$

'rate' because there is no time specification.

**Incidence rate**

The incidence rate is the no of subjects who develop a condition of interest out of a group of subjects who were initially free of the condition (but at risk of developing it), over a defined period of time. Thus,

$$\text{Incidence rate} = \frac{\text{No. of subjects who develop the condition over a defined period of time}}{\text{Total no of subjects initially free of the condition, and at risk of developing it, followed up for the required period of time}} \times 100$$

Let us give an example

In an effort to study systemic arterial hypertension at high altitude, we examined 25 young adults who were recently inducted into high altitude. 5 of them were found to be having HTN. We followed the remaining 20 who were initially normotensive for a period of 2 years posting at high altitude and found that over 2 years, 2 developed HTN.

Thus prevalence at initial exam = 5/25 X 100 = 20%

Incidence over a 2 years period =2/20 X 100 = 10% over a 2 year period (or, 5% over 1 year)

Thus, the period of time must be specified for incidence rate. An incidence of 10% over a year will have very different implication as compared to an incidence of 10% over a five year period.

The two types of incidence measures

Often, two different types of incidence measures are quoted in publications. These are

(a) Cumulative incidence (CI)

(b) Incidence Density (ID).

A brief overview is as follows

**Cumulative incidence (CI)**

This is the same as we have explained for Incidence rate above. It is also called the 'Risk Rate', or simply as 'Risk ', since it gives the risk of developing a disease.

**Incidence density (ID)**

Incidence density is thus expressed in terms of person years; it gives the "force of mortality or morbidity" of the disease of interest, reflecting the instantaneous change in the rate of disease at a given point of time. ID is the better measure in chronic diseases or survival studies where each subject is likely to contribute different follow-up periods in the study. However, in most of our routine clinical research works, where our subjects can be assumed to be a fairly "fixed population" who can all be followed up and with little inward or outward movement of the study subjects, CI is a good measure of incidence. (and also, when the time of follow up in not very long).

$$\text{CI} = \frac{\text{Total no. of subjects developing the disease over specified time of follow up}}{\text{Total subjects at the start of follow up who were at risk of developing the disease}} \times 100$$

In many diseases, the length of observation of subjects may be variable, e.g. as in table-2 when we follow up the pt for CA cervix

Table - 2

| Subject No. | Follow up details for CA cervix observed | | | | | | | | Total time |
|---|---|---|---|---|---|---|---|---|---|
| 1. | >---------- | | | | | | | * | 7 years |
| 2. | >---------- | | | | | | | * | 7 years |
| 3. | >---------- | | | | X | | | | 4 years |
| 4. | >---------- | | | | | ? | | | 5 years |
| 5. | >0 | | | | | | | | 0 years |
| 6. | - | | >---------- | | X | | | | 2 years |
| 7. | - | | | >---------- | | | | * | 4 years |
| Years | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 29 years |

>=follow up starts * = follow up ends;

0 = refused participation X = cancer detected;

? = lost to follow up

$$\text{ID} = \frac{\text{Total no. of cases}}{\text{Total person years of follow up}} \times 100$$

Thus, ID = (2 / 29) X 1000 = 70 per 1000 person years (also written as 0.07 per PY or 0.07 PY-1.

For choosing the correct incidence measure (ID or CI), it is suggested that in the usual epidemiologic health / clinical research settings, CI should be used. However, if the issue is to study the specific etiologic / risk factors or treatment modalities of chronic disease with long latency (eg, cancers, CVA etc), especially when different subjects are likely to be followed up for different periods of time (due to different points of entry into the study, migration, death, etc), then in such situation, ID should be preferred.

Table - 3 : Comparison between incidence and prevalence

| Incidence | Prevalence |
|---|---|
| Numerator consists of new cases | Numerator consists of all cases (old & new) |
| Denominator is all subjects who were at risk of developing the disease at start of follow up | Denominator is all subjects who were examined |
| Follow up is essential | No follow-up |
| All subjects examined at least twice once at start of follow up and once more at end point | All subjects examined only once |
| Is truly a "rate" | Is truly not a rate but a "proportion" |
| Gives the "risk" of developing the disease | Gives the probability of being found to be having the disease |
| Is like a "video recording" and tells how the disease occurred time | Is like a "snap shot" of what things are at a given point of time |
| Ideal for studying the natural history, risk factors and treatment | Ideal for making community diagnosis, assessing load of diseases and planning of health services |
| Expensive, time consuming | Less expensive, can be done quickly |

Col RajVir Bhalwar

## Making Comparisons between Two Summary Figures : Measurement of "Risk"

The measures of disease frequency as mean, median, incidence and prevalence, as discussed earlier, certainly do give the epidemiologist certain important answers like "serum cholesterol among patients of stroke is likely to be, on an average, 260 mg/dl", or, "the proportion of tobacco smokers among cases of acute MI is likely to be 60%, or, the incidence of acute glomerulonephritis over a 5 years period, among children who develop streptococcal sore throat is likely to be around 10%". These results give us important information for planning our preventive and curative services by way of knowing the 'load' of disease or risk factors (through prevalence), or for studying the natural history of a disease (through incidence), and for making tentative guess works regarding the role of certain risk factors or preventive/ therapeutic measures in a disease. But, most of the epidemiological questions do not stop here. The epidemiologist has to prove that the "outstanding phenomena" she has observed are really outstanding. So what if 80% of immuno-suppressed adults give history of sexual promiscuity? Even 80% of healthy adults may also give the same history ! If average serum cholesterol of stroke patients is 260 mg/dl, it may be possible that it is the same in patients of Peptic ulcer; then we cannot think in terms of hypercholesterolaemia related etiology in stroke. If 10% of persons suffering from streptococcal sore throat developed glomerulonephritis over a 5 years period, may be an equal percentage of those who never suffered from streptococcal sore throat also develope glomerulonephritis in the same period! Thus, while measures of 'frequency' strongly suggest a "causal hypothesis", they do not prove anything. The epidemiologist has to take another step - of proving that there is an "association", or "difference" , by comparing two groups, as described earlier. We show such effect by way of measures of "effect" or "difference" or "association". These measures are

### When the variables are recorded on a Numerical continuous or discrete scale

**See the following example**

To study the research question that Cancer Cervix (Ca Cx) is related to number of sexual partners, we could take 2 groups of subjects, one with Ca Cx and other of healthy ladies and take a history of total No. of sexual partners. We could work out that the average number of sexual partners among Ca Cx group was 2.1 as compared to 1.1 in the healthy group. We would now do the statistical tests for the differences between 2 means ('t' or 'Z' test) and draw conclusions. (See section on Biostatistics for details).

### When variables are recorded on an ordinal scale

For instance, we may be toying with the question "Is long term therapy of asthma with Salbutamol helpful in reducing dyspnoea as compared to the cheaper Aminophylline derivatives?" For answering this question, we would take 2 groups of comparable asthmatics, one on Salbutamol and the other on Deriphyllin. The "dyspnoea" grade of each subject would be worked out as per the grades of dyspnoea. We would finally work out the median in the two groups and compare them, eg, if median score in Salbutamol group is 1 and Deriphylline group is 2, we would do significance testing with a "non-parametric" test like Mann-Whitney U-test.

### When the variables are recorded on nominal scale

This is the setting which is most important to the epidemiologic researcher and takes the form of a "2 X 2 table". Let us illustrate with an example whether smoking is a risk factor for IHD. Now, we could address this issue by two different approaches

**First type**

We may proceed from the cause (exposure) to the disease (outcome). As an example, we took 5000 healthy adult males in whom IHD was excluded based on history and resting / exercise ECG. Then, on asking them about history of smoking we found that 1500 were smokers and 3500 non smokers. We followed up these 2 groups (1500 smokers and 3500 non-smokers) for 20 years and observed that during this period there were 150 cases of IHD among smokers and 175 cases of IHD among non smokers. This setting is a typical example of a "prospective" or "forward looking study, the details of which we shall discuss later. Our 2 X 2 table in this study would look as shown in above box.

The 2X2 table is so named because it has 2 columns and 2 rows. The two rows divide the subjects according to whether they have the exposure or not while two columns divide the subjects according to whether they developed the outcome or not. Accordingly, we get 4 cells noted at "a,b,c,d". Cell "a" denotes all those who have the exposure and also had outcome. Cell "b" denotes all those who were exposed but did not have the outcome. Cell "c" denotes all who were not exposed but developed outcome. Cell "d" denotes all those who were neither exposed nor had the outcome. One thing we would like to emphasise at this point is that you should, at the very planning stage of your epidemiologic study, clearly decide as to how you would define the exposure and non exposure as well as outcome achieved or not achieved. Secondly, never change the format of notation: cells a, b, c, d should represent what

| Exposure (E) | Outcome (O) | | |
|---|---|---|---|
| | Achieved (O+) | Not achieved (O-) | Total |
| Exposed (E+) | 150 (a) ($E^+O^+$) | 1350 (b) ($E^+O^-$) | 1500 (a+b) (all $E^+$) |
| Not exposed (E-) | 175 (c ) ($E^-O^+$) | 3325 (d) ($E^-O^-$) | 3500 (c+d) (all $E^-$) |
| Total | 325 (a+c) (all $O^+$) | 4675 (b+d) (all $O^-$) | 5000 a+b+c+d (all subjects) |

we have just explained. For instance cell "a" should always represent subjects who have both exposure and outcome; and so on. Your analysis will greatly depend on how accurately you have put the data in the 2X2 table.

Having given the notation, we would then proceed to calculate the "incidences of outcome" in the exposed ($I_E$) and non exposed ($I_{NE}$) as follows

$I_E = a/a+b = 150/(150 + 1350) = 150/1500 = 0.1$, or, 10%;

and $I_{NE} = c/c+d = 175/(175 + 3325) = 0.05$, or, 175/3500 =5%;

and the measure of effect i.e., RR (Relative Risk or Risk Ratio) is obtained by dividing the $I_E$ by $I_{NE}$. ( 30, 31). In our above example, RR = 10 / 5 = 2. We would conclude that the smokers are two times at a higher risk of developing IHD as compared to non-smokers. Against the foregoing discussion, we can now draw the following interpretations

(a) **That if RR is 1**, it means no risk, since the incidence of the outcome is the same among the exposed and non-exposed. This value of '1' for RR is also called as the "Null Value".

(b) **The higher the RR from 1**, the more is the risk. A RR of 8 would indicate a very high risk. RR is therefore a measure of the "strength of association" between the exposure and the outcome. An RR of 1.4 would mean that those having the exposure are at 1.4 times or 40% higher risk of developing the condition as compared to those not having the exposure.

(c ) **If the RR is less than 1**, it means "reversal of risk" or a "protective" effect. For example, the RR of developing IHD may be 0.6 among those who exercise regularly (exposure present) as compared to those who do not (exposure absent). In such settings, we would conclude that the risk of a physically fit person developing IHD is only 60% (or three-fifth or having a 40% reduction) as compared to one who is not physically fit. Apparently, if the RR is protective (i.e. <1) we can move on a narrow scale of '0' to '1', since RR can never be less than 0.

### The Second type of research

In a large number of epidemiological settings, the above example of 'prospective' research may be really difficult. Can we assemble thousands of subjects at the first instance and then, secondly, would it be a feasible proposition to follow up such large number of subjects for years and years - may be for a decade or two. Epidemiologists have devised an excellent, scientific short cut to overcome this dilemma. Instead of following up thousands of smokers and non-smokers for decades, seeing whether they develop IHD or not, why not undertake the easier exercise - walk down to the Cardiology centre, take 100 patients of IHD, another 100 subjects without IHD and compare them regarding smoking histories. The resulting 2 X 2 table would look like Table - 2.

Almost instantly, we would think of analysing the table to work out the RR as discussed above. However, this table is

Table - 2

| Smoking (E) | IHD (Outcome - O) | | |
|---|---|---|---|
| | O+ | O - | Total |
| E + | 80 (a) | 20 (b) | 100 (a + b) |
| E - | 20 (c) | 80 (d) | 100 (c + d) |
| Total | 100 (a + c) | 100 (b + d) | 200 |

much different. It has the following catch points.

(a) We can not calculate the 'incidence' of IHD among smokers and non-smokers because we have not started with smokers/ non-smokers and followed them up, rather, we have picked up cases / non cases which have already occurred and asked them about the history of exposure.

(b) We may try to calculate the 'prevalence' by saying that since there are 100 cases of IHD among 200 subjects, the prevalence would be 100/200, i.,e. 50%. Here again we would be wrong - these 100 cases of IHD would have come from say, 1,00,000 population and hence the prevalence would be 100/100000 i.e. 0.1%.

Thus in such a study (this is in fact the "case-control study" that we shall discuss in detail later on) we can not calculate either incidence or prevalence or RR. Then what is the use of doing such a study? The use is very much there. Epidemiologists have proved that, given certain assumptions have been met with, the odds Ratio (OR) calculated by the equation OR = (a X d) / (b X c), approximates the Relative Risk (32). Thus, in our above example, OR = (80 X 80) / (20 X 20) = 16.

This value of OR = 16 indicates that the risk of IHD due to smoking is likely to be approximately 16. There are 2 assumptions under which the OR is a valid estimator of RR Firstly, the 'controls' (i.e., the non-cases group) should be taken from the same source population that give rise to cases. Secondly, the disease should not be common, i.e., the incidence of the disease should be less than 5% (and, in fact, most of the human diseases are usually below that level , luckily for researchers). The Odds ratio as a measure of effect will have the same characteristics as RR, i.e., if it is 1, it means 'no risk'; if > 1 it indicates an increasing risk and if < 1, it indicates a protective effect. Summary of measures of risk ratio is given in Table - 3.

### Usual statistical measures of association

In addition to calculating the RR (or OR), we would do the 'Chi Square' test for finding whether the association is statistically significant or not (please refer to the section on Biostatistics). However, the epidemiologist must remember that chi square test does not tell us anything about the "magnitude" of the effect and hence can not replace the calculation of RR or OR. For example, the chi square test may give significant or highly significant result but it won't tell us whether the risk due to a particular exposure (eg. Smoking) is 1.1 times or 8 times or 0.6 times (protective). Hence we must calculate RR or OR,

Table - 3 : Summarising the Measures of Risk Ratio

- In Epidemiology, to produce the final proof of cause and effect relation, a comparison between two groups has to be made
- This comparison may be made by following forward a group of subjects with the exposure and another group without the exposure and calculating the incidence in exposed ($I_E$) and incidence in non exposed ($I_{NE}$)
- The division product between $I_E$ and $I_{NE}$ gives the 'RR' (relative risk or risk ratio). The RR is the "strength of association" between the exposure and outcome variable.
- If RR is > 1, it means increasing risk of outcome due to exposure; if < 1, decreasing risk; if = 1 NO risk (null effect)
- Farther the RR from "1", higher the strength of association
- In a retrospective (case-control or even cross-sectional) study, the incidences in exposed and non

besides doing statistical tests like chi-square.

## Measures of "Difference in Risk"

The measures of risk-ratio (RR or OR) as explained earlier are very important since they indicate to us the "strength of association" by telling us in a summary figure, as to "how many times" is the risk for those having the exposure compared to those nor having the exposure. However, that is only one facet. Besides the "ratio of risk", another important consideration is how much difference is there in risk between the exposed and non-exposed groups. Let us take the case of an advertisement which says that the cost of a new car is only two times that of a second hand car while the cost of a new music system is as much as 5 times that of a second hand one. This is apparently equivalent of the "RR". So, do we straightaway buy a new car and prefer buying a second hand music system. Well if I gave you some more data, as shown in the Table - 4, you may change your view-point.

Similarly, in epidemiology, while measures of Risk Ratio (RR and OR) are important, equally relevant are the measures of Risk Difference (RD). The most basic measure of RD is "Attributable Risk" (AR), a concept which was first

Table - 4

| | Car | Music |
|---|---|---|
| System | | |
| New | Rs. 5,00,000/- | Rs. 20,000 |
| Second hand | Rs. 2,50,000/- | Rs. 4,000/- |
| No of times : New / Old | 2 times | 5 times |

of all introduced by Levin. It is defined as the Difference in the incidences between the exposed and non exposed group. Thus, AR = $I_E - I_{NE}$. In our example on IHD, AR = 0.10 - 0.05 = 0.05. This value of 0.05 is a proportion out of 1; if we multiply by 100, we get it as 5%. To make AR more useful, two more measures of RD are derived and used

**(a) Attributable Risk (AR) % or Etiologic Fraction in the Exposed ($EF_E$)**

This is calculated as $(I_E - I_{NE}) \times 100 / I_E$. It can also be calculated as (RR - 1) X 100 / RR.

It tells us the percentage of outcome among the exposed group which is due to the exposure; conversely, if the exposed people give up their exposure habit, it would result in that much % reduction of the outcome in the exposed group.

In our example on IHD

AR% = (0.1 - 0.05) X 100 / 0.1 or else, (2 - 1) X 100 / 2 = 50%.

This means that 50% of the IHD problem among smokers is due to their smoking habit; or else, if smokers were to give up their smoking habit, it would result in a reduction of 50% in IHD among smokers.

In a case control study, since under certain assumptions, OR is a valid estimator of RR, the EFe can be calculated as :

(OR -1) X 100 / OR.

**(b) Population Attributable Risk % (PAR%) or Etiologic Fraction in total population ($EF_{TP}$)**

This is calculated as $(I_{TP} - I_{NE}) \times 100 / I_{TP}$, where $I_{TP}$ is the incidence in total population.

In our example, incidence of IHD in total population was 325 / 5000 = 0.065.

Thus, $EF_{TP}$ = (0.065 - 0.05) X 100 / 0.065 = 23%.

This means that if exposure (i.e., smoking) is removed from the total population, then it will result in a 23% reduction of the outcome (i.e., IHD) in the total population. Summary of measures of risk difference is given in Table - 5.

Table - 5 : Measures of Risk Difference (RD)

- Attributable Risk (AR) = $I_E - I_{NE}$
- AR % or, $EF_E$ = $(I_E - I_{NE}) \times 100 / I_E$ = (RR - 1) X 100 / RR
- PAR% or, $EF_{TP}$ = $(I_{TP} - I_{NE}) \times 100 / I_{TP}$

Where,

| | |
|---|---|
| $I_E$ | = Incidence of out come in exposed group |
| $I_{NE}$ = | = Incidence of outcome in non-exposed group |
| AR% | = Attributable Risk % |
| $EF_E$ | = Etiologic Fraction in Exposed |
| RR | = Relative Risk |
| PAR% | = Population Attributable risk % |
| $EF_{TP}$ | = Etiologic fraction in Total population |
| $I_{TP}$ | = Incidence in total population |

Col RajVir Bhalwar

# Epidemiological Measures (Indicators) of Health and Disease in a Community

In our previous chapter, we discussed about the "summary measures" in epidemiology i.e., incidence rate, prevalence, etc. In real health care practice, these measures are to be expressed in terms of indicators which provide a quick idea of the status of health, disease and health related conditions in the community. These measures (also called as "Indicators") can be grouped as :

(a) **Health Status Indicators** : These include Measures of Mortality and Morbidity

(b) **Indicators of health care** : (Health Infrastructure; Human Resources in health; Health Finance indicators; Indicators of accessibility & utilization).

(c) Indicators of "Quality of Life"

(d) Demographic Indicators :- measures of fertility and population distribution.

(e) Socio-economic development indicators related to health (literacy, income, accessibility to safe water supply and sanitary excreta disposal facilities, etc).

(f) Other Indirect Indicators related to health (as nutritional status, child development, environmental indicators, etc.).

## Measures Of Mortality

Measures of mortality in community health practice could be either Crude or else Specific indicators :-

### Crude Mortality Rate :

The Crude Mortality Rate, also known as Crude Death Rate (CDR), gives the deaths in a defined community in a year per 1000 population in the middle of year (i.e, on 1st July) .

$$CDR = \frac{\text{Total deaths in a defined Community / defined area in a year}}{\text{Mid-Year Population (01 July) of that community / defined area}} \times 1000$$

The CDR is useful for making "quick" comparisons regarding death rates between two population groups and for making a quick estimate of load of mortality in a given population. However comparison of CDRs between two populations may differ from each other because of confounding factors (eg, the observed differences in the CDRs of 2 populations may be because of the different age-structure of the 2 populations). Therefore, "adjustments" for such factors are made by the procedure of "standardization", to calculate "Standardized Mortality rates", by statistical methods of Direct or by Indirect Standardization. Secondly, the CDR does not tell us as to which particular "subgroups" are most affected or what are the important causes of mortality (eg, it does not tell us whether deaths are more due to TB or accidents). For this reason, "specific rates" are computed.

### Specific Morality Rates

Specific mortality rates provide more meaningful information as compared to CDR, by identifying the "risk of death" in different subgroups or risk of death due to specific diseases (35). The commonly used are

(a) Age Specific Mortality Rates (ASMR)

This is calculated as the No. of deaths in a particular age group in a defined area over a defined time period per 1000 "mid-point" population of that particular age group in that defined area

(b) Sex Specific Mortality rate

This is calculated as the No. of deaths occurring in a particular sex group in a defined area and defined period of time (usually 1 year) per 1000 Mid-point population (usually mid year population) of that particular sex in that area.

(c) Cause specific Mortality rate (CSMR) :-

The CSMR is calculated as No. of deaths occurring in a defined area due to a particular disease, in a defined period of time (usually 1 year) for every 1000 Mid point (usually mid year) population in the defined area.

(d) Cross combination of Age, Sex, cause etc.

Depending on the requirements, further combinations of age, sex, cause, occupation and so on (as relevant) may be made to further enquire and identify special risk groups. For example, we can make the cause specific (Lung CA) death rate in a specific age group (40 to 60 years) and in a specific sex (males) working in a specific occupation (Asbestos industry).

(e) Case Fatality Rate (CFR) :

The CFR is calculated as No. of persons, dying due to a particular disease, during a defined time period, in a defined area per 1000 persons in that area, having that particular disease . The CFR dose not give the risk of dying due to the given disease which a person in the defined community has or the importance of the disease as a leading cause of mortality in the community at large (that is given by cause specific mortality rate); it rather gives the "killing power" of the disease; eg, the CFR for Rabies is very high (100%); for acute MI and Japanese encephalits it is quite high (30-40%) while it is very low for common cold (almost 0%).

(f) Proportionate Mortality ratio (PMR)

This gives the proportion of total deaths that are due to a given cause, out of the total deaths. It is calculated as Total deaths due to the particular disease in a defined area over the given time divided by the total deaths (due to all causes) in that area during that time & multiplying the result by 100 to get it as a %.

While interpreting the various types of measures of mortality, the epidemiologist should be careful about certain "biases" that may occur. Such biases can occur in two ways :-

(a) Errors in the numerator

This can occur because of inaccurate or incomplete reporting of the various causes of death in large population groups; eg, in a developing country, road accident deaths may be diagnosed, recorded and reported more accurately as compared to deaths due to various neoplasms.

(b) Errors in the denominator

This may occur because of inadequate or incorrect enumeration of either the "population" or the deaths, depending on which one of the two is in the denominator.

**Special Mortality Indices Used In Maternal And Child Health Care**

(a) Infant Mortality Rate (IMR)

This is calculated as the No. of deaths among children less then 1 year age in a year for every 1000 live births in the same year in the same area. The IMR is one of the most sensitive indicators of the health and socioeconomic conditions of a community, since it is affected by diseases that directly cause infant deaths (Acute Respiratory Infections, Diarrhoeal diseases etc), by the availability and utilization of health care services & by various social factors like income, family size, customs, beliefs etc.

(b) Maternal Mortality Rate (MMR)

It is calculated as the No. of deaths due to "maternal causes" in a given community, in a year per 1000 live births in the same Year in the same area. (Maternal death is defined as death occurring to woman, while pregnant or within 42 days of termination of pregnancy, irrespective of the duration and site of pregnancy, from any cause related to or aggravated by pregnancy, but not from accidental or incidental causes). Similarly, the MMR is another very sensitive indicator of the health status of women in the reproductive age group, as well as of the obstetric services. The MMR is another very sensitive indicator of the health status of women in the reproductive age group, as well as of the obstetric services.

(c) Neonatal Mortality Rate (NMR)

This is calculated as the deaths in a year, in defined area, among children < 28 days age per 1000 live births in the same year in the same area. (Note that in IMR, MMR, and NMR, the denominator is the 'total live births' and not the mid point population of that particular group).

(d) Perinatal Mortality rate (PMR)

This is defined as the No. of foetal deaths of > 28 weeks gestation plus infant deaths of < 7 days age in a defined area in one year per 1000 "live births plus foetal deaths" of > 28 weeks gestation (i.e, total live and still births) in the same area and in the same year.

The point to be noted is that as overall socioeconomic conditions and health care systems improve, the IMR may decrease quite fast but the NMR, especially PMR may not decline so fast. This is because most of the causes of "Post-Neonatal Mortality" (i.e., deaths between 1 month to 12 months age) are amenable to good health care in the from of immunization of children, early diagnosis and treatment of acute respiratory infections / diarrhoeal diseases and nutritional care. However, the causes of NMR, and especially PMR) are less amenable to improvement in health care delivery, being often related to causes like congential malformations.

It also stands to reasoning that, since MMR, IMR and other indicators are all closely related, if the health care is improving, all of them should show decline. A decline in one without a proportionate decline in the others should initiate a search for a possible "disproportionate" development of health services. For example, a decline in MMR, without a corresponding decline in IMR may be because of much improvement in obstetric care to the community without simultaneous improvement in childhood immunization or early treatment of acute infections among infants.

## Measures of Morbidity

While mortality indicators are, by and large, "incidence measures", morbidity measures can be either in the form of incidence or prevalence and are calculated as counterparts of "mortality measures', as Crude morbidity rate, Age or cause specific Morbidity, etc. For example, the

Table - 1

| | |
|---|---|
| **Incidence** = | $\frac{\text{Total new cases of HIV occurring in a year in a community, out of those initially sero-negative}}{\text{Total persons who were 'at risk' of developing HIV at the start of follow up}} \times 1000$ |
| **Prevalence** = | $\frac{\text{Total persons in a community found to be having HIV positivity at the time of the survey}}{\text{Total persons in the community}}$ |

"annual incidence", or else the "prevalence" of HIV infection in a community will be worked out as shown in Table 1

## Measures of Fertility

Epidemiologic measures of fertility are extensively used in fields of demography, family planning and health administration. The selected indices are :-

**Crude birth Rate**

It is calculated as Number of live births in an area during one year per 1000 Mid year population. The CBR has the advantage of ease of compilation. However, the denominator in CBR is total population; on the other hand, the real contribution to the births in a population groups comes from the females in the reproductive age group (15 to 44 years age). This deficit of CBR is overcome in General Fertility Rate (GFR).

**General Fertility Rate (GFR)**

It is defined as Number of live births in a given area during a year per 1000 Mid year population of females in the reproductive age groups (15 to 44 years) in that area, during that year

While GFR is definitely an improvement over CBR, comparisons between two populations based on GFR may

not be accurate because the populations structure of ladies within the category of 15 to 45 years age may be quite different between the two population. Secondly, the GFR does not allow for indentifying the "high risk" age group of females, as far as conception is concerned, so that family planning activities can be directed towards such high risk groups. This difficulty is overcome by computing the Age Specific fertility rates (ASFR).

**Age Specific fertility rates (ASFR)**

It helps in identifying the age groups of women having the highest reproductive potential, so that family planning measures can be directed towards such groups. It is calculated as Number of live births to women in a specified age group (eg, 20 to 25 years age group) in a given area and in a given year per 1000 mid year population of females in the same age group (e.g., 20 to 25 years) in that area during that year.

**Total Fertility rate (TFR)**

This gives the estimated number of children which a group of 1000 women would bear, if they were to start their reproductive life at a common point of life, and were to pass through their entire reproductive span, subject to the current age-specific fertility rates. This measure is calculated by summing up the ASFRs for the different age groups and multiplying such sum by the class interval on which the age groups have been formed; eg, if we have made the age groups as 15-19, 20-24 years and so on (thus the class interval being 5 years), the ASFRs would be summed up and multiplied by 5 to get the TFR. The TFR is quite an accurate epidemiological measure of fertility and provides valid answer to the issue "How many children would a woman have, on an average?" (or, in case the ASFR have been calculated as per 1000, it will tell us how many children 1000 women are likely to have).

**Gross Reproductive Rate (GFR)**

is a measure of the average number of female live births that would occur to a female new born, growing up and passing her entire reproductive age, if the current fertility rate were to apply. The GFR assumes that these women will not die before completing their childbearing age, which is more of a hypothetical assumption, and this drawback is overcome through compilation of Net Reproductive rate (NRR). The GRR is thus equivalent to TFR for female children only.

**Net Reproductive Rate (NRR)**

The NRR is as measure of the average number of female live births that will occur to a newborn female as she grows up and passes through her entire reproductive age group, provided she was subjected to the current rates of fertility as well as mortality. Thus, the NRR is similar to GRR, but, in addition, also caters to the fact that some women will die before completing the child bearing age, while making the calculations. The NRR is a sensitive indicator of population growth. If the NRR is 1,00, it indicates that each generation of mother is being replaced by an exactly equal number of daughters; in other words, the female population is "maintaining itself". A large number of developing countries have kept a target of achieving a NRR equal to 1,00, as a part of their family planning programmes.

**Population growth rate**

This is also known as the natural rate of population increase. It is calculated as the difference between CBR and CDR.

**Dependancy ratio**

The dependency ratio is calculated as the ratio between Population < 20 years age + population > 65 years to the population in the age groups 20 to 64 years.

## Indicators Related To "Health Services"

These are indicators which either measure the "availability" (as, Doctor Population ratio, Population served by each Health centre, Population hospital bed ratio); or, "expenditure on health care" (as, percentage of national budget earmarked for health sector, Average finances spent per person on health care); or, "health coverage" (e.g., percentage of children fully immunized, deliveries conducted by trained birth attendants, % of cases of pulmonary TB brought under ATT, etc.); or "accessibility" (e.g., Mean distance in Kms required to be traveled in a village to reach the health centre); or, "utilization" (e.g., % of women who availed of cervical cancer screening camp out of those who were eligible); or, finally, the "policy" (e.g., availability of a stated health policy and enunciated targets).

## Indicators Related To "Quality of Life"

Some of the important indicators are

**Years of potential life lost (YPLL)**

This may be defined as the years of potential life lost due to premature death. In contrast to other mortality measures, YPLL emphasizes the processes underlying premature mortality in a population. By this method, deaths occurring at younger ages accrue more years of life lost than deaths occurring at later ages. Years of potential life lost resulting from few deaths at young ages may exceed the years of potential life lost resulting from many deaths at older ages. YPLL is often calculated using age 65 as the cutoff , with grouped age of death, and is calculated as follows, where 65 is the upper age limit established, i is the midpoint of the grouped year of age at death (e.g. 59.5 for age group 55-64) and di is the number of deaths at age "i"

$$YPLL = \sum_{i=0}^{65} [(65\ i)]d\ i$$

**Disability Adjusted Life Year (DALYs)**

This is a health gap measure that extends the concept of "Potential Years of Life Lost" (PYLL) due to premature death, to also include equivalent "Years of Life Lost due to Disability" (YLD) by virtue of being in states of poor health. The DALY combines in one measure the time lived with disability and the time lost due to premature mortality. One DALY can be thought of as one lost year of 'healthy' life and the burden of disease as a measurement of the gap between current health status and an ideal situation where everyone lives into old age free of disease and disability.

$$DALY = YLL + YLD$$

**The formula for YLL for a given cause is** : YLL = N X L, where, N = number of deaths and L = standard life expectancy at

age of death in years.

**The formula for YLD is** : YLD = I X DW X L, where, I = number of incident cases; DW = disability weight, and, L = average duration of the case until remission or death (years).

The "Disability Weights" (DW) have been discussed in the WHO report on Global Burden of Diseases 2000. Additionally, 3% time discounting and non-uniform age weights which give less weight to years lived at young and older ages are used in calculating DALYs. With above mentioned non-uniform age weights and 3% discounting, a death in infancy corresponds to 33 DALYs, and deaths at ages 5 to 20 to around 36 DALYs. Thus a disease burden of 3,300 DALYs in a population would be the equivalent of 100 infant deaths or to approximately 5,500 persons aged 50 years living one year with blindness.

YLL = N X L, where, N = number of deaths and L = standard life expectancy at age of death in years. The formula for YLD is : YLD = I X DW X L, where, I = number of incident cases; DW = disability weight, and, L = average duration of the case until remission or death (years). The "Disability Weights" (DW) have been discussed in the WHO report on Global Burden of Diseases 2000. Additionally, 3% time discounting and non-uniform age weights which give less weight to years lived at young and older ages are used in calculating DALYs. With above mentioned non-uniform age weights and 3% discounting, a death in infancy corresponds to 33 DALYs, and deaths at ages 5 to 20 to around 36 DALYs. Thus a disease burden of 3,300 DALYs in a population would be the equivalent of 100 infant deaths or to approximately 5,500 persons aged 50 years living one year with blindness.

### Sullivan's Indicator

Sullivan's indicator is a health state measure of a collection of persons which is independent of its age structure. It offers a possibility to compare health states of the entire population between two dates in spite of a modification of its age composition (provided that the

Table - 2

| Indicator | Current (Figures) | Goals |
|---|---|---|
| Crude Birth Rate (CBR) | 24.1(SRS, 2004) | 21 (NPP- 2010) |
| Crude Death Rate (CDR) | 7.5 (SRS, 2004) | 9 (NPP- 2010) |
| Total Fertility Rate (TFR) | 2.7 (NFHS-3, 2006) | 2.1 (NPP- 2010) |
| Net Reproductive Rate (NRR) | 1.5 (1990) | 1 (NPP- 2010) |
| Couple Protection Rate (CPR) | 56.3 (NFHS-3, 2006) | 60 (NPP- 2010) |
| Infant Mortality Rate (IMR) | 57 (NFHS-3, 2006) | <30 (NPP- 2010) |
| Under five Mortality | 74 (Unicef, 2005) | 41 MDG (2015) |
| Neonatal Mortality Rate | 43 (WHO Report, 2005) | ---- |
| Maternal Mortality Ratio (MMR) | 3.01 (SRS, 2003) | <1 (NPP- 2010) |
| Institutional Deliveries | 40.7% (NFHS-3, 2006) | 80% (NPP- 2010) |
| Delivery by Trained personnel | 48.3% (NFHS-3, 2006) | 100% (NPP- 2010) |
| Tuberculosis Mortality (per lakh) | 30 (WHO Report, 2006) | ---- |
| Children 12-23 months fully immunized | 43.5 (NFHS-3, 2006) | 100% (NPP- 2010) |
| Children 12-23 months who have received BCG (%) | 78.2 (NFHS-3, 2006) | 100% (NPP- 2010) |
| Children 12-23 months who have received 3 doses of polio vaccine (%) | 78.2 (NFHS-3, 2006) | 100% (NPP- 2010) |
| Children 12-23 months who have received 3 doses of DPT vaccine (%) | 55.3 (NFHS-3, 2006) | 100% (NPP- 2010) |
| Children 12-23 months who have received measles vaccine (%) | 58.8 (NFHS-3, 2006) | 100% (NPP- 2010) |
| | | |

(NFHS : National Family Health Survey; NHP : National Health Policy; NPP : National Population Project; SRS : Sample Registration Scheme; MDG : Millennium Development Goals)

Table - 3 : Calculation of Important Health Indicators

## Mortality

**CDR**

Total deaths in a community in a year X 1000
Mid year population (1st July) of that community

**ASMR**

Total deaths in a given age Gp. in a year X 1000
Mid year population (1st July) of that Age Gp.

**CSMR**

Total deaths due to a disease. in a year X 1000
Mid year population (1st July)

**CFR**

Total deaths due to a particular disease X 100
Total cases of that disease

**PMR**

Total deaths due to a particular disease X 100
Total deaths in that community during same time

**IMR**

Deaths among infants (age < 1 yr) in a year X 1000
Total live births in that year in same community

**MMR**

Deaths due to maternal causes in a year X 1000
Total live births in that year in same community

**PMR**

Foetal deaths after 28 weeks pregnancy plus Perinatal deaths of children upto 7 days age, in a year X 1000
Total live births plus still births in that year in same community

**NMR**

Deaths of children upto 28 days age, in a year X 1000
Total live births in that year in same community

## Morbidity

**Disease Incidence rate**

Total new cases of a disease occurring in a given period of follow up among those who were initially at risk X 1000
Total persons who were at risk at start of follow up

**Prevalence**

Total persons found to be having the disease X 1000

## Fertility

**CBR**

Total live births in a year in a community
Mid year population of that community

**GFR**

Total live births in a year in a community
Mid year population of females in age group 15 to 45 years in that community

**ASFR**

Total live births in a particular age group of Females (e.g., 20 24 yrs) in a year
Mid year population of females in that particular age group (e.g., 20 24 yrs)

**TFR**

$\Sigma$ (ASFRs) X class interval used for age groups

## Quality of life

**YPLL** = $\sum_{i=0}^{65}$[(65 i)]d i

**DALY** = YLL + YLD

WHERE, YLL = N X L, and YLD = I X DW X L

Col RajVir Bhalwar

## Sources of Data in Epidemiology

As we said earlier, "data" means an organised collection of individual measurements for each and every subject, in respect of each and every variable of interest. Once this data has been collected, collated and "summarised" it is called "Information". Thus, information is a "factual presentation i.e, a "Summary of facts" from the data and as they exist without any added element of interpretation of facts. Now, once this information is viewed and evaluated against the backdrop of a given "socio-demographic" setting by experts in their respective fields, it becomes transformed into what is called as "Intelligence". Obtaining data, in epidemiologic practice, may take either of the two modalities. Firstly, the investigator may decide the epidemiologic or research question, select an adequately large and representative sample, and collect the data by making measurements on each subject, herself. This situation, when the data is collected by the investigator primarily for the purpose of the epidemiologic study is called "primary data" . However, often the epidemiologist cannot be so idealistic but rather has to be more realistic, in that he may have to depend on various "other" sources of information. Such situation, when the epidemiologist utilizes the data which has been collected for some other purpose is called "secondary data" analysis. In the present chapter, we would have an overview of the various common sources of obtaining such secondary data for community health care. Such sources of information can be the following (36) :-

(a) Census
(b) Vital Statistics:-
  (i) Death certificates.
  (ii) Birth certificates.
  (iii) Registration of other vital events
(c) Health Surveys.
(d) Disease notifications
(e) Disease registries.
(f) Information for special population groups
(g) Records of hospitals and other health care facilities.
(h) Disease surveillance data.
(j) Other sources of information.

### Census

Census means "to enumerate". It consists of a sequence of activities concerned with collection, collation and factual presentation of data pertaining to social, demographic and health related factors, in respect of a nation (or, large population group), undertaken periodically, and having some sort of statutory back-up for it to be undertaken. A census, in essence, gives the information, regarding the size and composition of a population, the forces that determine such size and composition, and the trends anticipated in future. The periodicity of census kept as once in ten years, and it is generally undertaken during the first quarter of the first year of the decade. The amount of data collected may vary, from as little as population size and age / sex structure on one end to a large number of social, economic, demographic and health related variables on the other end; however, a fairly developed census mechanism would usually provide information regarding total population, density according to per square kilometers of land area, decadal growth rate, literacy rate, economic conditions, occupational characteristics, and selected indicators of mortality like overall death rate and infant mortality rate. A legal authority constituted by the Federal/ Provincial government is generally made responsible for the collection, collection, collation and publication of census data. There are two general methods of collection of data in a census :-

**de-facto method**

persons are enumerated according to their location at the time of enumeration. This method is used in developing countries like India.

**de-jure method**

This method is used in developed countries like U.S.A. The persons are assigned according to their "usual" place of residence and not according to their location at the time of census, as practiced in de-facto method. This method provides a better indication of permanent population and related socio-demographic factors of an area, though it is more expensive and needs much better level of training of census-data collectors.

In India, Census 2001 was carried out in two phases-the house numbering and the house listing operations followed by population enumeration. The house listing operation was conducted in different States and Union territories during April to September 2000. In addition to collecting data on characteristics of the house, information on availability on certain amenities and assets were also collected during this phase. The population enumeration was undertaken between 9$^{th}$ and 28$^{th}$ Feb 2001 with a revisional round from 1$^{st}$ to 5$^{th}$ March. The "census moment", i.e., the referral time at which the snapshot of the population is taken was 00.00 hours of 1$^{st}$ March, 2001. For the first time during census 2001, permanent location code numbers were assigned to ensure comparability of the data at the village and other administrative levels. Special features of Census 2001 included additional collection of data on drinking water (within premises/outside premises), source of lighting, availability of toilet facility within the house & type, number of married couples living in the household having independent room for sleeping, disposal of waste water, availability of separate bathroom & kitchen, etc. For the first time during this census, the signature/thumb impression of the respondent was taken. The salient findings were as shown in Table 1

Table - 1

| | |
|---|---|
| **Population** | |
| Total population | 1,027 million |
| Total increase in population | 180.6 million |
| Annual growth rate | 2.1% (2.5% for last 30-40 yrs) |
| Children in the age group 0-6 | 15.42 %( 17.94 % in 1991) |
| **Population Density** | 324 persons per sq km (267 in 1991) Highest density : 9,294 persons per sq km (Delhi ) |
| **Sex ratio** | 933 females per 1000 males (927 in 1991) |
| **Literacy** | |
| Overall Literacy | 65.4 % (52.2 %in 1991) |
| Male literacy rate | 75.8 % (64.1 %in 1991) |

## Vital Statistics

Vital statistics means the ongoing recording of all vital events' such as births, deaths, marriages etc. Registration of Births and Deaths is a legal requirement in our country.

**Death certificate :**

It is one of the most important source of information about the distribution of a number of diseases. The death certificate as recommended by the W.H.O is depicted in

PART I
**Disease Or Condition Leading To Death**
(a) Pulmonary Embolism Due to or as consequence of
(b) Pelvic Vein Thrombosis Due to or as consequences of
(c) Septic Abortion
PART II
**Other significant conditions contributing to death but not**

the following example :-

Part I requires the cause of death to be filled up. Cause of death is defined as “morbid condition or disease process leading directly or indirectly to death". It dose not mean the mode of dying as “heart failure” “asphyxia” “Hepato renal failure” “circulatory collapse” etc. In part-I, there are usually three lines. Here, the particular cause which started the final chain of events should be entered in the bottom most line, and this is taken to be the cause of death; on the other hand, the condition in the chain of events which finally directly led to death is shown in the top most line. In the example given above, the patient had septic abortion which is entered in the bottom most line of part-I and will be taken as the cause of death during compilations. This led to pelvic vein thrombosis which finally led to pulmonary embolism directly leading to death (note that cardiorespiratory failure is not entered as the final cause since it is the “mode of dying”). In this part II, NIDDM is entered as a significant condition contributing to death but not related to the disease causing it (i.e, septic abortion). In addition to entering the cause of death correctly, the international classification of Diseases (ICD) number of the particular cause should be entered . The problem with death certificates, regarding cause of death, is the inaccurate/incomplete filling of certificates as also inadequate reporting to the relevant statistical authority. This aspect must be especially considered if comparisons regarding cause of death are being made between two countries or areas.

**Birth certificates**

Birth certificates are useful for epidemiologic research as well as health services management; they provide a denominator data for calculating various rates. Ideally, a birth certificate should contain information about date, place of birth, details of parents, domiciliary / institutional birth, sex of newborn birth attendant's details, type of delivery and complications if any, age of mother and birth order of the child.

**Other vital events**

Other vital events include registration of marriages and divorces; reporting of still births; and reporting of foetal deaths.

## Health Surveys

Health surveys are an important source of reliable health information. Such surveys may be directed towards a particular disease (eg sample survey for TB); or, general health surveys directed towards specific population groups like a cluster of villages/ a tribal area/school children; or surveys concerned with planning and evaluation of health services in the form of survey committees appointed by the Government or private agencies to evaluate health programmes or assess general health situations and needs; or, surveys directed towards determinants of health, like dietary surveys or air/water pollution surveys. Surveys provide valuable information for planning/evaluation of health services / programmes; for identifying needs; for providing information about available health manpower and other resources; for suggesting “hypothesis” regarding individual or community risk factors; and for providing statistics for public health / educational programmes. A paradigm situation can be quoted regarding the “National Health survey” of USA.

In India, the National Family Health Survey (NFHS) is an important step for generating epidemiologic information. The NFHS-3 has provided information on population, health & nutrition in India and each of its 29 states. The main objectives are to collect data at the national and state level on demographic rates pertaining to fertility, IMR, PMR, reproductive health pattern; to measure prevalence of contraceptive practice; to collect and analyze data on HIV/ AIDS related behavior and health of slum populations. The survey is based on a sample of households which is representative at the national and

state levels. Total of 10.9 million households including 19.8 million men and women were interviewed using the method of multistage sampling, the sample being selected in two stages. Three types of questionnaire were administered in NFHS: - the village questionnaire to collect information about basic health care and education facility; the household questionnaire to collect general data about household and women's questionnaire for eligible women from household sample. The findings of HFHS 3 revealed that knowledge of HIV/ AIDS among men and women was found to be 80% and 57% respectively. In general, knowledge was found to be much better in urban setup rather than rural areas. Some findings regarding key indicators were as given in Table 2.

Table - 2

| INDICATORS | FIGURES |
|---|---|
| Total Fertility Rate | 2.7 |
| Institutional Deliveries (%) last 3 yrs | 41 |
| Contraceptive Use (%) (Currently married woman (15-49 yrs) | 56 |
| Children Immunization & Vitamin A supplementation (12-23 months fully immunized children) | 43.5 |
| Children under 3 yr who are underweight (%) | 45.9 |

## Disease Notification And Registration

At the international level, cholera, plague and yellow fever are notifiable to the WHO under International Health Regulations. In addition, Malaria, Rabies, Salmonellosis, Influenza, Polio, Epidemic (louse borne) Typhus and Relapsing Fever are subject to international surveillance. Similarly, under the national Integrated disease surveillance programme (IDSP), a number of diseases have been made notifiable. Similarly, the Indian Armed forces have a very well established programme of diseases (groups 'A', 'B', and 'C') which are notified as per format of AFMS Form 73. The general problems with notifications and registrations of diseases is the inadequacy in respect of complete coverage and the delay in initiating the notification report. However, it may be mentioned that even though under-reporting is common, still one can always monitor the trends and take action to prevent/control impending epidemics, using such information.

## Disease Registries

A disease registry keeps a record of salient features of the cases suffering form a particular disease in a defined population or geographical area. It also helps in monitoring trends of a disease . Population based as well as hospital based cancer registries have been established quite methodically in many countries over the world, including India (37).

## Information form Special Populations

Some groups have well maintained and extensive health data (eg, uniformed services, factories, mines, occupational groups, Insurance policy holders, persons covered by various health insurance programmes etc). However, one must remember that these groups have special characteristics and it may be difficult to apply the findings regarding health status and it's determinants on the general population.

## Records of Hospitals and Health Services

In developing countries with inadequate notifications of morbidity and mortality, hospital records are important tool for the epidemiologist as well as the health administrator. In addition to hospitals, records form other health services (national health programme offices, Community/Primary Health centers ) also provide valuable data. An advantage of these records is that the diagnosis is likely to be quite accurate. The disadvantage is that they tend to produce a 'biased' view of the disease picture since there may be many factors as to why patients come to a particular hospital for treatment ( eg, the patients may be having complications; or the hospital may be close by to their residence; or, may be they have the capacity to pay for the services). Secondly, hospital statistics tends to represent only a very small picture (generally the severe forms of the disease) of the actual disease in the community and hence it may be difficult to work out the 'rates' of disease occurrence from hospital or such records-based-data. The advantages and disadvantages of hospital based data have been reviewed in detail by Masi (38).

## Epidemiological Surveillance Data

Ongoing surveillance systems are generally built up in the various national health programmes. Such data can be used for calculating the incidence of the particular disease by relating it to population size being served by the surveillance system. Similarly, 'sentinel surveillance' data from selected hospitals can be utilised for various epidemiological purposes.

## Other Sources of Information

Depending on the information needs, the epidemiologist may need data from the meteorological / environmental

**Box - 1 : Important sources of epidemiological data in indian armed forces**

- Annual Health report of the Armed Forces issued by the DGAFMS
- Annual Health reports of Army, Navy & Air Force issued by respective DGsMS
- Notification of notifiable diseases (groups 'A', 'B' & 'C') raised by admitting hospitals on AFMSF 73
- AFMSF 40 & 42 showing monthly details of admissions & discharges, with diagnosis, raised by individual hospitals
- Monthly reports on HIV / AIDS & HAPO issued by Armed Forces Central Epidemiological Surveillance Centre (AFCESC) and AIDS Control Organisation (ACO) functioning at Dept of Community Medicine, AFMC, Pune.

Box - 1 (Contd.)

- Notifications of HIV infection (ACO Forms 1 & 2) and HAPO (HAPO Forms 1 to 4) raised by individual hospitals and sent to AFCESC / ACO
- Monthly Health Report initiated by Station Health Organizations (SHOs) and Preventive Medicine Staff Officers of various formation HQs
- Daily Hospital Admission & Discharge Registers of military hospitals
- Laboratory investigations registers of military hospitals.
- Strength returns forwarded by individual military units to the SHOs and feeding returns forwarded to Army Supply Corps (ASC) units (for denominator data)
- Reports of epidemic investigations forwarded by individual SHOs to AFCESC
- Reports of various health surveys undertaken by Preventive Medicine and Clinical Specialists
- Documents maintained by Regimental medical Offrs (RMOs) : barrack treatment register, sanitary diaries and register of low medical category persons
- Individual Health Record Cards maintained for All ranks both by the military units and individuals

Col RajVir Bhalwar

# The Epidemiologic Method (Designs) : (a) Descriptive Studies

The various aspects covered till now deal with the basic, fundamental principles, a knowledge of which is essential for any type of Epidemiologic practice. However, once the correct epidemiological question has been asked and due consideration has been given to the various basic principles dealt with earlier, the worker has to select out the particular type of epidemiological "design", most suitable for the question ((39). As described earlier, any epidemiologist would be, very broadly, undertaking one of the following 2 types of exercises :-

- We may be simply 'describing' a phenomena of interest, expressing it in terms of a measure of health or disease (as mean, median or incidence or prevalence). In such instances, we do not have a 'preformed hypothesis' regarding cause and effect relationship (ie., this particular 'exposure' leads to that possible 'outcome'). It is only after a 'descriptive study' has been completed that the researcher, based on the results of the study, develops one or more hypothesis regarding causal association. Such studies are called the "Descriptive Studies".
- The second general situation is that investigator may be proceeding with a "preformed hypothesis" regarding a cause-effect relationship (ie., this 'particular exposure' leads to that particular 'outcome'). In other words, the investigator proceeds to invstigate his hypothesis of cause-effect relationship between a possible exposure and postulated outcome. These studies are called 'Analytical Studies".

## Descriptive Studies

As stated earlier, on a number of occasions the epidemiologist does not have any preformed hypothesis regarding a cause - effect relationship. His object is, rather, to describe certain clinical or health related phenomena and, at the end of study, to develop some sort of hypothesis regarding a possible cause-effect relationship, which can be further subjected to evaluation by analytical studies. In medical research, the various settings in which the investigator may undertake descriptive studies are :-

- Describing certain health related variables and their "distribution" (eg, mean serum cholesterol among patients of IHD or among healthy people, and the distribution of serum cholesterol according to age, sex, time of day etc).
- Describing the "Natural history of disease" (eg, progress of untreated HIV +ve/AIDS patients) or "Natural history of health related phenomena" (eg, growth and development among children).
- To describe the load of a disease (eg, prevalence of TB in community) or a health related factor (eg, prevalence of smokers) or to describe the available health services, usually with a view to plan the health services.
- To describe the occurrence of a disease (eg, 'incidence' of poliomyelitis among children) or a health related phenomena (incidence of death among patients who suffer from CACx).
- To describe the occurrence of an interesting clinical or health related "episode(s)" (e.g. description of a case of a given disease, presenting with atypical symptoms).

A descriptive study gives a strong suggestion that a causal association may be present but doesn't prove it. Eg, the incidence of acute glomerutonephritis among children developing sore throat may be described as 10%. This gives a strong indication that sore throat may be causally related to glomerulonephritis; however for proving such an association, one has to do an analytic study by comparing the incidence of acute glomerulonephritis in two groups - a group which had suffered from sore throat and another that did not. Thus, a descriptive study does generate hypotheses; however to prove them, analytical studies are required.

As is evident from the nomenclature, a descriptive study "describes" our findings of the epidemiologic study. Such descriptions are given according to three types of epidemiological variables, namely, distribution of the disease according to time (when does the disease occur), place (where all) and persons (who all are affected). It is desirable to compile and analyse the data as per these three variables for certain reasons. Firstly, we become intimately familiar with the data and the extent of public health problem due to the disease. Secondly, it provides a detailed description of the health of a population which can be easily communicated Thirdly, such analysis identifies the subgroups that are at high risk of getting the disease and these clues can be used to plan the health services as well as converted into testable hypotheses.

### Time

Disease rates change over time. By knowing that malaria will increase during monsoons, health administrators can time their insecticidal spray rounds. Some other diseases make unpredictable changes over time. By examining events that precede an increase or decrease in disease rates, we may also identify possible causes and appropriate actions to control further occurrence of a disease.

We usually show time data as a graph. We put the numbers (or, preferably, "rate") of the disease along the vertical ('Y') axis and the time periods along the horizontal ('X') axis. Such a graph provides a simple visual depiction of the relative size of a problem, its past trend and future course, as well as how other events may have affected the problem. Depending on what event we are describing, we may be interested in periods of decades, or annual or monthly or weekly or daily periods along the 'X' axis. In general, for infectious diseases, the unit of time along the 'X' axis should be a quarter of the median incubation period of the disease. Thus, for clostridium perfringens food poisoning it could be 3-hourly period, for cholera, daily, for hepatitis A , weekly and monthly for hepatitis B. Depending on the length of period used along the 'X' axis,

we can have secular type of graphs, cyclical and seasonal graphs or short term variations, as follows :-

Secular Trends

Plotting the annual cases or rate of a disease by bi-annual, 5-yearly or decadal period for one or many decades shows long term changes or "secular trends" in the occurrence of a disease. These can be used to

(a) Predict the future course of the disease.

(b) Evaluate programs or policy decisions ( as a slight decline in incidence of IHD in USA, after 1980, seen in decadal secular trends from 1940 to 1990, could be related to extensive anti smoking campaigns during 1960s and 70s)

(c) Hypothesize as to what could have caused the changes in incidence (as a decline in tuberculosis in developed countries during initial period of 20th century, even though vaccine or chemotherapy was not still available, led to the hypothesis that improved housing and economic status could be preventive.

Seasonal pattern are studied by plotting the disease incidence according to 3-monthly (preferably monthly) periods for at least 2 to 3 years. Increase in incidence during particular seasons (malaria during monsoons, measles and scabies during winters, etc.) could also help us in generating possible hypotheses about the factors that facilitate the transmission of these diseases, besides planning the preventive measures well in advance.

Cyclical patterns

Some diseases show a spike in incidence after every 2 to 3 years or such regular periods. This is called as "cyclical pattern" and is seen in diseases like malaria, measles, etc. We may hypothesis that this may be due to collection of "susceptible, immunologically naive" people during the intervening period.

Short Term Fluctuations

Herein we plot the occurrence of diseases over short periods as monthly, weekly, or daily (or even hourly in a disease like food poisoning). Regular plotting of disease according to such small time interval helps us in undertaking 'surveillance" of these diseases and getting an early warning of an impending epidemic. If the time period of interest while plotting such short term fluctuation is one when an epidemic is actually occurring, the line diagram or the histogram depicting it is more specifically called the "epidemic curve". As said earlier, the optimum time interval along the 'X' axis would be a period which is about one-fourth of the median incubation period for that disease. The epidemic curve can give a lot of insight about the possible factors which led to the transmission and the possible point at which the infectious agent was introduced into the vehicle. The following are certain types of epidemic curves

(a) Point source

Classically seen in food poisoning outbreaks and shows

(i) A tight clustering of cases in time (nearly all cases occur within 1.5 times incubation period, if the disease agent is known).

(ii) It has a sharp upslope, a well defined peak and a trailing down slope.

(iii) The peak generally coincides with the median incubation period.

(iv) The approximate time of exposure may be pinpointed by counting back the median incubation period from the peak, the minimum incubation period from the initial cases and the maximum incubation from the last case. These three points of time would generally bracket the time of exposure.

(v) Sometimes, a point source outbreak of communicable disease produces a substantial number of infected individuals who, themselves, may serve as sources of agent to infect others. In such instances, secondary cases may appear as a prominent wave separated by the point source peak by about one incubation period. If the incubation period of the disease is short, this secondary wave may appear only as a more prolonged downslope. Such a graph is called as "point source with secondary transmission" (41)

(b) Common, Continuous Source Epidemic Curve

In contrast to point source, outbreaks may also arise from common sources that continue over time, known as "Common, Continuous Source"(42), as may happen when a water pipe line gets cross-connected with sewage pipe and the contamination continues till such time this is repaired. In such situations, the epidemic curve will have following characteristics :

(i) Rise sharply but the peak will be a gradual pleatau rather than a sharp peak.

(ii) The downslope may be sudden and sharp if the common source is removed (as repair of cross connection in above example) or else will be a gradual downslope if the common source gradually exhausts itself.

(c) Propogated curve

This is seen in cases of disease agents that are communicable between persons either directly or through an intermediate vehicle. The curve encompasses several incubation periods, begins with a small number of cases and rises with a gradually increasing upslope; often a periodicity which is equivalent to the generation period of the agent may be seen during the initial stages of the outbreak. After the peak occurs, the exhaustion of susceptibles usually results in a rapid downslope. Propogated curves are classically seen in airborne / droplet infections as mumps, measles; in STDs; and in insect vector borne disease outbreaks (43).

### Environmental Epidemic Curves

As a special case of propogated outbreaks, we have the "environmental" epidemic curves, which reflect complex interactions between agent, host and environmental factors which lead to the exposure of human beings. Such curves last for quite long, over many incubation periods. They differ from propogated curves in that they do not show the periodicity equal to the generation time in the initial stages and the downslope may not be as rapid as in propogated epidemics. In such cases we should attempt to represent the suspected environmental factor along with the curve, to give a clear idea of the possible association; for example while plotting an epidemic of leptospirosis, we may also present the weekly rainfall curve along with the epidemic curve to support the hypothesis of the importance of rainfall and water logging in transmission of leptospirosis.

**Place**

We describe a health condition by place to gain insight into the geographical extent of the problem. For such depiction, we may use a number of place related variables, as place of nativity, place of usual residence, place of work, school, district, hospital unit, etc., depending on which, as we suspect, may be related to the health event being studied. Often, rural versus urban or national vs. foreign differences, or larger place denominations as countries or continents may be plotted.

Although we can show the data in a table, it is often better to show it pictorially in a map, where we can use different shadings or colours to depict different numbers or rates of disease occurrence in different areas. Such depiction, especially when done for a localized area during an epidemic investigations is called as "spot map".

Looking at the differences in disease numbers or rates according to different places, we can generate worthwhile hypotheses about the factors that may be concerned with the transmission of the disease. For instance during the initial investigations of "American" (murine) typhus, Maxcy developed a spot map and found that the disease was clustered in the commercial areas which had a large number of granaries and not in residential areas which was expected for "european" (louse) typhus. This led to the hypothesis that in USA, typhus may be associated with rats (and not with louse as was the case with epidemic (European) typhus). Finally a different typhus (rat flea borne) was identified (44).

**Person**

There are a very large number of "person" related variables which could be available to us for describing the diseases. These may be classified into

(a) Firstly, the inherent characteristics of a person (age, sex, genetic background, blood group, ethnicity, serum cholesterol, and so on);

(b) Secondly, their acquired characteristics (immune status, marital status, etc);

(c) Thirdly, their activities and lifestyle variables (occupation, use of medications / tobacco / alcohol, leisure time activities, physical exercise, diet, etc)

(d) Fourthly, the conditions under which they live (housing, water supply, economic status, availability of health care, etc).

These various categories determine to a large extent who is at higher risk of acquiring the disease or health outcome that is of interest. We may show person related data either as "frequency tables" or a graphical representations (see chapter on biostatistics for details).

While analyzing data according to person characteristics, we must try to assess a number of different type of person variables, before we find which are the most meaningful and enlightening. Age and sex are most crucial; we almost always analyze data according to these. Besides these, depending on the disease and what may be relevant, we may study the data according to socioeconomic status, educational status, race, family history, marital status, blood group, blood sugar levels, height, weight, and so on. Sometimes we may analyse data into more than one category simultaneously. For example, we may look at age and sex simultaneously to see whether sexes differs in how they develop a condition that increases with age as it happens for heart disease.

### Developing the Hypotheses in a descriptive Study

After having studied the distribution of various time, place and person related variables, we make certain tentative guess-works, which we call "hypotheses". These guess-works are made by observing as to which person variables are very common among the disease. For example if we find that among cases of IHD which we studied, 70% are males, 80% are aged more than 45 years, 65% have waist circumference of > 94cms, 50% give history of IHD among first degree relatives, 15% have blood group 'A', 5% have brown coloured iris and so on, then we start hypothesisng that middle age, male sex, central obesity and family history may determine the occurrence of IHD while blood group 'A' and brown iris may not. But, do note that we only develop "hypotheses" based on descriptions of person, place and time variables. The final proof has still not come, as we shall explain in the next chapter.

Col RajVir Bhalwar

# The Epidemiologic Method (Designs) : (b) Analytical Studies

In contrast to descriptive studies, in analytical studies, the investigator proceeds with a 'preformed hypothesis' regarding a "causal exposure". A large number of epidemiological and health research questions are answered by undertaking analytical studies. The various settings in which the epidemiologist proceeds to establish a relationship between exposure and an outcome may address issues related to treatment, preventive or diagnostic modalities, or regarding the role of a risk factor

Table - 1 : Issues in which "comparative" (analytic) studies are required

**Risk factor** : e.g., "Is tobacco smoking a risk factor for IHD (as compared to when people do not smoke)?"

**Prognostic marker** : e.g., Is appearance of malena in viral hepatitis associated with increased mortality"? (as compared to when malena does'nt appear)

**Treatment modality** : e.g., can "Dopexitine be effective in treating premature ejaculation"? (as compared to when only placebo is given)

**Preventive modality** : e.g., " Can use of condom be effective in preventing STDs among promiscuous persons"? (as compared to when condom is not used)

**Diagnostic modality** : "Can a combination of cold intolerance and unexplained weight gain diagnose hypothyroidism"? (as compared to the gold standard of T3, T4 and TSH).

or prognostic marker (Table - 1).

The key word in analytical studies is "COMPARISON". The basic protype of such comparative research is the 2 X 2 table which we have already explained at length, earlier in chapter 4 of this section and which gives us the notations E+, E-, O+ and O-. Now, "Comparison" of the two groups in any analytical study can be made in either of the two methods :-

Either we take a group with the exposure ( E+) and another without it (E-); follow them up for a reasonable period of time and observe how many in each group have developed the outcome (D+); eg, we can collect two groups of subjects, all free of colonic CA, one group eating low fibre diet and another eating high fibre diet; follow up both these groups for 15-20 years and see how many in each group develop colonic CA. The comparison would then be made between "those who develop the outcome out of total exposed" (i.e., a / (a+b) and "those who develop the outcome out of the total not exposed", (ie., c / (c+d). This can be demonstrated as

$$\text{Criteria for comparison} = \frac{a/(a+b)}{c/(c+d)} = I_E / I_{NE} = RR$$

In case this resulting figure from this comparison is "much more than normally expected" (the "normally expected" being defined by statistical tests) we would conclude that the exposure is definitely associated with (or, carries a high risk of) the outcome.

The second way of doing the comparative analysis could be to collect a group of subjects who have already developed the outcome (D+) and another group of subjects who do not have the outcome, and then interrogate all the subjects regarding history of exposure (E+ or E-) eg, we may take a group of patients already suffering from colonic CA (D+) and another not suffering (D-) and take the history of low dietary fibre intake during last 15-20 years from all of them. In this contingency the comparison would be made between "those with the outcome having the exposure" (ie., a / (a+c) and those without the outcome but having the exposure b / (b+d). The comparison thus would be

$$\frac{(E+D+)/(a+c)}{(E+D-)/(b+d)}$$

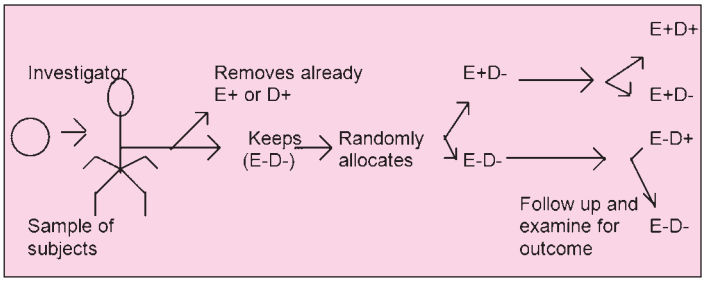
If the result is much more than 'normally expected' we would conclude that the association exists; i.e., the exposure carries a risk of the outcome.

## Individual types of Analytical Designs

### The ideal setting

The most scientifically reasonable setting would be, apparently, when the researcher collects a group of subjects in which neither the exposure not the outcome have occurred; ie., all subjects are initially "E-D-". Now the researcher "randomly allocates" these subjects into two groups, so that both these groups are exactly similar to each other in all respects. Now, one of the groups is deliberately given the exposure (ie., made to become E+D- from E-D-) and the other group is not given the exposure (ie., continues to be E-D-). The investigator now follows up both these groups over a reasonable period of time to see how many in each group become D+ and makes the comparison as

$$\frac{(E+D+)/(a+b)}{(E-D+)/(c+d)}$$



This type of research design is called the **'Experimental"** or **"Intervention"** design. This is scientifically the most suitable because :

Since it is the investigator who decides (on a random basis) and allocates the exposure, the possibility that "subjects might have taken up the exposure due to natural selection factors which may also be related to the outcome" is ruled out. For example, if we compare a group of children who have been already given measles vaccine and follow them up to see the occurrence of measles in each group, the possibility exists that children who have already been given measles vaccine are also possibly the ones who belonged to better socio-economic status, better housing, better nutrition, less overcrowding etc, and hence the lowered occurrence of measles in this group may not be due to vaccine per se but possibly because of the other factors. However in an Experimental (Intervention) design, the investigator will firstly take in only those children who have still neither been given measles vaccine nor developed measles (E-D-), (excluding those who have already been given the vaccine (E+) or who have already suffered from measles (D+). Secondly he would "randomly allocate" this E-D- subjects into 2 groups, one getting the vaccine (E+D-) and another not getting it (D-D-); since the division is by "randomisation", both the groups will be exactly equal to each other in respect of all other factors (like socio-economic status, nutritional status, housing etc). Hence no objection of the type as mentioned in the foregoing example on measles can be made against this design. (see chapter on Sampling Methods in section on Biostatistics and chapter on clinical trials in section on research Methodology for further details on randomization).

(a) Since the outcome has been excluded from both the groups to start with, (the investigator takes only E-D- to start the study) and then both the groups are followed up over a period of time for the development of outcome (D+ or D-), one is definite that exposure preceded the outcome; ie., the absolute requirement of "temporality" for a "cause-effect" relationship is fulfilled.

(b) Since the exposure status (E+ or E-) has been recorded by the investigator himself at the start of the study, there is no possibility of recall 'bias' which could happen if the investigator was asking the history of "exposure" from the subjects who have already developed the outcome (D+ or D).

This type of research, while the most scientifically sound, suffers from the outstanding problem that while studying "risk factors", "markers" and "prognostic factors" it is impossible for the investigator to randomise the subjects into two groups - one getting the exposure and the other not. Eg, in a study of the association between cigarette smoking (exposure) and Lung CA (outcome) it is impossible for the investigator to "randomly allocate" the subjects into 2 groups, one group being told to smoke and other being told not to do so". However, for any study directed to answer the questions about "treatment (therapy)" or "preventive procedure", the experimental design must be used since the subjects can be randomised into 2 groups, provided it is ethically correct do so.

Experimental (intervention) designs can be of further three types, as follows

**(a) Randomized Controlled Trial (RCT) (Clinical trial)**

Details are given in the chapter on clinical trials in Research Methodology section.

**(b) Preventive Trial**

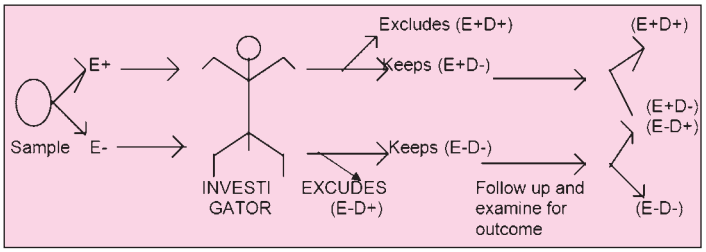
This addresses issues of prevention (as, vaccine, chemoprophylaxis, personal protective methods, etc.) as compared to therapeutic issues addressed by RCT.

**(c) Community Intervention Trial**

In a RCT or preventive trial the random allocation is done at the level of individual subjects; e.g, each individual subject will be randomly allocated by lottery into Gp.'A' which will get the vaccine and Gp. 'B' which will get the placebo. However, in situations like assessing whether fluoridated water is effective for prevention of dental caries, it will be impossible to randomly divide the individual subjects. In such cases, it is groups or "clusters" of human beings; e.g., we will randomly allocate villages into a Gp of villages to receive fluoridated water and another Gp of villages to receive non-fluoridated water. Such trials, wherein the unit of study are "individual human beings" but the unit of random allocation are "communities" are called "Community Intervention Trials".

**The next situation : "Cohort Study" :-**

In case it is not possible to "randomly allocate" the subjects into two groups, what we can do is that we can select out two groups at the start of the study, one having the exposure (E+) and other not having the exposure (E-). Now, those subjects, in both the groups, who already have the outcome (D+) at this point of starting the study are excluded, so that we have two groups, one having the exposure but no disease (E+D-) and the other neither having the exposure nor the disease (E-D-). The groups are followed up for the required period of time and comparisons made between (E+D+) / (a+b) and (E-D+) /



(c+d) as for an experimental study.

The advantages of this design, called 'Cohort Design" are the last two mentioned for experimental design, ie., temporal association is ensured and recall bias is minimised. The main scientific drawback of this study is that lacks the effect of "equal distribution due to random allocation" and hence the problem of "natural selection factors" related to both exposure and outcome may be forwarded. Hence, as far as effects of therapeutic regimes or preventive measures are to be seen, the experimental design is to be taken up since random allocation can be undertaken. However, for study of "risk factors", "markers" and "prognostic factors" the cohort study

remains the choice.

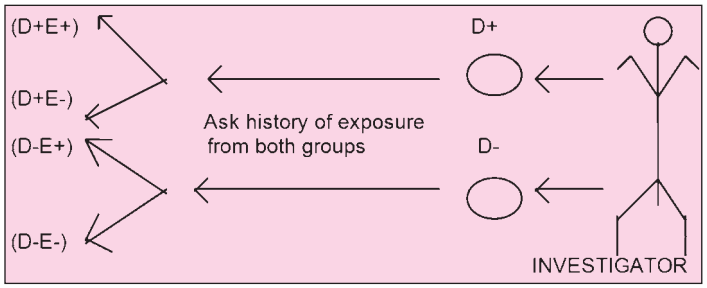
This design has disadvantages too. Firstly, if the period of follow up is very long, the medical fraternity has to wait for many years before the final conclusions can be drawn. Secondly, if the outcome is rare, the investigator needs to follow up a very large number of subjects to get a reasonably adequate number of subjects who develop the outcome. Thirdly, a large number of subjects may be lost to follow up/die/ drop out during the period of follow up leading to "loss to follow up bias". Fourthly, such study needs quite a bit of men, material and money.

**The third situation : Case control study :-**

The problem of "cohort study" can be sorted out by using the method we mentioned in making the second type of comparison between the two groups. What we can do is that we can start by selecting a group of subjects who have already developed the outcome (D+) and another who have not developed the outcome (D-) and ask the history of exposure (E+ or E-) from all the subjects.

The comparison is made as

$$\frac{(D+E+) / (D+)}{(D-E+) / (D-)}$$



The above situation is what we call a very special type of study, the "case-control" design. Intuitively, this study design appears very appealing. However, it suffers from a large number of outstanding problems :-

(a) The very direction of the arrows are 'reversed'; in other words, this study involves a reversal of "scientific reasoning" which should normally proceed from "exposure to outcome" as in an experimental or cohort design.

(b) The fact that the investigator has not recorded the exposure (E+ or E-) himself but is dependent on the history given by the subjects leads to a high possibility of "recall bias".

(c) Since the investigator has not started from the exposure and followed up subjects till the outcome (as happens in an experimental or cohort study), one is not sure whether exposure really preceded the outcome ie., "temporality" is not guaranteed. Eg, an association between poverty (postulated exposure) and mental illness (suspected outcome), if concluded by such a design, may not necessarily be because poverty led to metal illness but may be because after suffering from mental illness, persons may become poor.

(d) What the investigator starts with in such a design are the subjects who are present with a given outcome, ie., living with the outcome of interest but not those who have already died of, or have been cured of, the outcome. The possibility of "survivorship bias" is, therefore, high. (see example on suvivorship bias, in chapter -1 in section on Research methodology).

(e) The problem of "natural selection" also remains high as in cohort study. However, it may be mentioned that if all the potential confounding factors (PCF) are identified and data recorded, this problem can be overcome to a large extent (though not completely eliminated) in a case control or a cohort study.

The case control design has its own advantages, however. It is very good for a rare disease (in contrast to a cohort design) because cases of a rare disease can be picked up from a general / specialised hospital. It does not need any (prolonged) follow up effort. It is cheap and logistically simple. It becomes the method of choice when we are doing an initial evaluation of a hypothesis (fishing expedition) for "risk factors" and "markers". It becomes a particularly good method if the exposure is not likely to change over time and can be objectively ascertained (eg, blood group, race, religion, sex, seropositivity for certain infections etc).

**The fourth setting : Cross-sectional analytic design**

In a case control design, the researcher starts by collecting a group of subjects who have the outcome (D+). This he does in a hospital, or to a limited extent, at large OPDs. But if a disease is mild, or has a marked 'gradient' of mild, moderate and severe cases, a large number of cases will not be admitted in the hospital and hence will not appear in the case control study. In fact the mild (not admitted) cases may be systematically different from the serious hospitalised cases as regards the exposure itself.

In such settings therefore, instead of doing a case control design, the researcher takes a "sample" of subjects from the 'total population'. At this point he is not aware whether the subjects are having the disease or not. Now, the investigator examines each and every subject for the presence / absence of outcome (D+ or D-) and exposure (E+ or E-) at the same point of time and hence gets the four groups, E+D+, E+D-, E-D+ and E-D- at a given point of time. This is what we call the "Cross-Sectional Analytic Design". In addition to those diseases that have a wide spectrum of symptoms, the design is also quite useful when the investigator wants to see for correlations between variables which need to be studied among healthy people and not necessarily hospitalized patients; eg, if we want to see whether waist circumference correlates well with blood pressure we will have to do such a study and not a case control one. The problem of proving temporal relationship is a major drawback of cross sectional analytical studies as it is for a case-control study.

**The last setting : The Diagnostic test study**

The analytical approach for the evaluation of a diagnostic test (which may be a Pathological / Radiological / Microbiological procedure or even a "set of signs / symptoms") in diagnosing a given outcome (or, disease) is slightly different. Firstly, in such a study the investigator must enunciate a "gold standard", against which his diagnostic tool which is to be evaluated, will be validated. Secondly, each and every subject must be subjected to both the procedures (the gold standard as well as the test under study), thereby getting 4 category of subjects. Let us say, we are evaluating the efficacy of pap smear in diagnosing CA Cx, the gold standard being biopsy. We will then have the following setting as shown in Table 2.

a = Subjects who are having the disease (+ve by gold standard) and also identified +ve by the test under consideration (True positive or TP);

Table - 2

| Result of Pap Smear | Biopsy (Gold standard ) results | | |
|---|---|---|---|
| | CA Cx present | CA Cx absent | Total |
| Positive | a | b | a + b |
| Negative | c | d | c + d |
| Total | a+c | b+d | a+b+c+d |

b = do not have the disease but called +ve by the test (False positive or FP); c = have the disease but called -ve by the test (False negative or FN)

d = do not have the disease and -ve by the test (True negative or TN) ; (a + b) =Total number found +ve by test (ie., TP + FP);

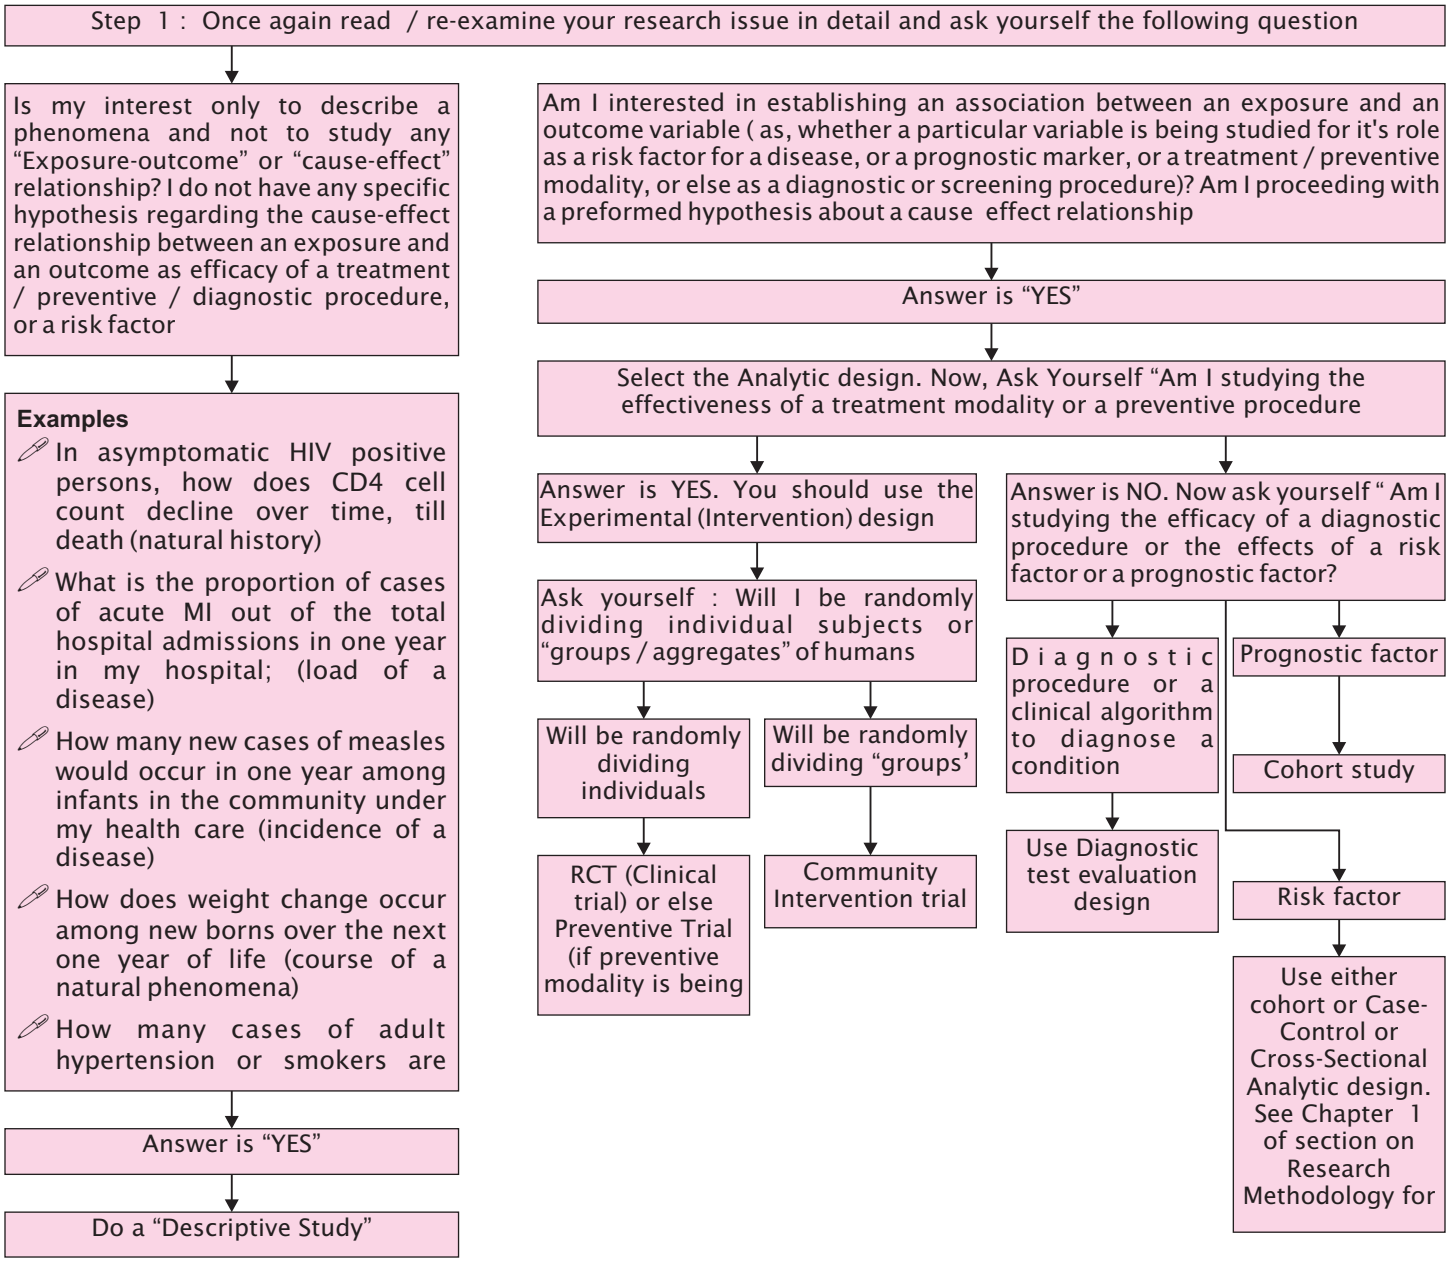
(c + d) =Total number found -ve by test (ie., FN + TN); (a + c) =Total number actually having the disease, by gold standard (ie., TP + FN);

(b + d) =Total number not having the disease by gold standard (ie., FP + TN)

The investigator now does **not** work out the statistical tests for associations ( as Chi-square) and risk (as RR or OR), but something different - he works out the validity (or accuracy) of the test under consideration by calculating the sensitivity, specificity, positive and negative predictive values and likelihood ratios, the details of which we shall discuss in the chapter on screening for disease and chapter on diagnostic test evaluation studies.

**How do we decide as to which Epidemiological design we should use ?**

It is of importance that the correct "Research Design" be selected by the researcher. The following guidelines are given in the succeeding flow chart to assist you in selecting the design most appropriate to your research question.



Step 1 : Once again read / re-examine your research issue in detail and ask yourself the following question
Is my interest only to describe a phenomena and not to study any "Exposure-outcome" or "cause-effect" relationship? I do not have any specific hypothesis regarding the cause-effect relationship between an exposure and an outcome as efficacy of a treatment / preventive / diagnostic procedure, or a risk factor
Examples
In asymptomatic HIV positive persons, how does CD4 cell count decline over time, till death (natural history)
What is the proportion of cases of acute MI out of the total hospital admissions in one year in my hospital; (load of a disease)
How many new cases of measles would occur in one year among infants in the community under my health care (incidence of a disease)
How does weight change occur among new borns over the next one year of life (course of a natural phenomena)
How many cases of adult hypertension or smokers are
Answer is "YES"
Do a "Descriptive Study"
Am I interested in establishing an association between an exposure and an outcome variable ( as, whether a particular variable is being studied for it's role as a risk factor for a disease, or a prognostic marker, or a treatment / preventive modality, or else as a diagnostic or screening procedure)? Am I proceeding with a preformed hypothesis about a cause effect relationship
Answer is "YES"
Select the Analytic design. Now, Ask Yourself "Am I studying the effectiveness of a treatment modality or a preventive procedure
Answer is YES. You should use the Experimental (Intervention) design
Ask yourself : Will I be randomly dividing individual subjects or "groups / aggregates" of humans
Will be randomly dividing individuals
RCT (Clinical trial) or else Preventive Trial (if preventive modality is being
Will be randomly dividing "groups'
Community Intervention trial
Answer is NO. Now ask yourself " Am I studying the efficacy of a diagnostic procedure or the effects of a risk factor or a prognostic factor?
Diagnostic procedure or a clinical algorithm to diagnose a condition
Use Diagnostic test evaluation design
Prognostic factor
Cohort study
Risk factor
Use either cohort or Case-Control or Cross-Sectional Analytic design. See Chapter 1 of section on Research Methodology for

Col RajVir Bhalwar

## Cause and Effect Relationship

Except in the limited situations of describing a phenomena of interest, most of the times epidemiologic research is directed towards finding out the "causal" association; eg., "Is smoking a cause of IHD ?" This is called as study of "cause-effect" relationship; it is also equivalently called as "exposure-outcome" relationship. A "cause and effect" (or exposure and outcome) relationship can be defined as "an association between two variables in which an alteration in the frequency or quality of one variable is followed by a corresponding change in the other" (45-49); eg, if smoking is a cause of Buerger's disease, increase or decrease in smoking should lead to a corresponding change in the disease occurrence.

The process of establishing a "cause and effect relationship : Establishing a cause and effect relationship, i.e., this particular 'exposure' is the cause of that particular 'outcome' needs epidemiologic research on the lines of 'hypothesis testing'. i.e., an analytic study, as described in previous chapter. Once the investigator proceeds with a "cause and effect" hypothesis and conducts a study, the final evaluation whether an "exposure-A" (eg., smoking) is a cause of the "outcome B" (eg., Buerger's disease) consists of a sequence of steps as follows :-

### Step 1

Has the study been done using correct methods ? Has the investigator 'measured' what he or she really wanted to 'measure' ? Has the validity and reliability been preserved in the study and there is no bias ? In other words, we analyze whether the results of the study are accurate and not "spurious"?.

### Step 2a

Do the statistical results indicate that the 'exposure' and 'outcome' are significantly "associated" ? In this step, the investigator ensures, through statistical tests of significance and 95% CI that the differences/associations observed in his sample are not simply due to matter of "chance" or, in other words, variations that could occur when different samples from the same whole population are drawn ("chance" or random variations or sampling variations). This entire aspect is dealt with in the section on biostatistics in this book.

### Step 2b

If the statistical results show that the statistical relationship is not significant, we must still give consideration to the possibility that a real association might have been missed out due to low power of the study i.e., a high Beta (type II) error consequent to a small sample size. Hence, before finally denouncing the association as "not statistically related", we must back-calculate the "power" of the study; in case it is found that the power was inadequate (say less then 80% for the usual research settings), the investigator should suggest additional studies using larger sample, (or else, a meta-analysis 'type of study). Further details of procedures are given in the section on Biostatistics.

### Step 3

If the tests of step 2 show that the relationship is "statistically significant" the investigator should now evaluate as to whether this relationship is due to 'indirect relationship' with a third variable; in other words, the investigator should undertake analytic procedures for control of confounding as described in the section on Research Methodology.

### Step 4

Once it has been demonstrated in step 3 that the exposure-outcome relationship is not due to confounding (i.e., holds good even after adjusting for confounding variables), the investigator should now test this postulated "casual" relationship on the following criteria of "casual association" as enunciated by Sir AB Hill (50):-

#### (a) Temporality

The absolute requirement for any postulated cause and effect relationship to hold good is to demonstrate that the suspected cause (exposure) preceded the effect (outcome). Eg., for smoking to be a cause of IHD, smoking should start before the occurrence of IHD.

#### (b) Strength of association

The "strength of causal association is shown by relative risk (RR) or, odds ratio (OR); higher the RR or OR, (i.e., farther the RR or OR from the value of "1"), more is our confidence regarding the casual association.

#### (c) Consistency

Whether a number of different studies conducted by different investigators at various times in different geographical areas on different populations have indicated similar "cause and effect" association as regards our exposure and outcome variables. Eg., smoking lung CA association has been consistently demonstrated in various countries, religions and sex etc.

#### (d) Biological gradient

Usually, increasing dose of exposure should be associated with increasing occurrence of outcome; eg., with increasing consumption of tobacco, the occurrence of IHD rises. This is also called "dose-response relationship". However, the investigator should remember that not all casual associations would demonstrate this phenomena; eg., the association between DES consumption by mothers and vaginal CA in daughters many years latter does not exhibit this 'gradient' phenomena, possibly due to a phenomena called "sufficient dose for maximum effect".

#### (e) Biological plausibility

Does the cause-effect association "stand to reasoning" i.e., commensurate with the already known and accepted facts. However, here too the researcher must note that biological plausibility is a relative phenomena based on present day knowledge of the state of affairs; what we

think nonsensical today may be accepted as correct tomorrow, eg., in the mid 19th century when Semmelwis recommended hand washing by medical students and teachers before attending obstetric units, his recommendations were dismissed by medical fraternity as "doesn't stand to reasoning" ! The rest is history (51, 52).

**(f) Experimental evidence**

An evidence, in the laboratory or in human subjects, based on deliberate introduction of the cause (exposure), thereby demonstrating that the outcome (effect) occurs in the group which has been subjected to the exposure and not in the other group. Here again it should be noted that such experimentation on human subjects may be often impossible; (eg., we cannot deliberately tell a group of human beings to smoke and the other group not to smoke and watch them for the development of lung CA). However, basic laboratory proof (eg., microscopic demonstration of histological changes in the respiratory tract of animals subjected to tobacco smoke or in tobacco using humans) may further strengthen our belief in a "causal" association.

**(g) Other criteria**

Like, 'analogy'. (eg., if one drug can cause congenital malformations, others can also do so); 'specificity' (i.e., one cause, one effect) and 'coherence' (findings should not conflict with the known natural history of the disease) have also been forwarded to finally test a casual association. However, in general, criteria mentioned in step (a) to (c) are most important; (d) to (f) may lend additional support to the causal reasoning while those mentioned in (g) may also be considered. Sequence of establishing a cause and effect relationship is shown in Table-1

Table-1 : Sequence of establishing a "cause and effect relationship" from a epidemiological study

- Is the Internal validity maintained? Any measurement errors? Any Bias?
- Are the results statistically significant? Or, is it that they may be due to chance?
- Any indirect association (confounding)?
- Test for Hill's criteria of causal relationship :- Strength of Association (magnitude of RR); temporal relationship; consistency; plausibility; dose-response

## Epidemiological Theories of Disease Causation

Epidemiologists have developed various models to explain the causation of human disease

**Germ theory**

This was the central philosophy of the famous Koch's postulates, formulated by Robert Koch (now also known as Henle-Koch postulates) (53, 54), which enunciated that firstly, the disease agent occurs in every case of the disease and under circumstances can account for the pathological changes and clinical course of disease; secondly, It occurs in no other disease as a non-pathogenic parasite; thirdly, after being fully isolated from the body and repeatedly grown in pure culture, it can induce the disease anew, from where again it can be isolated, grown in pure culture and should be able to cause a new case of disease if transmitted to another healthy human. However as the 20$^{th}$ century started rolling, it was realized that the germ theory could not fully explain the causation of human diseases. The occurrence of tuberculosis in western world fell down dramatically in the beginning of 20$^{th}$ century, even before the availability of a specific vaccine (to specifically prevent infection) or a specific treatment (to specifically kill the tuberculosis "germ"). Simple facts like disease does not necessarily occur in everybody who has the tuberculosis germ in the body (i.e., infection does not necessarily lead to disease in Tuberculosis) started putting a question mark on the ability of the germ theory to completely explain causation of human diseases.

**The epidemiological triad theory**

Though not refuting the importance of germ theory, thinking processes were started to explain the role of other factors in accentuating or attenuating the effect of the "germ" or "agent" of disease. This finally culminated into an extremely well known theory of human disease - the "Epidemiological triad". The epidemiological triad theory hypothesizes that there are 3 important determinants of the state of health or disease in a human being, namely, firstly, the agent factors, related to the various characteristics of the "agent" which causes the disease; secondly, the host factors which relate to various characteristics of the human being himself, and thirdly, the environmental factors which relate to the various characteristics of the environment in which the human being is living.

As per the theory, as long as a state of fine balance or equilibrium is maintained between the various agent, host and environmental factors, the person stays in a state of health. On the other hand, the moment this fine balance is disturbed due to change in any one or more of the agent, host and environment related factors, a departure from the state of health occurs (though, outwardly, evidence of disease may still not occur because manifest evidence of disease may take sometime to develop. The various agent, host and environmental factors fall into the following categories :-

(a) Agent factors

These include Physical agents (as heat, cold, vibrations, electricity, mechanical forces, etc); Chemical agents (as acids, alkalies, heavy metals, allergens, etc); and, Biological agents (as viruses, bacteria, parasites).

(b) Host factors

These include Sociodemographic factors as age, sex, occupation, education, marital status); Psycho-social factors (as attitudes, practices, behavioural patterns, life style, etc); and, Intrinsic characteristics (eg., genetic factors, HLA types, biochemical and physiological

characteristics, etc).

(c) Environmental factors

These include Physical environment (as seasons, climate, altitude, rainfall, etc); Biological environment (eg., arthropod vectors of diseases like mosquitoes, animal reservoirs like canines for rabies, etc); and, Social environment (eg., community attitudes, beliefs, practices and cultural factors affecting disease; level of socio-economic development; availability of health services, etc).

**The theory of "web of causation"**

The "epidemiological triad theory" was very effectively used by Leavel and Clark in explaining the natural history of disease, and levels of prevention. However, difficulties come up when an attempt is made to explain the causation of non communicable diseases like IHD or road accidents on the basis of epidemiological triad. For example, no single agent can be ascribed for IHD; a wide variety of interacting factors like Hypercholesterolaema, hypertension, tobacco, obesity, physical inactivity, genetic background, age, sex, just to name a few, interact in various ways to finally lead to IHD. For explaining the causation of such non communicable disease in particular, MacMahon and colleagues forwarded the theory of "web of disease causation" (45), which hypothesizes that various factors (eg., hypercholesterolaemia, smoking, hypertension and so on) are like an interacting web of a spider. Each factor has its own relative importance in causing the final departure from the state of health, as well as interacts with other, modifying the effect of each other. The web theory also postulates that for preventing a disease, it is not necessary to take action against all the factors if we could identify a few "weakest links" in the inter-lacing webs, actions directed to break these chains at their weakest links may be of considerable value in prevention.

**Epidemiological wheel theory**

As medical knowledge has advanced, the additional aspect which has been exciting interest is the comparative role of "genetic" and the "environmental" factors (i.e., extrinsic factors outside the host) in causation of disease. The "triad" as well as the "web" theory do not adequately cover up this differentiation. To explain such relative contribution of genetic and environmental factors, the "wheel" theory has been postulated. The theory visualizes human disease in the form of a wheel, which has a "central hub" representing the genetic components and the peripheral portion representing the environmental component. The peripheral portion is further subdivided into 3 sub components, representing the social, biological and physical components of the environment. For every disease, the genetic, social, biological and physical environmental components take different sizes, according to their relative importance in causing the disease.

**The theory of "necessary" and "sufficient" cause**

It is being realized that the "cause" of a particular human disease is like the constellation of various factors, and when all of them come into play in optimum combination, the pathological process which finally produces the disease, gets initiated (49). This led to the concepts of "necessary" cause and "sufficient" cause. "Necessary cause" is one whose presence is essential for disease causation, but which alone, by itself may or may not be able to finally cause the disease. Thus, while disease cannot occur in its absence, it may or may not occur if it is present. For example, Tubercular disease cannot occur if TB bacillus is not present in the body; however, if it is present, still tubercular disease may occur or may not occur. On the other hand when the required combination has been achieved, say, presence of TB bacillus,

## Principles of Infectious Diseases Epidemiology

One way of broadly classifying human diseases is according to whether they are "infectious (communicable)" or else, "non-communicable". Out of these two, infectious diseases account for lion's share of death, disease, ill-health and suffering. This is especially true of the developing countries. For this reason an epidemiologist must have a sound understanding of the epidemiologic principles that underlie infectious disease practice.

### General Terms And Definitions (55)

**Infection & Infectious Disease**

This refers to the entry and development or multiplication of an infectious agent in the human (or, animal) body, with an implied response (eg, immunological response) on the part of the human or animal. It must be remembered that "infection" by itself does not mean "infectious disease". An infectious disease is that part of the spectrum of "infection" which is clinically apparent. In fact, this is the basic difference between epidemiologic practice and clinical practice as regards infectious disease the clinician is mainly interested in "infectious disease" while the epidemiologist is interested in "infection" and its dynamics including the subclinical cases, the carriers, the reservoirs of the infectious agent and its modes of transmission.

**Colonisation**

Colonisation indicates presence of infectious agent in the human body but without any evidence of specific host immune responses to the agent. In short, colonization means "infection less specific immune response".

**Endogenous infection**

Infection due to a colonizing agent; eg, *E Coli* normally colonises the human GIT; however, under certain circumstances, it may enter the blood stream and cause endogenous infection.

**Contamination**

Refers to a infectious agent being present in inanimate articles like food, water, linen, patient care items or routine usage items like cutlery, toys etc. often, the term is also used to denote presence of infectious agent on skin surface, particularly on hands.

**Pollution**

Refers to presence of either infectious agent or such other disease causing noxious agents (as industrial effluents) or mechanical agents (as sound), usually in the general environment, air or water (eg, sound pollution, water pollution, air pollution).

**Infestation**

Infestation may refer to human beings, animals or personal usage items, wherein it implies either the presence and development of insect vectors on the body or linen (eg, louse infestation, infestation with acaius) or else on the mucus membranes (eg, roundworm infestation). Infestation is also sometimes used for describing a state wherein an accommodation or such articles as containers have the presence of arthopods or vectors (eg, cockroach or rat infestation in the houses).

**Communicable disease**

A communicable disease is one that is caused by an infectious agent (or its toxic products, eg, preformed toxins of *B cereus* or *C botulinum*) which can be transmitted to a human being either directly, or indirectly (through food, water, insect vectors, soil), or else a disease which can be transmitted between humans and animals. All infectious diseases are not necessarily communicable; eg, osteomyelitis or brain abscess are infectious diseases but not communicable. Similarly, an infectious disease may be communicable in one form (eg pneumonic plague) but not in the other form (eg, bubonic plague).

**Dead-end infection**

A state when an infectious disease, which is usually "communicable", cannot be transmitted any further between human beings or from humans to animals or vice versa, for various agent, host and environmental reasons. Examples are Japanese Encephalitis, Rabies, Tetanus, Bubonic plague, scrub typhus in humans.

**Subclinical infection (inapparent infection)**

It is a state when there is a host immune response following entry of the infectious agent; the agent may also multiply in the host body, but there are no clinical manifestations of the disease. Thus, the presence of infection cannot be recognized clinically though the infectious agent is constantly passed out of the human body and hence a person with subclinical infection is a greater health hazard for community then those having apparent disease (since the latter can be identified, treated and isolated if required). Diseases like viral hepatitis A have large number of subclinical infections; on the other hand, diseases like measles hardly have any subclinical infections. Thus, infections which have a large proportion of subclinical infections in their spectrum are less amenable to prevention; on the other hand, diseases which have very few or no subclinical infections are more amenable to prevention by surveillance methods.

**Latent infection**

This refers to a state when the infectious agent lies "dormant" within the host body, without any clinical manifestations but does not come out of the human body (thus it is different form subclinical infection). After a period of time, under certain circumstances, the agent which had been lying dormant, reactivates and produces a different type of disease (eg, Herpes Zoster; Brill-Zinser disease) or else the same type of disease (eg, reactivation Tuberculosis).

**Zoonoses**

Zoonoses are infections which are normally transmitted between vertebrate animals, either directly, or indirectly through a vehicle or insect vector. Those which are of

health importance are the ones that are transmitted to man from vertebrate animals, either directly, or indirectly through vehicle or vectors. These are called "anthropozoonoses" and include a long list of infections like Rabies, plague, bovine TB, salmonellosis, Japanese Encephalitis, scrub and murine typhus, echinococosis, Anthrax, Brucellosis, and so on. The second group are infections which primarily infect man but can be transmitted to animals; these are called as zooanthroponoses. The third group is amphixenosis which includes infections that may be transmitted from man to animals and vice versa.

**Opportunistic infections**

The term refers to disease, caused by infectious agents, which are normally not pathogenic, due to a decline in the general or specific immune status of the host. The term has assumed greater importance following identification of HIV infection whose clinical manifestations comprise of a wide variety of such opportunistic infections like P carini, T gondi, CMV etc.

**Nosocomial infection**

This is an infection contracted while in hospital, as a result of health care or related procedure. Such infections would include those whose clinical presentation may start after discharge from the hospital but NOT those which were "incubating" in the patient's body at the time of admission. The field of "Nosocomial Epidemiology" is fast becoming a specialized one. Hospital epidemiologists should ensure prevention and control of such hospital infections.

**Eradication**

The term refers to a complete cessation of transmission of the infectious agent. Usually this would imply that the infectious agent as well as the disease has also been completely reduced to zero. Small pox is the only example wherein eradication has been achieved.

**Control**

This refers to reducing the transmission of a disease to a level when it no longer remains a "public health problem". Control is more pragmatic then eradication but needs ongoing preventive measures, and consequently continuing expenditure, alongwith an efficient surveillance system to give an early warning of increase in the level of transmission.

**Elimination**

Elimination implies either a 'regional eradication" (say from a country or continent), or else reduction of disease to zero without total removal of infectious agent.

## Epdiemiologic "Chain" Of Infection

There are 4 inter- related factors, which together are referred to as the "epidemiologic chain of infection'

(a) the infectious agent and its characteristics.

(b) the human host who is suspectible to the infectious agent, and various factors which determine such suspectibilty.

(c) characteristics of the infectious process which are determined by the interactions between agent and the host.

(d) inter-connecting the agent and host are the "channels (or, modes) of transmission of the agent to the host. Let us discuss the details of each of these components of the chain of infection.

**Agent**

There are three broad groups of characteristics that are important in respect of infectious disease agent, viz., the reservoir and immediate sources of the agent; the characteristics of an agent that are connected with its survival in environment; and, the characteristics of agent which determine the production of infection and, consequent to infection, the production of disease.

**Reservoir And Immediate Source Of Agent**

Any infectious agent has a primary habitat, called the "reservoir of infectious agent" which can be defined as "a person, animal, or inanimate environment (like soil), where an infectious agent lives, depending primarily for its survival, and where it propogates itself so that it can be transmitted to a human host". On the other hand, a source of infection is the person, animal, or their excretions or inanimate environment from where the infective form of the agent is immediately available to the susceptible human host. Let us take the example of hookworm. The adult forms live in human gut, depending primarily on the human being for their survival; they multiply there and propagate themselves, the eggs being passed out for further transmission to another human so as to further propagate the species. The worms do not depend primarily for survival and multiplication on any other animal, soil, plants, etc. Thus, the "reservoir of infection" is "human being, infected with Hookworm", (human reservoir). On the other hand, infection of another human being occurs due to skin contact with soil contaminated with infective stage larvae. Thus, the "source" is "soil contaminated with infective stage larvae".

Types of "Reservoir of infection"

The most important "reservoir" for large majority of human infectious agents is the human being himself. The "human reservoir" of infectious agents can occur in two forms, viz., Cases and Carriers :-

**(a) Cases**

Those who have clinically apparent disease .

**(b) Carriers**

A carrier is a human being who harbours an infectious agent and sheds it, thus becoming a potential source of infection for other human beings, but does not exhibit any manifestation of the disease. The fact that they cannot be detected despite being a potential source of infection for other makes carriers extremely important from epidemiological point of view. Depending on the stage of disease in its natural progression, a person may be a carrier either during the incubation period (incubatory carriers) as occurs in measles, mumps, Hepatitis A, etc. The importance of the incubatory carrier state lies in the fact that after the incubation period is over and the disease manifestations come up, we may isolate and treat the person, but the damage has already been done by him, by transmitting the infection during incubation period. Secondly, he may be having subclinical or clinically inapparent disease (contact or healthy carrier), eg.,

Hepatitis A, Cholera, Poliomyelitis, diphtheria, etc. A subclinical carrier should be differentiated from a subclinical case, which refers to a person who has the infection beyond the incubation period but do not show clinical manifestations and do not shed the organisms so that the infection cannot be transmitted to other human hosts; eg., subclinical case of Japanese Encephalititis in which the infectious agent is present in the body, but the low titer viraemia is inadequate to infect the mosquito vector. Thirdly, the person may continue to shed the infectious agent even after apparent recovery, during the convalescent stage, and hence known as convalescent carrier as occurs in cholera, typhoid and bacillary dysentery. Such "convalescent carriers" may be short term or temporary carriers (lasting upto 4 weeks or so) or chronic carriers (lasting beyond 4 weeks; may be upto years as in chronic typhoid infection of gall bladder) (56).

Animals and other forms of reservoir

Besies human beings, animals form another reservoir wherein the infectious agent lives primarily, thrives, multiplies and is available for being transmitted to the human host. Such diseases fit in the scope of "zoonoses" as has been already described. Finally some infectious agents like fungi may primarily thrive and multiply in the contaminated soil.

**Characteristics of Agent concerned with Survival in Nature**

The capability of an agent to thrive outside the reservoir and withstand adverse environmental effects like drying, heat, acidity, etc is known as "survival capacity in nature". Some agents can hardly survival outside the human body (eg., measles, chicken pox). Others may survive for limited time provided conditions are favorable (eg., cholera vibrio, polio virus, Hepatitis A, etc can survive in water, ice, sewage, milk, etc; HIV can survive in blood and blood products; however all of them are quite vulnerable to drying, heat and disinfectants). Finally some organisms or their intermediate forms are quite sturdy and can withstand adverse environment very well (eg., clostridal spores, cycts of intestinal protozoans, ova of helminths, etc). Usually, agents which have very poor survival in nature tend to adopt the direct modes of transmission like droplet infection or direct mucous contact. Survival in nature becomes all the more crucial for the agent, if human being is the only reservoir.

**Characteristics of Agent Involved in Production of Infection and Disease**

The various characteristics of an infectious agent which determine the production of infection, as well as the causation of disease are (57) :-

Infectiousness

This is the relative ease with which the agent is transmitted to the host. Infectiousness is more of function of environmental factors; eg infectiousness of measles would be higher in overcrowded conditions but lesser in affluent communities.

Infectivity

This is the ability of the agent to cause infection, i.e, to enter, survive and multiply in the host. A useful epidemiologic measure of infectivity is Secondary Attack Rate (SAR). It is defined as the number of susceptible persons who, within the duration of one incubation period, following exposure, develop the disease out of the total susceptibles who were exposed. SAR is usually measured by conducting studies in closed communities or families wherein the first case which brings in the infection is called the index case. Thus,

$$SAR = \frac{\text{No. of susceptables exposed to index Case, who develop the disease, within the duration of maximum incubation period of the disease X 100}}{\text{Total number of susceptables exposed to the Index case.}}$$

Pathogenecity

It is the ability of the agent to produce manifest disease out of those who have been infected. Generally, agents which have high pathogenecity have features which protect them from non-specific host defenses, and elaborate toxins or similar products (eg, Diptheria, Tetanus) or else, may cause such host immune response that leads to disease (eg, Rheumatic fever, Glomerulonephritis).

Virulence

Higher in order, from infectivity and pathogenecity, is virulence. It is the ability of the agent to produce severe disease. If "serious' infection is being measured in terms of death, then Case Fatality Ratio (CFR) becomes a reasonably good measure of virulence.

Infective dose

Infective dose is important for certain infectious disease agents like V cholera and S typhi in which, if the inoculum is not adequate, then infection may not settle, or at least, manifest disease may not occur. On the other hand, in infections like plague, even a very small dose may be enough to cause infection.

**Host Factors**

Like the agent is on one end of the epidemiological chain of infection, the "HOST" is at the other end of the chain. The host factors which determine the dynamics of infection fall into two broad categories:-

Host Attributes Which Affect The Probability Of Being Exoposed To The Infectious Agent

These include age (eg, young children, because of hygienic innocence and habit of "orally exploring" the items, are more susceptible to exposure to soil transmitted helminthic infections); Sex (eg, females, by virtue of leading a mainly indoor life may be less exposed to sylvatic zoonoses like Kyasanur Forest Disease), Economic status (poverty, squalor and infection form an almost invincible trinity and this needs no further highlighting), Occupation (eg, agricultural workers and veterinarians are much more likely to be exposed to certain zoonoses), Education (by way of improving the knowledge regarding causation and prevention of infection, may help in reducing the chances of exposure), Living conditions (Poor housing, overcrowding, lack of sanitary eating and drinking facilities will all increase the

chances of exposure), Life style and behavioral factors (eg., permissive attitude toward sex will increase the probability of exposure to reservoir of STDs), and use of Personal protective measures (eg, use of mosquito nets and repellents decrease the chances of exposure to mosquito borne diseases).

Host Factors that Influence Occurrence of Infection and Disease

Once the host been "exposed" to the infectious agent, certain factors will determine whether disease will actually occur and the severity of the same. These include "status of host immunity", whether actively or passively (or naturally or artificially) acquired; Age (In general, extremes of age viz., the very young, i.e, < 2 years and the old, > 65 years are more susceptible); Genetic make up (known to occur in respect of diseases like tuberculosis and malaria); and, Availability and utilization of health services (by providing chemoprophylaxis, immunization and health education at the primary preventive level and early diagnosis and prompt treatment)

**Herd Immunity**

Herd immunity refers to the level of immunity that is present in a population against an infectious agent. It is, thus, concerned with the protection of a "population" from infection, the protection being brought about by the presence of immune individuals. It may be defined as "the resistance of a group to attack by a disease to which a large proportion of the members are immune, thus decreasing the probability that a person having the infectious agent will transmit it to another susceptible person in the same population". In general, while dealing with childhood infectious diseases amenable to prevention by immunization, vaccination coverage of about 85% is likely to provide adequate herd immunity, which will effectively block the disease transmission, even if remaining 15% children are not immunized (though there may be many exceptions to this generally held belief).

## Factors affecting the Process of Infection as a result of Interaction between Agent and Host

There are certain features which are peculiar to each infectious disease as follows

**Incubation period**

Incubation period is the time period between the entry of infectious agent (or its toxin) into the human body to the point when the earliest clinical manifestations of the disease are apparent. During this period, the host does not exhibit any outwardly clinical manifestations, though immunological and histopathological changes within the body would definitely occur. If, during this period, the organism is also shed form the body of the host, the host qualifies to be an "incubatory carrier". Incubation period is usually measured in terms of "median incubation period", i.e, the time in which half of the infected subjects will develop clinical manifestations, following entry of the organism into the body. Alongwith the median incubation period, a "range" is also given which indicates the minimum and maximum incubation periods. Incubation period of a diseases is found out by studying the time taken for onset of secondary cases following exposure to the index case, in family groups or in closed communities, or else during investigation of "common-vehicle, point source epidemics. Different diseases have different values of median incubation period and range, and a specialist in Public health should remember them well.

**Latent period**

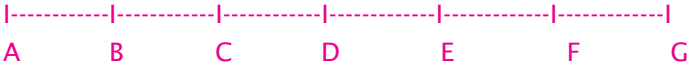
In infectious disease epidemiology, latent period refers to the time that elapses between the entry of the agent in the human body to the point when the shedding of organism.

**Period of communicability (Infectious period)**

This is the duration for which the host sheds the agent, i.e, remains infectious. This may be very long in case of diseases like leprosy and HIV infection.

**Generation time**

The generation time is the duration between the entry of infectious agent into the body to the peak infectivity of the host. As a crude calculation, generation time (G) is equal to (latent period + period of maximum communicability). The relationship between the various landmarks of a typical infectious disease is depicted as follows :-



**Landmarks**

A = Entry of agent into host

B = Shedding of agent starts

C = Clinical manifestations start

D = Maximum infectivity of host

E = Clinical disease ends

F =Shedding of agent ends

G = Convalescence ends

A to B = Latent period

A to C = Incubation period

A to D = Generation time

C to E = Clinical phase

E to G = Convalescence phase

B to F = Period of communicability

B to C = Incubatory carrier phase

E to F = Convalescent carrier

E to G = convalescent phase

C to F = Subclinical (healthy) carrier phase (if clinical disease did not occur).

**Biological Gradient (Gradient of infection)**

Biological gradient of a disease refers to the range of manifestations that may occur in the host as a result of infection. Thus, it is like a "spectrum", ranging from inapparent infection at one end, and passing through mild illness, clinical disease, serious forms of disease, to death at the other extreme of the spectrum. Diseases like viral Hepatitis-A, poliomyelitis and cholera have a classically wide biological gradient with all varieties of severity as outlined above being present. On the other hand, measles and chicken pox tend to have only the middle part of the

spectrum with either subclinical cases or deaths being uncommon. Diseases like rabies occupy only the other extreme of the spectrum, having a very serious biological gradient, with certain death being the only outcome.

**Frequency of disease**

As has been repeatedly stressed in this chapter, the epidemiologist should not go simply by observed number of cases of a disease but convert it into some form of frequency measure (like incidence or prevalence) by relating the number of cases to a denominator (the population at risk). Depending on the "frequency" of the disease, the occurrence may be

(a) "Epidemic"

This is the occurrence of disease frequency, in a defined population or area, which is clearly in excess of the normal expectation.

(b) "Endemic"

Endemic frequency refers to continued transmission of a disease, in a defined population or area, at a relatively low level (without any importation from an outside area or population). It would also be appreciated that the difference between an epidemic and an endemic situation is dependent on two factors firstly, the high frequency and the "abrupt increase" which occurs in epidemic situation, compared to "continued transmission" in endemic settings. Depending on the "frequency" with which this continued transmission is going on an endemic scenario, the endemicity could be described as "hypoendemic" or "low endemic", (incidence being low), mesoendemic, hyperendemic, and holoendemic. In both hyperendemic as well as holoendemic situations, the transmission continues at a very high frequency; however in the latter situation, exposure to infection generally occurs during early childhood so that by the time adulthood is achieved, the population becomes immune and a high level of herd immunity occurs. For this reason, epidemic outbreaks of the disease are not likely in holoendemic situations (the classical example being "stable malaria" situations). The epidemiologist should note that half-hearted or unscientific measures (eg., sudden introduction of insecticidal spray programs without full coverage and without concurrent coverage with surveillance for prompt diagnosis and treatment for a disease like Malaria) would tend to convert a "stable", holoendemic situation into an "unstable" meso-endemic one, thus increasing the propensity to epdemic outbreaks.

(c) "Sporadic"

Sporadic frequency which refers to few, scattered cases of infection, which do not have any relation to each other temporally or spatially (i.e, according to time or place). The difference between a "low endemic" disease and sporadic disease is based on this fine dividing line-that in a low endemic disease, the frequency of disease is low but the cases would show a reasonable relation to each other according time or place which will not be the case in sporadic situations.

**Channels Of Transmission**

The two end points in the epidemiological chain of infection are the infectious agent and the (susceptible) host. Now, to the complete this link, the infectious agent must be transmitted to the susceptible host. Such establishment of the link between agent and host is brought about of two types, viz "direct" and "indirect" modes of transmission.

(a) Direct Modes Of Transmission

A direct mode of transmission is one in which the infectious agent has to be in a state of actual physical or physiological proximity with the susceptible host, or even if not in such proximity, should be within a very close distance so as to be able to directly come in contact with the host.

There are five methods of such direct transmission

(i) Contact of host skin or mucous membranes with the infectious agent contained in a living tissue; eg., sexually transmitted diseases.

(ii) Contact of skin or mucous membranes with the infectious form of the agent contained in inanimate environment. The examples include transmission of hookworm (infective form in soil) and leptospirosis (infective form in water or soil contaminated with urine ).

(iii) Inoculation of the agent, directly from the reservoir into the skin or mucous as in Rabies.

(iv) "Vertical transmission" from mother to child, through the placenta, eg., HIV, syphilis, "TORCHES" agents etc.

(v) Direct transmission due to the agent being within a reasonably close distance of the host, as occurs in "droplet infection". Droplets are actually very finely dispersed aerosol containing the infectious agent, which are formed when a person harbouring the agent in his respiratory tract undertakes such activities like coughing, sneezing, talking etc. if another susceptible host is within a 'reasonably close' distance (usually taken to be 1 meter at the most), such infective droplets can be directly deposited on to the mucous membrane of oral cavity or respiratory passage (i.e, the relevant portal of the respiratory tract infections.) TB, common cold, influenza, measles, mumps, pertusis, diphtheria, meningococcal infection, leprosy etc are transmitted by such mode.

(b) Indirect Modes Of Transmission

An indirect mode of transmission can defined as one in which its infectious agent requires an "intermediary agency" to convey it from the source of infection to the susceptible host. Like for direct modes, there can be five types of indirect modes of transmission

(i) **Vehicle borne :** The various types of "vehicles" which can convey the infectious agent, from the source of infection to the susceptible host include anything which is eaten (eg, food, sweets, milk products, confectioneries and so on, or anything which is drunk (eg, milk, ice, water, beverages etc). Infections of the gastrointestinal tract are classically transmitted by this mode and include

such common examples as cholera, typhoid, hepatitis-A, ascarisis, amoedeasis and so on. A vehicle also would include anything which can be "injected" (eg, blood and blood products, drugs, vaccines, diluents; examples are HIV, Hepatitis B, Malaria etc).

(ii) **"Fomites"** which are defined as inanimate objects of general use by the infected person (eg, untensils, linen, fountain pens, tooth brushes ) The infectious agent may remain on the surface of such fomites and may be transmitted to the susceptible host usually when such objects are put into the mouth or come in contact with conjunctiva.

(iii) **Fingers** : Fingers form a very important mode of indirect transmission. If Contaminated, they can transport a number of gastrointestinal infection (especially, shigella, salmonella typhi, vibrio and Entamoeba).

(iv) **Air** : Often droplets containing the infectious agent may dry up, or may settle down on the dust. Now, if the agent can survive environmental adversaries like drying or heat, it can be carried for long distances by air currents, alongwith the dust or droplet nuclei; and if deposited on the portal of entry of a susceptible host, can initiate infection. Important examples are legionnaires disease, 'Q' fever, tuberculosis, nosocomial infections. Air borne infected nuclei and dust should be differentiated from "droplet infection". As explained, the latter is a 'direct" method of transmission in which the agent is directly deposited from the immediate source of infection onto the portal of entry of a susceptible host, the intervening distance being very short (maximum 1 meter). On the other hand, in an air borne transmission the agent is not directly deposited from the source of infection on to the portal of entry of susceptible host but transported indirectly by air over long distances.

(v) **Vector borne indirect transmission** : A vector is a living invertebrate which transfers the infectious agent from the source of infection to another susceptible host. Usually the term encompasses arthropods, and to a smaller extent, molluscs like snails. Such transmission by a vector could be either "mechanical", in which the vector simply acts as a "fomite", transferring the infectious agent from the host on to another vehicle like food, by carrying the agent on its body surface or in the gut (finally excreting them in the faeces). The common example is of the housefly, which mechanically transmits a number of oro-faecal disease agents from the faeces to the food. Secondly, it could be a "biological" transmission, wherein the infectious agent is transmitted, not simply in a mechanical form, but undergoes, within the body of the vector, one or more of the biological changes pertaining to the stages in its life cycle. Such biological changes may occur in one of the following three ways :-

- Take the example of plague bacillus. After being taken up by the rat flea following a blood meal on the rodent, the bacilli so taken up with the blood, multiply enormously, increasing in number, in the mouth parts of the rat flea. However, there is no developmental change as regards stages of life cycle of the bacillus. Such a method of biological transmission in which the agent "multiplies" but does not "develop" in the body of the vector before being finally transmitted to the susceptible host, is known as "propagative" mode.
- As another example, once a female culex mosquito takes in a microfilaria along with the blood meal, the microfilaria so taken up will undergo developmental changes of life cycle in the body of the mosquito (the three larval stages, finally becoming the infective stage larva). However, there is no multiplication and for each one microfilaria taken up with blood meal, there will be, finally, only one infective form larva. Thus, if the agent undergoes developmental changes in the body of the vector but no multiplication, the same is known as "developmental" or "cyclo developmental" method.
- Finally, let us consider the sequence of events that occur following ingestion of malarial male and female gametocytes along with blood meal by a mosquito. The gametocytes transform into gametes, form a zygote, followed by oocyst and sporozoites. Thus, there are developmental changes pertaining to the life cycle of the agent. In addition, for one each of male and female gametocyte taken in by the mosquito, there will be formed, not one but thousands of sporozoites; thus, if in addition to developmental changes, there is multiplication, it is know as "cyclo-propogative".

## Investigation of an Epidemic

Investigations of epidemics is one of the most important duties of not only the epidemiologists but for all medical officers concerned with health care of the community. Investigating an epidemic involves a series of steps, as narrated in the succeeding paragraphs. These steps are not necessary to be undertaken in the same sequence. In fact, often, at any given point of time during the course of an investigation, it is quite possible that a number of steps may be addressed simultaneously(58 - 60). In this chapter, we will explain the various steps in detail, alongwith an example of an epidemic which occurred in a large military cantonment.

**Example : Real Life Situation**

Maj. 'X', a classified specialist in Preventive Medicine was posted as Officer Commanding of Station Health Organization (SHO) in a large cantonment. In the evening of 10th May, the Regimental medical officer (RMO) of a large Army camp rang up to inform that 2 cases of diarrhea and vomiting with mild dehydration had occurred and he was referring them for admission to the dependent large military hospital. The Army camp was meant to provide accommodation and messing to almost one thousand army personnel, mainly clerks and office runners, working in various large Army offices located at various places in the city. There were four "messes" with dining halls (named 'A', 'B', 'C', and 'D' mess) to provide for meals, besides a canteen run by a contractor to provide snacks. These army personnel used to leave early morning in buses for their respective offices, after breakfast and used to carry packed lunch. They used to come back in late evening from their respective offices and have their dinner in the camp, before going to bed. Another about 300 personnel were staying with families in family quarters located in close vicinity of the camp and shared the same general piped water supply and sewerage system (from military engineering sources). These family members also used to go to the same offices with the single staying personnel. There was a small cantonment market nearby with all daily requirements available. (Dates, locations and number of personnel have been slightly

### Step 1 : Verification of the diagnosis

The earliest report regarding an outbreak is often obtained from a non medical or paramedical person. Often the initial report is not in the form of particular diagnosis but rather in the from of a "syndromic" constellation of symptoms and signs (eg, outbreak of diarrhoea and vomiting , or fever and skin rash). It is therefore essential to verify the diagnosis of the condition that one is dealing with in epidemic form. This also helps in developing the epidemiological case sheet and planning the laboratory, environmental and entomological procedures for investigations. At this point, talk in detail with the patients (cases), about their signs / symptoms, about their movements, about the possible exposures and what they think could have caused their present illness, and whether they know of similar cases in their neighbourhood, workplace or among friends. Recording as much details at this point of time may be of great value later when hypotheses are being developed. Verification of the diagnosis is usually made on clinical, laboratory and epidemiological parameters. Most important are the clinical parameters. In real life situations, it may not be necessary to confirm 100% cases by lab parameters; a 20% to 30% random sample, if confirmed by lab tests to be having similar disease should be adequate. At this point it is also very wise to describe the distribution of various signs / symptoms according to frequency distributions, which greatly helps in suggesting the diagnosis and also in developing the case definitions.

**Continuing with the example of the real life situation,** To start with, a "syndromic" diagnosis of "gastroenteritis, without fever & with moderate dehydration" was made. The possibilities which were kept within this tentative diagnosis were food poisoning (due to either of *S aureus*, non-typhoid salmonella, *C perfringens, B cereus*); cholera; ET EC gastroenteritis; and algid malaria. The patients were contacted by the SHO at the hospital in the night itself and a quick clinical history and examination was done, and cases were discussed with the Medical splt and Pathologist. Both the patients were young soldiers working in the same office and dining in the same ('B') mess. They had 1-2 bouts of vomiting in the afternoon, followed by 4-6 watery loose motions and felt "weak". There was no fever or tenesmus or blood / mucous in the stools. Except for moderate dehydration, physical examination was non-contributory. GBP, PBS for MP, and stool examination for microscopy, hanging drop and culture for enteropathogenic organisms was requested.

### Step 2 : Confirm the existence of an epidemic

An epidemic is defined as "occurrence of a disease in a frequency which is clearly in excess of the normal expectations". Thus, having verified the diagnosis, one must work out the incidence rate, by dividing the total cases by the population at risk. This rate is compared with the rate occurring in the same population, during the corresponding period of the past three years. Often, the decision as to whether the present rate is clearly in excess of the normal expectations (based on past three years' rates) is taken on the basis of informed and experienced judgement, through various statistical procedures for calculation of "control limits" are available to further assist in such decision (see Chapter on "surveillance" in this section for details). Quite often, in such situations, rates may not be able to be calculated in such an emergency and so, numbers may be compared. Usually, comparison is done of the present rates (or number of cases) with those

## General guidelines for "syndromic approach" to "common epidemic prone" diseases

Quite often, reporting of epidemic is often in the form of a "syndrome". Moreover, laboratory diagnostic results may take time to be available and till then the epidemiologist has to proceed with some tentative diagnosis, to give some direction to his investigations. The following list is intended to provide a general reference for the epidemiologist in the field, till definitive results are available.

### Syndrome of fever without rash

**Usual manifestations** : Sudden or insidious onset with fever of continuous, biphasic or recurrent type; frequently headache, myalgias, arthralgias; sometimes GIT manifestations, polyadenopathy or hepato-splenomegaly;

NO specific localizing sign.

**Common Diseases** : Vivax Malaria; Enteric fever; Leptospirosis; Uncomplicated Dengue fever (without haemorrhages or shock; Chikungunya (without

### Syndrome of haemorrhagic fever

**Usual Manifestations** : Onset with fever and systemic symptoms; often a second phase of fever after 3 to 5 days with cutaneous haemorrhages (petechiae, ecchymosis or puncture oozing); sometimes internal bleeding (haemetemesis, malena, haematuria, vaginal bleeding); sometimes jaundice with or without terminal shock syndrome.

**Common Diseases** : Dengue Haemorrhagic Fever or DSS; Kyasanur Forest Disease; Lassa Fever; Chikungunya (very few patients would have

### Fever & respiratory manifestations

**Usual manifestations** : Onset with fever and often fatiguability; sometimes systemic manifestations; cough; dyspnoea; chest pain; persistent or blood stained sputum.

**Common Diseases :**

URTI :Pertusis; Influenza; Acute bacterial or viral pharyngitis.

LRTI :Streptococcal pneumonia; Pneumonic plague; Influnza, SARS, Avian influenza; Pulmonary anthrax (keep possibility of bio-terrorism).

### Syndrome of fever & lymphadenopathy

**Usual Manifestations** : Onset with fever and systemic symptoms; Lymphadenopathy (generalized or localized; supputrative or non-suppurative)

**Common Diseases** : Bubonic plague; kala azar; hyperendemic filariasis.

### Syndrome of fever with jaundice

**Usual manifestations** : Initial phase with only fever and systemic symptoms; sometimes there may be no such initial phase; jaundice; sometimes haemorrhages.

**Common diseases** : Viral Hepatitis 'A', and 'E'; Viral hepatitis 'B' (due to common parenteral experience); sometimes Leptospirosis

### Syndrome of fever with rash

**Usual manifestations** : Onset with fever and systemic symptoms; macular, papular, vescicular or pustular eruptions, either generalized or localized to certain parts of skin or mucous membranes; eruptions are NOT haemorrhagic.

**Common Diseases** : Chickenpox; Measles; Rubella; Typhus group of fevers (scrub, louse borne, murine and tick borne typhus); Meningococcal bacteraemia.

### Syndrome of fever & neurological manifestations

**Usual manifestations** : Onset with fever and systemic manifestations; signs of meningitis or encephalitis or paralysis of central or peripheral type.

**Common Diseases :**

Mainly paralysis : Paralytic poliomyelitis.

Mainly meningitis : Meningococcal meningitis

Mainly encephalitis : Japanese encephalitis

### Fever with GIT Manifestations

**Usual manifestations** : Fever; nausea / vomiting; diarrhea with or without blood or mucous; abdominal cramps; systemic manifestations usually mild or absent; sometimes neurological manifestations or rash may follow.

**Common Diseases** : Non-typhoid salmonella food poisoning; Shigella dysentry; Enteroinvasive / Enteropathogenic *E coli* diarrhea; rotaviral enteritis especially in children; Giardiasis; Amoebiasis; Yersinia or Campylobacter food poisoning.

### Syndrome of "Afebrile" illness

**Afebrile neurological disease** : Convulsions, shock or GB syndrome (search for common vaccination history); botulinum food poisoning; Organophosphate Insecticide poisoning (food borne or after spray); mushroom poisoning.

**Afebrile GIT illness** : Cholera (epidemic 'O' Gp); Food poisoning due to *S aureus*, *C perfringens, B cereus, giardiasis, V parahaemolyticus;* (common-vehicle-food-borne)

**Afebrile Conjunctivitis** : Bacterial or adenoviral.

**Afebrile rash** : Swimming pool associated dermatitis.

**Afebrile genito-urinary syndrome** : Gonorrhoea, Chanroid, HSV

Table - 1

| Sr No | Name | Age | Sex | Residential address | Work-place address | Date / time of onset of symptoms | Main symptoms/ signs | Name / address of medical facility |
|---|---|---|---|---|---|---|---|---|
| | | | | | | | 1 2 3 | |

of corresponding time period of preceding three years. For finding out as to what is the "normal" expectation during the period being compared with, we use the existing data based on records of hosp admission and discharge data and if these are not available, find out from various physicians in the community whether they have been observing more number of cases with the given set of symptoms recently; or, lastly, undertake a survey of the community to get an idea of the baseline (historical) data. Ultimately pragmatic considerations are also important as to whether to investigate or not. There could also be situations when a single case of a disease may be enough

**In Our Example :** With 2 cases out of 1000 personnel staying in the camp, the rough incidence was worked out as 2 per 1000. Daily epidemiological surveillance system available with the SHO indicated that maximum of one case of gastro-enteritis with dehydration could be expected in a day in that military station, during that part of the year. Moreover, since "cholera" was also one of the possibilities, it was decided to tentatively consider the situation as one of "epidemic". The Sr Exec Med Offr (SEMO) of the cantonment (Commandant of the military hospital) and Dy Dir Med Services (DDMS) of the Area HQ were intimated for their permission to investigate and their administrative & technical help was sought.

to call for investigations, eg, a suspected case of plague, or in many of the military situations, even a single case of cholera.

### Step 3 : Develop an Initial (Rough) "Line-listing" of cases

A line list is like a nominal roll of the cases which have already been reported to the various health care establishments (like MI Room, OPD, or admitted to the hospitals) till now. Line listing of the cases is a major help in initial definition of the disease / syndrome that has occurred in epidemic form, in delineating the population at risk & in preliminary definition of the transmission dynamics of the epidemic according to place and time. A line list is a serial, chronological listing of all the known cases till now, as per the following headings in Table 1

### Step 4 : Define the population at risk

By knowing the general population from where the cases have been coming, as evident from the initial line listing and subsequently from the details of cases as recorded on the epidemiological case sheet (see below), one can define, in a demarcating manner, the source population. For example, the population at risk may be defined as "19 Satpura Battalion", or " Units and family lines under GE (South)" or "Male cadets of AFMC", etc. The more clearly

**In Our Example** : Urgent telephonic calls were made to the various RMOs in the city whether similar cases of gastroenteritis were seen by them on that day. The duty Medical Officer of the hospital was asked whether any other case (other than the two in question) with similar symptoms were also admitted to the hospital that day from some other military units. Since there were no other case, these two were taken as the initial cases and their details were noted on a line list as per format already discussed above. Since both these cases were from a single unit, "people living in that particular military camp" were defined as the "population at risk".

such source population is defined, better the results of investigation would be.

### Step 5 : Develop valid case definition

Often the search for additional cases would involve a number of medical officers / paramedical personnel. It is therefore important that the investigator develops case definitions which are adequately sensitive (i.e. include all those who are having the target disease, though this may entail including many who do not really have the disease) as well as adequately specific (exclude all those who do not have the target disease, though many mild or equivocal cases of the disease may also be missed out). Apparently, the case definitions should be developed in a way that there is adequate trade-off between both sensitivity and specificity. Development of proper, standardised case definitions is important to ensure uniformity during the investigations. For practical purposes, it is better to have cases in three categories, viz., definite, probable and suspect. Initially during the

**In Our Example** : The case definitions were developed as :- Suspect case (for use by the paramedical nursing / health assistants) : any person with at least one vomiting and 2 episodes of watery loose motions in a day; Probable case (for use by RMOs and Duty Med Offrs) : suspect case criteria plus no fever , no tenesmus, and no blood in stools; Confirmed case (for use by SHO for investigating the epidemic) : probable case criteria plus laboratory demonstration of ETEC / V cholerae / salmonella sp / Shigella sp / Giardia / Entamoeba from

investigations, while formulating the hypotheses, it may be desirable to have more sensitive definitions, and later, as the hypotheses are being refined / tested, the definitions may be made more specific by removing the "suspect" category.

### Step-6 : Develop the epidemiological case sheet

The epidemiological case sheet is an extension of the clinical case sheet on which, for each and every subject, the personal and clinical details are filled up. In addition , the details of all factors which are relevant to the mode of transmission for a period which is equal to the range of incubation period of the disease, going back from the date / time of onset of symptoms, are also recorded. For example, in an outbreak of cholera, the epidemiological case sheet would include the personal particulars, clinical features, laboratory investigation results, and details of all meals, casual meals, snacks, sources of water supply, drinks, soft-drink etc, consumed by the person between 1 day to 5 days prior to the onset of symptoms. Thus, if the patient had onset of first symptoms of cholera on 10 Aug, we will record all these relevant factors for the period of 06 to 09 Aug. In addition, it will also include details of his movements in time and place during I day to five days prior to the onset of symptoms (i.e., the range of incubation period of cholera).

**In Our Example** : Maj 'X', as the SHO, had been undertaking regular visits to the various units in health cover, to assess various aspects of hygiene & sanitation, during the past one year, since she had joined. She could identify that the disease being investigated would have come from either of drinking water being provided through water coolers placed in each of the mess and each barrack; or from food which was prepared in the various messes; or from some snacks / Lassi consumed at the unit run canteen; or from water consumed from coolers at workplace; or from one of the two sugar-cane-juice stalls or a sweet-meat shop in the cantonment market; or a "bara-khana" (unit level community feasting) which was held in the unit on 8th May. These various possible factors which could have led to the transmission were specifically kept in the epidemiological case sheet. By now, the hospital laboratory had intimated that organisms with darting motility were seen on hanging drop exam from the two patients; hence the diagnosis was finalized as "cholera" and it was decided to record the history of these various transmission factors for a period of 1 to 5 days, retrospectively from the date of onset of symptoms.

### Step-7 : Organise the laboratory (including Entomological and public health lab) work

A very important step in epidemic investigations is laboratory work. This would include collection, storage and dispatch of body samples (blood, CSF, stool, throat swabs, rectal swabs etc), environmental samples (water, food items), entomological samples, and animal samples. It would be extremely desirable to consider what all items would be required for such laboratory procedures keeping in view the possible disease which is being investigated.

**In Our Example** : Maj 'X' had kept her SHO laboratory in a state of constant readiness to deal with any such public health emergency. However, she once again had detailed discussions with the hospital pathologist as regards various samples to be taken and their method of dispatch to the lab. She quickly organised a portable container having gloves, rectal swabs, rectal catheters, sterile Winchester bottles, specimen vials having Cary-Blair transport medium, sterile vials, centrifuge, and personal protective equipment. She decided to collect and dispatch stool samples / rectal swabs, food samples, water samples and serum for immunology.

Close liaison with the local hospital laboratory and with the pathologist / microbiologist needs no emphasis.

### Step 8 : Contact administrative and engineering authorities and establish rapport

In a service set up, it is extremely important to explain the objectives and requirements to the unit/stn cdr and est close rapport with them. This way a lot of information can be obtained without any resistance. Similarly, it is also desirable to establish close rapport with the engineering auth since a substantial part of investigations is likely to be directed towards public health engineering systems like water supply, excreta disposal etc. The layout maps of water supply and sewerage system should be obtained from the eng/adm authorities.

**In Our Example** : Maj 'X' had kept "spot maps" showing hygiene and sanitation of various military units under her health cover, and constantly updated them after her regular visits to units. She had also liaised with MES authorities and kept updated maps of water supply and sewage disposal systems. However, she once again contacted the MES authorities and asked for their assistance in conducting the investigations. She also sought the sanction of DDMS and SEMO to undertake the investigations. Thereafter she contacted the Commanding Officer of the affected military unit, took him into confidence and discussed the details as to how the investigations would be undertaken. Finally, she had discussions with lower level MES functionaries, with the junior functionaries of the affected unit (JCOs / OR) and with the paramedical members of her investigative

### Step 9 : Collection of Information

Having undertaken the preliminary steps, the investigator proceeds to collect the information, recording the details on the epidemiological case sheet for each subject. Information is collected in respect of all possible modes of transmission which are relevant to the disease being investigated, and going back for a period which is equal to the "range" (difference between maximum and minimum) incubation period of the disease, going back from the time of onset of first symptom. For example, in an epidemic of hepatitis A, we would ask for details of sources of regular meals, casual meals, water, milk, sweets, snacks, and so

on, from the date of onset of symptoms and going back for a period of two to 6 weeks. The information is collected from the following sources :-

**(a) From the cases**

The persons who have already reported to the health care facility (MI Room/OPD or admitted to the hospital) now (as indicated in the line list) or who report subsequent to the initiation of investigations are the straightway available source of information.

**(b) Search for additional cases and make the final "line-list"**

The cases who have reported to the health care facility may not represent the entirety of epidemic. Many cases may be lying hidden in the community, being mild cases, or those who may have reported to some other agency for treatment. It is therefore mandatory to search for additional cases so that the complete picture of the epidemic may be obtained. Using the standardised case definition, an extensive search is made using door to door survey in the entire population defined to be at risk. In case of very large populations, a random sample (usually a systematic sample) can be taken. The population must be informed well in advance about the search, through mass-media, announcement systems, fixing hand-bills describing the symptoms and requesting the people to report the disease, Part -I Orders, evening roll calls, etc. Apparently, assistance of adm authorities would go a long way in this process. In addition, other health sources like other hospitals and general practitioners in the area may also be contacted to find out additional cases. In addition to clinical and epidemiological information, laboratory specimen, as applicable, should also be obtained in the field, from suspected cases. Fill up the epidemiological case sheet for cases detected during the search.

Now, a final line list is made. It would include a list of all cases, including those detected on search for additional cases, in a chronological order as they occurred, showing their personal particulars, date of onset, place of stay, place of work and all exposure histories that are relevant to the disease (eg, sources of meals and water in case of an epidemic of oro- faecal disease). A review of the line listing of cases will give important clues as regards the various possible sources of exposure - these would be those exposures which are commonly shared by the cases, as seen in the line listing.

**(c) Environmental information**. Besides clinico-epidemiological information from cases, a detailed environmental assessment is made of the area, depending on the disease one is investigating. Thus, while investigating an epidemic of cholera , one would make a detailed assessment of water supply system, nightsoil disposal system, cook houses and other eating/drinking establishments in the area where the defined population is staying. Similarly, in a suspected epidemic of dengue, one would make a detailed environmental assessment of vector breeding areas. In addition, various environmental samples (eg, water, food, etc) and entomological samples (eg, larval and adult mosquitoes) would also be collected as relevant.

**(d) Information for those who did not suffer from the disease**. This is a very important step which is often overlooked. While search for additional cases is going on, one must record the information regarding possible exposures (eg, movements, sources of meals, casual meals, snacks, water, drinks etc.) not only from those who suffered from the disease symptoms, but also from those who were a part of the population at risk but did not suffer (i.e., the controls). This information from controls is of vital importance in the later part of investigations, when hypothesis regarding various suspected exposures are to be analysed by comparing cases and controls.

**In Our Example** : By now a total of 7 cases had been admitted with same presentation. All were from the same unit and all showed growth of V cholerae Biotype O-1, serotype Ogawa from stool samples. The line list was accordingly revised. All cases were interviewed personally by Maj 'X' and detailed information about various transmission factors was recorded on the epidemiological case sheet for the retrospective period of 1 to 5 days from date of onset. Cases were also asked in detail about any other factor which could have led to the transmission and which might not have been included in the epidemiological case sheet. In this regards, 5 of the cases said that they had also been often going to a kiosk selling "fruit chaat" (mainly water melons) which had come up in the cantonment market recently; accordingly, this was also included in the epidemiological case sheet.

All the units in the cantonment were asked to announce the "suspect case definition" during evening roll calls and Part-1 orders and direct any person or family member having such symptoms to their respective RMO. The RMOs were asked to refer any person or family fitting into "probable case definition" to the hospital for admission and also inform the SHO. The Health Assistants & Lab of SHO went "door to door" in the affected unit including their family quarters and asked if any person had suffered with symptoms fitting into "probable" case definition; if yes, their stool samples

**In our Example** : A team of the SHO and MES staff conducted a detailed physical, on ground check of water distribution and chlorination system and sewage pipe lines. Water and food samples were taken from all messes, water coolers, eating joints in the market and water taps in work-places. These samples were dispatched to hospital lab. Water supply pumps in the affected unit were run for continuos 3 hours by MES, while the ground was being observed. At one place, there was apparent moistness on the ground overlying a major water pipeline. The affected ground was dug open and it was noticed that there was a break in the water pipe line at that spot; this water pipe line was running approx. 5 feet above a sewage pipe which was also slightly damaged. These were immediately repaired. However, this particular water pipe was a main trunk, which was supplying water to the entire affected unit as

well as the adjoining family quarters and not to any single mess.

No other case could be confirmed despite extensive search for cases. Hence information was recorded on the epidemiological case sheet from the seven cases. In addition, 50 healthy people (who did not even fit in the definition of even suspect or probable case), from the same affected military unit were selected from the list of personnel supplied by the unit authorities, by systematic random sampling and all information about various transmission factors as recorded from cases was also recorded from these "controls".

## Step 10 : Describe the epidemic

Once the information has been obtained, an epidemiological description of the epidemic is prepared. This description is vital for developing hypotheses regarding various possible sources of exposures that could have caused this outbreak. The description of epidemic would include:-

**(a) Developing the overall attack rates,**

Developing the overall attack rates using the cases (reported to health care facility plus found during additional search) as the numerator and the population defined to be at the risk at the denominator.

**(b) Describing the clinico epidemiological profile.**

This would include a percentage wise distribution of clinical presentation among the cases a description of the mild/moderato/severe forms, and fatalities.

**(c) Describe the cases according to distribution of person related variables.**

This step involves development of proportional distribution of cases according to relevant, person related variables like age, sex occupation, source of water supply , etc . The detailed line list described in the preceding paragraph is used to describe the cases according to all possible exposures. For example, in an epidemic of cholera, description of cases according to person related variables will include their distribution according to age groups, sex, occupation, place of regular meals, sources of drinking water, sources of casual meals / snacks, etc.

**(d) Describe the epidemic according to time.**

An epidemic is described according to time by plotting an epidemic curve. This curve is developed by plotting the attack rate along the vertical (Y) axis and unit of time along the horizontal (X) axis. The unit of time would depend on the disease; in food poisoning epidemic it would be in hours, in days for cholera and in weeks for Hepatitis A or E outbreaks. Often, it may not be possible to compute the attack rates according to time; in such instances, the epidemic curve may be prepared by plotting the actual number of cases along the vertical axis, instead of attack rates. The shape of the epidemic curve give us important leads as regards the cause. For details of the shapes of various epidemic curves and their interpretation, refer to the chapter on descriptive epidemiology.

**(e) Describe the epidemic according to place.**

Description of the epidemic according to place is given by making the spot map of the area on which the frequency of the disease is plotted as coloured dots. Often, instead of plotting the frequency, only the actual number of cases are plotted and this may be simple and effective method too. Sometimes, different spot maps may have to be developed, eg, separate spot maps for place of residence , place of work etc, depending on the possible places where exposure to disease could have occurred. For example, in a suspected epidemic of scrub typhus, we may have to prepare separate spot maps for cases, according to places of residence, place of work, places visited on patrolling all for a period equal to the range of incubation period of the disease, going back from the day of onset of signs / symptoms. Spot map also gives important insight in to the possible causes of the diseases. One would be inclined to develop possible hypothesis regarding the cause of the outbreak, considering those places where the local concentration of cases is high.

**(f) Describe the environmental conditions just before and**

Table - 2 : In our example, the following was the description of the 7 cases, according to history of major transmission factors as were recorded in epidemiological case sheet as shown

| | | | | | |
|---|---|---|---|---|---|
| Living in barracks | 7 (100%) | Age < 35 yrs | 6 (85%) | Took sugar cane juice from kiosk No. 1 | 5 (72%) |
| Living with family | 0 (0%) | Age > 35 years | 1 (15%) | Took fruit chaat from market | 6 (85%) |
| Eating in 'A' mess | 0 (0%) | Took water from workplace No. 1 | 4 (58%) | Ate during barakhana on 8th May | 6 (85%) |
| Eating in 'B' mess | 6 (85%) | Took water from work place No. 2 | 2 (28%) | Had snacks / Lassi from unit canteen | 5 (72%) |
| Eating in 'C' mess | 0 | Took water from workplace No. 3 | 1 (14%) | Ate sweet-meat from cantonment shop | 2 (28%) |
| Eating in 'D' mess | 1 (15%) | Male sex | 7 (100%) | Ate snacks at workplace | 2 (28%) |

In our example :- 2 cases had onset on 10th may, 3 on 11th and 1 each on 12 and 13th may. There was no case thereafter. The 7 cases were plotted according to the date of onset of their symptoms. The resultant curve showed a sharp rise, a sharp peak and an abrupt fall, indicating a "common vehicle, single exposure (point source)" transmission. It indicated that all these cases had probably got infected at a common source which existed only for a brief period of time, as can occur when a particular meal or drink gets contaminated, or a water storage cistern gets contaminated for a small time till the water is used, or when a infected food handler who is "incubatory carrier" contaminates a food or drink for a brief period of time, before himself coming down with symptoms.

3 different spot maps were made according to workplace, place of staying and place of routine eating and drinking, and cases were plotted as coloured dots on these maps. A clear-cut "clustering" was seen in all the three maps in mess No. 'B', at workplace No 1. and in Living barrack No. 4 and 5. Further assessment indicated that large majority of these cases were staying in barrack No. 4 and 5, as well as eating in Mess 'B' and

**during the outbreak.**

A clear description of the findings of environmental and entomological assessment is given. For example, details of damaged water supply lines, cross-connections with sewer lines , unhygienic conditions in cook house, vector breeding and densities are described and efforts made to correlate these finding with description of epidemic according to line listing and distribution according to person, place and time, thus developing various hypotheses regarding possible causes of the outbreak. It is often worth while to superimpose these environmental findings on the spot map for a quick visual evaluation.

### Step 11 : Developing various alternative hypotheses regarding the cause of outbreak.

Once the epidemic has been described according to its clinico-epidemiological profile, line-list, and distribution according to person, place and time, various hypotheses are developed regarding possible cause(s) of the outbreak. The basis of developing these hypothesis is to start with the descriptions of cases according to various person, place and time related variables and see as to what are the possible exposures which are very common among cases. If the investigations have been done rightly till now, a large number of hypotheses will be developed.

### Step 12 ; Testing the hypotheses : Comparisons using analytical epidemiology .

**In our example** : The factors which were very commonly found in a large proportion of cases were male sex, staying without family, age < 35 years, eating meals in mess 'B' or drinking water from its water cooler, drinking water from water cooler of work-place No.1, staying in barrack No. 4 or 5, having lassi or snacks from unit canteen, eating barakhana on 8th may, consumption of sugarcane juice from kiosk No. 1, and eating fruit-chaat from the market. These were kept as possibilities which could have transmitted the organism (hypotheses). On the other hand, eating snacks at work-place, eating sweetmeats from cantonment shop, eating / drinking in messes Nos. 'A', 'C', or 'D' or drinking water from workplaces No. 2 and 3, were very uncommon among cases and hence not kept as "hypotheses" requiring further exploration.

This step is the backbone of epidemic investigations. A comparison is made between the cases, and those who did not suffer, though being a part of same source population (controls), in respect of each and every possible hypotheses developed in the previous step. The Odds Ratios for each of these exposures are calculated and their statistical significance is seen by 95% confidence interval of odds ratios, or more simply, by a chi square test. Thus, out of the various hypothesized exposures, one would find out one particular exposure in which the cases and controls differ significantly and this is, then, the likely source of the outbreak (See Table - 3)

Further exhaustive search is now made, based on the indications given by the preceding step, to explore in detail as to what could have been the reason for transmission of the organism.

**Final Laboratory proof of cause and effect relationship** . This is a difficult proposition, but if done, can give the final

**In our example** : Once the results of hypothesis testing step focused the suspicion on 'B' mess, the conditions in 'B' mess that existed at the time of the outbreak were further evaluated. Extensive study of hygiene and sanitation of cook house and dining halls, drinking water storage and handling, health state of food handlers and cooking / food serving practices were evaluated. It was noticed that the tap of the water cooler was not functioning and hence drinking water was drawn manually by civilian mess waiters, by immersing a "jug" into the cooler. Water samples were dispatched fro bacteriological exam. There were total of 9 civilian food handlers, including 2 cooks, 2 cleaners and 5 waiters in the 'B' mess. 1 of the waiters (named herewith as waiter No. 'Q') had not reported for duty because of "upset stomach" from 10th may to 13th May. Clinical exam of all these food handlers was undertaken and rectal swabs of all 9 were dispatched to the laboratory

proof of the cause and effect relationship. For example, if the same organism that is isolated from the food handler, who has also been incriminated by analytical epidemiology (case control step above), is also isolated from the cases, then the link is finally proved. However, it is not necessary that this step must always be completed, though best efforts should be made. In most of the real life situations, description of epidemic and test of hypotheses

Table - 3

| In our example, comparison of the 7 cases and 50 controls as regards the 6 different hypothesized factors indicated | | | | | | | |
|---|---|---|---|---|---|---|---|
| **Hypothesized factor** | **Cases** | **Controls** | **Statistical results** | **Hypothesized factor** | **Cases** | **Controls** | **Statistical Results** |
| Eating in 'B' mess | 6 (85%) | 11 (22%) | $p < 0.001$ | Fruit Chaat | 6 (85%) | 39 (78%) | $p > 0.05$ |
| Water from workplace no. 1 | 4 (58%) | 32 (64%) | $p > 0.05$ | Barakhana | 6 (85%) | 44 (88%) | $p > 0.05$ |
| Sugar cane juice | 5 (72%) | 38 (76%) | $p > 0.05$ | Lassi / snacks from canteen | 5 (72%) | 35 (70%) | $p > 0.05$ |

based on analytical epidemiological are enough proof of the cause.

## Control and Prevention

**In our example** : Water samples from water cooler showed very high coliform count of 180 per 100 ml but no *E coli*. Rectal swab of the food handler 'Q' grew *V cholerae* O-1 Ogawa, i.e., the same biotype and serotype as was isolated from the 7 cases.

Steps for immediate control measures and long term prevention should not wait for the final proof of the cause of epidemic but should start immediately and continue concurrently as the investigations proceed. The following broad categories of steps are to be undertaken:-

**(a) Measures directed towards the source of infection**

These would include detection and treatment of cases and carriers, isolation if required, notification, and control of zoonotic reservoir if applicable.

**(b) Actions directed towards channels of transmission**

These would include measures like protection of water supply and food hygiene, vector control, proper disposal of night soil and solid waste, various disinfection procedures, etc, depending on the disease.

**(c) Protection of susceptible population**

This includes steps like immunization, immunoprophylaxis, chemoprophylaxis, personal protective measures etc.

**(d) Developing a long term early warning system**

A proper epidemiological and public health surveillance system should be developed and launched, so as to give ongoing data regarding the frequency of disease and changes in various environmental risk factors, with a view to give early warning of impending outbreaks. Details of surveillance are discussed later.

## The Armed Forces Central Epidemiological Surveillance Centre (AFCESC)

AFCESC has been established at Dept of Community Medicine (PSM), AFMC. This est is headed by Prof & HOD of the dept of PSM, and consists of a team of classified splts in Epidemiology, Medicine, Microbiology and Entomology, who are all faculty members. The functions of this est include :-

(a) Keeping "Mobile Epidemic Investigations Team" consisting of the epidemiologist, physician, microbiologist, and entomologist ready for moving to any location, if so directed, to assist in investigations and control of epidemics. Move of the specialized team is on the directives of the DGAFMS / Commandant, AFMC, Pune.

(b) Developing a surveillance and early warning system for all the important, epidemic prone diseases, in the armed forces.

(c) Establishing a Central registry for various important diseases in the armed forces.

(d) Assisting Medical officers and Specialists in the periphery to undertake investigations, as and when requested and to develop protocols for investigations of common epidemic prone diseases.

Further information on the above mentioned organisation and its objectives may be obtained from :- Officer i/c, AFCESC & CDR, Dept of Community Medicine (PSM), AFMC, Pune 411040; e-mail : psmafmc@rediffmail.com; Tele : 020 (2630) 6029, 6031, 6032, 6339

## Investigating an outbreak of food poisoning

**In our example** : Super-chlorination of water supplies to bring the level of free residual chlorine at consumer end point at 1 ppm was ensured from the very first day the epidemic was reported and was periodically checked by SHO staff. As investigations proceeded, the damaged water pipe lines and sewage lines were promptly repaired. The cantonment market and civilian canteen were ordered to be placed "out of bounds" for all ranks and families on 12 may, till further orders. The food handler 'Q' was removed from duty for 5 days and treated with oral tetracyclines at the cantonment general hospital; all other food handlers, though not found infective were given a presumptive dose of oral doxycycline, on orders issued by DDMS. The damaged tap of the water cooler in 'B' mess was repaired and the top lid was closed and locked. Unit RMO was provide guidance to launch a daily surveillance system for diarrhoeal diseases and their reporting to SHO. Cook house in-charge NCOs were trained to undertake regular, daily medical surveillance of all food handlers.

**Some Tips for Specialists in Preventive Medicine and Medical Officers of Armed Forces for Readiness For Investigating Epidemics**

Officers Commanding Station / Field Health organizations (SHO / FHO) and Medical Officers in charge of health of troops and families should develop readiness for investigating and controlling epidemics and public health emergencies. Some tips to ensure such readiness are:-

- Know your area and the clientele very well. Move out regularly of your offices and scan the area on foot. Where all are the personnel and families staying? Where all do they eat and drink, not only regular meals and water supply but also casual meals, snacks and drinks? What are the defects in water supply and sewage disposal systems? Where are the potential vector breeding areas? Where all do the troops and recruits from training centres go for their patrolling? For their camp training? It is a thorough awareness of all these factors in respect of your clientele that will come greatly handy while developing hypotheses regarding various exposures. There is no short-cut to these painstaking steps. It has been rightly said that a public health specialist need not be necessarily a good epidemiologist but a good epidemiologist has to be a good public health specialist.
- Identify the common epidemic prone diseases in your area. You would be able to do that on the basis of previous records of disease occurrence and your own assessments of the health conditions as said above.
- Maintain a good liaison with engineering authorities. Get the maps of layout of water supply and sewage disposal systems and check them on ground. Keep "spot maps" showing various aspects of geographical layout and areas with adverse hygienic conditions, ready and continuously updated.
- On the basis of the common epidemic prone diseases in your area of health cover as well as the various observations regarding the health related habits of your clientele, as explained above, keep draft "epidemiological case sheets" ready. For example, in case there is an outbreak of viral hepatitis A, I may ask about the history of source of routine water supply, about snacking at a particular wet canteen, about drinking sugar-cane juice from a particular vendor, about consumption of sweets from a particular shop in the training camp area and so on.
- Again, on the basis of the commonly expected epidemic prone diseases in your area, keep your laboratory and entomological procedures ready the equipment and expendables required to collect, store and dispatch the samples. Ascertain well in advance from the pathologist as to what all tests she can undertake at the local hospital? If some test is necessary but is not available at the local hospital, where would the samples be sent and how they will be dispatched?
- Keep your ongoing surveillance for common diseases in place and well established (details are given in next chapter). This will greatly help you in detecting any potential outbreak at a very early stage.
- And, finally, in the event of an outbreak, BE THERE at the site. Your presence may make the difference for

Investigations of an outbreak of food poisoning, takes the same general approach as any other epidemic, as has been outlined earlier. However, there are certain differences in approach, vis a vis the details often described in other textbooks. In a civilian setting, where generally all people live and eat separately, the "common" meal (as a banquet, religious get-together, picnic etc.) can be easily identified and the details of food histories of that meal can be obtained. On the other hand, in armed forces settings, the fact that personnel live and eat all meals together, every meal is a common meal, and hence identification of the common meal which caused the episode of food poisoning may not be as simple a common-sense conclusion. For instance, if 25 soldiers from an infantry company, eating from a common cook house are admitted with symptoms of gastro-enteritis between 9 a.m. and 3 p.m. on 10 May, which meal do we investigate whether breakfast of 10 may, or dinner of 9th may or lunch of 9th May? Secondly, the idea of investigations is not simply to incriminate a given food stuff. The goal is to trace back the entire history of that food item to find out why contamination occurred so that the episode does not repeat. We shall deliberate on the steps to be undertaken for investigating an outbreak of food poisoning, illustrating it with a real-life example. (The location and general settings have been slightly modified in the example, for reasons of confidentiality).

**Step 1: Confirm whether it is an outbreak?**

An outbreak of food poisoning has three characteristics firstly, the symptomatology should be usually referable to GIT (and sometimes systemic in case of mushroom or organophosphate etiology or neurological in botulinum etiology). Secondly, a large number of cases should occur in a small period of time. Thirdly, the cases should have some history of sharing at least one common meal. If these three criteria are fulfilled, we would say that it is an outbreak of food poisoning.

**Step 2 : Verifying The Diagnosis & Deciding Which Meal To Investigate?**

In a food poisoning episode one has to decide as to which meal is to be investigated and this is done by making a "tentative" verification of diagnosis mainly on clinical grounds. While microbiological diagnosis is always desirable, for all practical purposes it is extremely difficult to establish lab diagnosis quickly because the procedures are highly specialized, available only at specialized centres and take time; more important, the food samples are themselves usually not be available due to ignorance or deliberation on the part of food handlers. For example, lab confirmation of C perfringens food poisoning requires

Table - 1

| Etiologic agent | Median incubation (range) | Nausea / Vomitting | Loose motions | Abdominal Cramps | Fever | Blood / Mucous in stools | Neuro-muscular symptoms |
|---|---|---|---|---|---|---|---|
| Staph aureus & B cereus - 1 | | 2 hr (1-6) | +++ | + | + | - | -- |
| C perfringens & B cereus 2 | | 13 ( 10-18) | + | +++ | +++ | - | -- |
| Salmonella spp | 18 (16-24) | ++ | +++ | ++ | +++ | - | - |
| Shigella spp | 24(12-96) | +++ | +++ | +++ | +++ | +++ | - |
| Insecticides / mushroom | Few Mts. | ++ | + | - | - | - | +++ |
| C botulinum | 24(18-36) | + | - | - | - | - | +++ |

**( Legend :- +++ = occurs in 90 to 100% patients; ++ = 40 to 60%; + = 20 to 30%; - = 0 to 5% patients show this manifestation)**

demonstration of $10^7$ spores per gram of faeces from patients or food handlers and S aureus or mushroom poisoning requires toxin assays available only at few centres in our country.

The mainstay is therefore to see the "clinico-epidemiological" profile of the outbreak by quickly analyzing the frequency of symptoms in the present outbreak and comparing this profile with what is expected during outbreaks caused by common etiological causes of food poisoning, as shown in the Table 1

So, the first thing is to work out the % of various signs / symptoms in the present outbreak (besides taking all available samples as food samples, water samples, stool samples of cases and food handlers). Now, see with which etiologic symptomatology (as shown in above table) does the present outbreak match and make a tentative diagnosis of the cause of the present outbreak.

Now, draw an epidemic curve, plotting the number of cases along the vertical axis and the time according to hourly period (i.e., 9 a.m, 10 a.m. etc.). See where the peak of epidemic curve comes, as also the first case and the last case. Go back in time by the known median incubation period of the suspected etiologic agent (as shown in table above) as also the the minimum and maximum incubation periods from the first and last case respectively. The meal which was consumed where all these three time periods converge gives the meal which was most probably contaminated and needs to be further investigated. (See example in Box - 1)

**Step 3 : Getting the Food Histories About the Suspected Meal**

Once the meal which was most probably associated with the epidemic has been identified, a list of each and every dish (including even chapattis, rice and water / drinks) which was served during that meal is made. Now, each and every person who attended that meal is interviewed and asked about the history of consumption of each and every food item that was served during that meal. The information is recorded as per the following work-sheet, which, in fact, is nothing but the line-list as shown in Table 2 and example in Box - 2.

Box - 1

**Example** : On 8th March, Maj 'X', the Dy Asstt Director of Health (DADH) got the information that yesterday, i.e., 7th March, an episode of gastroenteritis had occurred in an Infantry company located independently at a company post. Out of 87 personnel, 36 developed symptoms and have been admitted at the nearby Advanced Dressing Station (ADS). Since the incident was concerning, the ADMS of the Division directed the DADH to move to the affected site and investigate. Maj 'X' left immediately and reached the location at 2 p.m. on 8th Mar. Preliminary investigations revealed that out of the 36 patients, 31 were admitted to the ADS while another 5 were detained for treatment by the RMO. All the cases (100%) had 6 to 8 watery loose motions, 100% had abdominal cramps, 3% had nausea / vomiting, none had fever or blood / mucous in stools. No case had dehydration or any complications. The first 3 cases had onset of symptoms at 7 a.m. on 7th March, 7 between 7 and 8 am, and similarly, 9, 5, 4,3,2,2 and 1 had onset between 8 and 9 am and similar hourly periods; the last case had onset at 3 pm. The peak of the epidemic was reached at 9 a.m. by which time, 19 cases had onset. No food sample of any meal had been kept since the infantry company was in a field area with no electricity or refrigeration facilities.

The epidemic curve plotted with the above data showed a classical "common vehicle point exposure" curve typical of food poisoning. As evident from clinical profile, the entire epidemic was clearly due to either C perfringens or B cereus type 2. Going by the median and range of incubation periods of these organisms, the

Box - 2

In Our Example :- Maj 'X' made a list of each and every item which was served during the dinner on 6th march. These items were Mutton Curry, Matar-Paneer, Moong Daal, Chapati and Rice. She then interviewed each and every of the 81 persons of the Infantry company who had attended that dinner in their company dining hall and asked them whether they developed any symptom. If they had developed symptoms, details of each symptoms were enquired. Details were also taken each and every of these 5 food items whether eaten or not eaten, irrespective of whether the person developed sickness or not.

Table - 2

| Serial No. | Name & Personal particulars | Whether developed illness (Yes or No) | If ill, Presence of symptoms (Yes / No) | | | | History of eating various food items served during the suspected meal | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|
| | | | Nausea / Vomitting | Watery Diarrhoea | Abdominal Cramps | Fever | Matar Paneer | Mutton Curry | Kheer | Item No. 4 | Item No. 5 |
| 1 | ABCD | No | - | - | - | - | Yes | No | Yes | Yes | Yes |
| 81 | XYZ | Yes | No | Yes | Yes | No | No | Yes | No | Yes | No |

**Step 4 : Consolidating the food histories and sickness histories**

The details recorded on the above line list are now consolidated into a summary table as follows

| Food Item | Those who ate the item | | | | Those who did not eat the item | | | | Relative Risk | Attributable Risk |
|---|---|---|---|---|---|---|---|---|---|---|
| | Became Sick | Did not Become sick | Total | Incidence among those who ate the item | Became Sick | Did not Become sick | Total | Incidence among those who did not eat the item (INE) | | |
| (a) | (b) | (c) | (d) | (e) (b ÷ d) | (f) | (g) | (h) | (i) (f ÷ g) | (j) (e ÷ i) | (k) (e - i) |
| Item 1 | 31 | 9 | 40 | 78% | 5 | 42 | 47 | 22% | 3.6 | 66% |
| Item 2 | | | | | | | | | | |
| Item 3 | | | | | | | | | | |

In our example : Maj 'X' now consolidated the line list that she had made into a summary table as follows

| Food Item | Those who ate the item | | | | Those who did not eat the item | | | | Relative Risk | Attributable Risk |
|---|---|---|---|---|---|---|---|---|---|---|
| | Became Sick | Did not Become sick | Total | Incidence among those who ate the item | Became Sick | Did not Become sick | Total | Incidence among those who did not eat the item (INE) | | |
| (a) | (b) | (c) | (d) | (e) (b ÷ d) | (f) | (g) | (h) | (i) (f ÷ g) | (j) (e ÷ i) | (k) (e - i) |
| Mutton Curry | 31 | 9 | 40 | 78% | 5 | 42 | 47 | 22% | 3.6 | 66% |
| Matar Paneer | 30 | 31 | 61 | 49% | 6 | 20 | 26 | 23% | 1.9 | 7% |
| Dal Moong | 27 | 24 | 51 | 53% | 9 | 27 | 36 | 25% | 2.1 | 28% |
| Chapati | 32 | 43 | 75 | 42.7% | 4 | 8 | 12 | 33.3% | 1.27 | 14.4% |
| Rice | 34 | 46 | 80 | 42.5% | 2 | 5 | 7 | 28.6% | 1.5 | 13.1% |
| Water | 36 | 50 | 86 | 42% | 0 | 1 | 1 | 0% | Infinite | 42% |

Now, the food item which shows the maximum Attributable Risk is the food item which most probably was involved in the transmission of the epidemic.

Sometimes all persons who ate the suspected meal may not be available for interrogation. In such instances, the "cases" and a "random sample" of those who ate the meal but did not become ill (controls) are interrogated about the food histories. This is the case-control approach, wherein we would calculate the Odds ratio (OR) and not the Attributable risk. The food item showing highest OR would be taken as the suspect item.

**Step 5 : Undertake an extensive assessment of the sanitary history and food hygiene of each constituent of the suspected food item :**

The objective of investigations is, naturally, to find out why a particular food item got contaminated so that recurrences are prevented in future. Therefore, once a particular dish has been identified as per details given in previous step, it's each and every constituent (including condiments and water) should be noted and detailed history of every constituent should be taken

(a) From where they were procured;

(b) What were the hygienic conditions at the point of procurement;

(c) How they were stored in the cook house;

(d) Sanitary conditions at the time of cooking;

(e) What temperature did the initial cooking achieve;

(f) Whether the cooked food was eaten hot and freshly cooked or else stored;

(g) If stored, at what temperature and under what hygienic conditions was it stored; and, if stored, was it adequately re-heated before consumption. ( Box -3)

Box - 3

**In our Example** : Once mutton curry was identified as the possibly contaminated dish, the suspicion became strong regarding C perfringens etiology, since B cereus is more likely to be conveyed through rice dish while C perfringens is more likely through a meat dish. Maj 'X' quickly made out a detailed list of all items used in making the mutton curry, including condiments, vegetables and water. She thereafter took a detailed sanitary history of each and every item, starting from the point of procurement till the final cooking and subsequent storage / serving of the cooked dish. She also verified the details by personally observing the hygienic conditions on ground.

Maj 'X' noticed some peculiar and interesting findings. The affected infantry company was located in a cut-off field area, hence supply of meat and other fresh items was through a local contractor. The cook house and dining hall were in tentage accommodation, under improvised field conditions. The contarctor used to get mutton from a local civilian butchery. On visiting the civilian butchery it was found that the conditions were grossly unhygienic. The floor was cracked and there was no arrangement for washing the floor, nor there were arrangements of hygienic disposal of excreta of slaughtered animals. There was no system of starving the animals prior to slaughtering. Animal excreta (which is a rich source of C perfringens spores) was seen lying all over the floor of the butchery and the raw meat was apparently getting mixed up with the excreta.

On 6th March, the contractor could finally reach the company location, with mutton and other fresh items by aroung 1 p.m. since there was a breakdown in his vehicle. By that time, lunch had been cooked and was being eaten. It was therefore decided to cook the mutton for dinner. Cooking of mutton curry started at about 3 p.m. and was completed by about 4 p.m. Thereafter, this cooked mutton curry was stored in the large utensil, which was kept on a table, since there was no arrangements of a fridge. This dish was therefore kept at an environmental temperature of about 30°C for almost 4 hours, till 8 pm, giving optimum time and temperature for the heat-shocked C perfringens spores in the mutton to germinate and produce large amount of toxin. At 8 pm, the mutton dish was "warmed" (to about 40°C) (and not reheated thoroughly which could have inactivated the preformed perfringens toxin) and served for dinner starting at about 8.15 pm till 10 pm.

**Step 6 : Make focused recommendations based on the findings of investigations**

Make specific and "do-able" recommendations, based on the actual findings and develop a system of keeping a check that these recommendations are being adhered to.

Box - 4

**In our Example** : Based on her findings, Maj 'X' made the following do-able recommendations :

- Meat should not be taken from the particular civilian butchery, since it was difficult to have adequate sanitary control on it.
- Meat on Hooves be provided to the affected unit and slaughtering be undertaken at unit level.
- Slaughtering be undertaken early morning.
- Meat should be lunch dish and not dinner dish.
- Meat dish should be the last one to be cooked for lunch.
- All meals should be served freshly cooked and hot.
- No cooked food item should be stored, unless operationally essential.
- If cooked item is to be stored, the storage should be on ice, in ice box and not more than 4 hours
- Cooked food item, if stored (even on ice) should be thoroughly reheated to > 60°c before serving
- Company Nursing Assistant to check implementation.

Col RajVir Bhalwar

# Epidemiological Basis of Public Health Surveillance for Disease

Epidemiological Surveillance is a major function of Public Health. The genesis of modern surveillance can be traced back to 1662, when John Gaunt was the first to quantitatively study the patterns of human disease and its possible causes. However, it was only after almost 200 years, when William Farr, in 1838, while working in the office of Registrar General, UK, created a modern surveillance system; he is aptly called the founder of "Epidemiological Surveillance" (61). Twentieth century saw a rapid growth in the scientific concepts and data collection / analytic procedures. By now, public health surveillance activities have widely proliferated, encompassing a large gamut of communicable as well as non-communicable diseases. In fact, surveillance played a major role in the conquest over small pox.

## Definition

(By Langmuir and adopted by WHO in 1968) : "Surveillance, when applied to a disease, means the continued watchfulness over the distribution, and trends of the incidence, through the systematic collection, consolidation and evaluation of morbidity, mortality and other health relevant data, as well as regular dissemination of interpretations to all who have contributed and to all those who are in a position to take action". In a nutshell, surveillance means "information for action". In addition, surveillance is distinguished by methods having practicability, uniformity and rapidity, rather that by complete accuracy" (62 66).Summary of definition and uses of surveillance is given in Table -1

Table - 1 : Surveillance : Definitions & uses

**Definition** :- continued watchfulness over the distribution and trends of the incidence, by systematic collection, consolidation and evaluation of health data, as well as regular dissemination of interpretations to all concerned. In a nutshell, "information for action". It is distinguished by methods having practicability, uniformity and rapidity, rather than complete accuracy".

**Uses** :-

- To study the trends of disease
- Early warning of epidemics
- To provide quantitative estimates of magnitude of health problem
- To study the natural history of disease
- Demonstrating the spread of a disease in time and place
- To develop epidemiologic research questions
- To test epidemiologic hypothesis
- Evaluation of control and preventive measures
- Monitoring of changes in infectious agent

## Surveillance Vs Monitoring

The term 'surveillance' and 'Monitoring' are often used interchangeably but they are, in fact, distinct. Monitoring refers to ongoing measurements of health services or a health programme with a view to 'evaluate' the particular programme / service or intervention, with constant adjustment of performance in relation to the results. In addition, surveillance concerns general populations while monitoring applies to specific target groups (eg, vaccinated infants).

## The objectives of Public Health Surveillance

The specific objectives of surveillance systems are one or more of the following (67)

### To study the trends of disease

Changes in the frequency over short term or long term periods help in identifying as to whether significant rising of falling trends are present and to predict the future course of the disease.

### To provide quantitative estimates of magnitude of health problem

By providing data on incidence and prevalence and further descriptions of incidence/ prevalence according to various socio-demographic characteristics, surveillance helps in identifying the priority (i.e, high risk) groups.,

### To study the natural history of disease

Surveillance of AIDS during the last decade has added significantly to our knowledge regarding the natural history of HIV infection and AIDS.

### Early warning of epidemics

Constant analysis of surveillance data of a disease would identify any upward trend, at a very early stage.

### Demonstrating the spread of a disease in time & place

Description of surveillance data using time and space combinations can demonstrate the spread of a disease and identify the possible vehicles and routes of spread.

### To develop epidemiologic research questions

Sensible interpretations of surveillance data can open up interesting research questions; eg, increase in the request for pentamidine noted by CDC Atlanta, in 1981, led to generation of research questions and finally "AIDS" was recognised.

### To test epidemiologic hypothesis

Sometimes surveillance data can be used to test hypothesis; eg, in 1973, a particular insecticide was suspected of being related to birth defects. However surveillance data for 1970 73 showed decrease in total birth defects even though there was five fold increase in insecticide sales during the same period, thus acquitting the particular insecticide.

### Evaluation of control and preventive measures

Surveillance data on poliomyelitis during 1950's in USA showed a dramatic decline in disease incidence, thereby confirming the efficacy of polio vaccination campaign.

Monitoring of change in infectious agent :- Development

of antibiotic resistant gonococci have been identified with the help of surveillance data.

Detecting changes in health practices

Surveillance of delivery practices has shown that caesarian deliveries increased from 5% to 25% in USA.

## Criteria for identifying high priority areas for establishing surveillance activities

Surveillance activities are costly and hence should not be launched inadvertently. Careful consideration should be made beforehand as to whether the particular disease is a high priority area from public health point of view. This includes review of the data on Frequency of the disease (in terms of incidence of mortality, and incidence/prevalence of morbidity, due to the disease); Severity (in terms of case fatality ratio, proportionate mortality ratio, hospitalization rates due to the disease and disability rates); Economic impact (in terms of direct costs that accrue due to medical treatment for the disease and indirect costs due to reduction in productivity); Preventability; and, Public interest (community attitudes towards the disease and political will).

## Organization and structure of a surveillance system :

The essentials of a surveillance system are

(a) An overall organization : Consisting of personnel, finances, logistic and administrative back up.

(b) The originators of data : This would include the sources of data, data collectors and data collecting mechanisms.

(c) The transmission of data to the surveillance center, with specification of the mode of transmission and frequency of such transmission.

(d) Data management and analysis : This includes manual /computerized data files, and statistical analysis procedures.

(e) The sensible interpretation or results : Including their consolidation and preparation of reports.

(f) A system of feed back of results : To the originators of data and to those who are in a position to enforce preventive steps.

(g) A system to periodically evaluate the surveillance system itself.

## Steps In Establishing A Surveillance System

**Step - 1**

**Is It Justifiable To Establish A Surveillance System ?** As said above, at the outset we must analyse whether it is really required to initiate a surveillance system by asking whether the disease is of public health importance (see criteria above) and whether prevention / control measures are available.

**Step - 2**

**Spell out the objectives of surveillance system** :- The following issues should be addressed :-

(a) Clearly specify the disease (s) proposed to be brought under surveillance.

(b) Specify : Who needs what information, for what purpose? (eg, whether a rapid case count for epidemic warning is required by the DDMS Corps or detailed information to identify temporal trends is required by the DGAFMS?)

(c) The target population : eg, whether it is "mothers and children" or "blood donors" or "all troops inducted into high altitude".

(d) The health problem : eg, whether only MI or entire spectrum of IHD is to be put to surveillance ?

(e) Nature of control programmes : eg, if it is a rare disease/disease moving towards eradication, a fine surveillance will be needed; on the other hand if it is a common disease, a crude surveillance would suffice.

**Step - 3**

**Specify the organization and structure of the surveillance**

At the very planning stage, clear specifications should be made as to "who will do what, how, and will be responsible to whom" .

**Step - 4**

**Clearly define the disease(s) being considered for surveillance**

Case definitions should be meticulously worked out after detailed consultation with experts. They should be adequately inclusive. (ie., sensitive) as well as adequately exclusive (i.e, specific). All those involved in the collection of data should be well trained in the use of these case definitions/ diagnostic methods. Case definitions/ diagnostic procedures should be simple enough so as to be understood and used by all those on which the system depends for reporting. It would be desirable to report the cases under three different diagnostic categories, viz., confirmed / probable / suspect, with clear definitions for each category stipulated.

**Step - 5**

**Specify the Details of Collection of Information**

Collection of data is the most costly and difficult component of a surveillance system. The quality of a surveillance system is as good as the quality of the data collected. The Epidemiologist will therefore have to make the following specifications :-

(a) Select the proper sources of data

Various sources of data are available (65) as described in an earlier chapter. It would require an intelligent thought by the surveillance officer as to what all sources would be optimum.

(b) Specify the method of data collection

Alternative methods can be :

**Passive surveillance**

In passive surveillance, the data recipient has to wait for the data providers to report, (eg, various headquarters wait for AFMSF-73 to be raised by hospitals). Passive surveillance is the most common method of data collection. All the passive surveillance agencies that are required to report should be sensitized and trained. The frequency of reporting should be clearly laid down and a system of issuing prompt reminders established.

**Active Surveillance**

In certain circumstances, data must be obtained by searching for cases (e.g., health workers go into the

community, search for cases of fever and take their blood slide for malarial parasite), and also by periodically contacting those who may know of cases, as RMOs, GPs, etc. For rare disease, or disease on way to eradication, or during outbreaks, active surveillance is necessary, so that cases which could have been otherwise missed, are promptly identified. Since it is expensive, active surveillance is usually limited to specific diseases, and for a specific situation.

**Sentinel Surveillance**

Data is obtained from selected hospitals who agree to report all cases of the disease.

**Special Surveillance teams**

Sometimes, special surveillance teams may be formed for carrying out surveys or epidemic investigations and to undertake clinical examinations Laboratory, Entomological and Environmental assessments.

(c) The forms that will be used

The forms should be simple and as brief as possible. The question should be clear cut, preferably with closed - ended answer categories and pre-coded for computer data entry. An example is the "Disease Notification Form" (AFMSF-73) for infectious diseases or ACO-1 form for notification of HIV infection which is used in the armed forces.

(d) What time/place of diagnosis will be entered

One has to specify as to whether one would go by the time and place a case is actually diagnosed or else the time/place the case would have got the infection, or the time / place when first symptoms appeared. What is important is that one should ensure strict criteria and not fluctuate from case to case. If everything is at disposal, it would be better to ask for the time and place the case actually got the infection and the time / place when first symptoms appeared.

(e) What will be the frequency of reporting?

For a disease like cholera and food poisoning it would be daily (or at the most weekly) report; for HIV infection a monthly report would be reasonable while for cancer, a quarterly or even half yearly report would be required.

(f) Decide the method of transmission of reports

The simplest is a letter. For diseases that may cause public alarm (plague, JE etc), reports by telegram/ telephone may be stipulated. The data originators should give due consideration to possible postal delays that may occur, especially in developing countries or in operational areas and originate the report in time. In addition, the central surveillance node should keep a centralized cross-check mechanism and issue a reminder if timely report is not received from a particular reporting unit.

**Step - 6**

**The Organization and procedures of data Analysis**

The ideal is to have a computerized system, with back-up hard copies on central register. Computerized data should be maintained on a "Database" programme (as ACCESS or Foxpro) or else on a worksheet as EXCEL. For Statistical analysis, the software "EPI-2002" developed by WHO and CDC Atlanta is quite good. Details are given in a subsequent section. It is better to maintain 2 sets of data bases - one provisional and another final. The statistical analysis will include :-

Simple display of data

By means of visual representations through histograms/ bar diagrams/ line diagrams describing the data according to various characteristics of person, place and time. For depiction of "time trends", line diagrams and histograms are the best. (refer to section on Biostatistics).

Descriptive statistics

Give the "summary statistics" (Incidence rates / prevalence / proportions /Mean / Median ) along with the measures of dispersion (SD) and the 95% confidence intervals. This should be done in respect of the important and relevant variables related to person (age, sex, occupation etc), place (differences in geographical distributions, distributions according to place of contracting the infection, etc) and distribution according to time. The tables should be small (ideally a 2 x 2 or maximum 2 x 4 table) and should be accompanied by descriptive notes.

Inferential statistics

Analytic procedures usually are based on comparing the current incidence against the "Upper and Lower Control Limits" (UCL & LCL).

**{A quick method of calculating the UCL and LCL is : UCL or LCL = R ± 1.023 X A ; ( Where R = Average of Incidence rate per 1000 population for the corresponding period for the past 3 years and A is the average of "ranges" for the past 3 years. The resulting UCL and LCL will encompass 99% confidence interval)}.**

Analysing Time (temporal) trends

The comparisons are made between the rates during present period with the rates during the corresponding periods of the last 3 to 5 years; or between the rates or No. of cases reported during current week (or month) with the immediately preceding 4 weeks (or 4 months). For long term secular trends and cyclical trends, the most simple and suitable method is to present a line graph or histogram, indicating the occurrence of disease according to calendar years. More rigorous procedures as "test for linear trends for categorical data" and "time-series analysis" are available. They can referred from advanced texts (see list at end of this chapter).

Place (Spatial) data

This analysis is important to identify the 'places' where significant number of cases are occurring; it may also reveal localized outbreaks. It is always desirable to plot the 'spot maps' according to 'place of contracting the infection' as well as according to the place of reporting.

**Step - 7**

**Making Scientific interpretations out of the results**

It is not really in the analysis of the data but rather in making sensible interpretations that the skill of epidemiologist lies. Firstly, the epidemiologist should consider whether the apparent, statistically significant, increases or decreases in the disease incidence at a given

place and time represent true changes. Fallacious increase or decrease may be due to changes affecting the numerator as improvement in diagnostic procedures, duplicate reporting, or enhanced reporting; or else may be due to changes affecting the denominator as increase in population size. Secondly, one must carefully consider the biases that could have occurred in detecting and reporting at various levels. The epidemiologist should always be cautious of the fact that the cases which have been reported to him MAY NOT be truly representative of the total target population which he has put under surveillance and he should verify this by studying the characteristics of the total population under surveillance and compare it with the characteristics of cases which have been reported.

**Step - 8**

Ensure proper feedback to all concerned

It is extremely important to provide regular (usually monthly) feedback reports to all those who are in a position to take action on your surveillance data (as, SEMO, Station Commander, DDMS of higher formation, MES authorities) and not to forget, all those who have provided you with the data (RMOs, COs of hospital / Field Ambulances, Pathologists and other relevant specialist in the hospital, etc.). This will go a long way in keeping their interest alive.

**Step - 9**

**Periodically evaluate / review the surveillance system**

See whether the case definitions need a change? Are there some problems in the timely and accurate reporting and how can it be improved? Peridic evaluation is important to identify defects and reorient the methodology. Summary of steps involved in developing a surveillance system is given in table-2

**Some Tips for Specialists in Preventive Medicine and Medical Officers of Armed Forces for developing simple and effective surveillance systems**

As a Officer Commanding Station or Field Health organization (SHO / FHO), undertake the following steps :

(a) Yourself or your trained health assistant / Lab assistant should go to the military hospital (s) of the station, daily, early morning and collect the data, for past 24 hours as regards the personal particulars, unit, date of admission, date of discharge, and provisional / final diagnosis, in respect of

- (i) All admissions
- (ii) All discharges
- (iii) All deaths
- (iv) All laboratory investigations from Microbiology / immunology Dept and relevant investigations from Biochemistry (as LFT) and Haematology (as PBS)

(b) All above details should be recorded in 4 separate registers, column-wise, and put up to you as soon as you come to office. You should eyeball the data and underline with red ink, all cases (either admitted or discharged or deaths or found positive on lab investigations) of diseases which are either notifiable (Gp A, B or C) or are of public health / military importance and need to be investigated.

(c) In addition, on reaching your office, ring up the RMOs / MOs incharge of section hospitals in your health cover, and find out the number of cases of major diagnostic categories ( as gastroenteritis, fever, rash, injuries, etc) seen by them during last 24 hours. Have a word on tele with the cantonment hospital, local civil health authority and OC SHO / FHO of sister stations, as regards the occurrences in their jurisdiction.

(d) Now, for all cases which need notification / epidemiologic investigations, undertake the investigations by contacting the patient and later visiting his home or unit, either personally or by your trained health / lab assistant.

(e) Inform your SEMO and Station Commander of the trends during last 24 hrs and any unusual occurrence, by tele or personally.

(f) Concurrently, take action on the "Entomological surveillance" and "water quality surveillance" as per details given in the respective chapters. Holistically analyse the epidemiological surveillance and vector / water surveillance.

(g) Develop a computerized database on either ACCESS or FOXPRO or else on an EXCEL file, as per following

Table - 2 : Summary : Steps in Developing a Surveillance (SVL) System

- Specify the exact spectrum of the disease(s) or health conditions proposed for Svl
- Decide :- Is it really required to establish a svl. System?
- Clearly define the target population.
- Decide the Objectives : Who needs What information for What purpose?
- Specify in detail the organization.
- Specify clear-cut case definitions
- Clearly specify what all information is to be collected
- Define the sources of information.
- Specify who will collect what information and send to whom?
- Specify the modalities of Svl : active, passive or sentinel
- Specify the method and frequency with which information will be sent
- Develop proper forms for reporting
- Centrally train all data collectors & reporters.
- Do a pilot run
- Receive and analyse data
- Ensure feed back reports to all who can take action and to originators of data.

general field-names as shown in Table 3.

(h) For UCL, enter the formula / programme in the concerned column and the same will be calculated automatically

(j) Preferably, link up your database with a power-point file so that weekly number of cases / rates along with the UCL will be automatically displayed as well as auto-updated. Have a look at the trends of various important diseases, whether there has been a sudden increase over just a few days or there is a more sustained increase over past few weeks; if so, get alerted.

(k) Ensure regular feed back to your SEMO and Stn Cdr personally or on tele, preferably daily about the health situation and disease trends. Send simple, well illustrated weekly and monthly reports to them; if there seems to be an impending epidemic, inform them as also others who need to know (MES / Field Engineers, Cantonment Officials, Concerned units, Sister SHOs, medical controller of formation HQ).

(l) As DADH / ADH at a formation HQ, select out the common epidemic prone diseases which you would like to keep under surveillance. Now develop case definitions for these diseases, with adequate trade-off between sensitivity and specificity. You may develop definitions to classify the diseases into three categories (suspected / probable and confirmed). Now, clearly inform the different reporting levels about these case definitions. Next, for each disease selected for surveillance, specify the periodicity and modality of reporting for each of the reporting level (Nursing assistant at the isolated post; RMO; OC ADS, OC Section Hospital; CO, Mid-Zonal hospital; DADsH of subordinate formations HQs; Comdt, Zonal / General hosp; and so on). Depending on the disease you may, for example, specify that any death, any food poisoning, cholera and any meningitis case should be reported by telephone every day in the morning by all reporting functionaries; malaria, hepatitis, scrub typhus and typhoid, by signal on every Saturday; and other selected diseases at the end of the month by a letter. Now, develop your computerized database on Foxpro / Access / Excel as explained earlier, with an additional field for the name of the formation / unit. Analyse the data regularly for any early warning of increasing incidence. Ensure feed back, in the form of an interesting and simple report, duly illustrated, to your formation commander, DDMS of the higher formation, DDsMS / ADsMS of lower formations and not to forget, all functionaries who have sent the data to you right upto RMO level.

Table - 3

| Week starting date | Week ending date | Malaria | | Viral Hepatitis | | Dengue | | Disease - 4 | |
|---|---|---|---|---|---|---|---|---|---|
| | | No of cases | UCL | No of cases | UCL | No of cases | UCL | No of cases | UCL |

Col RajVir Bhalwar

# Epidemiologic Basis of Screening for Diseases

One of the priority duties, not only of a public health physician but for all medical personnel is to ensure an early diagnosis and treatment (i.e, the secondary level of prevention), through "screening for diseases".

## Definition

Screening has been defined by the commission on chronic illnesses (68, 69) as "the presumptive identification of unrecognized defect or disease by the application of tests, examinations or procedures which can be applied rapidly, to sort out apparently well persons who probably have a disease, from those who probably do not. A screening test is not intended to be diagnostic. Persons with positive or suspicious findings must be referred to the physicians for diagnosis and necessary treatment". Objectives of screening are given in Table -1

Table - 1 : Objectives of Screening

Screening in community health care is undertaken with the following broad objectives :-

- To ensure early detection of a disease among individuals, so that prompt treatment may be instituted; eg, screening for cervical cancer, breast cancer, hypertension etc. This is also called prescriptive screening.
- To protect the community from disease that the person being screened has, also called "prospective screening"; eg, screening the blood units for HIV,
- For entry into certain forms of occupations (armed services, industries, etc) with a view to "weed out" those who are unfit, or whose existing health status

## Requirements of tests used for screening :

**Screening test should be :-**

Valid

Test should be "accurate", i.e, should measure correctly what it intends to. It should have high sensitivity, specificity, and positive & negative predictive values.

Reliable

(Precision, consistency, repeatability) i.e, should give consistent results when repeated applications are made.

Yield

It should give enough number of cases to commensurate with the expenditure and inputs involved.

Practical

The test should be easily administered by even persons with ordinary training, should be innocuous, acceptable and should give fairly quick results.

Efficient

The amount of inputs (in terms of expenses and time) should result in reasonable amount of outputs in terms of improved health & satisfaction.

## The following are the important aspects of validity and reliability (See general notations in Table 2)

**Sensitivity**

It is the ability of a test to detect those (i.e., correctly call positive) who really have the disease.

$$\text{Sensitivity} = TP / (TP + FN) = a / (a + c)$$

**Specificity**

It is the ability of a test to identify those (i.e correctly call negative) who do not have the disease.

$$\text{Specifity} = TN / (FP + TN) = d / (b + d)$$

Ideally a test should be both highly specific as well as highly sensitive. However, in practice this is not possible

Table - 3 : A highly sensitive test

- Will have a large number of true positives and very few false negatives.
- Will also give a lot of false positives.
- Helps in "ruling out" the diagnosis
- Is of value when it is negative.
- Is the ideal screening test.

Table - 4 : A highly specific test

- Will have a large number of true negatives and very few false positives.
- Will also give a lot of false negatives.
- Helps in "ruling-in" the diagnosis
- Is of value when it is positive.
- Is the ideal "final diagnostic test.

Table - 2

| Screening Test | Gold Standard (Final Diagnostic Test) | | |
|---|---|---|---|
| | Positive | Negative | Total |
| Positive | TP (a) | (b) FP | TP+FP=Total test+ve (a+b) |
| Negative | FN (c) | (d) TN | FN+TN=Total test-ve (c + d) |
| Total | TP+FN (a+c) = total actually Diseased | (b+d) FP+TN = total actually healthy | N = Total subjected to screening |

(TP = True Positives, FP = False Positives, FN = False Negatives, TN = True Negatives)

and some trade off, depending on the disease under consideration is required. If a disease has serious implications if not treated early and has adequate treatment available, then our aim would be to not leave out any "false negative", even at the expense of getting many false positives; in such instance we would go up for highly sensitive test.

For a screening test in which the result is measured on a continuous scale, the decision regarding cut off point would need consideration by experienced clinicians & public health administrators. For example, if tonometry is being used as a screening test for glaucoma, the results (18, 18.5, 22, 26.8 mm etc) would be measured on a continuous scale. Now, possibly most of the eyes with intra ocular pressure upto 22 may be, in fact, non glaucomatous while most of the eyes with intra ocular pressure more then 26 mm will be, in fact, really glaucomatous. The main problem will be the eyes having ocular pressure between 22 and 26mm Hg, ie., the area of overlap between glaucomatous and non glaucomatous eyes. If we keep the cut off point low, say at 22 mm Hg, we will correctly identify nearly all the glaucomatous eyes (high TP) but will also identify a number of normal eyes as glaucomatous (large FP). On the other hand if we keep the cut off at 26 mm Hg, we would correctly identify nearly all the normal eyes (high TN) but would miss out a large number of glaucomatous eyes (large FN). In the former instance, when we have a low cut off point (i.e, less stringent criteria) we have, thus, higher sensitivity but lower specificity.

On the other hand, in the latter instance, when we have a higher cut-off point (i.e, more strict criteria) we get a higher specificity at the cost of a lower sensitivity. In practice the public health decision regarding the level of cut off is done based on the potential for treatment following early detection, the availability of treatment and the "labeling effect of having a disease", if any. In such cases, advanced statistical techniques in the form of "Receiver Operator Characteristics (ROC) curve analysis" are available to scientifically work out the optimum cut off point, which gives the best trade off between specificity and false-Positives (i.e. 1 - Specificity).

Sensitivity and specificity of any diagnostic test are fixed, i.e, they will not change. However, our interest in screening is not only the sensitivity or specificity but rather the predictive values; i.e, if an individual has tested positive on a screening test, what are the chances that he really does have the disease. This is called the positive predictive value (PPV or PV+)

$$PPV \text{ or } PV+ = TP / (TP + FP) = a / (a + b)$$

Similarly, the probability that an individual with a negative test result will really not have the disease is called the Negative predictive value (NPV; PV-)

$$NPV \text{ Or } PV- = TN / (FN + TN) = d / (c + d)$$

Unfortunately, predictive value are highly dependent on the prevalence of that disease in the population being screened. The same test with the same levels of sensitivity and specificity will give a very high PPV if the prevalence of disease is high but a very low PPV if prevalence is low. The problem can be overcome by calculation of positive and negative likelihood ratios (LRs) as :

$$LR \text{ Positive} = (Sensitivity) / (1 - Specificity)$$
$$LR \text{ Negative} = (1-Sensitivity) / Specificity$$

The optimum prevalence to get a very high PPV as well as NPV is between 30-60%. Thus, the health administrator should aim at getting the population to be screened in such a way that prevalence of the condition for which screening is being undertaken, is between 30% to 60% (70).

**Reliability**

Reliability is ability of a test to give consistent results when repeated applications are made. It is adversely affected by variability; such variations may occur due to Observer (Intra and Inter observer) variations; variations among or within subjects; and variations due to equipment, tools and techniques. The key word for ensuring reliability is 'standardization'. Centralized training and certification of all observers, use of standard instruments and reagents, use of standard techniques, writing down the entire methodology in an operation manual, laboratory and clinical quality control procedures, and frequent cross check on the observations made by data collectors will go a long way in ensuring reliability.

**Yield**

This indicates the amount of previously unrecognized disease that is diagnosed and brought to treatment as a result of screening. Yield will depend on Sensitivity of the test, Prevalence of the disease (If screening is applied to a high risk group, the yield will be better) and availability of medical care (if medical care has not been available to the community being screened, a large number of people with the disease will be diagnosed). Characteristic of diagnostic test is given in Table - 5

Table - 5 : Summary measures of characteristics of a diagnostic test

**(Please refer to 2X2 table and understand that notations; a = TP, b=FP; c = FN; d = TN)**

- Sensitivity = (a) / (a+c)
- Specificity = (d) / (b+d)
- Positive Predivtive Value (PPV) = (a)/(a+b)
- Negative Predictive value (NPV) = (d)/(b+d)
- LR positive = (Sensitivity) / ( 1 – specificity)
- LR Negative = (1-Sensitivity) / Specificity
- Accuracy = (a+d)/(a+b+c+d)
- ROC analyses for optimum trade-off between (sensitivity/ (1-specificity); where (1-specificity) can also be calculated as False positive Fraction (FPF)
- Reliability (Repeatability, Consistencey, Precision) : the ability of a test to give consistent results when

## Serial and parallel screening tests

2 screening tests can be applied in serial one after the other. In fact the same test (eg, ELISA for HIV) can be done two times in serial. This procedure will greatly increase the positive predictive value. Similarly two tests can applied in parallel and the person can be considered as +ve if any one of the test is +ve (increase in sensitivity) or he may be considered +ve if both the test are +ve. (increase in specificity).

## Considerations before launching a screening programme

Screening in public health care should only be launched after carefully considering various aspects, as summarized in Table 6. Detection of cancer of uterine cervix using "pap test" is a procedure which meets all the above 10 criteria. The test is based on the assumptions that, firstly, a high proportion of cancer cervix detected in situ would progress to invasive cancer over time; secondly, most cancers remain in situ long enough for screening at reasonable intervals to detect a high proportion of cancer cases; and, thirdly, Carcmonia in situ is highly curable. Other diseases which are amenable to screening include breast cancer, Hypertension, Anemia during pregnancy, Diabetes Mellitus, growth screening in children, CHD screening in high risk groups, phenylketonuria among new born etc.

Table - 6 : Considerations for a screening programme

- ☐ The condition should be an important health problem.
- ☐ There should be an acceptable and effective treatment.
- ☐ Facilities for confirming the diagnosis and for treatment should be available.
- ☐ There should be recognizable latent / early symptomatic stage.
- ☐ There should be a suitable screening test or examination available.
- ☐ The test should be acceptable .
- ☐ The natural history of the condition, including development from latent to apparent disease, should be adequately understood.
- ☐ There should be an agreed policy regarding whom to treat as patients.
- ☐ The cost of case finding (including final diagnosis and treatment) should be economically balanced vis-a-vis the expenditure on medical care as a whole.

(After Wilson & Jugner) (71).

## Evaluation of screening programmes

Contemporary medical evidence strongly recommends that the effectiveness and impact of screening programmes must be evaluated by Randomised controlled trials (RCTs) by comparing the outcome measures between the screened and unscreened groups.

## Biases in screening programmes (72, 75)

### Lead time bias

Lead time is defined as the interval between the point a condition is detected through screening and the time it would normally have been detected due to appearance and reporting of signs and symptoms. If early detection has no effect on the course of disease then it will be like giving the patient a few more years of sickness and apprehension rather than health! (eg, HIV detection). In such cases, it is possible that screening, through earlier detection, will advance the time of diagnosis without delaying time of death, thereby increasing the "diagnosis to death - time" and tend to show "increased survival" among the screened group as compared to the group not given screening test, though in reality there would be no increase in survival.

### Length bias

It has been observed that cases detected through periodic, early detection programs, tend to have longer preclinical stages then those missed out by screening but self detected between examinations. This preclinical stage is defined as the interval between the time a screening test is capable of detecting disease and the time the patient seeks care as a result of experiencing symptom detected patients. Thus, the length bias tends to spuriously show a better survival among screen detected cases.

### Self selection bias

If the screening program evaluation is not based on a RCT but rather on self selection (volunteers) it is possible that such volunteers may be more health conscious, educated and more likely to give up associated risk factors; hence survival in such a screened group is likely to be better, not due to screening but because of associated factors.

## Medical Officer's Check List while planning a Screening Programme

In the past many screening programmes have been launched simply due to over enthusiasm, without any consideration to the epidemiological facets of proper health planning. The result has been often quite adverse, creating unnecessary public aversion towards screening programmes (due to lack of proper diagnostic test or treatment), and wastage of resources. It is therefore necessary that the Medical Officer in charge of Community health care should check the following list sequentially, while launching a screening programme.

Undertake a quick collection of information, by going through existing records of health institutions and other governmental / non-governmental agencies, or else, collect information by a quick survey, in respect of the community to be screened about the

(a) Demographic profile;

(b) Attitudes towards utilization of existing health services;

(c) Knowledge & practices about disease(s) proposed to be screened;

(d) Prevalence of important diseases with special

reference to the diseases proposed to be screened;

(e) Expected load of population likely to come up for screening, in respect of the community to be screened.

(f) Resource analysis

(i) Available medical and paramedical personnel, buildings, vehicles, equipment (for screening and final diagnosis), etc. What additional resources in terms of men, money and material will be required to smoothly undertake the screening test (and the final diagnostic test for those who are positive on screening)? Are adequate treatment facilities available?

(ii) Reports on previous screening programmes which were undertaken in the same community earlier and the "grey areas" noticed.

(g) Decide whether it is worthwhile and feasible to screen for the disease (s) in question :

(i) These considerations are very important before launching a screening programme. The important questions that you must ask yourself at this stage are :-

(ii) Is the disease proposed to be screened an important health problem?

(h) What are the high risk groups for the disease?

(j) What is the prevalence in these groups?

(k) Is a screening test available and can be administered to the subjects at a place near their home (say within 5 kilometers)?

(l) Will the screening test be acceptable to the clientele?

(m) Have the "diagnostic characteristics" (sensitivity, specificity etc) of the screening test been worked out authentically?

(n) Is a confirmatory test available? Will you be able to administer it to all those who are positive on screening test?

(o) If the confirmatory test is to be given in a specialised center, will that center entertain your referred subjects? Will the subjects be able to afford the travel and stay at the place of final diagnostic test?

(p) Are you sure that there is a proper, proved modality of treatment for the disease you are going to screen?

(q) Will those finally diagnosed be able to "afford" this treatment? Or, will you be able to provide treatment out of governmental funds?

(r) Are you sure that the disease you are screening for does not carry an over-riding "labeling" effect?

(s) Identify the high risk groups :

As we know, the prevalence will be high in high risk groups and hence the PPV and yield will be high; eg, for screening for cervical cancer, "women > 35 years from lower socioeconomic status" may be identified as the high risk groups.

(t) Collect your logistics together :

Remember, not to start a screening programme, in anticipation of the resources you may cut a sorry figure and cause adverse publicity. First get all your required personnel, equipment, reagents, and other logistics ready.

(u) "Standardize" your personnel, instruments and techniques :

The only method of ensuring a high repeatability of screening test is to centrally train your observers/ technicians, pretest and certify them, standardize your equipment and reagents, and establish quality control procedures.

(v) Ensure community participation :

Remember, a good epidemiologist never takes her community for granted. Your finest screening camp may not draw even a few subjects, simply because community participation had not been ensured. Contact the community leaders, Commanders, senior ladies, peer groups and other members of the community who may matter, right in the planning stage itself. Explain to them the importance of the disease to be screened, and the usefulness of screening and early treatment. Emphasise on them that you need their active participation. Take their opinion as regards how they would like to get the camp organized.

(w) Give proper publicity :

Make sure that at least 2 to 3 rounds of wide publicity have been undertaken, with an additional round of publicity for the high risk groups. The last round should ideally be undertaken 2 to 3 days before the start of screening camp. Ensure that those living in the remote, cutoff areas are covered well with your publicity they are usually the ones who will benefit most by your screening programmes but are generally missed out by publicity campaigns.

(x) Conduct the screening programme :

Do not leave things to chance. Be there yourself at the site, or at least ensure that one of your senior subordinates is there to address the "unforeseen" problems.

(y) Evaluate the screening programme :

Set up your "criteria of evaluation well in advance. Write down your evaluation report at an early date while things are still fresh in the mind this will serve as a good reference document for subsequent screening programmes.

Col RajVir Bhalwar

# Epidemiological Basis of Planning and Evaluation of Health Services / Programmes

In contemporary times, the importance of planning and evaluation needs no further emphasis. What is relevant to note, at this point is that epidemiology is central to the successful execution of these key managerial functions. The reason is simple - the indispensable requirement for any planning or evaluation process is "valid and reliable data" and epidemiology is the science which deals with valid and reliable data collection, collation, analysis and interpretation (76).

## The planning process

Planning is a very scientific and systematic process which essentially visualizes as to where we are at present (present situation or baseline), where do we want to go (the future or "outcome"), why do we want to go there and how do we get there (process). It consists of a series of steps and we need accurate data at each of these steps (77).

### Step 1 : Laying down the premises (scope)

This defines the general perimeters or "boundaries", in terms of place, time, population and disease condition(s), within which the health program being planned, will be restricted to (78).

### Step 2 : Situational analysis

Relevant Demographic (age, sex, population distribution etc.), socio-economic (literacy, occupation, economic status etc.) and disease data (mortality and morbidity) is obtained and analysed.

### Step 3 : Resource analysis

Data on available resources (health manpower, money and material) is obtained and analysed.

### Step 4 : SWOT analysis

The strengths (S), weakness (W), opportunities (O) and threats (T) are identified in context of the proposed programme. S and W are permanent phenomena that exist within the organization or community; O and T are temporary, often flitting, phenomena that exist in the external environment. For example, in a proposed programme for prevention and control of HIV in our armed forces, the organizational philosophy of the armed forces to ensure the top level of health and fitness for all personnel is a "strength" which should be utilized to the maximum. At the same time, the often seen tendency to condone sexual promiscuity as an indication of manliness or a basic need is a weakness pitched against us, and we need to either neutralise it or circumvent it. The fact that recently funds have been made available for developing health educational material and that the new incoming President of AWWA is strongly in favour of educating personnel and families for HIV / AIDS, is an opportunity and we should grab this opportunity. However, if there has been some recent resistance and objection from parents against sex education of children, it is a threat and we need to either negotiate it or else bypass it.

### Step 5 : Ensure Community participation

Identify the community leaders, peers and voluntary groups and involve them fully in the planning process.

### Step 6 : Enunciation of the "Community Needs"

We now carefully evaluate our findings of situational, resource and SWOT analyses and decide as to what are the major issues (within the boundaries defined by our scope) which need to be addressed and which can be feasibly addressed by us. We should also work out an optimum trade-off between 'normative" or 'professionally assessed needs" (what we, as Doctors, feel that the community requires) and the "felt needs" of the community (what the community members feel is their need). By way of community participation, educate and convince the community if, in your perception, their felt needs are unscientific or cannot be addressed within the resources (79 82).

### Step 7 : Setting the Priorities

Now, on the basis of our judged community needs and the resources, work out the "priority" areas within the proposed programme, which are the most important requirements and we, given our available (and expected) resources, can feasibly address them. An epidemiological method for according priorities is to consider the following three headings and give marks (1, 2 or 3) to each heading as per following description. Disease which gets the highest score (max possible will be a score of 9) would get the highest priority while the lowest scoring disease (minimum possible score will be 3) gets lowest priority.

(a) Importance of disease, (based on mortality, morbidity, suffering, cost of treatment and loss of productivity) :- 3 marks if high importance, 2 if moderate, 1 if low importance.

(b) Effectiveness of Interventions :- 3 marks if interventions known to be very effective, 2 if moderately effective, 1 if low or non effective.

(c) Cost of interventions : 3 marks if cost is low, 2 if moderate cost and 1 if cost is high. (Intervention could be a treatment or preventive modality).

### Step 8 : Identify the "High Risk" Groups

High Risk groups are those persons, who due to some characteristics, have a much higher chance of being affected by the disease or it's adverse consequences. It is important, at this stage, to identify who are the high risk persons, based on our situational analysis and identification of community needs, so that extra efforts may be directed towards them, Young children, women of child bearing age, the elderly, people living in slums or inaccessible area are some of the usual examples of hisk risk groups. However, it depends on the disease or condition being addressed. For example, in a educational programme to obtain favourable change in lifestyle, the JCOs, the NCOs and the recruits may be identified as high

risk group. The importance of identifying these groups lies in the fact that while we shall direct our activities to all members of the community, special, more focused and more elaborate (targeted) actions will be directed towards these groups. Consequently, large amount of benefit will occur from the programme if these groups are addressed.

**Step 9 : Enunciate the Goal (Aim), Objectives, Indicators and Targets of the Programme**

Once the community needs have been identified within the context of the proposed programme, we enunciate the Aim or the Goal. This is a broad statement of the overall end-point which the programme intends to achieve. Objectives, on the other hand, are specific statements, through which the overall goal would be achieved. Objectives are thus specific, quantifiable and usually relate to a time-plan. Indicators are parameters and targets are numerical quantities written in conjunction with the indicators, which actually quantify the end points which the objectives are to achieve. For example in a program directed towards healthy lifestyle, the statement "to bring about healthy improvement in various aspects of lifestyle and a reduction of lifestyle diseases so that they are no more a significant health peoblem" is the broad goal or aim. The statement "To ensure that by 31 Dec 2008, at least 80% of the personnel undertake 45 minutes of brisk walk daily on at least 5 days a week" is an objective, in which "community members who are undertaking regular aerobic exercise as per defined criteria of 45 mts a day on at least 5 days a week" is an indicator and "80% achievement by 31 Dec 2008" is the qualifying target.

One of the most crucial steps in planning process is to intelligently enunciate the goal, objectives, indicators and targets. A lot of thought process and expert evaluation should go in at this stage. They should be realistically set, should be do-able, neither too ambitious nor too under-achieving.

**Step 10 : Choose a Strategy and Draw an Action Plan :**

With the background of the enunciated goal, objectives, targets and indicators, and duly considering the resources (step - 3), Select out as to what overall strategy you will use in the proposed programme. For instance, in a proposed programme for prevention of HIV, the strategy could be to only have health educational efforts, or else it could be a comprehensive strategy of combination of health education, blood safety, diagnosis and treatment, surveillance and PPTCT. Obviously the choice of strategy will be strongly guided by the programme objectives and your available / expected resources. If you do not have lot of resources, naturally you would select a strategy of limited activities which are likely to give you the best results. Now, having decided the strategy, write down a detailed action plan as to how the programme will be executed. Do ensure that a "time-line" has been given for each objective, target and indicator, giving the date of each end point.

**Step 11 : Address the Issues of Accessibility and Coverage :**

Get detailed spot maps of your areas and work out the aspects of population distribution, roads, communications and transportation. Do remember that very often, those who would benefit most from your programme, are also the ones who are living far off, do not have access to your services, are often thought to be not really in need of the proposed preventive or curative services. Hence at this point, work out where are your high risk persons located and how will you ensure that they are covered adequately.

**Step 12 : Organise the manpower, material & finances**

Place the required manpower, equipment, material, logistics at the required places. If some more resources are expected, make a plan as to where they will be relocated and how. Make out detailed, written "operations manual" including the operative procedures for each activity, i.e., "who will do what to whom and in what manner". Ensure that your personnel have been centrally trained and tested for undertaking the procedures.

**Step 13 : Undertake a "Pilot Run"**

This is another very important step. Do a small scale trial run of your procedures and rectify any defects that are observed.

**Step 14 : Conduct the Programme**

Launch the programme in a full fledged manner. Ensure that you or your dependable deputies are there always at the sites where the services are being delivered. Make it a point to regularly obtain and analyze data on various aspects as the programmme progresses, making changes if required.

**Step 15 : Evaluate the programme**

Evaluation is the process of assessing the extent to which our results are commensurate with our pre-decided objectives. Evaluation should be a continuous process as the programme progresses (concurrent evaluation) and not simply an exercise to be undertaken at the end of the programme (terminal evaluation). For evaluation, we again need valid and reliable data in the same way that we obtained in the planning stage. Broadly, evaluation is undertaken for six different facets, as follows :-

Evaluation of Relevance

This evaluates whether there is need to continue it as such or in some modified manner (concurrent evaluation) or, at the end when we do terminal evaluation, to find out whether the programme was required at all. This requires obtaining and reviewing the data / intelligence about situational analysis, resources and community needs.

Evaluation of Adequacy

Whether the required amount of manpower, equipment, expendables, logistics, other type of material and finances have been provided? Have they been suitably placed?

Evaluation of Process

How are / were the services / activities undertaken? What has been the quality of services? Were the services accessible to or provided to all the beneficiaries or only few segments? For example, are the targeted number of children being vaccinated, have some areas been left out,

the scheduled number of patients being seen and the planned number of health education sessions being taken, and so on?

### Evaluation of Efficacy, Effectiveness and Efficiency

Efficacy answers the question "can the programme or procedure work" (maybe in ideal or controlled situations); Effectiveness addresses the question "Does it work" (i.e., in the real life situations); Efficiency answers the issue "Is it the most economical way (in terms of time or money)". For example the conventional combination regime of Streptomycin, INH and Thioacetazone may still give pretty good results for curing pulmonary tuberculosis if we were to treat patients admitted into the sanitoria for 18 months (i.e., is efficacious), but in the real domiciliary settings, bring about only about 30% cure (is not effective), while MDT would cure 70 to 80% patients in real life domiciliary settings (is effective). Finally, comparison between the total costs of the two regimen (drugs, duration of treatment, requirement of doctors, paramedics and hospital buildings, commuted cost of reduction in human suffering due to earlier cure, etc) vis-à-vis the overall cure rate may finally indicate that short term MDT may be more "efficient". Summary of steps for planning and evaluation of health programme is given in Table -1

Table - 1 : Summary Box : Steps in planning the health programme

- ☐ Laying down the premises (scope)
- ☐ Situational analysis
- ☐ Resource analysis
- ☐ SWOT analysis
- ☐ Enunciation of the "Community Needs"
- ☐ Setting the Priorities
- ☐ Identify the "High Risk" Groups
- ☐ Enunciate the Goal (Aim), Objectives, Indicators and Targets of the Programme
- ☐ Choose a Strategy
- ☐ Draw an Action Plan
- ☐ Work out where are your high risk persons are located and how will you address accessibility and coverage
- ☐ Ensure Community participation
- ☐ Organise the manpower, material, and finances
- ☐ Undertake a "Pilot Run
- ☐ Conduct the Programme
- ☐ Evaluate the programme
  - Relevance
  - Adequacy
  - Process

# The Essential "Building Blocks" of Research Methodology

The question that we may, quite intuitively, ask is that we are all very well qualified and experienced; we can conduct research pretty well, with the capability to execute research improving with increasing clinical experience. Why should we have text books or training curriculum in "Medical Research Methodology". In fact, medical research methodology (often referred to as "Clinical epidemiology" to make it more attractive to the clinicians) is nothing but an extension of the wise clinician's intuitively explorative faculties. However, such an extension of this faculty (of educated thinking, observing, analyzing and reasoning) as well as the understanding of essential principles and methods of research does not occur simultaneously and concurrent to the learning and practice of medicine. For instance, history of medicine is replete with examples, wherein results based on unscientifically conducted research (gastric freezing, blood letting, "tape-seton' and so on) have been applied, only to cause harm to the patients, just because they were based on unscientific research methods. It therefore needs, in addition to our qualifications and experience in medicine, a working knowledge of the essential principles of research methodology and biostatistics, that need to be clearly understood by all medical persons who are interested in research. This chapter would be explaining these essential principles.

## The first building block : The research question

Funny though it may sound but as per the collective opinion of a number of expert referees of some of the most esteemed international medical journals, in almost half of the research articles that they get for reviewing, the authors did not seem to be clear as to what they wanted to do! Therefore, the first stepping stone in any effective medical research is to develop a proper research question. An appropriate research question, developed after fair amount of academic reading and discussions, is not only an essential requirement for a good research work but also ensures that a major part of research work is effectively sorted out (1).

### Steps In Developing The Research Question

Step 1 : Find a general area of interest

"General area" means a broad field; eg. 'AIDS' or 'Urinary Tract Calculi'. This would depend on our basic, intrinsic interest, our own clinical observations, discussions with colleagues, and deliberations at medical conferences.

Step 2 : Read 'around' the topic

A superficial, very wide (extensive) (but NOT an in-depth intensive study) in the selected area of general interest should now be undertaken, including papers published in related journals for previous 3-5 years, text books and reference books.

Step 3 : Identify a specific area of interest

The broad reading undertaken in step-2 helps us identify those areas where gaps in knowledge exist (work has not been done) and which we, given our strengths and limitations, can try to fill up, e.g., after a wide reading in the general area "Urinary Tract Stones" we may get specifically interested in "Risk factors for Urinary Tract stone formation among Army soldiers".

Step : 4 Read "into" the topic

Once the specific area of interest has been identified, we must now do an 'in-depth' (intensive) study into this specific area (in contrast to the wide, extensive study of step 3). In addition to text books, reference books and relevant journals, detailed discussions with experts in that particular field should be undertaken and published journal articles dealing specifically with our topic of specific interest should be now studied, using the library and internet.

Step 5 : Formulate a "tentative" research question

We would, by now, after going through step 4, have identified a very specific item where some amount of work has gone by, but still gaps in existing body of knowledge exist which need to be investigated. We would also have acquired substantial knowledge as to what other workers and authorities in this field have already studied, how they have undertaken the studies, what results they have already got and what lacunae remain. We can thus write a statement, indicating our "tentative guess", quite specific in nature, which we wish to prove or disprove, in our proposed research work.

Step 6 : Evaluate the tentative research question for its suitability

This evaluation is based on following four parameters :-

**Feasibility**

Is our proposed work "DO-ABLE" in terms of technical / professional capabilities, manpower, money, equipment, time, availability of subjects and logistic support. Feasibility is, in fact, an extremely important consideration. In case it is not feasible, then either we should try and increase our "capabilities" as by organizing funding, equipment and personnel, or else postpone the proposed work.

**Ethics**

Is there any likelihood of breach on confidentiality of human beings, or, exposure of subjects to potentially hazardous agent, or else deprivation of subjects from a potentially useful agent? Will it be cleared by the Institutional Ethical Committee? In general, the major ethical considerations revolve around the issues of protection of confidentiality of subjects; Physician's obligation to his subjects vs. societal good; and, additionally, in a clinical trial, the issues of informed consent, randomization and the use of placebo (2 8).

**Relevance**

Is the topic relevant to our colleagues in our own speciality and the settings in which we generally practice.

**Novelty**

Is there something new? Or, is it that the research

question been already answered clearly on a large number of occasions previously ?

Step 7 : Make the research question as "Specific" as possible

The more specific a research question, the more fruitful will be the research, e.g. " Can drinking 5 litres water per day reduce the risk of renal stone formation by 25% in young, physically active male soldiers serving in desert areas, after duly considering the confounding effects of primary renal disease, dietary factors, racial background, hypercalciuria, hyperoxaluria and hyperuricosuria?" A specific research question would give an idea of the suspected cause or "exposure" (lack of drinking water), the postulated effect or "outcome" (urinary calculi), the expected magnitude of effect (25%), the dose-response (5 litres water per day leading to a 25% improvement), the potential confounding factors (dietary factors, renal disease etc.), and the subjects / settings (young male soldiers in desert areas).

Step 8 : Write down the research question and its significance

It would be a very fruitful exercise to reduce the research question, once finalised, to writing, in a paragraph or two. This would provide a permanent reference during the entire conduct of study; we may further refine it also. In addition to writing down the actual research question, at this point of time, we should also write down its significance in brief. The same would come very handy when writing the introduction of our dissertation / research paper and is, in any case, an obligatory requirement when we put up our research proposals for allocation of monetary grants. The significance of the research question should briefly bring out the following aspects :

(a) The Research question itself, in adequate detail as explained above and it's importance in contemporary clinical / public health practice.

(b) What is already known about the question, based on review of recent literature, and communication with experts.

(c) What are the "gaps" in the existing body of knowledge in this field which need to be filled up, and which this research question proposes to fill up.

(d) What are the possible problems in executing the research on this question in terms of feasibility, methodological issues and ethics.

(e) How the findings of the present study are likely to resolve the present uncertainties in this area, and influence / improve clinical and public health policy.

## The second building block : one subject or many?

Let us look at an example drawn from a report in a reputed journal published in 1969 "..... a 58 year old woman with moderately severe Parkinson's disease recounted to her family physician that 3 months ago, while taking amantadine hydrochloride 100 mg twice daily to prevent flu (then used as an anti-viral drug), she experienced a remarkable remission in her symptoms of rigidity , tremors and akinesia . These symptoms promptly returned on stopping the drug after six weeks ....."(9). The effect in the patient was striking. At that time, medical world was in desperate need of an effective drug for Parkinsonism . However, this report based on a single case could not lead to immediate change in clinical practice. Clinicians tried out Amantadine in a limited number of patients of Parkinsonism and observed beneficial effects in many of them. They, thereafter, tried out the drug in a standard clinical trial, randomly dividing a group of patients of Parkinsonism into two, giving Amantadine to one group and the existing standard therapy to the other and noticing the much larger beneficial effects in the Amantadine group. From the initial description in 1969, it took the medical fraternity a couple of years before introducing Amantadine into clinical practice as an anti-Parkinsonism drug .

> The major difference between clinical practice & clinical research is that in clinical practice we are concerned with only one subject i.e., the patient while in research our focus is on a "large" number of subjects.

There is reason for such delays, for no inferences regarding a risk factor, or prospective marker, diagnostic agent, therapeutic procedure or preventive agent can be drawn from observations on only one or even a few patients or subjects. Why is this so? Because, there is a well known natural phenomenon of variability - no two human beings are likely to be the same. Hence what happens in a

**Summary : Developing the research question**

A well formulated research question ensures that half the job of research work is well completed. Developing a research question is a very scientific and deliberate process involving comprehensive academic inputs. Developing a good research question involves the following steps

- Find a 'general' area of interest
- Read 'around' the topic : A wide and extensive study in that area
- Find a 'specific' area of interest
- Read 'into' the topic : An indepth, intensive reading in the specific area
- Formulate a tentative research question
- Make the research question as 'specific" as possible specify the exposure, outcome and confounding variables, the settings, the dose response relationship & the expected magnitude of effect
- Test the tentative question for feasibility, relevance, Ethical angle, and novelty.
- Write down the final research question and its background significance in a page or two.

single patient may be simply due to chance just because of this natural law of variability. It may be just because of chance that the first patient of lung cancer whom you see may not have even touched a cigarette over his lifetime but that does not mean that smoking is not a risk factor for lung cancer. Inferences about the role of smoking in causation of lung cancer were based on history taken from hundreds of patients of lung cancer & comparing them with the history taken from another hundreds of healthy persons without lung cancer (10, 11).

Thus, an important building block in research methodology is the concept that while clinical practice and research utilize exactly similar procedures, in clinical practice, our focus is on a single individual - the patient, but in clinical research, the interest is not on a single but large number of patients or subjects. And it is from here that many of the (apparent) difficulties of research methodology originate, because, in research, you have to study a "large" number of patients ("subjects") vis-a-vis only one patient that we are used to study, in clinical practice.

### Third building block : Ultimately, research is the relationship between "Variables"

In the process of medical research, we decide the various headings on which we will make measurements on our subjects. For example in a trial of the efficacy of a new lipid lowering drug, we would note down the age, sex, blood pressure, blood glucose, total / LDL / HDL cholesterol, whether the particular subject was given the standard lipid lowering drug or else the new drug, final level of lipids after, say, 6 months and so on. In research methodology, these various "headings" are called "Variables" (12). Thus, Age, Sex, name of the drug administered, LDL level etc., are all "variables". A variable is thus any quantity or quality of a subject which can be measured and which 'varies', i.e., likely to have a different value from one subject to another. Thus, sex is a "variable" since it is a "quality" which is likely to take some different value (either male or female) between two subjects. In fact, when reduced to the lowest terms, all medical research is simply the study of relationship between variables. We will enter these findings initially on individual forms for each patient and later transfer the information to a chart (manual or computerized) wherein the "value" of each of these "variables" will be entered for each patient. This chart, duly completed with all details for the required sample of patients / subjects is what is known as 'DATA'. Data can thus be defined as an organised collection of information, containing the 'values' of the various variables, obtained from a sample of subjects, and which would be subsequently used to derive conclusions through the process of scientific analysis and reasoning. Depending on how the values of various variables are recorded, the data that we collect can, broadly, be either of two types, viz., "Qualitative" and "Quantitative". Each of them can be of further 3 subtypes, i.e., Continuous, discrete and ordinal numerical for quantitative types and dichotomous, polychotomous nominal and polychotomous ordinal for qualitative data (refer to chapter 2 of the section on "principles of epidemiology" for details). As we shall see subsequently, the various variables in a research work would fall under either of the three broad categories of 'Exposure', 'Outcome' and 'Confounding or Control' variables.

**The process of deciding the study "variables"**

- Read your research question in detail
- Decide what are the :
  - Exposure variable
  - Outcome variable
  - Confounding (control) variable
- Decide how would you measure these variables to best answer your question
  - Quantitative Continuous
  - Quantitative Discrete
  - Quantitative Ordinal
  - Qualitative Dichotomous
  - Qualitative Polychotomous Nominal
  - Qualitative polychotomous Ordinal

It becomes very important for the investigator to specify as to what 'variables' will be studied and what would be the 'measurement scale' for each of them, because the subsequent analysis of data will depend upon the type of measurement scales used for different variables, and because the measurement scales are a by-product of study objectives. For example, the same variable, e.g., Diastolic blood pressure can be measured on a continuous scale (DBP recording); or on a dichotomous scale (Hypertensive / normotensive), or polychotomous ordinal scale (Normal, Mild, Moderate and Severe hypertensive) or a numeric ordinal scale (hypertension grade 0,1,2,3 etc.). The decision as to which scale to use will depend on the research question and study objectives; for physiological effect of nicotine or pharmacodynamic study of a drug, we may record it on a continuous scale; for an initial preventive research (whether alcohol use is related to hypertension) we may record it as a dichotomous variable; for a drug trial on hypertension we may record it as an ordinal variable (normo, borderline, mild, moderate, severe). However, whenever in doubt, remember that a continuous (or discrete) variable contains the maximum amount of information followed by a ordinal scale while the dichotomous scale records least information (DBP of 96 or 130 will be both recorded as 'hypertensive'). If the data has been recorded on a continuous or discrete scale, it can be later collapsed into polychotomous or dichotomous categories

### Fourth building block : The "Data" needs to be summarised

In the process of medical research, we would collect the information on a large number of variables as are relevant to our research work. However, as we have already explained in the section on "Principles of Epidemiology",

this large collection of data does not convey any meaning. Hence, we need to summarize our data into "summary figures" which will convey, in one sight, what our data tends to convey. Depending on the scales on which we have measured various variables, these summary figures would be either "mean", or "median" or, more commonly, a proportion or a rate. In turn, a proportion is generally worked out as "prevalence" while a rate is worked out as "Incidence". We have already clarified these concepts in the earlier section on Principles of Epidemiology. You may go through the same, before proceeding further.

### Fifth building block: Whether to study one group or two groups

"….. Some strokes are caused by cerebral infarction in the area of brain distal to an obstructed segment of the internal carotid artery. It should be possible to prevent stroke in people with these lesions by bypassing the diseased segment so that blood can flow to the threatened area normally. Also, it is technically feasible to connect the superficial temporal artery to the internal carotid artery, distal to an obstruction. Because its value seemed self evident on anatomic and physiological grounds, the procedure was applied on a series of patients who were offered surgery, out of which quite a few showed improvement. With this background, as also the documented success of another analogous procedure, the CABG, this new surgical procedure of extracranial-intracranial arterial bypass became widely used in 1970s & 1980s. (However it may be noted that no control group was studied at that time)…..". In1985, the EC/IC bypass study group conducted a randomized controlled trial in which patients with cerebral ischemia and an obstructed internal carotid artery were randomly allocated to surgical or medical treatment. In the surgical group, the operation was a technical success - 96% of the anastamosis were patent a year after surgery. However, surgery did not help the patients. Mortality and stroke rates after 6 years were, in fact, slightly higher in the surgically treated patients as compared to medically treated patients; Moreover, deaths had occurred earlier in the surgically treated patients ….." (13).

An important building block of research methodology is to realize the fact that final conclusion about the risk factors, therapy, prevention or prognosis can be drawn only after comparative research. While results derived from observations made on only one group of subjects may give valuable suggestions for further exploration, however, putting into action, conclusions based on only one group may be fallacious. Studies which describe certain phenomenon or clinical outcomes on only one group are called descriptive studies; they generate strong suggestions or hypothesis but certainly do not give us the final verdict. For getting the final verdict we have to do a comparative study in which a group having the factor of interest is compared with another group which does not have the factor. If the result is better in the group with the factor, then only we can conclude that the particular factor really makes a difference.

### Sixth building block: quantifying the exposure (cause) outcome (effect) relationship

In the 1970s, an issue in the treatment of pulmonary TB was that the patients who were issued their medicines for the complete month (Domiciliary, self administered ATT) were not showing the desired cure rate despite the documented efficacy of multidrug regimen. It was felt that some form of directly observed intake of drugs, which ensures compliance, may be more effective. To test this question, 300 patients of Pul. TB were divided into 2 groups of 150 each. One group was managed with directly observed regimen while the other with the conventional, self administered regimen. Outcome criteria of cure were based on microbiological, clinical & radiological parameters after six months of treatment. The results were as follows(Table - 1)

Table - 1

| Exposure (intervention modality ) | Achieved outcome (cured) | Did not achieve outcome (not cured) | Total |
|---|---|---|---|
| Given Trial modality (DOTS) | 121 (80 %) | 29 (20%) | 150 (100%) |
| Not given trial modality but given control modality | 59 (40 %) | 91 (60%) | 150 (100%) |
| Total | 180 (60%) | 120 (40%) | 300 (100%) |

It is clear that out of the 150 patients given the exposure, 121, i.e., 80% achieved the outcome (were cured) while 40 % of the non exposed group achieved the outcome. These values of 80% and 40% are in technical language called the incidence of outcome in the exposed and the non exposed groups respectively. If we were to ask you whether DOTS was effective, you would immediately say yes. How many times is DOTS more effective than self administered treatment? : 2 times. How did you work out this figure? : by dividing 80% by 40%. In research practice this value of "2 times more" is called the RR (Relative risk or Risk ratio) and we work it out by simply dividing the incidence of outcome in the exposed group with the incidence of outcome in the non exposed group.

These simple issues are actually one of the most important building blocks in research methodology, describing the exposure - outcome relation and calculating the overall effect through the conventional 2×2 table. We can convert the findings of the DOTS trial that we have just presented into a 2×2 table for the sake of understanding the notation. The 2X2 table is so named

One of the key issues in understanding medical research methodology is to understand and be comfortable with the 2 X 2 table. It is a cross combination of exposue at 2 levels (given or not given) and the outcome also

because it has 2 columns and 2 rows. The two rows divide the subjects according to whether they have the exposure or not while two columns divide the subjects according to whether they developed the outcome or not. Accordingly, we get 4 cells named as "a, b, c, d". Cell "a" denotes all those who have the exposure and also had outcome. Cell "b" denotes all those who were exposed but did not have the outcome. Cell "c" denotes all who were not exposed but developed outcome. Cell "d" denotes all those who were neither exposed nor had the outcome. One thing we would like to emphasise at this point is that you should, at the very planning stage of your research, clearly decide as to how you would define the exposure and non exposure as well as outcome achieved or not achieved. Secondly, never change the format of notation: cells a,b,c,d should represent what we have just explained. For instance cell

Table - 2

| Exposure (intervention) | Outcome | | Total |
|---|---|---|---|
| | Achieved (O+) | Not achieved (O-) | |
| Exposed (E+) | 121<br>**a** ($E^+O^+$) | 29<br>**b** ($E^+O^-$) | 150<br>a+b (all $E^+$) |
| Not exposed (E-) | 59<br>**c** ($E^-O^+$) | 59<br>**d** ($E^-O^-$) | 91150<br>c+d (all $E^-$) |
| Total | 180<br>a+c(all $O^+$) | 120<br>b+d (all $O^-$) | 300<br>a+b+c+d<br>(all subjects) |

"a" should always represent subjects who have both exposure and outcome; and so on. Your statistical analysis will completely depend on how accurately you have put the data in the 2X2 table (Table - 2).

Having given the notation as a 2 x 2 table, we would then proceed to calculate the "incidences of outcome" in the exposed (IE) and non exposed (INE) is as follows

IE = (a / a+b)

IE = 121/(121+29) =121/150= 80%

INE = (c / c+d)

INE = 59/(59+91) = 59/150 =40%

And finally we calculate the "effect" by calculating Risk Ratio or Relative Risk (RR) as

**Cautionary note**

Remember that the 4 cells (a, b, c and d) are very specific and their configuration should not be changed. First of all you have to decide as to how do you define "exposure given or not given" and "outcome achieved or not achieved". Notate these as E+, E-, O+ and O-. Now, cell 'a' will always stand for "given exposure and achieved outcome (E+O+), cell 'b' for E+O-, 'c' for E-O+ and 'd' for E-O-. With this configuration we will calculate incidence of outcome in exposed (IE) and non exposed groups (INE) as (a / a+b) and (c / c+d) respectively and the "effect",

RR= IE/ INE

RR = 80%/40% = 2

In case of a retrospective research, however, the correct measure of comparison is not the RR but Odds ratio (OR), which is calculated as (a Xd) / (b X c) . You are requested to turn back to the chapter on "making comparisons" in the previous section on "Principles of Epidemiology" for a detailed description.

## Building block no. 7: Concept of population and samples and external validity

In the second building block we had agreed that in medical research, to make any valid conclusion, we have to study not one, but many patients or subjects. But then, what do we mean by "many". How many? Ten ? Thousand ? A million ? Or all the patients with that disease in this universe. Let us say, we want to address a very simple issue- What is the seroprevalence of HIV infection among the Indian Armed Forces? For conducting this research, we have to first visualize as to what is that large collection of people whom we have is mind, to whom we would be applying our results? Our answer would be that large collection can be defined as "all personnel of Indian Armed Forces". Well, in research language this is precisely what we refer to as "Reference population" or "Total population" or "universe".

So, whom do we study? Do we do HIV testing on all the 15 lakh personnel of Indian Armed Force to derive our results? Not at all: Not possible! Not required also. We would, probably, study about a 1000 personnel, do their HIV testing and get our results. Let us say, we found 10 out of the 1000 were positive, thereby giving us a seropositivity of 1%. After the study is over, we will start saying "the seropositivity of HIV among Indian Armed Forces is 1%". This is one of the key issues in any medical research. We always keep a large population in mind but actually study only a sample, and we do not restrict our final result to our sample but apply it to the large population. And with this, a very major issue in medical research comes up - that of "population" and "sample". The concept becomes important because two types of serious errors can creep into our research just because we study samples but apply their results on to the large populations.

Let us continue with the above example of HIV seropositivity in Armed Forces. Let us say we decided to study a sample of 1000 service personnel. For the sake of convenience of our study we got in touch with all STD treatment centers and got the data about seropositivity. The result showed that 50 out of the 1000 were HIV positive and so we concluded that HIV seropositivity in Indian Armed Forces is 5%. Doesn't sound quite convincing, as it seems to be pretty high. Yes, there is something gone wrong. We had actually defined our reference population as all persons of Indian armed forces, most of them being healthy people. What we actually studied was STD patients of armed forces and, naturally, had to get such a high seropositivity rate. With this background, the first requirement of a sample is that it should be perfectly representative of the large reference

population. If a sample in not representative, the results will be erroneous since they will be different from the reality in the large population and which we want to estimate. This problem, in research language is known as loss of external validity or loss of generalisability because the results cannot be generalized to the large reference population (14).

How do we overcome this problem? We must firstly, clearly define as to what is our reference population and our actual study population, as explained in the following paragraphs. Secondly, having so defined, we must select our study subjects / patients from the actual study population, using proper methods (probability or random techniques) of selection of sample.

**"Total Population" : (Syn : 'Reference' Population; 'Target Population', 'Universe')**

This is the large and total collection of all subjects or patients that the investigator keeps in mind while planning his study and while defining the "actual (study)" population and on which he proposes to generalise his results, e.g,. in the above example the total population is "All personnel of Indian Army". Often, the 'Total Population' is very large, difficult to define, and more of "conceptual" in nature; e.g., "All patients with acute MI". In a nut shell, it is the investigator's study question / objectives and the clinical and demographic characteristics that define the Actual Population.

**Actual (syn : "Accessible" or "Study") Population**

Since the total population (universe) is often difficult to delimit, the investigator specifies a "reasonable subset" of the universe from which he actually proposes to select his sample, since it may not be at all practical or feasible for her to select the sample directly from the "Total Population". For example, in the above study we may specify "All Army Personnel in Pune and Kirkee" as the actual (study) population out of the reference population of "All Indian Army Personnel". In a nut-shell, it is the similarity to the Actual Population and the geographic and temporal (time related) characteristics that define the actual or accessible population.

**Sample**

The sample is that subset of the actual (study) population which is selected from it, which is of an 'adequate size' (as calculated by statistical methods) and selected in such a way, using laid down procedures, that it is "representative" of the study population. "Representativeness" is ensured by using certain scientific methods which see to it that every person in the study population has an "equal chance" of being selected in the sample and nothing is done by which we systematically depart from this "equal chance" principle, e.g., from the actual (study) population, defined as "all army personnel in Pune and Kirkee", for ensuring the principle of "equal chance" we may get a list of all such persons and select out the required sample size of 1000 by random numbers. However, if we systematically depart from this rule, e.g., by selecting all personnel of AFMC, CH (SC), ALC, and MH(CTC), the sample will not be representative, being biased towards the (more aware) medical personnel and hence would show an underestimate of the seropositivity.

## Eighth building block : concept of random error or chance

In the previous building block, we said that there are two major issues which come up when we study samples. First one is the issue of "representativeness" which affects the external validity. Which is the second issue? Now, in research, the moment we start studying a sample, besides the issue of external validity and generalisability due to a non representative sample, there is another major issue that needs to be addressed that of Sampling error, also called Random error, Sample to Sample error, or more simply, Chance.

Let us take an example of a very simple but stupid study. What is the amount of heads that we will get on tossing a coin. Obviously the reality or truth is well known : it is 50%. However, let us start doing this experiment just for the sake of understanding this concept. You toss the coin only once. You get a tail and so you conclude very erroneously that there is no head in a coin, if you were to make your decision on only one toss. Okay, toss it ten times. You may get 9 heads and 1 tail concluding that 90% of the coin is heads, a conclusion still far drawn from the truth. Toss it 100 times, 1000 times and 1 lakh times. The result that you would get is summarized in Table - 3

Table - 3

| No. of times coin was tossed | No. of heads (%) | Actual reality or truth about heads | Deviation of the results from the truth |
|---|---|---|---|
| 1 | Nil (0%) | 50% | 50% |
| 10 | 9 (90%) | 50% | 40% |
| 100 | 31 (31%) | 50% | 19% |
| 1000 | 605 (60.5%) | 50% | 10.5% |
| 100000 | 47800 (47.8%) | 50% | 2.2% |
| Infinite no. of times deviation | 50% | 50% | No |

The take home message is as long as you are studying a sample, even in the most honest way, the results from your sample are always likely to be different from the truth or reality that exists in the reference population and which you are trying to estimate from your sample. However, as you increase the size of your sample (as happened in the example when we increased the number of tosses) this error will reduce and your sample result will get closer and closer to the truth. However if you want your result from the sample without any error, no different from the real value in the reference population, well, then you have to study the total population itself, like tossing the coin for your entire lifetime to finally get the truth of 50%.

See one more situation. Let us say we decided to estimate the truth about the coin with the sample of one lakh tosses and we decided to do five such experiments. The results

Table - 4

| Expt.No. | No. of Heads | Truth |
|---|---|---|
| 1. | 47800 (47.8%) | 50% |
| 2. | 55301 (55.3%) | 50% |
| 3. | 51980 (51.9%) | 50% |
| 4. | 48002 (48.0%) | 50% |
| 5. | 53067 (53.9%) | 50% |

are as shown in Table - 4.

The next take home message from the above study is even if we study repeated samples of the same size, drawn in the most representative manner, no two samples are likely to give us the same result, nor the result for any sample likely to be the same as the truth which exist in the large population from which the samples were drawn. Why does this occur ? This occurs because of a very interesting natural phenomenon called " Random Error" or "Sample to Sample error" or more simply "chance". As long as we are studying a sample, which we would be doing any way, some error should always be accepted. But we can actually do two things about this error.

(a) Firstly we can minimize this error by using an adequately large sample. Calculation of adequately large sample, using statistical procedures, is dealt later in the section on Biostatistics.

(b) Secondly after the research is over, while analyzing the results we apply statistical procedures to calculate the probability by which our result may differ from the real value in the "total population", because of random error. In fact when we finally say that the "p" value is less then 0.05 we are only saying that from our study we have found that the new drug is better then the existing treatment and the probability that these results would be different from the reality that exists in the large population is less than 5 in a 100 chances.

## The ninth building block : confounding : compare apples with apples, not with oranges

Well, while minimizing the random error by studying an adequately large and representative sample and calculation of the p- value which gives the probability of the random error is all very important, it is just one of the three major errors that we have to guard against, in medical research. In fact, it is more important to effectively neutralize the other two errors rather than only worrying about the p-value and statistics. These two errors are, firstly, confounding error and secondly, systematic error also called bias or loss of internal validity or error of measurement.

Let us take a hypothetical study which evaluated the risk factors of IHD by taking 100 cases of IHD and 100 comparable but perfectly healthy people and obtaining the history of various putative risk factors. One of the

Table - 5

| Exposure (defecation Habit) | Outcome | | Total |
|---|---|---|---|
| | O+ (IHD cases) | O- (Healthy controls) | |
| E+(Privy latrines) | 70 (70%) | 30 (30%) | 100 |
| E-(Open fields) | 30 (30%) | 70 (70%) | 100 |
| Total | 100 | 100 | 200 |

factors which the investigators considered was the history of habitual defecation in privies versus open fields. The findings are displayed in the Table - 5.

70 % of the IHD patients gave h/o defecation in proper latrines, while much less (30 %) of the healthy people gave this history, preferring the traditional "open air" practice. Going to the open fields apparently, seemed to be a great protective factor against IHD while sitting on the pot inside a privy increased the risk by more than two fold! The authors were about to recommend that the entire nation should start lining up in the fields early morning to prevent the oncoming epidemic of IHD when the Prof of Cardiology told them that something seemed to have gone wrong! What had actually gone wrong was the occurrence of a very common phenomenon which occurs in research: that of confounding.

In this case there was another variable which created all the confusion - it was socioeconomic affluence, for the rich who used their privies and had more IHD not because of their hygienic habit but because of the affluent unhealthy lifestyle. This phenomenon occurred because the study in example did not follow the basic doctrine of research which says that the two groups being compared should be similar to each other in all other respects except for the factor being studied. Never compare apples with oranges. In all correctness the authors should have selected the groups whose subjects should have been similar in all other respects like age, sex, race, family history and socioeconomic status except for that one group had IHD, and other did not.

In confounding, an observed association between an exposure (eg, defaecation practice) and an outcome (eg, IHD) is "explained away" by a "third" variable (eg, `socio-economic status, in our example). This creates a `confusion' or a nuisance. The above example also tells few more things. The third variable ie, the `socio-economic status' has created this confusion, i.e., confounded the observed relationship because of the following characteristics (15 - 17):-

(a) It is associated with the exposure (e.g., with the method of defaecation, because socioeconomic status does determine such practice).

(b) It is associated with the outcome, independent of its association with the exposure (e.g. richness and affluent lifestyle can independently cause IHD, whether a rich person defaecates in a toilet or in the open).

**In medical research we should understand where all "errors" can occur, in following manner :**

- Since we study a 'sample" from a "population", error of loss of external validity may occur if representative sample is not taken
- Random error (sample to sample error or chance) will occur because we study samples from a population.
- Error will occur if our basic measurement process is wrong.
- If we systematically differentiate while comparing the two groups (Bias or systematic error or loss of internal validity)
- If the groups being compared are dissimilar in

(c) It is `differently' or `unequally' distributed in the 2 groups - (more of the rich will be found in the group having IHD and using privies as compared to the other group which is not having IHD).

(d) It does not lie in the chain of the relationship between the exposure and outcome variable, (eg., it is not that closed-door defaecation leads to richness & then to IHD).

### The importance of confounding in research

Medical literature is replete with examples when a particular factor has been proved to be a risk factor for a disease simply because the effect of third variable (the confounder) was not thought of, thereby making the entire research work invalid. See the following example. A study was done to see whether consumption of alcohol is a risk factor for oral CA. 100 cases of oral CA and 100 healthy subjects were asked regarding the history of alcohol consumption during past 15 years. The results are presented in Table - 6

Table - 6

| History of Alcohol | Oral Cancer | | |
|---|---|---|---|
| | Present | Absent | Total |
| Present | 80 | 20 | 100 |
| Absent | 20 | 80 | 100 |
| Total | 100 | 100 | 200 |

Since the above is a case-control type of study, we can calculate the odds ratios as

Odds Ratios = ( a X d / b X c )

i.e., (80 X 80) / (20 X 20) = 16

Thus we would conclude that the risk of getting oral cancer is 16 times higher if a person drinks alcohol. Someone would object to our findings, saying that this observed association is false, due to the confounding effect of tobacco use - tobacco use is related to the outcome (oral cancer); it is also related to the exposure (alcohol) since it is a known fact that people who drink, are more often the ones who use tobacco. Apparently with the above objection, the only way left for us is to make two "strata" or groups - the group which uses tobacco and another which doesn't use tobacco. Now, by simple reasoning, if the risk of cancer due to alcohol remains high in both the strata, i.e., the risk of cancer due to alcohol is high whether a person uses tobacco or not, we would conclude that the risk is not due to tobacco but due to alcohol itself. On the other hand, if the risk is not evident in the 2nd strata, then we would conclude that there was a "confounding" due to tobacco; alcohol, by itself does not carry any risk. Let us see what happens when we dissect our hypothetical data into two strata:

Stratum - I : Tobacco users

| History of Alcohol | Oral Cancer | | |
|---|---|---|---|
| | Present | Absent | Total |
| Present | 60 | 15 | 75 |
| Absent | 20 | 5 | 25 |
| Total | 80 | 20 | 100 |

Stratum OR = (60 X 5 / 15 X 20 ) = 1

Stratum - II : Non-users of tobacco

| History of Alcohol | Oral Cancer | | |
|---|---|---|---|
| | Present | Absent | Total |
| Present | 5 | 20 | 25 |
| Absent | 15 | 60 | 75 |
| Total | 20 | 80 | 100 |

Stratum OR = ( 5 X 60 / 20 X 15 ) = 1

Surprisingly, we notice that after making adjustment for the use of tobacco as above, the odds ratios in both the stratum falls down to 1 each, i.e., there is no risk of cancer due to alcohol, after adjusting for the effect of tobacco. The earlier observed association between alcohol and oral cancer (OR=16) was only because of a confounding effect of tobacco. When we made adjustment for this confounding effect of tobacco, we found that alcohol, by itself, has no risk. Had we not done this adjustment for confounding we would have drawn a wrong conclusion that alcohol causes oral cancer. The phenomena of "differential distribution" also becomes more apparent from the above 2 - strata tables. We would appreciate that a very large number of cancer patients who consume alcohol are tobacco users (60 out 80 i.e., 75%) while very few patients who consume alcohol are non-users of tobacco (5 out of 20, i.e., 25%).

### How do we overcome the problem of Confounding

There are various methods by which we can overcome this issue, either while we are planning our research or else during the stage of analysis. However, what remains extremely important is that all the Potential Confounding Factors (PCFs) must be identified and, if the adjustments

are going to be in the stage of analysis, the data on them must be recorded. Now, since all the PCF must be identified before the actual study, one must work meticulously on this issue from the very time he / she is working on the issue of developing the research question itself. In fact, while reading and discussing regarding the research question, one must very specifically start identifying what are the exposure and outcome variables of interest and what all PCF can confound this relationship between exposure and outcome because of their independent and indirect relationship with both the exposure as well as the outcome variable. The following steps should be taken :

### Controlling for confounding

Once the confounding variable(s) have been identified, action must be taken to prevent or adjust for them. Such actions can be taken either during the stage of planning and, secondly, during the stage of analysis.

#### Control during planning (designing) stage

This can be achieved by any one or more of the following methods :

#### Randominsation

If a group of subjects is divided into two, using "random allocation" (syn. Randomization) (described in the section on Biostatistics), the 2 groups will be similar to each other in all respects. The beauty, therefore, is that the 2 groups will be "similar" to each other not only in respect of all "known PCF" (age, sex, blood groups and so on) but also in respect of those factors which may be "confounders" but we are not aware of them (eg, HLA type and, may be, the average number of hair on the head!). Thus the 2 groups will be absolutely similar to each other with the only difference that one group gets the trial modality while the other will get the control modality. Any difference in the outcome between the two groups can be safely assumed to be due to the intervention being studied. The singular drawback of randomisation is that it can be done only in an experimental design (eg, drug trial, vaccine trial etc); however, it is not applicable to most of the "cause - effect" research that we do in clinical practice (you can not "randomise" people into 2 groups, telling one group to "smoke" and the other "not to smoke"). However, when we talk of clinical trials, please remember that the most important, rather essential, tool for control of confounding and equating the 2 groups at baseline is randomization, also known as random allocation.

#### Restriction

We can so plan our study that the subjects having the particular confounding variable(s) are not taken up at all; eg, in a study of the possible association between physical inactivity and IHD, young age (< 35 years) and female sex may be the PCF. In this case we may restrict our study to "only males more than 35 years age". The difficulty with restriction is that one tends to exclude out a lot of potential subjects, thus increasing the cost and effort of study; Secondly, the effect of the variables on which restriction has been done can not be studied - eg, in this example, the role of female sex and younger age can not be studied.

#### Matching

We said earlier, that a confounding variable exerts its nuiscance effect due to "unequal distribution" in the two groups. It stands to simple reasoning, therefore, that if the groups could be made "equal" in respect of the confounder, the nuisance effect can be nullified. This is the basic principle behind the very commonly used procedure in medical research - "Matching". Let us say we are doing the above mentioned study on alcohol and oral CA. Once we identify tobacco use as a confounder, what we can do is that for every case of oral CA, we would take a healthy person as control who has the same tobacco use as that of the case, ie., if the case is a tobacco user, we take the control also who is tobacco user and vice versa. The final result will be that we will have equal number of tobacco user cases and controls as well as equal number of non-user cases and controls in our study and any relation between alcohol and oral CA will now be due to alcohol, without any confounding due to tobacco. This method in which we match "one for one" (i.e., for every subject or case we take a control who is similar to that case in respect of the confounding variable), is called as "Pair Matching". The second method of matching is to do a "group matching" or "frequency matching". Suppose we want to match on 3 variables (tobacco use, age and sex ). Let us say, out of 100 cases we have 25 of them as "40-50 years old female tobacco users". We will then select out an equal number, ie., 25, healthy females who are 40-50 years old and tobacco users. In general, it is advisable for the researcher engaged in usual clinical/health research not to lay too much stress on matching. "Frequency matching" can be done for the 'universal confounders', ie., age and sex and additionally for any particular confounder which can be easily matched. As regards other PCF, which have not been matched, data regarding them must be collected and later adjustment for their confounding effect should be made during analysis (18 20).

#### Adjustment during analysis

If matching has not been done for a PCF (but the data has been collected), adjustment for its confounding effect can be done during analysis by following methods :

#### Stratified analysis

The logic of stratified analysis has been presented earlier when we described that we would make 2 strata, one with the confounder and one without the confounder. If the risk in individual strata is the same as overall risk then there is no confounding. On the other hand, if the odds ratios in the strata are very different from the overall OR (eg, in our very first example of alcohol-oral CA study where the overall OR was 16 but the stratum OR after adjusting for tobacco was 1 each), we would conclude that there is confounding. Finally, if the risk estimates in the two strata are quite different among themselves, then we should think of a more important issue of "Effect modification" (Interaction) rather than confounding.

#### Adjusted estimates (Mantel Haenszel) in stratified analysis

Very often, the interest of the researcher is not simply to see whether there was confounding or not but to actually work out the actual risk, in terms of RR or OR, after "adjusting" for the confounding effect. Eg, in a study to see whether use of Oral Contraceptives is associated with the risk of Thromboembolism, the overall OR was found to be 4.4. However, since age (> 35 versus < 35 years) could have confounded the results, the data was further analysed in two strata (women aged > 35 and women aged < 35 years). The results indicated that there was slight confounding due to age, the risk being 4.16 times in younger women and 4.83 times in older women. However, we would like to have a "summary" figure which gives us the overall risk of TE due to OC use, after adjusting for the confounding effect of age in this relationship. This is what we call the "Adjusted RR" or "Adjusted OR" or "Mantel Haenszel adjusted RR/OR", which is worked by a special statistical procedure (21). Let us say in this example, the overall (crude) OR was 4.43; the OR in the 2 strata was 4.16 and 4.83 respectively and the Mantel Haenszel adjusted OR works out to 4.35. We would conclude that the risk of TE among women who use OC, after duly adjusting for the confounding effect of age, is 4.35 times. We suggest you may take the assistance of a trained epidemiologist or statistician for calculating the same, or else use the statistical software EPI- Info 2002, the use of which is described in another section in this textbook.

**Multiple regression analysis in the control of confounding**

While stratified analysis is very effective in control of confounding during analysis, however, if there are a large number of confounding factors, then a large number of strata will have to be made and the figures in the individual strata will become very small, often zero. This is the limitation of stratified analysis. In such cases one has to resort to regression analysis (22). In very common terms, the results of the estimates (reflected as Beta Coefficients) obtained from regression analysis (Syn : mathematical models, multivariate analysis) are "adjusted" for the confounding effects and hence represent the 'net' effect of that particular variable. Further explanation about the 3 common types of regression analysis is presented in the section on Biostatistics.

### Confounding

**Definition** : A confounding variable is one which throws into confusion, an observed association between an exposure and an outcome variable, since :-

- It is related with the exposure variable.
- Independent of it's association with the exposure variable, is also associated with the outcome variable.
- It does not lie in the chain of sequence between the exposure and outcome variable.
- It is "differentially" distributed in the two groups.

**How do we control for confounding**

The most important step is to be aware of the phenomena of confounding and to identify all potential confounding Factors (PCF) right at the time when the research question is being developed. Once all PCF have been identified, action may be taken to control them either in planning stage or during analysis, by following methods :-

- During planning :- By
  - Randomization (random allocation)
  - Restriction
  - Matching

## The tenth building block: precautions against "BIAS" (Syn : Systematic Error, Measurement Error, Misclassification, Lack of Internal Validity)

Some trials undertaken earlier showed that patients with inguinal hernia who get laparoscopic repair seem to have less post operative pain and more rapid return to work than open conventional surgery. Is this result really correct or might be that laparoscopic repair may appear better because of certain biases as follows :- Perhaps laparoscopic repair is offered to patients who are in a better health or seen to have better tissue strength because of age or general health; or else, may be that surgeons and patients are more inclined to think that his procedure should cause less pain, because it is new. As the scar is smaller, the patients report less pain and the surgeons are less likely to ask for pain or record it in the case sheet; or else, perhaps patients who get laparoscopic surgery return to work earlier, than those who get open surgery, because the surgeons have so guided them. If any of these were so, the favorable result of laparoscopic repair may be related to systematic differences in how the patients are selected for laparoscopic procedure, how they report their symptoms or are asked about them, or how they were told what they can do rather than a true difference in the success rates. A clinical trial conducted after carefully taking care of these possible biases, found that patients given laparoscopic surgery in fact do experience less pain and a more rapid return to work, every thing else being equal (23).

Let us take another example of a simple clinical trial in which we gave a new drug, `A' to a group of patients with headache while the standard existing drug `B' was given to another group. After analysing the data we finally concluded that drug `A' was better in relieving headache than drug `B'. Such conclusion might have been correct, but may also have occurred because we might have selected subjects who were mentally robust in gp `A', or weaklings in gp `B'; or else, the severity of headache in gp `A' as such was lesser than gp `B'; or, perhaps the subjects, knowing that we (their treating physicians) were studying the good effects of drug `A' were too willing to please us, without our knowledge; or, maybe, the nursing officer i/c, knowing our hypothesis, ensured a high level of drug intake (compliance) in gp `A'; it may also be possible that gp `A' was assessed in detail by a highly experienced professor, while the task of assessing gp 'B' was left to inexperienced interns; or perhaps our

questions regarding relief from headache were ambiguous - we were actually asking them "how are you feeling?" Finally, it may have occurred that a much larger number of subjects in gp 'B' who actually finally got relief, also got them discharged before our assessment and so were not available for the final evaluation (selective loss to follow up).

One of the essential requirement in any scientific process is to measure correctly what we actually want to measure. In our above example, we had actually intended to measure "the difference in relief from headache" as brought about by drugs `A' or `B'. However, at a number of points we systematically departed from the correct state, making measures which were different than what we really intended to. It is a surprising as well as concerning fact that while a majority of researchers give due consideration to sample size and statistical analysis ( and, of course, to `p' value), many of us, while planning our study tend to overlook this central and key issue in research - that in our study, we should be measuring what we really intend to measure, and that the information recorded by us should actually reflect the correct state of affairs - in other words, "Any error of measurement must be prevented". Any measurement that we make must have the following two characteristics :-

**It should have `reliability' (Syn : precision, repeatability, replicability) -**

Repeated measurements should give consistent results. Reliability would be compromised in the following situations :

(a) Due to observer

This can occur due to "between observer variations" (2 different data collectors can produce different results from a medical interview or even BP measurement) or may be due to "within observer variations" (same interviewer can get different values of BP on 2 different occasions using the same sphygmomanometer and same patient).

(b) Due to subjects

Again this may be due to "within the subject variations" (circadian-rhythm, mood fluctuations) or "between the subjects variations" (biological variations - no two human beings are alike).

(c) Due to instruments and techniques

Different BP instruments or different techniques (recumbent or sitting position) will produce different BP values.

**It should be `valid' (i.e., accurate)**

It must measure what is really intended to measure. Loss of validity (accuracy) will occur if there is any process, which while making the measurements, will tend to produce results that depart systematically from the true value. This state is also called `Bias'. Whenever we are testing hypothesis regarding associations or differences, we would apparently be comparing two "groups". **Remember that validity will be compromised and bias will occur if at any point, while either selecting the subjects or else while making measurements on them, we tend to systematically depart (consciously or, as happens most of the times, unconsciously), thereby treating the two groups being compared in a different manner (24).** Thus, bias can occur at two points.

(a) Firstly, it may occur if the two (or more groups of patients or subjects) that we intend to compare, are selected in a differential manner. This is called **"Sampling" or "Selection"** bias.

(b) Secondly, it can occur if while recording the information / making measurements, we tend to treat these two groups differentially. This is known as the **"Information"** or **"Measurement"** bias.

Loss of Internal Validity leads to "systematic error" or "Bias". This will occur when we are actually measuring something other than what we actually wanted to measure, as follows

- Basic measurement technique is wrong
- Variations between observers or subjects
- Systematically differentiating between the two groups being compared at the point of
  - Selection (selection Bias)
  - Making measurements (measurement /

The extremely important thing regarding bias is that while the effects of "chance" (Random error or sampling variation) and "confounding" (as discussed earlier) can be assessed quantitatively (by `p' value and adjusted estimates), assessing bias quantitatively becomes next to impossible in the usual settings of clinical research. Bias, therefore, has to be visualised during the planning stages and steps taken to prevent it.

**Selection bias**

Selection bias is a systematic error resulting from the way the subjects are either selected in a study or else due to selective losses to follow up, of subjects. In a case control study, the major source of selection bias is the manner cases or controls or both are selected and the extent to which the presence (or absence) of exposure may influence such selection. On the other hand in cohort and experimental studies, the major source of selection bias is non-response / withdrawal from the study / losses to follow-up. In a cross-sectional study (as also in a case control study), the primary source of selection bias is "selective survival", because only those who are alive can be included in such studies. The following are the ways in which selection bias can occur :

Self selection bias / Volunteers induced bias

In general, as far as possible, avoid volunteers in any research study since they may be systematically very different from the usual population (25, 26).

Berksons' bias (hospital selective admission )

This can be a problem in case-control studies. It occurs because patients with two concurrent diseases or health

problems are more likely to be admitted to a hospital than those with a single condition. For example people who have both peptic ulcers and also smoke are more likely to be admitted to the hospital than people who have either of them. A case control study trying to evaluate the relationship between smoking and peptic ulcers may therefore find a much stronger association between the two than would really exist in the general community.

Another form of hospital admission related bias is the fact that patients who are in the severe part of the spectrum of disease are more likely to be admitted than the mild forms and these severe forms of the disease may be selectively more related to the possible exposure. Thus, an initial case control study found a strong association between high fever and febrile seizures, just because children with seizures actually fall into the severe spectrum of the disease and these children are more likely to have had high fever. (27-29)

Incidence-prevalence bias (Syn : Survivorship bias, Neyman's bias )

This is a major issue in case-control and cross-sectional studies (30, 31). For example, a case control study to evaluate the protective effect of physical exercise on MI was undertaken by taking cases of MI and healthy controls and asking them about the history of regular physical exercise. Surprisingly, a large no. of both the cases and controls gave a history of regular physical exercise; the study concluded that regular physical exercise does not protect against MI. The conclusion was, in reality, a biased one. We know that 25% to 33% of the cases of acute MI die within the first 3 hours. Only those who live get admitted to the hospital and are available as cases. Now, regular physical exercise may be an important factor in helping the person to overcome the acute myocardial episode. Thus, out of the cases of MI those who did not undertake regular exercise died while the ones who did exercise were the ones who lived to give such a history.

Healthy worker effect

A comparison between health status of army and civilian population may show a better health status of the soldiers; one of the important reasons may be because of the initial medical examination during which the `unfit' persons are excluded and only `healthy workers' are included in the army. The basic dictum of selection and comparisons in research should be to "compare likes with likes" (32).

Exposure related bias

This is a special type of Berkson's bias. If the hospital admission probability is different among those who have and those who do not have the suspected cause, such a selection bias can occur. This is specially liable to occur in case control studies. As another example, such an exposure related selection bias was viewed with concern in a case-control study that found an association between use of dietary supplementation with L-tryptophan and "Eosinophilia-Myalgia Syndrome" (EMS). The main criticism was that the initial press publicity about a suspected association may have resulted in a preferential diagnosis among known users of L-tryptophan as compared to non-users. Thus the estimate of risk (OR) obtained from such studies may have overestimated the true effect of risk.

Bias due to loss to follow-up

This is a special problem in cohort and experimental studies. If subjects drop out / are withdrawn / die before assessment of outcome / Do not respond later on / cross over to the other treatment modality in between the follow up phase, then it is also possible that those who were lost to follow up could have been systematically different from those who continued.

Bias due to selection of inappropriate control group

This is another major issue in case control studies. The basic dictum that should be followed in a case-control study is that the controls should be derived from the same source population from which cases have come and that the controls should also be equally at risk (i.e., have equal opportunity of being "exposed" to the suspected risk factor) as the cases. Take the example of a case-control study which desired to assess the risk associated with non-use of condoms (exposure) with the development of STD (outcome). In a hurry, the investigator selected cases from a STD clinic and also controls from the same STD clinic who were found to be free of STD after evaluation, at this clinic. However, many of these controls may not have developed STD probably because they had sex partner who did not himself / herself had STD, and hence these subjects had no chance of exposure (to STD) whether they used condom or not. Hence the right choice of control group in this research would have been to take people who were known sex partners of persons known to be having STD but were themselves found clear of STD, while cases should have been those who had known STD persons as sex partners and were detected to be having STD.

**Information (Measurement) bias**

Information bias is a systematic error that arises because of incorrect information while making measurements on one or more variables in the study. As said earlier, it may occur, firstly, when the basic measurement process is incorrect (Wrong instrument, wrong technique, wrong definitions, and so on). Secondly, it would occur even when the basic process of making the measurement is correct but the measurements are made in a systematically "differential fashion" between the two (or more) groups being compared. This will result in "misclassification" of either the disesase ( outcome) or "exposure" status, or even both of them. Information bias is likely to occur in the following ways :

Recall bias

This is a major problem in case-control as also in cross-sectional studies. The fact that a person has become diseased, he or she is more likely to recall the possible exposure; eg., in a study of X-ray exposure during pregnancy and subsequent leukaemia in children, mothers of leukaemic children are likely to recall more and thus give more history of X-ray exposures (31, 33).

Detection bias

This is more of a problem in prospective studies. Those who are exposed to the factor of interest may also be more liable to be subjected to diagnosis and hence detection of the disease of interest (24, 31); e.g., in a follow up study on the question whether smoking is the cause of emphysema, we would take a group of smokers and another group of non-smokers (both groups free of emphysema at the start of follow-up) and would follow them for a defined period of time to see for development

| Types of bias | |
|---|---|
| **Selection Bias** | **Measurement Bias** |
| Self selection (volunteers) Bias | Recall Bias |
| Berksons Bias | Detection Bias |
| Survivorship (Neyman's) Bias | Observer's Bias |
| Healthy worker effect | |
| Loss to follow-up Bias | |
| Inappropriate control Gp | |

of emphysema. Now, because of various other problems (cough, IHD, dyspnoea etc.), smokers are more likely to report sick and hence more likely to be diagnosed as emphysema, once they report to a medical facility.

Observer's (Interviewers) bias

If the interviewer is aware as to which group is having the particular exposure (in a follow up study) or the disease (in a case control study) then he/she would be more inclined (subconsciously) to interrogate/examine that particular group more exhaustively, to prove the research question (24, 31).

**Prevention of Bias : Checklist.**

The following check list will help in preventing bias in most of the "usual" settings of clinical and health research.

(a) General points for preventing basic errors of measurements

(i) Clearly write down the research question in adequate detail.

(ii) Identify the "variables" in the study, in respect of which the measurements are going to be made. This should be written down as "Exposure", "Outcome" and "Confounding" variables.

(iii) Now, write down clear details of what measurements should ideally be made for each of these variables. This is done by going through the published evidence and consultation with experts. For example, if one of the outcome variables is IHD, the ideal (gold standard) measurement would be either coronary angiography, or a combination of echocardiography and exercise ECG.

(iv) Now, write down how you are actually proposing to measure this variable in your study and whether it is scientifically acceptable. How near does it come to the gold standard. Most of the times the measurement process actually being used may not be ( rather cannot be) the gold standard itself. For instance, in a field / community based research on IHD, it may not be at all possible to do coronary angiography on such healthy, free living subjects. In such case, one may decide to use a combination of symptoms with resting ECG findings as evidence of coronary insufficiency.

(v) Next, discuss with the experts whether the methods of measurements you are planning for each of the variables is scientifically sound / accepted by eminent organisations / has already been used by some eminent workers earlier ? For example, a combination of symptoms and resting ECG, using the laid down Minnesota code criteria, is often used for healthy, population based subjects for evidence of IHD in epidemiological research work which is accepted by WHO and used in earlier large scale community based epidemiological studies.

(vi) Now, write down a detailed "protocol" on how exactly the measurement is going to be made, e.g., how the ECG will be recorded, who will record it, and how it will be read.

(vii) Next, write down how "quality control" will be ensured. For example, one may specify that a random sample of the positively and negatively read ECGs will be reviewed by a cardiologist for independent evaluation and quality control.

(viii) Now, see the equipment, reagents etc., which will be used for measuring this variable. Are they accurate? Standardise them, initially and periodically in between the study, against some standard machine. Remember that questionnaires are also instruments. Develop them properly. As far as possible, use such questionnaires and other scales which have already been used and standardised (e.g., Jones criteria; quality of life questionnaire; MPQ etc.).

(ix) Standardise the method (technique) of making any measurement. Preferably use a standardised technique as recommended by a standard professional body (e.g., WHO, Amer Heart Assn etc. ) or a standard text book. Write down the detailed technique in an "operations manual".

(x) Train all the interviewers/ data collectors centrally about the technique, test them and certify them. If you are yourself the sole data collector, get trained and certified by an expert.

(xi) If possible, take repeated measures (e.g., 3 readings of BP).

(xii) Try to make "unobtrusive" measures so that subjects are unaware; eg., alcohol consumption may be recorded by going through wine bills rather than only asking the subjects.

(b) General points for preventing Selection and Information Bias

(i) As far as possible ensure blinding - definitely in an experimental design; even in a case control study

or cohort study, the observer can be "blinded".

(ii) If possible, do not tell your research hypothesis to the subjects (helps preventing recall bias). In addition, if possible, try and take information about exposure from other sources, in addition to the subjects.

(iii) In a follow up study (cohort study or clinical trial), take a well defined population to avoid loss to follow up; develop methods to retrieve those subjects who are getting lost to follow up .

(iv) Select two or more than 2 "groups" of controls in a case control study (e.g., one from hospital and another healthy group); try and take different categories of diagnoses if selecting hospital controls.

(v) In cohort or experimental studies (follow up studies) specify clearly the future dates of examination and examine all subjects of both groups at the pre-decided dates using "similar" methods of history taking, physical examination and investigations, and make arrangements that losses to follow up are minimized.

(vi) In a case control study, use the correct time frame for recording exposure (e.g., for a study between pneumonia and cold exposure, the time frame should be 6 days and not 6 months).

(vii) See, in a case control study, specifically for

- That the controls come from the same "source" population from where cases have come; and that cases and controls have the same "selection factors" for getting admitted to that particular hospital
- Is there any possibility of "survivorship" bias ?
- Is the disease such that the initial symptoms may have led to a change in exposure? (eg, initial dyspeptic symptoms of gastric CA may cause the patient to give up tobacco)
- Did the controls have a reasonable chance of being exposed to the factor of interest? (hysterectomised women in any case do not have a `chance' of exposure to OC, so do not keep them in controls in an Oral Contraceptives - Thromboembolism study)

(viii) In any type of study, see the "entire spectrum" of the outcome or disease - e.g., in IHD, also see in addition to MI, angina, sudden death and a symptomatic ECG changes.

(ix) In an experimental design (clinical trial), ensure Random allocation, Blinding and Placebo control.

### The eleventh building block : selecting the appropriate "research design"

It is of importance that the correct "Research Design" be selected by the researcher. The various types of designs "Descriptive, Analytic (Case-Control, Cohort, Cross-sectional), Experimental, and Diagnostic test studies have already been described in detail in the previous section (Principles of Epidemiology) and you are advised to refer to the same. However, the following guidelines are given in the succeeding paragraphs to assist you in selecting the design most appropriate to your research question.

First of all read your research question and ask yourself the following question : Am I interested in establishing an association between an exposure and an outcome variable ( as, whether a particular variable is being studied for it's role as a risk factor for a disease, or a prognostic marker, or a treatment / preventive modality, or else as a diagnostic or screening procedure), OR, whether I am only trying to describe a phenomena. If my interest is only to describe a phenomena and not to study any "Exposure-outcome" or "cause-effect" relationship, then I should select the "Descriptive study design". Some examples of situations when we would select out the descriptive design are

(a) In asymptomatic HIV positive persons, how does CD4 cell count decline over time, till death (natural history)

(b) What is the proportion of cases of acute MI out of the total hospital admissions in one year in my hospital; (load of a disease)

(c) How many new cases of measles would occur in one year among infants in the community under my health care (incidence of a disease)

(d) How does weight change occur among new borns over the next one year of life (course of a natural phenomena)

(e) How many cases of adult hypertension or smokers are there in my community (prevalence of a disease)

The above are just a few examples; the basic consideration is that if the focus in our research question is simply to make a description without any intention to make comparisons and prove a point regarding a cause (exposure) effect (outcome) relationship, then the right design for us to do is a "descriptive" study. Depending on the issue at hand, the descriptive study could take the lines of either a case report (description of a single report of an unusual / interesting case), a case-series (description of signs, symptoms or course of disease in a number of cases of the same disease), or a "cross-sectional descriptive (describing the prevalence of a disease in a community or the percentage of some signs / symptoms in a given group of patients of a disease)' or else a "longitudinal descriptive" study (incidence of a disease or such other outcome in a group of subjects or patients followed up over a period of time).

On the other hand, if we realize that our research question intends to make comparisons with a view to analyse some cause (exposure) - effect (outcome) relationship, i.e., we have some "preformed hypothesis" in mind saying "this is the cause of that" or, "this is better than that" then our choice of research design should be out of one of the "analytical" studies. Some examples are

(a) Does presence of a transverse ear lobe crease (as compared to those who do not have it) indicate an

increased risk for developing IHD? Or, are those with waist size 90 cms or more at higher risk of IHD (compared to those with waist < 90) (risk marker or risk factor).

(b) Does occurrence of multidermatomal herpes zoster in an asymptomatic HIV positive individual predict an earlier death (as compared to those asymptomatic HIV positives who do not develop herpes zoster or develop only uni-dermatomal) (prognostic factor)

(c) Will administration of oral Doxycycline to troops proceeding on flood relief duties, be useful for preventing leptospirosis (as compared to those who are not given Doxycycline (prevention)

(d) Is laparoscopic repair of hernia better (as compared to conventional open surgery) (treatment)

(e) Does a combination of "cold intolerance and unexplained weight gain" diagnose hypothyroidism (as compared to when the gold standard of thyroid function test is given) (Diagnosis)

Now, once we have decided that we should be using analytic design, the next question which immediately comes up is which analytic design? To further proceed, ask yourself the question "Do I intend to study the effect of either a preventive procedure (a chemoprophylactic drug or a vaccine or sera or even a health educational measure) or else the effect of a treatment (a new drug or operative procedure or even a ward procedure intended to improve the clinical management). If the answer is yes, the only design we can use is the Experimental i.e., Intervention design. It could take the form of a clinical trial (RCT) or a preventive trial or else a Community Intervention trial.

On the other hand, if the answer to the above question is No, then ask the next question "do I intend to study a prognostic factor, i.e., some variable which will help me predict the course of illness. If the answer is yes, the only design available to me is the "Cohort" design.

Now, if I am neither studying the effect of a treatment nor a preventive procedure nor a prognostic factor, ask yourself whether you intend to study the performance of a diagnostic test (pathological or radiological procedure or even a clinical diagnostic rule) as to how well it would diagnose a disease vis-à-vis the gold standard. If this what your research issue is, then select the "Diagnostic test evaluation design".

Finally, ask yourself whether you intend to study the role of a risk factor (or risk marker) in causing a disease. If this is the issue, then you can select either of the following two designs as follows :

(a) If the disease you are studying is a rare one, enough number of cases of the disease will be available at your hospital, and the hypothesis being tested is relatively a new hypothesis (eg, whether using mobile phones is a risk factor for leukaemia) then select the "Case-Control" design.

(b) If the hypothesis you are persuing has already been tested by a few case-control studies, or the

Col RajVir Bhalwar

# Planning, Design and Conduct of Case Control Studies

We have already deliberated on the situations in which a medical researcher should select the case control design to answer her research question. The case control design is one of the finest and easiest methods of analytical research available to the doctor who has an easy access to patients of a particular disease admitted to the hospitals. At the same time, case control studies may be considered as the "Acid Test" for the capabilities of an epidemiologist and seasoned researcher because of the high potential for 'bias' that they have.

In a case control study, the researcher starts by picking up 'cases' who have already developed a particular disease or 'outcome' of interest, and a comparison group (controls) of subjects who, except for the fact that they have not developed the particular disease, are otherwise similar to the cases. Having assembled the two groups, the investigator finds out the presence (or, the history) of the particular 'exposure' which he thinks is a risk factor and compares the two groups (cases and controls) as regards the presence of exposure.

The case control study has a special value in medical research because of the special advantages that if offers However, the method carries certain distinct disadvantages and the researcher choosing this design must remain careful to take preventive action against them. (see adjoining box).

**Case control studies**

**Advantages**

- Inexpensive, requires only a few subjects gives quick results
- Well suited for diseases which have a long latent period (eg, cancers, AIDS, MI, CVA etc)
- Well suited for an outcome which is 'rare'
- Well suited for conditions in which medical care is usually sought
- Helps in examining multiple etiologic factors - once we have the cases of the disease, we can take history of all the factors that we feel may be risk factors
- Reasonably good for diseases that have a "relatively rapid onset" and are usually hospitalised (eg, most of the acute infections; injuries etc)

**Disadvantages**

- Not a good method for studying rare 'exposures'
- Does not give any idea of 'incidence' or 'prevalence'; it only gives us a measure of Odds Ratio (OR)
- Particularly prone to various forms of selection and information biases, particularly survivorship Bias, Recall Bias and observor's bias.
- 'Temporal relationship' is usually only a matter of conjecture but not a proof

## Designing and conducting a case control study

**Step 1: Specify the total population and actual (study) population.**

Specification of actual (study) population at this stage becomes especially important as it will give us an idea of the "population" from which cases have come and thus we would be able to ensure that our controls should also represent the same population, (an essential requirement of a case control study).

**Step 2 : Specify the major study variables and their 'scales' of measurement**

Firstly, the Outcome variable : In case control study this will be the particular disease or outcome of interest. Most of the times this will be measured on a 'dichotomous' scale (ie., disease present = cases, and disease absent = controls). Secondly, the Exposure variable(s) :- This is the suspected 'cause' that the investigator is studying for the association with the disease under study. Next, Specify the scales of measurement - usually it is dichtomous (exposure present or absent). Finally, the Potential confounding factors (PCF) :- List out all the PCF by thorough reading of the literature and discussion with experts. Specify the 'scales' of measurement of each PCF.

**Step 3 : Calculate the sample size**

The details have been discussed in the section on Biostatistics and "use of Staistical software".

**Step 4 : Specify following selection criteria of cases**

Diagnostic criteria

Enunciate clear cut diagnostic criteria for the disease of interest. As far as possible use criteria given by expert bodies. If there is doubt, make categories like "definite", "probable" and "possible" and analyse them separately.

State the inclusion or exclusion criteria

One of the central issues in a case control study is that cases should have had a reasonable possibility of the disease being induced by the suspected exposure; and that the controls should have had a "reasonable chance" of being exposed to the exposure. This leads to the fact that any case or control who does not meet these criteria should be excluded from the study. Eg., in a study of recent OC use (exposure) and TE (outcome) we would like to exclude "TE cases occurring postpartum/ during pregnancy / post operatively/ post menopausal ladies / ladies on other contraceptives / hysterectomised ladies". One thing the worker must ensure is that the exclusion / inclusion criteria should be clearly defined and must equally apply to cases as well as controls.

Source of cases

The usual source of the cases is "hospital". However, for diseases for which a large number of subjects may not be admitted (low backache; anal fissure etc) the researcher must tap the OPDs, General practitioners or even think of population based cases by searching them in the

population.

Incident or prevalent cases

Specify whether you would like to consider only the newly occurring (incident) cases or all those who are already present including the old cases (prevalent). It is always advisable to take the incident cases since the prevalent cases might have changed their exposure status due to medical advice etc.

Method of sampling

The most common method of sampling is either to take a systematic random sample of cases as they keep reporting; alternatively, if all the cases have already collected and a detailed list is available, a simple random sample may be drawn.

**Step 5 :- Specify the selection procedure of controls**

One of the most important issues in a case control study is the selection of controls. The following specifications are to be made :

Source of Controls : Whether Hospital based or else Population based controls

Patients admitted to the same hospital for diseases other than the one under study can be used as controls. They are easy to obtain, cooperative, and more likely to remember the exposure. The disadvantage is that they do not represent the healthy population and being ill, may be different from the healthy persons in number of ways. While selecting hospital controls, the best is to take a diagnostic assortment, ie., patients from various diagnostic categories. On the other hand, healthy controls from the population would give a very good comparison provided it is logistically possible to study them and provided that they represent the same source population that gave rise to cases. The difficulties are that they are expensive and may refuse to participate.

Exclusion / inclusion criteria :-

The same criteria as for cases should equally apply.

Number of controls per case

In general, 1 control per case is studied. The number of controls per case may be increased to upto 4 or 5 per case with slight increase in statistical precision but the cost of the study will increase tremendously. In any case the number of controls should never be less than the cases.

Number of control groups

Usually, one "control group" is studied. However, if feasible, the worker may study 2 different control groups (eg, one from population and another group from

Summary : planning, design conduct & analysis of a case-control study

- Review your research question and confirm that case-control study is the right design (you should be studying a risk factor and not any prevention / treatment / diagnostic / prognostic factor.
- Specify the outcome, exposure and confounding variables.
- Specify the "reference" and "actual" population.
- Specify the inclusion and exclusion criteria; apply them equally to cases and controls.
- Specify the selection modality for cases :-
  - Diagnostic criteria for cases / case definitions.
  - Source (hospital, OPD, or population based).
  - Sample size for cases
  - Procedure for sampling the cases
  - Incident (new) or prevalent (old & new) cases.
- Specify the selection procedure for controls :-
  - Source of controls (healthy population based or hospital based)
  - No. of controls
  - No. of control groups
  - Method of sampling the controls
  - Matching, if considered.
- Specify the methods of measurement of various variables.
- Set up checks for obviating "biases" :
  - Ensure that controls are derived from same source population from which cases have come.
  - Ensure that controls have same chances of getting the exposure as cases had.
  - See if there is any problem of survivorship.
  - Avoid recall bias
  - If possible, blind the observers to case / control status.
  - If possible, use multiple sources of information and make "unobtrusive" measurements
- Do a pilot study on 5 to 10 cases and controls.
- Conduct the study.
- Statistical analysis
  - Calculate Odds Ratio (OR) as (aXd) / (bXc) and not the relative Risk (RR)
  - Calculate 95% CI of OR
  - Do a Chi-square test for hypothesis testing, or a 't' test, depending on scale of measurement.
  - For control of confounding, undertake stratified analysis using mantel-haenszel" method.
  - For many confounders, undertake multiple logistic regression analysis.
- Make interpretations :- specifically see if "temporal relation" can be shown; is there any possibility of bias remaining; have all potential confounders been

hospital); the procedure will improve the validity of the results.

Matching

The details of 'matching' have already been explained in the chapter on control of confounding. In general, in a case control study it is recommended that one must carefully list out all the PCF; match for the universal confounders, ie., age ( in broad categories of 5 or 10 years of age groups) and sex, using frequency (group) matching. Record the data on all other PCF and adjust for confounding during analysis.

**Step 6 : Specify the procedures of measurement and specially take care to ensure validity and reliability**

The biggest disadvantage of a case control study is its particular susceptibility to various forms of selection and information biases. The detailed methods of prevention of bias and ensuring validity and reliability have been presented in chapter no. 1. In addition, quite often the investigator would be using a questionnaire, in a case control study. The guidelines for preparation of questionnaires have been given in a subsequent chapter.

**Step 7 : Do a pilot study**

Pretesting on 5-10 cases and controls would be adequate in most situations to refine the methodology. If major changes are made following the results of pilot study, then do not include the pilot study cases and controls in the analysis.

**Step 8 : Conduct the study**

Ensure valid collection of data, as described under the details of making measurements.

**Step 9 : Analysis of data**

Calculate the Odds Ratio (OR) and it's 95% Confidence Interval (95% CI). Undertake hypothesis testing by a chi square test, as described in the chapter on Biostatistics. Usually it will be a chi-square for 2X2 table or, at times, a chi-square for linear trentd in proportions. At times there may be requirement of a 't' test instead of chi-square test, depending on the way the variables have been measured. Control of confounding will require stratified analysis using Mantel-Haenszel technique or a multiple logistic regraession. The details are described in the chapter on Biostatistics. If the data is from a “Pair matched” study, use McNemar's procedure for calculating chi square, odds ratio (OR) and 95% CI of OR. Consult a research methodologist for assistance.

Col RajVir Bhalwar

# Planning, Design and Conduct of Cohort Studies

As discussed earlier, a major disadvantage of case control study is that it is prone to various types of selection and information biases. Some of the major problems of case control study are overcome by cohort study, though by paying a higher cost and tremendous increase in logistic effort.

A cohort means a group of people sharing a common exposure. In this study, the investigator starts by picking up two comparable group, one having the exposure (eg, tobacco users) and the other not having the exposure (eg, non users of tobacco). She then excludes the presence of the outcome of interest (eg, lung CA) in both the groups at the start of the study, and then follows up both the groups for a reasonable amount of time, observing for the outcome of interest in both the groups and finally makes comparison as regards incidence of the outcome in the two groups. The cohort study has certain major advantages in medical research.

**Major advantages of a "cohort study"**

- Scientifically a much "stronger" design as compared to case-control or cross-sectional study.
- Temporal association is more convincingly demonstrated since investigator actually starts from exposure, before outcome has occurred and follows up till outcome.
- No recall bias since exposure is objectively assessed by investigator at start of the study
- Can study many outcomes of a given exposure of interest.
- Provides a direct estimate of "incidence" of outcome in exposed and non-exposed groups and hence the "RR".
- Results are not biased due to "survivorship".
- Good for studying 'rare" exposures.
- Any change in exposure status during the course of study can be recorded.

**Major disadvantages of cohort design**

- Quite expensive; needs large number of subjects.
- Results may take very long time to be available.
- Ascertainment bias due to "differential" assessment of exposed and non-exposed groups can lead to bias.
- "Loss to follow up" is a major potential for bias.

## When to select a cohort design

The cohort design should therefore be undertaken if the answer to the following question is "Yes".

Is the disease (outcome) a reasonably common one?

(a) Is the follow up period required "reasonably short", so that you can conveniently complete the study within the time frame?

(b) Has some amount of evidence regarding the association between exposure and outcome been provided by case control studies?

(c) Are the subjects in your two groups (exposed and not exposed) reasonably likely to continue in the study?

(d) Are you sure you are studying risk factors / markers / prognostic factors and not therapeutic/ preventive/ diagnostic procedures?

## Steps in designing, conducting and analysing a cohort design

**Step 1 - Specify the research question, objectives and background significance.**

**Step 2 - Specify the variables of interest and their scales of measurement**

(a) Exposure variable

Usually in a cohort study the exposure variable is measured on a 'dichotomous scale' (ie. exposed or not exposed), or, at times on a 'polychotomous ordinal scale' (not exposed, slightly exposed, moderately exposed, intensely exposed etc).

(b) Outcome variable

The outcome variable would be the disease or other health related outcome which the investigator hypothesises to occur as a result of the exposure. The outcome may be dichotomous (eg, developed / did not develop lung CA) or polychotomous ordinal (remained normotensive/ developed mild hypertension / developed moderate hypertension / developed severe hypertension) or quantitative (eg, serum cholesterol levels, no. of DMF teeth, score of respiratory disability 0,1,2,3 due to occupational exposure).

(c) Potential Confounding Factor (PCF)

Make an intensive search of the literature and contact the experts to find out all the variables that could be potential confounders of the exposure - outcome relationship and record the data regarding confounders during the study.

**Step 3 - Specify the exclusion criteria**

eg, we may like to restrict the study to males with a view to control confounding due to sex, or exclude such subjects who are likely to be lost to follow up or subjects with a disease which may interfere with the occurrence of outcome of our interest.

**Step 4 - Calculate the sample size**

The details have been discussed in the section on Biostatistics and "use of Staistical software".

**Step 5 - Select the study cohort**

The study cohort is the one which has the 'exposure'. This may be either Special exposure groups ( eg, radiologists for studies on effect of radiation; ANC cases having PIH for

studying the outcome of pregnancy, etc.); or else it could be Cohort defined on basis of geographical or administrative boundaries (eg, people living in a given state or district like Framingham heart study). The special advantage of such cohort is that the same group will give an exposed as well as unexposed (comparison) cohort; e.g, for the study on association of smoking during pregnancy (exposure) and low birth weight (outcome) all patients enrolled at an ANC may be followed up. This group will give, within itself, an exposed cohort (smokers) and an unexposed cohort (non-smokers). Thirdly, we may select a study cohort from Groups offering special resources (eg, all registered doctors can be followed up for development of IHD after recording their physical activity levels. They will give special advantage of an accurate reporting as well as ease of follow up).

**Step 6 - Select the comparison cohort**

This is very important. It can be done by either selecting an "inbuilt comparison group" as in example given in step 5 above. This is, in fact, the best method of obtaining a comparison group in general, in the usual settings of clinical research. Secondly, we may make comparisons with general population rates, often done in study of diseases due to occupational exposures. Finally, if required, we may assemble a special comparison cohort - eg, in a study of the association between exposure to petroleum fumes and subsequent bone marrow damage, workers handling the filling equipment at petrol pumps may be taken as exposed cohort while workers sitting in the offices or ancillary workers in the same petrol pumps may be taken as the specially assembled comparison cohort.

**Step 7 - Specify the sampling procedure**

The usual method of sampling both the exposed and unexposed cohort groups is by simple random or by systematic random sampling method. Select about 20% extra subjects, because some will be removed on initial medical examination as already having the outcome and some will be lost to follow up.

**Step 8 - Exclude the disease or outcome of interest in both the exposed and unexposed cohort groups at the outset**

Do an initial medical examination to exclude out all those subjects, in both the cohort groups, who already have the disease (or outcome) of interest.

**Step 9 - Obtain data on exposure level**

This is an extremely important issue. We obtain this data by various methods, including Direct interview of cohort members (e.g., details of smoking, alcohol, sexual activities, personal habits, dietary information, physical exercise, personality type etc). Secondly, by medical examination or diagnostic procedures by examining both (exposed as well as non-exposed) groups similarly; thirdly, by measures of environment (e.g., levels of pollutants in home environment, drinking water pollution levels etc); and fourthly by going through existing "records" (e.g., for recording the levels of exposure to irradiation, use of drugs, etc medical records can be used. Initial medical examination card at the time of entry to school or service can provide valuable details of an exposure).

**Step 10 - Obtain Data on all PCF**

Using methods as described in step 9 above, record detailed data on all the potential confounding factors.

**Step 11 - Consider matching**

Usually, in a cohort study, matching is not important; Data should be collected for all PCF and adjustment for confounding may be made during analysis. However, if considered feasible, the exposed and non exposed cohort groups may be "frequency matched" in respect of important confounders like - age, sex or other important PCF.

**Step 12 - Follow up and ascertainment of 'outcome' of interest**

Follow up should be meticulously undertaken for the period already decided. Due attention should be paid while making measurements for detecting the outcome of interest. The general measures for ensuring validity and reliability have already been detailed in chapter no. 1. In addition, special attention should be paid to the following types of measurement biases that can crop up in the cohort studies :

Measurement bias

This would occur because of 'differential ascertainment' of the outcome between the two groups. For obviating this, inform all subjects of both groups well in advance of the dates and timings of medical examination and ensure that both the groups are examined by observers who have similar type of training and using similar type of instruments and techniques.

Observer bias

This occurs because the investigator is aware about the fact as to which subject is 'exposed' and who is not exposed. For obviating this, if possible, 'blind' the observer to the exposure status, the details of exposure being known only to another co-worker who is himself not making any observation regarding ascertainment of outcome.

Cross over bias

This may happen because those having the exposure (eg, smokers) may cross over to the non exposed group (i.e, become non smokers) and vice versa. Periodic evaluation of both the groups as regards level of exposure, making prompt record entries and subsequent adjustments in the data analysis can help overcoming this problem.

'Loss to follow up' bias

Some subjects in any case are likely to be lost to follow up / drop out. However, at times it may become a substantial problem. It is generally accepted that if more than 30% of the study subjects are lost to follow up, then the results of the study are to be viewed skeptically. The following steps help in overcoming this type of bias :

(a) Take detailed addresses of the subjects as also of their friends and relatives; contact them and make best of efforts to trace those who have been lost to follow up.

(b) If the subjects have migrated, try to get information about them through a mailed questionnaire. If they have died, try and obtain information from medical records and death certificates.

(c) Do an analysis in respect of certain demographic variables (eg, age, sex, education, general health status etc) to see whether those who have been lost to follow up are similar or else quite different from those who have remained in the study.

**Step 13 - Analysis**

In a cohort study we would calculate the relative risk (RR) as (incidence among exposed divided by incidence among non-exposed), the 95% confidence interval of RR, and hypothesis testing, using a chi-square test or a 't' test or such other relevant procedure as described in the section on Biostatistics.

## Certain special types of cohort studies

**Retrospective cohort studies**

The investigator identifies a group of individuals based on their characteristics in the past and reconstructs their subsequent disease experiences upto some defined time in the more recent past (34); e.g., in a study, all military persons who were exposed to "agent orange" many years back during wartime were identified on the basis of records, alongwith another similar group of soldiers who were not exposed to this agent. Both these groups so identified on the basis of records were then traced forward till the more recent past for various organ / system diseases. This type of study thus differs the usual prospective cohort study (as described above) in which the cohort is identified on the basis of current characteristics and then followed forward in time.

**Nested cohort (syn : Nested case control) study**

Combines the advantages of a cohort and a case control study. The investigator identifies a cohort and follows it up for the required period of time, after recording details of exposure in the subjects. As the cases of disease keep occurring, the investigator keeps picking up these cases alongwith equal number of controls from the same cohort and compares them for the exposure history (35). As an example, we may be working on a hypothesis that high serum lithium levels are a cause of subsequent mental illness. The problem is that undertaking serum lithium analysis may be a very costly affair; however, blood samples can be preserved for 15-20 years. So, we can take a cohort of say 1000 persons who are free of mental disease, collect their blood sample, cold preserve them and watch for 15-20 years. Over this period if 20 cases of mental disease occur, we can take out their blood samples alongwith 20 randomly selected samples of those who have not developed mental illness (controls who are "nested" in the cohort), analyse these 40 samples for serum lithium and make comparisons between the two groups (who developed mental illness and did not develop it) as regards lithium levels. The tremendous advantages that have occurred are that firstly, instead of doing 1000 serum lithium tests (as we would have done in a normal cohort study) we have done only 40 samples. Secondly, we can calculate the incidence of the disease which would not have been possible in a usual case control study. Thirdly, the problem of recall bias and that the controls may be from a different source population than cases (which occur in a case control study) have been prevented.

Col RajVir Bhalwar

# Planning, Design and Conduct of "Diagnostic Test Evaluation" Studies

In each and every area of clinical as well as public health practice, "diagnosis" becomes the central issue. The process of making diagnosis involves the use of certain tests, laboratory procedures or a constellation of signs and symptoms, in an effort to find out the truth, i.e., the real pathophysiologic state of affairs that exist inside the body. The common settings of use of diagnostic tests can be microbiological (eg, ELISA for HIV infection), pathological (eg, pap smear for CA Cervix), radiological (Chest X-ray for Pulm. TB), clinical (cold intolerance and weight gain as diagnostic for hypothyroidism) or public health (mammography for mass screening for Breast CA).

## Essential Requirements Of A Diagnostic Test Study

In any diagnostic test assessment with the above mentioned broad aim in mind, there would be, therefore, 3 essential things required, viz., firstly, the diagnostic test, which is to be evaluated; secondly, a `gold standard' criteria of diagnosis, i.e., that diagnostic criteria which, in the current day level of knowledge, can be assumed to be 100 percent accurate in diagnosing the condition. Apparently, a "perfect gold standard" is more of a hypothetical state. For all purposes, we take a pragmatic view and, nearly always, use a "relative gold standard". Thirdly, we would need a group of subjects, each of whom should be subjected to both the tests - the test under evaluation as well as the gold standard test.

> CAUTION
>
> In a diagnostic test evaluation study, all subjects should be put through to both the tests; it should never happen that only those subjects who have tested positive to the test being evaluated are only subjected to the gold

## Parametres On Which A Diagnostic Test Is Evaluated

Broadly, any diagnostic test should be evaluated in terms of three types of parameters. These are Validity or Accuracy (which includes sensitivity, specificity, predictive values and likelihood ratios), Reliability and Efficiency. We have already discussed these aspects in detail in the chapters on "Screening for Disease" and "architecture of epidemiologic Designs" in the section on "Principles of Epidemiology".

In the the usual settings, as above, the results of diagnostic test are recorded in either of the two categories - "Positives" and "Negatives" (ie., a categorical, "dichotomous" scale). Sometimes the research scenario may be a bit different. Let us take the following hypothetical example :- In a hypothetical study to evaluate Alanine Aminotransferase (ALT) as a screening test for chronic parenchymal liver disease, 500 patients attending a gastroenterology centre with symptoms of liver disease were subjected to both, an assay of serum ALT levels as well as a diagnostic liver biopsy which was taken as the gold standard in this case. The results are given in Table - 1.

Table - 1

| Serum ALT levels | Chronic parenchymal liver disease (As diagnosed by Liver Biopsy) | | |
|---|---|---|---|
| Units / Litre | Present | Absent | Total |
| <= 20 | 0 | 120 | 120 |
| 21-40 | 20 | 150 | 170 |
| 41-60 | 40 | 15 | 55 |
| 61-80 | 40 | 12 | 52 |
| 81-100 | 40 | 3 | 43 |
| > 100 | 60 | 0 | 60 |
| Total | 200 | 300 | 500 |

In such situations, various values of sensitivity and specificity will occur depending on the levels of "cut-off point", eg, if we chose a cut-off point of 20 U/L the sensitivity will be 100% (200 / 200), but specificity will be 40% only (180 / 300). On the other hand, if the cut-off point is placed at > 100 U/L, then the values of sensitivity and specificity will be 30% (60 / 200) and 100% (300 / 300) respectively. The conclusion that the above table gives us is that nowhere would we find a cut-off point where both sensitivity and specificity are 100%. If we lower our cut off point (ie., make the diagnostic criteria less strict), there will be an improvement in sensitivity (from 0% at >100 to 100% at >20 units) but this will be obtained at a corresponding decline in specificity (from 100% at >100 units to 40% at > 20); and contrarily as we keep raising the cut off point (ie., make the diagnostic criteria more strict) our specificity will keep increasing but with corresponding decline in sensitivity. The question is, what should be the "optimum cut off point", ie., how do we decide the cut off point which gives us the best combination of specificity and sensitivity. For doing this, we undertake the exercise of constructing the "Receiver-operating-characteristic curve" (ROC curve) in which we plot the values of sensitivity along the Y-axis and the values of (1-specificity) along the X-axis (horizontal axis).

## Steps In Planning A Study On Diagnostic Test Evaluation

### Specify the "Outcome"

This means we should clearly define the disease for which the diagnostic test is being evaluated (eg, chronic parenchymal liver disease, HIV infection etc). As far as possible, include the complete spectrum of disease in your study - the mild, moderate and severe forms; the typical as well as atypical forms; and also those disorders which are likely to be confused with the target disease.

### Give a clear description of the "settings" of your study

This should include the type of hospital where you are going to do the study (eg, specialised centre; secondary level care hospital etc); the demographic profile of the subjects (age, sex, race, education, economic status etc); and the "referral filter" that they have passed through before coming to your hospital (i.e., whether they come directly or passed through a referral filter of peripheral hospital, mid zonal hospital etc.).

**Give a clear description of the "Gold standard" of diagnosis in your study**

Give a clear description of the "Gold standard" of diagnosis in your study why you are adopting it as a gold standard and a clear description of the technique of undertaking the gold standard test.

**Give a clear and detailed description of the technique of doing the diagnostic test under study**

Give a clear and detailed description of the technique of doing the diagnostic test under study so that your colleagues who read your research paper can also undertake it on their patients.

**Clearly mention the Replicability (Reliability)**

Clearly mention the replicability of your diagnostic test in terms of variations that may occur due to observers (inter and intra observer), subjects (inter and intra subject); and, Instruments and techniques.

**Calculate the sample size**

For calculating the sample size, be prepared to give the following information :

(a) What is the expected sensitivity or specificity of the test being standardised (a rough, approximate estimate)

(b) How much "deviation" from this expected sensitivity / specificity is acceptable to you

(c) What is the expected prevalence of the disease (in the population being studied).

**Analysis**

The analytic techniques for a diagnostic assessment study are calculation of sensitivity, specificity, overall accuracy, PPV, NPV, Likelihood ratios, their 95% confidence intervals and an ROC analysis, if warranted. Do not undertake hypothesis testing procedure as a chi-square test in a diagnostic test study. All these tests can be undertaken on statistical software, as described in one of the subsequent sections on EPI - 2002

Col RajVir Bhalwar

# Planning, Design and Conduct of a Randomized Controlled Blinded Trial (RCT) : Clinical Trial

In medial research practice, a clinical trial or RCT represents the strongest design, the ultimate in medical research. The history of clinical trials is not very old. In fact the first scientific clinical trial was done just 250 years ago under the name "Ceterius Paribus", on board the British Naval Ship "Salisbury" when James Lind had tried out various treatment modalities and shown that a ration of fresh lime juice and oranges was curative for scurvy (36).

Actually, what we commonly refer to as clinical trial is just one phase of the entire gamut of clinical trials. In fact, clinical trials have four phases which are sequentially studied on human beings, viz, Phase I to IV (37 - 42). Before phase I is undertaken, the new drug or treatment modality should have passed through the animal and laboratory testing and should have shown to have the desired pharmacological effect, safe and free of carcinogenic and teratogenic effects. Only thereafter can a drug enter the phase I of clinical trials. Phase I is undertaken on a small number of patients or healthy volunteers and refers to dose finding studies, to find out as to how large a dose can be given before an acceptable toxicity is experienced by patients (Maximally Tolerated Dose or MTD). Phase-II can be called as pharmacokinetic and pharmacodynamic studies, undertaken on a small number of patients with the target disorder. It proceeds to evaluate the biological activity and to estimate the rate of adverse events at that MTD. Phase-III is the actual, classical stage of clinical trial which is also known as the Randomised Controlled trial (RCT). Following phase III, the drug is marketed and simultaneously phase IV also starts. Phase IV is also called as "Post Marketing Surveillance". Data on the effect of the drug or procedure is collected from various agencies during this phase. Side effects which did not which appear in phase III, are detected in this phase and the drug may be withdrawn or its usage modified. Classical examples are Thalidomide, Isoprenaline containing bronchodilators, and DES.

## Steps in Planning, Designing and Conduct of a Clinical trial

### Step I : Deciding whether a clinical trial really required? Should it be done? Can it be done?

Undertaking a clinical trail is not an easy affair. It costs considerable amount of specialized manpower, finances, equipment and dedicated efforts. It is therefore advisable that before one starts thinking of a clinical trail one should carefully asses whatever it is really necessary to undertake a clinical trial. Firstly, a detailed review of literature should be undertaken to see whether the question has already been answered by some other workers and whether the findings can be adopted by us for our patients. Meta-analysis of published and even unpublished papers are also advisable because that may answer the issue without actually undertaking the clinical trial. For example reports of 21 randomized clinical trials on the efficacy of the antibiotic prophylaxis for colorectal surgery were published between 1969 and 1987. All of them were small size studies and had given statistically not significant results. However a meta-analysis was done and it clearly showed that antibiotic prophylaxis was, indeed protective. The issue was thus clearly answered without undertaking a time and money consuming clinical trial. (43).

Secondly, decide whether the issue is really an issue. Does it have some novelty and relevance? Thirdly, ask yourself whether it is feasible to do a clinical trial - whether you have the required expertise; the required equipments and expendables; the required infrastructure facilities and manpower; the required finances; and above all - will the required number of patients/subjects as calculated through sample size be available. Finally, ask yourself, whether the trial is ethical? Broadly answer the following questions:- Are the subjects likely to be exposed to an intervention modality which has high probability of causing adverse effects? Is the control group going to be deprived of an intervention modality which is known to be beneficial? Will an informed consent be taken - this means that the subjects will be informed of the scope including the possible side effects and of the fact that, through a lottery (Randomization), they may either get the trial modality or else the control treatment and having been so informed they should then agree to participate voluntarily and willfully without any coercion and unnecessary motivation. Will there be enough safeguards in place to maintain the confidentiality of the subjects? (2 8).

### Step2 : Clearly state the research question and the variables of study

The research question should be developed after lot of reading and deliberations with experts. At times, the researcher may have more then one research question. In such cases one should clearly define out the primary question - this is one in which the investigators are most interested. The main statistical issues including the sample size calculation would revolve around the primary question. The secondary questions are subsidiary to the primary question; or else, sometimes, the data collected for the primary question may also be used for answering the secondary question.

Having clearly defined the research question, the investigator should exactly and clearly list out as to what all "variables" will be studied to answer the research question. Broadly, there are four categories of variables that need to be enunciated:

The exposure variable

This means the "intervention" under study. The complete details including the dosage, method of administration, etc. should be clearly defined. Secondly, the way this variable is going to be recorded should be described. For example, in the clinical trial to study whether oral aspirin prevents the recurrence of acute MI over the next one year,

the recording may be made as a dichotomy (subjects given aspirin 150mg/day are recorded as E+ and those given placebo recorded as E-), or recorded at many levels in a graded fashion (given placebo / 75mg/ day / 150 mg/day / 225 mg/ day). Such clear definitions are important since subsequent statistical analysis will depend on how variables have been recorded.

Co-Interventions

Often co-interventions may be studied in addition to the primary intervention. For example in a trial of new ACE inhibitor as primary treatment of hypertension, the researcher may also desire to study the effect of "life style change" as co-intervention. Co- interventions should be as clearly defined as primary exposure variable.

The outcome variable

The outcome variable is the end point that is of utmost importance to the investigator. Usually it is recorded as outcome achieved (O+ , e.g. patients who got cured) and outcome not achieved (O - , e.g. patients who were not cured). Care should be taken to clearly define one "primary outcome" or the "endpoint" variable which is of most interest to the researcher and around which the analysis and sample size calculation would revolve. In addition, "secondary outcome" or the "other endpoints" variables can be defined. For example, in the trial of Buprepion 300mg/ day vs placebo for bringing about smoking cessation in patients with acute cardiovascular disease the outcome variable was defined as :- Primary outcome: "7 day point prevelance of tobacco abstinence, one year after discharge, self reported and validated by saliva cotinine"; Secondary outcomes:- Cotinine validated cigarette abstinence at the end of treatment (12 weeks) and duration of post discharge abstinence (No. of days till first cigarette smoked after discharge). (44)

The confounder variables

Ideally there should be no need to measure the confounder variables in a clinical trial once randomization has been done, since randomization is itself a very powerful tool for controlling confounding. However, in small size trials, randomization may not have that much effect. Secondly it may also be worthwhile to do a baseline comparison between the intervention and the control group in respect of important confounding variables to show that randomization has been effective. It is therefore advisable, rather necessary, to collect data on major confounding variables i.e. those which are directly related to both the exposure and the outcome variables. For example in a clinical trial on the efficacy of different antimalarial regimens in bringing about Falciparum parasite clearance in 4 weeks among antenatal cases, the confounding factors which were recorded and compared at the baseline were age, gravidity, parity, trimester, evidence of previous chloroquin use, hemoglobin concentration and pre-treatment parasite density (45).

**Step3: Enumerate the inclusion and exclusion criteria**

Clearly define the characteristics of patients who would be eligible for entry into the trial, by specifying the "inclusion criteria" based on demographic, and clinical criteria. The more important aspect are the "exclusion criteria" - those who will not be eligible to be included in the study. More the exclusion criteria, more precise will be the findings and lesser will be the requirement of sample size. However, more the exclusion criteria, more difficult will be for you to find the particular type of subjects, and the generalizability of your study will be restricted. Let us illustrate the guidelines for deciding on the exclusion criteria with the example of clinical trial to assess Tamoxifen for breast cancer. In this trial, the reasons for excluding certain types of patients and the actual exclusion criteria that can be stated are described in Table 1 (46).

**Step 4 : Defining the populations**

We would define the reference population also called the "universe" or the "target population". This is the very large collection of patients or subjects to whom the results of the study would be generalized. For instance, if we wanted to do the earlier mentioned Tamoxifen - breast cancer trial as an Armed Forces Medical Research Committee (AFMRC) project, we could define our reference population as "Wives of serving / retired armed forces personnel, aged 40 to 70 yrs having at least one breast intact, not having history of venous thromboembolism, not taking oestrogen, mentally alert and who agree to participate". The reference population is very large, scattered and difficult to delimit, and hence we cannot directly draw a representative sample from it. For this reason we often specify a well defined subset of the reference population from where we actually draw the sample of subjects. For instance, in our example we may define the actual study population as all the women of the type defined in the reference population "who are staying in Pune Kirkee - Khadakwasla - Lohegaon complex". It is from this actual study population that we finally draw our required sample. Specifying the actual study population is more of a matter of administrative convenience but we must be convinced that the actual study population is a reasonably representative subset of the reference population.

**Step 5 : Sample Size Calculation**

Sample size is a major issue in clinical trials. Too small a sample would produce insignificant results and would be a waste of efforts. With a small sample the chances are very high that the result would be statistically insignificant. Hence an adequately large sample is important. At the same time we must remember that every subject in a clinical trial costs tremendous amount of money, so even one additional subject may mean poor financial management. Keep in mind is that there is nothing like an absolutely adequate sample size. Very often we have an impression that a minimum of 15 patients in each of the study and the control group is good enough to get significant results but this is not true.

Before we go we go to the statistician and ask her as to what should be the size of the sample for our study, or else use the statistical software for calculating the sample size, we should be prepared to specify the following parameters (47). Firstly, the Type 1 or Alpha error. We may, by convention, specify it as 5%. Secondly, the Type 2 or Beta error. By convention you could specify it as 20%

Table - 1: Broad reasons for exclusion criteria with example of Tamoxifen in Breast Cancer

| S No | Broad Reasons for exclusion | Actual Exclusion criteria stated "The following will be excluded" |
|---|---|---|
| 1. | Intervention modality may carry high risk of adverse effects | History of venous thromo-embolic (TE) event (since tamoxifen increases risk of venous TE) |
| 2. | Unacceptable risk of assignment to placebo group in that death during treatment among control group is not acceptable | Cases of oestogen receptor positive breast cancer (since tamoxifen is an effective standard treatment modality, hence in such cases random allocation to "placebo" group would be disastrous) |
| 3. | Do not have the risk of developing the outcome | Patients with bilateral mastectomy |
| 4. | Have a type of disease that is not likely to respond to treatment | Patients with breast cancer susceptibility gene that causes oestrogen receptor negative cancer |
| 5. | Already taking a treatment that is likely to interfere with the intervention being used | Patients taking oestrogens ( which are likely to compete with tamoxifen ) |
| 6. | Subject is unlikely to adhere (comply) with the regime | Patients showing poor compliance during run-in period |
| 7. | It may be unethical to include non-consenters | Patients who do not agree to participate |
| 8. | Unlikely to complete the follow up, or | Patients who plan to move out before trial ends; short life |

and specify the power of the study as 80%.

The next two parameters are more important and only we as researcher can specify these based on our professional experience and academic reading. These are, firstly, the expected proportion of the outcome in the Non-exposed group (p0). To simplify, what is being asked is the percentage of subjects who are likely to improve when on the "control" modality of treatment (i.e. who are not exposed to the intervention). To clarify, let us take the example of a clinical trial wherein we want to study the effect of a new antihypertensive drug and compare it to a drug already in use, say Ramipril. Now p0 is the percentage of subjects on Ramipril who are likely to improve. Let us say, based on your experience and academic reading you know that 70% of the hypertensives on Ramipril will improve, then you state p0 as 70%. The next parameter to be specified by us is "What is the amount of effect due to intervention modality you would consider clinically significant". In the above example of Ramipril, let us say we decide that we would consider the new drug worthwhile only if it produced at least 25% additional effect to what Ramipril already does, you specify a detectable risk as 1.25.

### Step 6 : Detailed Descriptions Of Measurement Protocols

The most important facet of clinical trials is to ensure that the measurement process is accurate. So, at the stage, develop the detailed protocols of clinical procedures, laboratory investigative procedures, as well as the details of questionnaire and interview protocols. For each and every variable (intervention, co-intervention, confounders and major and minor outcome variables), write down very clearly and explicitly , in great detail as regards Who will make the measurement ? When will it be made ? What equipment / instrument will be used ? What technique will be used ? How the equipment, techniques and personnel be standardized and validated ?

For example, a trial was conducted to study the efficacy of Dopoxetine for treatment of premature ejaculation. The primary outcome( major end point) variable was defined as " Intravaginal Ejaculation Latency Time (IELT)". The measurement process for this primary outcome variable was described in the final published article as follows:

"Couples were supplied with the stopwatch and instructed about their use in detail. The female partner was to activate the stopwatch immediately on penovaginal penetration and to stop the watch immediately at the point of intravaginal ejaculation or at the point of withdrawal without ejaculation and this time in the stopwatch was noted by the female partner to give the IELT. This technique has already been validated in other studies. If ejaculation occurred even before the penetration the IELT was noted as zero" (48).

You would note that the investigators took pains to describe the exact measurement process of this variable, though they may be sounding a bit immodest.

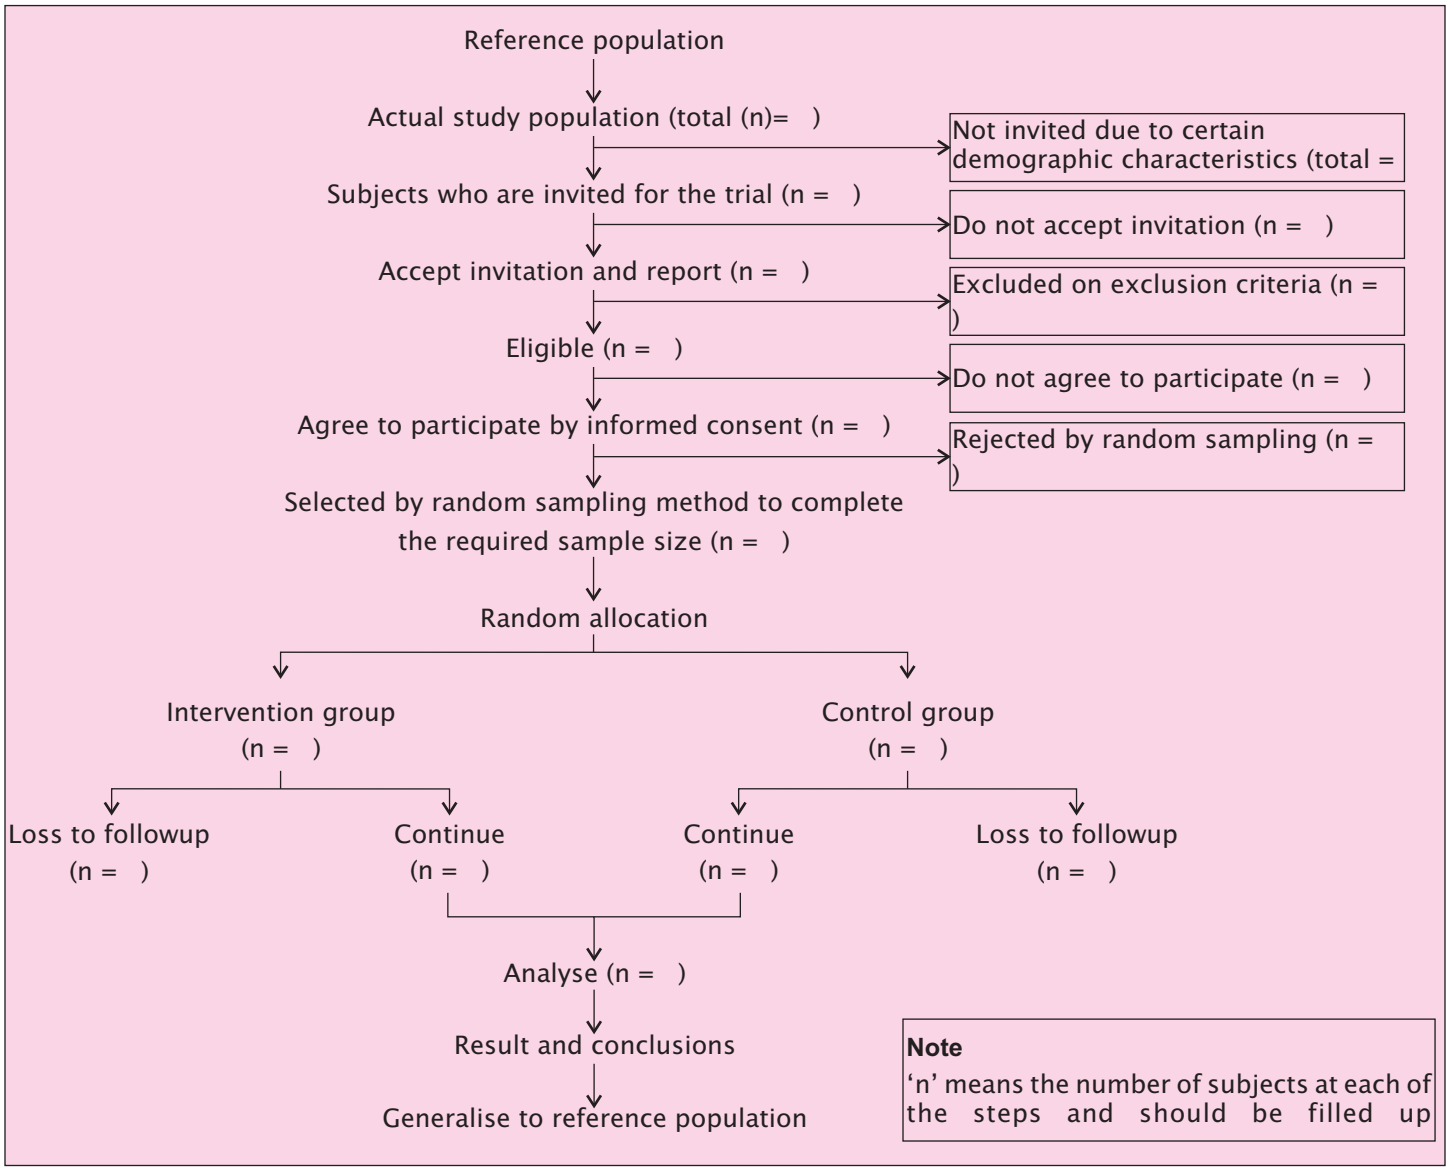
### Step 7: Enrolling The Participants

Once the minimum sample size has been calculated the next step is to enroll a representative sample of the patients from the actual study population. Let us take a hypothetical example: Suppose that a specialist in Venereology desires to put up an AFMRC project to

replicate the clinical trial on dopoxetine 30mg (daily) in treating premature ejaculation in our settings. He has defined the reference population as all married personnel of Indian Armed Forces staying with family and who self report or give a history of premature ejaculation ( defined as IELT of <1 mt.). Subsequently he has defined the actual study population as all Indian Armed Forces personnel with the above characteristics who are seen at MI rooms, OPDs and speciality clinics at Pune and Kirkee. By way of statistical procedures, he has worked out that he will need 400 subjects in each of the dopoxetine group and the placebo control group. Now, to actually enrol the participants for this trial, we will make a list from available records of all such subjects who have been diagnosed as premature ejaculation during the past one year. Of all the patients who have been invited, some may have been posted out and some may not turn up due to other pressing commitments, while the others will report.

In the next stage we will see who are not eligible by applying the "exclusion criteria" (Having erectile dysfunction, psychiatric illness, using tricyclic anti-depressants or using other pharmacological or behaviour therapy for premature ejaculation). This will further reduce our list to now include those who are "eligible". Now, those subjects who are eligible will be informed of the details of the study and asked if they would like to participate under informed consent. Out of the ones who agree to participate, 800 will be selected by random sampling process (say, every third patient) and we will keep randomly allocating them to receive either the intervention modality (Dopoxetine) or the control modality (placebo). In fact, during the planning and conduct of a clinical trial as well as during writing your research paper, it is important to present the " Recruiment and Participation Flow Chart" giving the numbers ('n') at each step, as per following format (Fig - 1):

Fig - 1



**Step 8: Randomisation**

The basic dictum of any research is that the groups being compared should be absolutely similar to each other except for the factor which is being studied. In methodological terms, it means that all confounder variables must be controlled. There are various methods of control of confounding. When it comes to clinical trials the method is randomization or random allocation. So essential is randomization that the other name is 'RCT' (Randomized Control Trial). The procedure is quite simple. Random number tables available in any book on statistics or computer statistical packages are used to generate random numbers. Accordingly the subjects are allocated to either, receiving treatment A (the intervention under trial) or else treatment B (the control modality). The power of randomization is such that, the two groups are similar to each other. Let us see an example as to how randomization equally divides subjects into two groups:-

"….In a clinical trial, to evaluate the protective effect of hormone supplementation with estrogen plus progesterone on the risk of fractures and the bone mineral density , a total of 16608 women who were eligible and finally agreed to participate were randomly allocated into 8506 women who received hormonal supplementation and 8102 receiving a placebo. The comparison regarding the major characteristics of the two groups is presented in Table-2 and shows how effectively randomization has created two identical groups……" (All figures in percentage) (49).

Table - 2: Example of equal distribution of characteristics following Randomisation

| Characteristics at baseline | Estrogen Plus Progesterone Gp.(8506) | Placebo group (8102) |
|---|---|---|
| Age 70-79 yrs | 21.3 | 21.8 |
| White skin | 83.9 | 84 |
| BMI<25 | 30.5 | 30.8 |
| Total Cal. Intake < 600 mg./ day | 24.4 | 24.2 |
| Smoker | 10.5 | 10.5 |
| >= 2 falls in past 12 months | 12.8 | 12.4 |
| Fracture | 38.8 | 39.1 |

However, there is a note of caution. Randomization works well to create 2 similar groups only when the sample is adequately large. In a small sample, the effect diminishes and may become erratic (50).

**Step 9 : Introduce The Intervention And Placebo Control Modalities**

Having created the two groups by random allocation, the investigator now needs to intervene with the trial modality in one group, and the control or the baseline modality in the other group. Certain aspects to be ensured at this stage are:

(a) Ensure ways and means to bring about compliance in both the groups. Give adequate amount of medicines to all the subjects in both the groups and instruct them clearly on the dose, mode of administration, frequency of intake, etc.

(b) Develop procedures for checking compliance as for example check count of balance pills, testing the urine/ other excretions for metabolites and so on.

(c) Brief both the groups clearly about co-interventions in the trial, if there are any.

(d) Ensure a placebo control, so that the control group who are not getting the trial intervention cannot make out that they are not getting it. Ensure that they get the placebo drug in the same shape, colour, size and taste and is also administered using similar procedures.

**Step 10 : Ensure Blinding**

What if the subjects know they are getting a new drug? They may start feeling better just because of this knowledge! They may report improvement just to please their Doctor! And those not getting the new treatment may not feel relieved thinking that they have been deprived of some new, good treatment. And may be, just because of this awareness, some of them may quietly start taking the new regimen or some other co- intervention. More bias may be introduced if the investigator is aware of the status of the subject. The investigator may differentially probe or investigate more in one group or less in the other group.

To overcome these biases in the standard clinical trial, Blinding is used as an essential requirement. In single blinding, the subject is not aware of his status but the investigator is aware. The ideal of course is double blinding, in which neither the investigator nor the subject is aware as to which group a particular subject belongs to. Only the codes are given and these codes are handled by the data manager. The gold-standard in contemporary times for clinical trials is double blinding. Double blinding may sound difficult but can be implemented even in testing situations.

Take for example the clinical trial undertaken to assess the efficacy of Ancrod, a natural defibrinogenating agent from snake venom, when given within first 6 hours of an acute ischemic stroke. Patients were randomly allocated to receive Ancrod (608 patients) or placebo, isotonic sodium chloride(618 patients). Identical looking 1 ml ampoule containing Ancrod or isotonic sodium chloride solution were prepared in sequentially numbered pre packs. The randomization scheme was handled through a centralized interactive voice response system. An independent blinded physician adapted the infusion rates, on the basis of regularly obtained fibrinogen concentration of individual patients. The clinical researchers received no information about the method of randomization or the group (Ancrod or placebo) to which a given subject belonged to. Fibrinogen data was provided

only to the different independent unblinded supervisors based at each site who monitored adjustments to the infusion rates, based on a dosing algorithm provided by the investigator. (51)

In surgical trials double blinding may become difficult at times. In such situations, we may ensure that the surgeons who evaluate the outcome, should be independent of the research group and preferably different from the surgeon who operated. The operating surgeon may, however, keep monitoring the patients for purpose of management, not for research. We may also make the outcome criteria as objective as possible.

**Step 11: Follow Up And Assessment**

The last but one step in the conduct of clinical trial is to follow up the subjects till the end point, or the period of trial, whichever is earlier and to make ascertainment. The key issue in follow up is to avoid losses to follow up, which may otherwise seriously bias the study results as seen in the following example:- "A trial of nasal calcitonin spray to reduce the risk of osteoporotic fractures reported that the treatment reduced the risk of fractures by 36 %. However, critical evaluation revealed that 60 % of those who were originally randomized were lost to follow up and it was not known whether fractures had occurred among those who were lost to follow up. Because the overall number of fractures was small, even a few fractures among participants who were lost to follow up could have altered the results of the trial. This uncertainty diminished the credibility of the findings (52). It is therefore imperative that actions be taken right from the planning stage to retrieve those getting lost to follow up. The following general steps are worthwhile:

(a) At the very start, inform the participants of the scope of trial, and the time and place where they should report for follow up.

(b) Exclude, in the beginning itself, those who have a very low probability of continuing.

(c) Note down the detailed telephone numbers and addresses of the participants, their close friends, relatives and employers and their permanent home addresses to retrieve them.

(d) Treat them properly when they come for follow up; don't make them wait too long.

(e) Every time they come for follow up, talk to them about their condition and also about the progress of the trial to keep their interest alive.

(f) Even if some participants violate the study protocol or discontinue the trial intervention, they should still be followed up so that their outcomes could be used in "Intention to treat Analysis"

During ascertainment, take care to fill up all the headings in the form fully and correctly and examine all subjects, irrespective of their trial status, with equal methodology and vigor. Do ensure that every subject has a file where follow up records are filed and that these are checked by an independent data manager at least once a month. Enter the data from these forms to the computer database within a week to detect any missing data points. And, finally during the follow up stage, keep the "Stoppage Rules" open. In brief there can be three reasons for prematurely stopping a trial

(a) Evidence comes up in between against the intervention modality :- The Atrial Fibrillation Anticoagulation Study was initiated to study the role of warfarin in decreasing the rate of strokes over 3-5 years. However the trial was stopped after 1-2 years since, by then, strong published evidence had come up in support of the intervention modality (53).

(b) Evidence of clearly high mortality or complication in the intervention group comes up

(c) The Cardic Arrhythmias Suppression trial was initiated to study the role of Anti ventricular dysarrythmia drugs Encainide or Fecainide in patients of Ac MI over a 5 year period. Trial was stopped after 18 mnths since interim results showed clearly high mortality in the treated group (54).

(d) Statistical, Methodological or Sample size assumptions are proved wrong

The Physicians Health Study was initiated to assess the protective effect of oral aspirin 325 mg alternate day in preventing cardiovascular disease. Trial was stopped midway since as against an expected of more than 700 cases, only 88 had occurred and hence the trial was left with hardly any statistical power. ( However, protective effect on occurrence of MI was clearly demonstrated by then) (55).

**Step 12 : Satistical Analysis**

Statistical analysis is indeed a very important aspect of any research design, clinical trials included. Let us start with an example of a clinical trial which has been published in one of the recent issues of Lancet (56). The DREAM Project was a clinical trial to evaluate whether Rosiglitazone (RG), a thiazolidinedione drug said to improve insulin sensitivity can prevent the onset of diabetes type 2 among subjects who were having IGT or impaired fasting glucose. 5629 samples with IFG were randomly allocated to either receive Rosiglitazone 8 mg per day (2635 subjects) or a placebo (2634 subjects) for a follow up period of 3 years. The primary clinical end point was development of diabetes. Those who did not develop diabetes were taken to have achieved the outcome. The final data is

Table - 3 : Summary results of Rosiglitazone data

| Exposure | Outcome | | Total |
|---|---|---|---|
| | O+ (Did not develop Diabetes) | O- (Developed Diabetes) | |
| E+ (Given RG) | 2329 (89%) | 306 (11%) | 2635 (100%) |
| E- (Given Placebo) | 1948 (74%) | 686 (26%) | 2634 (100%) |
| Total | 4277 (81%) | 992 (19%) | 5269 (100%) |

summarized in Table - 3

The data shows that as much as 88.4 % of the exposed group, i.e, given Rosiglitazone remained free as compared to much lesser 73.45 among the placebo group. As the data apparently shows, Rosiglitazone is an effective chemo prophylactic against Diabetes. So the first question is , why at all should we do a statistical analysis? .

We undertake statistical analysis to estimate the effect of "chance" (random error or sample to sample error or sampling variations). It has been very clearly brought out earlier that due to a natural phenomenon of random error, as long as we are studying a sample drawn from the population, which anyway we shall always be doing, the results from the sample are likely to be different from the reality that exists in the large population. What we should, therefore, do is that we estimate the probability with which the results from our study may be different from the reality which exists in the large reference population to which our sample refers to. This probability is estimated by statistical procedures. Please do note that statistical results are only a probability statement about our sample results being different from the reality in the large population due to the natural phenomenon of random error. We presume that your study had no measurement error, no bias and no confounding. Very good statistics is no panacea for data which has been collected by poor measurement methods, or is differentially biased against one group or is suffering from confounding.

Another decision to be taken at this point is whether we want to undertake an "Intention to Treat Analysis" or else a "Per-protocol" analysis. In the former, which is being often undertaken these days, the outcome is analyzed among subjects according to the group into which they were originally randomized ("analyse as you randomize"). Thus, even if participants assigned to the original intervention group may have discontinued or even crossed over or some of the placebo control group may have finally ended up taking the intervention modality, the analysis will be as per the subjects' original randomization plan. On the other hand, the per-protocol analysis will include only those participants in both groups who undertook at least 80% of the assigned study medication, completed a certain percentage of their expected follow-up visits, and had no other protocol violation (1).

The first thing in undertaking statistical analysis of a clinical trial is to present the participant's recruitment and flow chart, giving the actual data at each step, as explained in Step 7. The next step is to give a table showing baseline comparison between the intervention group and the placebo group as we have given earlier in the step of randomization. The next step is now to clearly visualize what are your primary exposure and outcome variables and what is meant by exposure present or exposure absent and by outcome achieved or outcome not achieved. Now, make a 2X2 table and place your data in the 2X2 table exactly as per the specifications for cells a, b, c and d that we have already discussed. (Table 4)

In the DREAM clinical trial, out of 2365 who were exposed to RG, 2329 achieved the defined outcome while in the non exposed(Placebo) group, 1948 out of 2634 achieved the outcome. Please do take care to indicate both the numbers and percentages in the cells. Now, having placed the data in the 2X2 table, calculate the incidence of outcome in the exposed and non exposed group as :- $I_E$ = a/a+b = 2339/2635 =89% and $I_{NE}$ = c/c+d = 1948/2634 =74%. And, as the next step, calculate the risk ratio (RR) i.e, the "effect" of the intervention as RR (Effect) = $I_E$/ $I_{NE}$ =89/74 =1.20. This calculation of the effect size is a simple but extremely important parameter which you must calculate. In our example, it means that patients of IFG who got Rosiglitazone will be 1.2 time more likely to remain free of diabetes as compared to those on placebo, over 3 years.

In the next step, calculate the 95% CI of RR. In the DREAM trial example, the RR was 1.20 and its 95% CI was 1.16 to 1.23. The interpretation is like this: "our sample results show that the effect of Rosiglitazone is to bring about 1.2 times more improvement". We do not know what the real effect would be in the 2 large populations but we are 95% confident that the real effect in the two large population would be an improvement between 1.16 times to 1.23 times improvement as compared to placebo.

And, in the basic presentation, finally calculate the numbers needed to treat as : NNT = 100/ ($I_E$ . $I_{NE}$) . (57). In our example, it works out as : 100/(89-74) = 100/15 =7. It means that we will need to treat 7 patients with Rosiglitazone to get one additional case of cure (prevented diabetes) as compared to placebo.

Having presented the basic statistics, the next step in statistical analysis is to undertake probability testing procedures. In deciding the statistical procedure, we should first of all see which is the exposure variable and which is the outcome variable. Next we should clearly make out as to how the exposure and outcome variables have been recorded. The correct statistical procedure will depend on which way the recording has been done for the exposure and outcome variables. In the above example, both the exposure as well as the outcome variables have been recorded on a dichotomous scale. In such exigency, a chi-square test for 2 X 2 table will be done, and the 'p-value' worked out against a degree of freedom (df) of 1. For further details on statistical testing procedures, please refer to the section on Biostatistics in which a detailed table has been given indicating the correct statistical test, depending on how the exposure and outcome

Table - 4 : 2X2 Table for initial presentation of results

| Exposure | Achieved outcome (Did not become Diabetic)(O+) | Not achieved Outcome (became Diabetic) (O-) | Total |
|---|---|---|---|
| Given RG (E+) | 2329 (89%) **(a)** | 306 (11%) **(b)** | 2635 (100%) |
| Given Placebo (E-) | 1948 (74%) **(c)** | 686 (26%) **(d)** | 2634 (100%) |
| Total | 4277 (81%) | 992 (19%) | 5269 (100%) |

# Research in Economic Aspects of Health Care

Till about 3 decades back, medical research was mainly directed towards the etiology, risk factors, natural history, prevention and treatment of various diseases. Once the results indicated that a particular preventive or therapeutic measure is efficacious, no further questions were asked about its usefulness. Things are different today. For almost any health care procedure, we are required to be ready to answer questions like- "At what cost?"; "Can't the same result be achieved with a lesser cost?" These questions, all of which pertain to the area of "health economics" assume importance because of the ever increasing cost of health care and the fact that somebody has to pay for it, be it the individual patient or else the entire community (by way of taxation). These issues do not simply involve straight forward questions like " Is norfloxacin more effective, cost for cost, than gentamycin for UTI", but often more complicated issues like :

(a) Should a private practitioner routinely undertake opthalmoscopic examination of all her patients aged > 35 year , irrespective of the signs / symptoms?

(b) Should the health administrator take away "scarce" Auxiliary Nurse Midwives (ANM) from the well baby clinics and, instead, ask them to pay home visit for nutritional education?

(c) Should the hospital administrator buy a newly marketed imaging equipment or continue with what she already has?

The above are just a few examples of often asked questions regarding research into issues of "health economics".

## Types of evaluation

Broadly speaking, there are three types of evaluations in respect of any health care procedure :-

### Efficacy

This answers the question " can the procedure work at all, given the ideal settings?" For example, if we randomly divide a group of 10 patients with pulmonary TB and give streptomycin + INH + Thioacetazone to one group and only a placebo to the other group , we may find that the 3 drug combination definitely cures pulmonary TB as compared to placebo. In other words, when the settings are ideal ( Patients are well supervised, compliance is ensured and so on ), the 3 drug combination is "efficacious".

### Effectiveness

In contrast to efficacy, evaluation of "effectiveness" is intended to answer the question "Does the procedure actually work in the real life situations, when the settings will be subject to the various constraints" rather than being ideal. For example, the 3 drug combination of strepto, INH and thioacetazone may be highly "efficacious" (almost 90 to 95% against pulmonary TB), but when it is actually put into practice on a large scale in the community, the overall cure rate in the community is just about 40% , mainly due to lack of compliance. Thus , while the efficacy of strepto + INH + Thio may be as much as 95%, the actual "effectiveness" is just about 40%. On the other hand, four drug combination (Strepto + INH + Rifampi + Pyrizinamide) administered under direct supervision, is not only 95 to 100% "efficacious" but is also 70% to 80% "effective" possibly due to a better compliance consequent to a shorter duration of therapy.

### Efficiency

Efficiency evaluation answers the issues related to "costs". In a layman's language, it answer the question "Is this the "best" way of doing the things? Can the same results be achieved in some other way, paying a lesser price?" .

## Definition

An economic analysis can be defined as the comparative analysis of alternative courses of action, in terms of both the costs (inputs) and results (outputs) and comparing the costs and the results of the alternatives being considered.

## Architecture Of Health Economic Research Studies

The architecture of health economic research studies can be described on the basis of cross combination of the following two basic questions :-

(a) Are both the costs (i.e. inputs) as well as results (i.e., the outputs) of the alternatives being examined.

(b) Are two (or more) different alternatives being compared or only a single alternative is being considered.

Depending on the answer we get to our above questions the various types of economic research designs are being described in succeeding paragraphs and being summarized in the summary (Box 1)

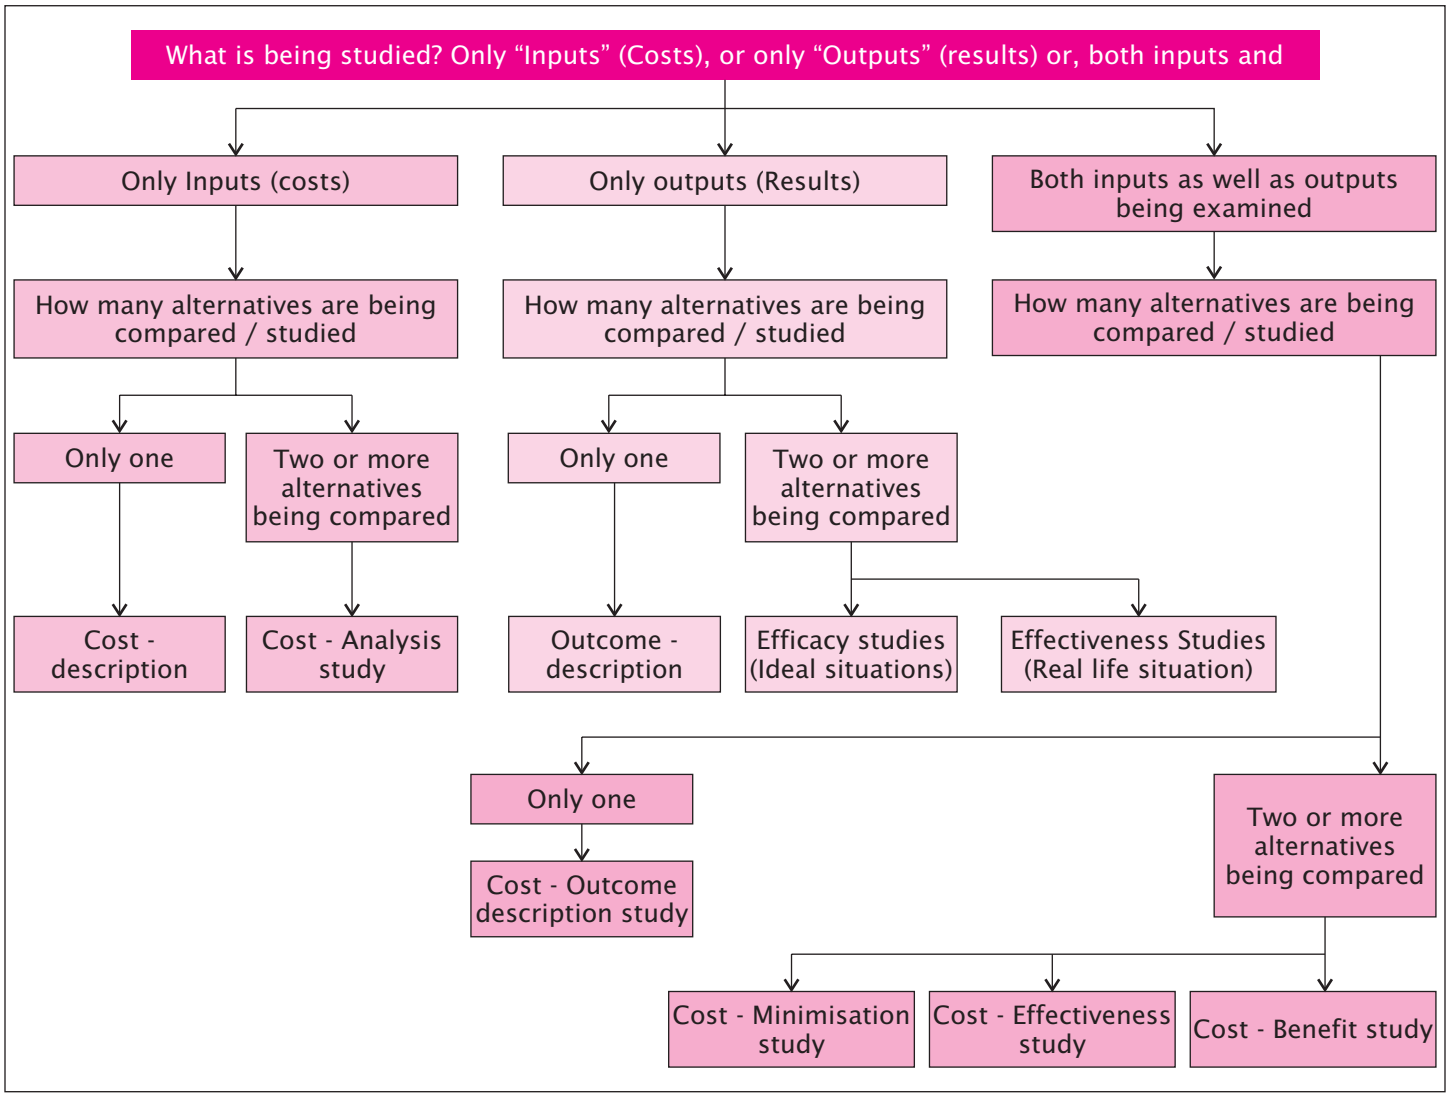
### Situation 1

Only the cost (inputs) but NOT the results (outputs) are being studied. The two situations that can further arise are :

(a) Only one alternative is being considered : For example, we may work out the total cost (per patient) of treatment with a latest antibiotic (total cost includes cost of drug , overhead expenses, cost of syringes, commuted cost of hospital stay and so on). However, we would not work out the total benefit that occurs with this antibiotic, neither we would compare the cost so calculated, with the cost of any alternative antibiotic, say penicillin. Such a type of study is called as **"Cost Description Study"**.

(b) Two or more alternatives are being compared : In the above mentioned study we could compute the cost of treatment with the newer antibiotic (of course, without considering the economic aspects of results) and compare this cost with that of ampiclox and augmentin. Such a study is called **"Cost Analysis Study"**

Box - 1: Summary description of health economics research studies



**Situation 2**

Only the results (outputs) are being examined but NOT the cost (inputs). Once again, two situations can further arise :-

(a) Only one alternative is being considered : For example, we may give a group of patients, in one hospital, a newer antibiotic and describe only the outcome (say in terms of cure rate, hospital days, acute-period days and so on). However, we would not describe the cost of the newer antibiotic , nor do we have any other group of patients receiving another antibiotic with which we could compare the result. Such a study is called as **"Outcome Description Study"**.

(b) Two or more alternatives are being compared :- For example, in the above mentioned type of study, we could have another group (s) of patients on penicillin / ampiclox and make comparison of the "result" of this group with the results of the new antibiotic, without considering the cost of any of the antibiotic regimens. This type of study is a **"Efficacy"**, or **"Effectiveness" Study** (depending on whether we are making the comparisons in the ideal settings (for efficacy) or in the real life settings (for effectiveness). Most of the experimental designs concerning RCTs (drug trials, clinical trials, preventive measures trials) fall in this category of economic evaluation.

The four different types of studies mentioned in situations 1 and 2 above are called as **"Partial Economic Evaluation".** Partial economic evaluations are quite important; however, they do not answer the issue of "efficiency".

**Situation 3**

Both the inputs (Costs) as well as results (outputs) are being studied : Once again we can have 2 types of situations in this group :

(a) Only one alternative is being examined : For

example we may take a group of patients and give them newer antibiotic. We work out total costs (in terms of cost of antibiotic, hospital stay costs etc) as well as the results (Cure rate, satisfaction level, etc). However, we are not having any other alternative (as penicillin or ampiclox) to make comparisons. Such a type of study is known as **"Cost Outcome Description Study"**. Such studies are also a type of partial economic evaluation."

(b) Two or more alternatives are being compared For example, in addition to having a group of patients on the newer antibiotic , we have another group on penicillin for making comparison. We work out both the costs (inputs) as well as results (outputs), as above, for both the groups and make comparisons. This is the classical **"Full Economic Evaluation"** or **"Efficiency Study"**. In general , such studies can be of three types:

(i) Cost Minimisation Analysis

(ii) Cost Effectiveness Analysis

(iii) Cost Benefit Analysis

Cost minimistation Analysis

In such a study, the result (outputs or consequences) of the two (or more) alternatives are identical and we compare the cost of the two (or more) different alternatives. For example, we may have the research question : "Whether to keep a patient hospitalized overnight after an Incision and Drainage for a carbuncle, (1st alternative), or else, perform a day-care surgery and discharge after a few hours of observation (2nd alternative). Here, the "outcome" (i.e, consequence or output or result) is assumed to be the same for both the alternatives, ie., " operation has been successfully performed without any immediate or delayed sequelae". We would now work out the costs for both the types of strategies and see as to which carries the smaller cost. Statistical issues would involve comparing the "mean cost" for the two strategies by a 't' test (or, ANOVA if there are more than 2 alternatives being compared).

Cost effectiveness analysis

Let us say, our outcome of interest is "Years of life gained after onset of renal failure" and we are comparing the costs to achieve this outcome through "periodic hospital based dialysis" (Strategy No. 1) with "kidney transplantation" (Strategy No.2). Now, in this setting, the outcome of interest is common to both the strategies. However, the two different strategies may bring out different achievements of this outcome (ie. the average years of life gained may be different for the two strategies, as also the total costs of the strategies may be different. Thus we would calculate the "Costs (i.e., inputs) per unit of the result" (i.e, output). More precisely, in this example we will calculate the "total costs in rupees per additional year of life gained" for the two different alternatives and make comparisons. Alternatively, we can calculate the "results (outputs) per unit of the costs (inputs), i.e, we can calculate the "life years gained per rupee (or per one lakh rupees) spent" for both the strategies and make comparisons. The latter approach is more appropriate when we are working under certain budgetary constraints. The statistical issues would involve comparison of the two "mean" outcomes using a 't'-text. Cost effectiveness analysis are, thus, such studies wherein costs (inputs) are related to a single, common outcome (output); however this single common output (e.g. "life years achieved" in the foregoing example) would differ in magnitude between the alternative strategies that are being compared. Cost effectiveness studies may also be performed for comparing widely different alternative strategies which have a common effect; for example, if the common outcome of interest is "life years gained" as in the above example, we can compare not only dialysis vs renal transplant but even "dialysis" vs "education programme to ensure crash helmet use" to decide whether scarce public funds be diverted towards educating the community in use of crash helmets to prevent head injuries or towards renal units for undertaking dialysis of renal failure cases.

Cost benefit analysis

In a cost effectiveness analysis we make comparison between the costs of two strategies on the basis of a common (single) outcome of interest (e.g, "life years achieved" in the above example). However, often it may not be possible to measure the consequences of the alternative strategies by a single, common effect of interest. Broadly, two different types of issues may come up :-

(a) We may be interested in consequences which, though common to both the alternatives, are multiple. For instance, in the above example of renal disease, we may be interested in answering, in addition to "life years gained", such other consequences as "quality of life" and "incidence of medical complications" etc.

(b) Secondly, we may be interested in comparing two different strategies which produce entirely different outcomes. For example, we may be comparing a cervical cancer screening programme among middle aged women having the outcome of interest as "life years added due to early treatment" with a pulse-polio immunization campaign among infants, the outcome of interest being " improvement in the quality of life of children due to disability prevented"

Here, in both the above situations, the outcomes of interest are either multiple (situation 'a') or else, differ between the various alternatives (situation 'b') and hence a meaningful cost effectiveness comparison is impossible. In situations like these, we need a common denominator to facilitate comparison of outcomes. We therefore attempt to go beyond the consideration of specific effects alone, and try to work out a measure of "value" to the various "consequences" resulting from the different alternative strategies. One such measure of these "values" could be the currency expressions as "rupees". Thus, the various results or consequences of a particular strategy may be worked out and expressed in terms of "rupees benefit" in order to facilitate comparison to the costs of

the strategy. This would, of course, require that we convert such abstract outcomes as "quality of life" or "patients' satisfaction" into their "rupee benefit", which may be quite a difficult task. Such analyses which measure both the inputs as well as outcomes in terms of money, for making comparison between two different strategies are called "cost benefit analysis", the methods of analysis of these studies is to work out the "rupee cost to rupee benefit" of each of the 2 (or more) different strategies, so as to get a "relative benefit". Alternatively, the absolute difference between the benefit of the two strategies can be calculated. Let us dilate on the example given above on the "overnight hospitalization" vs "OPD treatement" for incision and drainage. We randomly divided 100 patients into 2 groups of 50 each receiving either of the two strategies. The costs of the two procedures included cost of drugs, surgeon's fees, hospital stay charges, money spent by relatives of patients on transport and visits, and so on. The various outcomes were cure, occurrence of complications, pain and inconvenience at home/work place as an after effect of operation, patient's satisfaction, loss of work days and wages, as so on. All of these various outcomes were commuted to "rupees" by " expert and sensible "value judgement". The data set would look like as given in Table - 1.

Next, calculate the means and standard deviations of "Rupee cost to Rupee benefit" for both the groups. Let us assume these are as follows :

(a) Strategy 'A' (Admission) : Mean (X1) = 1.36, SD1 = 0.24, no. of subjects (N1) = 50

(b) Strategy 'B" (OPD groups) : Mean (X2) = 1.65, SD2 = 0.26, no. of subjects (N2) = 50

(c) Ratio of "average rupee cost to rupee benefit " of OPD group over admission group = 1.65/ 1.36 = 1.21. The interpretation is that strategy No B. (OPD

Table - 1

| Patient No. | Strategy (A=OPD) (B=Hosp) Adm. | Age | Sex | Baseline Condition | Other Diseases | Total Input cost (c) | Total Benefit in Rs. (b) | Rupee cost to Rs benefit ratio (b/c) | Absolute Diff. (b-c) |
|---|---|---|---|---|---|---|---|---|---|
| 1 | A | 36 | M | Fair | No | 181.50 | 257.82 | 1.42 | 76.32 |
| 2 | B | 40 | F | Fair | Yes | 348.90 | 384.10 | 1.10 | 35.20 |
| 50 | B | 58 | M | Poor | Yes | 310.10 | 526.70 | 1.69 | 215.80 |
| 100 | A | 24 | F | Fair | No | 257.10 | 318.20 | 1.24 | 61.10 |

Col RajVir Bhalwar

## Questionnaires and Interviews

In a large number of clinical measurements (pain, fear, satisfaction, attitudes, practices, beliefs, etc.), there is no clear cut physical standard. The usual approach in such settings is to construct a questionnaire, consisting of a group of questions designed to measure these specific phenomena. The first thing to remember is that one should do an extensive reading and find out if any questionnaire is already existing which caters to one's requirements. It is best to use an already existing questionnaire in toto (or, use it after slight modifications) because the same has already been standardised / validated by earlier workers. However, if one has to devise a new questionnaire, one should work out the details of the items and specific questions to be included by the following methods.

(a) Recapitulate from your own theoretical knowledge & your observations in clinical practice, in this field, thinking extensively on what all should be included.

(b) Do an extensive study of research works done in the past 5-7 years (at least) to get an idea of the variety of topics /questions that need to be included.

(c) Consult experts in the field for their opinion regarding various items/ questions.

If the outcome is to be recorded on a "continuous" scale, try to record the answer on a Visual Analog Scale (VAS), to get the maximum possible information. E.g., for a question on pain, we can draw a line of 100 mm, with '0' indicating 'no pain' and 100 indicating 'pain of the most extreme type" and ask the patient to put his finger at the point he feels optimally describes his severity of pain.

If the response is to be recorded on a "nominal" scale (i.e., as "categories), the optimum is to keep 5 to 6 categories. Also try and change the order of response in successive questions; e.g. if Q.1 is recording the response from "high" to "low" try to record the response on Q.2 as "low" to "high". "Likert's" type of scales, in which the responses are framed on an "Agree - Disagree" continum can often be used in such situations. E.g., for a question "Is the OPD giving satisfactory service?", the responses could be

| strongly agree | Agree | No opinion | Disagree | strongly disagree |
|---|---|---|---|---|

Decide whether you want to have a "structured" or an "unstructured" questionnaire. In the former, the interviewer asks the same questions in the same way and in the same order from all subjects; in other words there is a pre-designed schedule on which questions are already written down in sequence. On the other hand, in "unstructured" questionnaire, there is lot of flexibility and the questions asked from the study subjects may vary at the discretion of the interviewer (e.g., interviews taken by a journalist; psychiatric history taking). By and large, it is always desirable to have a structured questionnaire since it ensures standardisation and reduces variations. Now decide whether you want to have a "closed ended" or "open ended" questions.

**Specifically check the following points while making the questions**

(a) Avoid ambiguity :- Avoid statements or questions which are likely to be interpreted differently. E.g. instead of the question "Have you been on leave recently?", it will be more apt to ask " Have you been on leave since 01.01.2007?".

(b) Avoid "double-barrelled" questions : e.g., "Do you have precordial pain and dysonoea while walking?". Now, what if the subject has any one of them? In such cases make two different questions.

(c) Avoid technical jargon : The question "Are you hypertensive" may be interpreted by a layman as "too much mentally tense" .

(d) Avoid "value-laden" words or hypothetical questions : e.g., In the question "Would you like to move to a better hospital?" would evoke various judgement responses because of words "like" and "better" which are hypothetical. In such cases, increase the number of questions and be more specific, eg :-

(e) Do you want to move out from this hospital? Yes/No.

(f) If Yes, to which hospital?

(g) Why do you want to move to that hospital? Better administration/ better doctors/ better investigations / less expensive/ any other (specify)

(h) Avoid questions that are not self explanatory : e.g. The answers to question "What type of home do you have?" may bring out different answers like "happy", "concrete", "well ventilated", "small" and so on. In such cases specify the question in details or give closed / semi closed answers in front of the question.

(j) Do not ask about events which most people will not remember : e.g., "How many times per week did you drink milk when you were between 6 and 10 years old?" may be quite difficult to answer. In such cases, if you must ask about such a long past, try to verify/ supplement this information from other sources (records, parents, friends, siblings, spouse etc.).

(k) If you are using interviewers to carry out the interview, train them centrally, test them and

certify them to ensure standardisation. Do a 20% cross chick on the filled proforma by cross checking information yourself. Do a random check on how the various interviewers are carrying out the interview.

(l) If possible, ensure "blinding".

(m) Start with general questions and gradually move on the sensitive questions (e.g., sexual practices, family violence, etc.) later on in the questionnaire.

(n) Ensure "pretesting" your questionnaire as well as interview technique by pilot study.

(o) To start the interview, establish rapport with the subject. Do not forget to assure him of confidentiality- this will itself greatly increase the validity of information.

(p) Alternate questions which are likely to bring out 'yes' answers with those likely to bring out 'no' answers.

(q) Keep some "Dummy, check questions" in the questionnaire. These questions may not be related to the study but may enable us to cross check the validity of information. E.g., in a study on sexual practices, tobacco use and details of postings may not be directly relevant to study objectives; however, answers to such questions may be cross checked with records, friends, senior officers etc. and would give an overall idea of the validity of information being provided by the subject.

# Writing the Research Findings

The discussion in the present chapter is intended to serve as general guideline for writing a research paper or dissertation. The researcher is advised to obtain a copy of specific guidelines from the journal to which he or she intends sending the article (or the academic council or research body in case of a thesis or project report) and adhere to the finer details provided in such instructions. For instance, in so far as Medical Journal of Armed Forces of India (MJAFI) is concerned, the guidelines for authors are published in the January issue every year.

The general sequence of presentation in an original research paper or thesis is usually as follows :

(a) Title
(b) Abstract (Summary in case of thesis)
(c) Key words
(d) Introduction
(e) Aim and objectives
(f) Review of literature
(g) Material and Method
(h) Findings (Results)
(j) Discussion
(k) Conclusion
(l) Recommendations
(m) References
(n) Annexures
(o) Other Enclosures.

All or most of these headings should be sequentially covered up, whether you are preparing an original research article or a thesis, keeping one major difference in mind, that in a thesis or project report, the various aspects are dealt with in great detail while in a research article, these are condensed. As a general guideline, try and restrict your research paper to 8 to 10 double spaced A-4 sized typed pages and your dissertation/project report to 125 to 150 pages.

### Title

A large majority of the readers of medical journals generally browse through the list of contents and tend to select the article whose title attracts attention. The take home message is that you must select the words in the title in such a way that it attracts attention. Do not keep the title either too long or too short. A good method is to write down a few titles, revise and modify them a number of times till you get the one which appears to be the best. The optimum number of words in a title are between 15 and 25. The title should be, in fact, a very short, "telegraphic form" summary of your objectives . In addition, the title may also give a very brief indication of the place and general settings of the study and the type of study design; e.g., "A randomized Controlled Clinical Trial (i.e., the "design") of the effectiveness of acetazolamide in preventing Acute Mountain Sickness (i.e., the research question)among young healthy soldiers inducted to high altitude in Northern Himalayas (i.e., the general settings).

### Abstract

In a research paper, the title is followed by the Abstract. In case of a dissertation or project report, there is an additional page giving the Index (list of contents) interspersed between title page and the "Summary". In a dissertation / project report you would write a Summary which occupies approximately 5% to 7% of the total pages that are present in the report. The abstract is a short crisp summary of your entire research paper. Usually, it should be limited to 200 to 300 words (about one typed page in double spacing). Some of the standard journals, including MJAFI, want the Abstract section to be further subdivided into four sub-headings namely Background significance, Material and Method, Results and Conclusion. The abstract should start with a sentence or two on the background of your research question followed by your actual research question (i.e, objectives) summarised in a sentence or two. Thereafter the salient features of methodology are summarised in about three or four sentences, so as to give an idea of the general settings, the reference population, the sample size, sampling method, type of design, the methods used in making measurements / obtaining information from the subjects and the intervention procedure if any. This is followed by the salient findings (giving the measures of effect like OR and p value in brackets) and finally the main conclusions drawn from the study. In case of summary, the above aspects are explained in slightly greater detail, paragraph wise, in about five to seven typed pages. Avoid including aspects pertaining to "Review of literature" or "Discussion" in the abstract/summary.

### Key words

After the Abstract, indicate four or five key words that will help "indexing" your article in Index Medicus or computer based databases.

### Introduction

Keep it as brief, but, at the same time, as clear as possible. The optimum space for introduction is about half page in your typed manuscript; in a thesis/project report the optimum space is 3 to 4 pages. The Introduction should bring out, systematically, the definition of the disease/health problem that you have studied, its "magnitude" in terms of morbidity, mortality and suffering, a brief note on what is already known in this area and finally the facets where gaps exist in the present body of knowledge and which have prompted you to take up the present research work.

### Aim and Objectives

In a research article, aim and objectives are usually covered in the last one or two sentences of introduction, without giving any separate heading. In a thesis/project report, a separate heading must be given and the aim and objectives should be spelt out in detail.

### Material & Methods

This section is the "backbone" of your entire study. Write your methodology with great care and accuracy. It would be worthwhile devoting half to one complete page to material and methods in a research paper, and up to 12 to 15 pages in your thesis/project report to this aspect. Coverage of all the headings described in material and method section of the next chapter (on research proposal) must be ensured, in detail when writing a thesis and in a summarised form when writing a research paper.

### Review of Literature

A review of literature is not required in a research paper. On the other hand it is a must for thesis / project report, wherein it should be a detailed review of recent literature (generally covering the past 5 years). In a dissertation / project report the review of literature may generally occupy 30 to 40 pages. The order of proceeding with the review of literature usually takes the following sequence :-

(a) Definition(s) of the condition(s) of interest in the present research.

(b) Historical review of the condition of interest.

(c) Magnitude of the problem due to the condition of interest, in terms of mortality, morbidity and suffering

(d) Major risk factors for the condition.

(e) Other (minor or possible) risk factors for the condition.

(f) Review of diagnostic/therapeutic strategies (in case of a study addressing issues of "therapy" or "diagnosis") Or Review of preventive strategies (in case of study addressing issue of "prevention" or "risk').

### Findings (Results) and Discussion

The findings should be "grouped" into broad headings, commensurate with the study objectives. Graphical presentations should be made using appropriate types of figures (diagrams) or tables. Each figure should be appropriately referred to in the text. Each table should have a table number, usually in Arabic numerals, which should be clearly referred to at the appropriate place in the text. The table number should be followed by a clear but concise heading, and the actual findings. It is always a good practice to indicate the percentages along with the number. Do not forget to indicate 100% besides or below the number out of which you have calculated the percentage. Also make sure that the totals of the columns as well as the rows have been presented. Following the table, you must give the abbreviated statistical findings as "t = 3.21, df = 28, $p < 0.05$ (significant)". An example of a table is given as Table - 1.

Following the table, describe your own findings in two or 3 sentences. Do not leave it on your examiner or the reader to make interpretations from the tables. Having given an overview of your findings, bring out such studies which have given similar findings. Next, give a brief account of studies which have obtained findings that are dissimilar from your findings, and "reason out" the possible causes as to why your findings could be different from theirs. Finally, in a sentence or two, summarise the overall findings and how your findings would affect the clinical or preventive policy.

Table - 1 : Comparison of cases of IHD and controls regarding smoking

| Smoking History | Cases No. (%) | Controls No. (%) | Total |
|---|---|---|---|
| Present | 67 (76.1%) | 54 (42.5%) | 121 |
| Absent | 21 (23.9%) | 73 (57.5%) | 94 |
| Total | 88 (100%) | 127 (100%) | 215 |

X2= 23.9, df = 1, $p < 0.001$ (very highly significant)
(OR = 4.3; 95% CI of OR = 2.4 to 7.7)

### Conclusions and Recommendations

A point which needs to be emphasised is that the conclusion should be drawn from the premises of your study and not from possible factors which you have not studied. Similarly, while making your recommendations, make sure that they are based on facts which you have studied and not simply a repetition of standard recommendations given in some text book or by some other author. Moreover, the recommendations should be "do-able" (practicable).

### Annexures and Enclosures

In general the annexures that are attached in a thesis/project report are the same as have been explained subsequently in the chapter on writing a research proposal. In addition, if necessary and possible, in a thesis/project report, interesting ECG tracings, Skiagrams etc may be attached as separate enclosures. Annexures and enclosures should be properly referred to at appropriate places in the text.

### References

The references should be serially numbered in Arabic numerals, in a chronological order, as they appear in the text. Do make sure that a particular reference number should appear in the text for the first time, only after the immediately preceding reference number has appeared in the text at least once. For example, reference number 9 should appear in the text only after reference number 8 has appeared in the text at least once. The style of writing the reference should conform to the one used in Index Medicus. The details are provided in the guidelines for authors which are included in every January issue of the MJAFI and all researchers should go through the same. For example, for writing a reference of an article published in a journal, the format is as follows : "Reference No. Name of author(s). Title of article. Name of journal & Year; Volume : Pages from - to". A hypothetical example is - "18. Singh BB, Kumaran R. Epidemiological study of murine typus in a rural area. Indian Jr Biology 1968; 37: 368-73". If there are up to 6 authors, then give the names of all; if more than six, give the names of first three, followed by "et al".

Col RajVir Bhalwar

# Writing the Research Proposal

This chapter lays down the general guidelines for writing a research proposal. Apparently, researchers should also abide by the format which are specifically laid down by the respective agencies as AFMRC projects, ICMR, or by the concerned University. The specific guidelines for writing down the AFMRC proposals are given in Office of the DGAFMS letters and one should refer to the same as and when required (Latest letter which can be referred is Office of DGAFMS letter No. 15965/ 46th / 2008 / DGAFMS / DG 3B dated 14 Mar 07).

## Introduction

This the first group heading. In a nutshell, the introduction should give a good overview of two aspects - firstly, the background importance about the area of study and secondly the relevance of the proposed work. The introduction should generally be limited to within 300 to 600 words (2 to 3 double spaced A-4 size typed pages). The introduction should have specific paragraphs which should logically and sequentially bring out the following aspects :

(a) Definition of the problem in which the research is going to be undertaken.

(b) Magnitude of the problem in terms of morbidity, mortality, disability, suffering and socioeconomic consequences.

(c) A brief statement of what is already known about the condition, depending on the review of literature.

(d) A statement on what is not known, or areas where gaps in knowledge still exist and which need to be filled.

(e) What is the research question to be answered in this proposed study. This will include a paragraph giving general statement, enunciating the broad issue of the study.

(f) A final paragraph should be written on how the study findings will contribute to the existing knowledge, and help in improving the health care or clinical practice.

## Aim and objectives

The AIM is a general statement about the research question. The OBJECTIVES are very specific issues through which the aim is going to be achieved. Be very careful while writing down your objectives, since any funding agency will examine them very closely and you are also expected to fulfill these objectives at the end of your research.

## Review of Literature

Brief review of literature of 3 to 4 double spaced typed pages should be given. The review should generally be of the "recent literature" (i.e., past 5 years or so). The review should bring out the definition of the condition of interest, the magnitude of the problem, a review of what is already known about the topic of research and finally a review of the gaps which exist in the present body of knowledge as far as it pertains to the proposed research.

## Material and Method

This is the "heart" of the research protocol. Great care should be exercised while writing this part. In general, the following aspects should be clarified in adequate detail, point wise.

(a) **General Settings** - Define the general settings, ie, whether the study will be done in a hospital or in general community, the type of hospital (primary / Secondary/ tertiary level or OPD), or the community (Urban, Slums, rural) etc, and the time-line.

(b) **Study design** : Specify the exact study design (eg, "cross- sectional analytical study"). In a few lines, describe as to why this particular study design is being used as compared to the other available study designs.

(c) **Reference and Study (Actual) population** : Define the reference (total) population on which the study results will be generalised. Next, define the actual (study) population from which the study sample will be drawn. Add a line to justify that the actual (study) population is a reasonably representative subset of the total (reference) population.

(d) **Sample size** : Clearly specify the statistical procedure that you have followed for calculating the sample size. Do consult a epidemiologist or statistician since this heading is quite thoroughly scrutinized by various research bodies.

(e) **Sampling method** : Describe as to what will be the sampling ratio and by which particular method (simple random, systematic random, multistage, cluster, stratified random, etc) will the sample be drawn from the actual (study) population.

(f) **Exclusion criteria** : If you are having “exclusion criteria”, then be very specific in defining them; e.g., "all cases who have undergone hysterectomy will not be included in this study".

(g) Specify the variables of interest under the headings of Exposure variable(s) of main interest, Other exposure variables, Outcome variables (Primary outcome variable and secondary ones, if required) and the Potential confounding variables.

(f) **Instruments** : Give a clear description of all instruments that will be used to collect the data. This should include the physical instruments (eg., sphygomanometer), or laboratory instruments (eg., stereoscopic microscope) or special instruments (eg., portable 12 lead ECG machine) and the Questionnaire (Remember, Questionnaire is also an instrument).

(g) **Techniques** : Give a clear description of the technique of using the instruments and making

the measurements. In addition, give a description of who will collect the data (e.g., by the principal worker, trained interviewers, trained laboratory technicians etc). Finally make a mention as to how training in data collection will be imparted and how testing and certification of the data collectors will be done.

(h) **Details of randomization, blinding and Intervention :** If the study involves any intervention (eg, drug, vaccine, program, therapeutic procedure, etc.) then give a very clear and detailed description of the process of Random allocation, the details of blinding (single / double) and the "intervention" which is going to be studied (who will do what to whom, how and how frequently). Even minor points like dose, formulation and frequency of administration of the drug or details of operative procedure must be mentioned. Similarly, details of "Placebo" in case of a clinical trial should be mentioned.

(j) **Follow up procedures** : In a cohort study as well as a experimental design, mention the details as to how the follow up of the two groups will be done, including details as who will be ascertaining the final and interim outcomes, when and where. In addition, give a clear description of modalities of "retrieving" those who are getting lost to follow up.

(k) **Description of gold standard test in diagnostic test study :** In a study proposing to evaluate the performance of a diagnostic test, including clinical algorithms, a detailed description of the "gold standard" against which the current test under study will be evaluated, should be given.

(l) **Pilot study** : In case a pilot study would be done to refine the material and methods, then give a clear description of how many subjects will be required for the pilot study, how will they be sampled, and whether the pilot study subjects are likely to be included in the main study or not, going a brief justification for the same.

(m) **Issues of analysis** : A general description must be given in the protocol as to what statistical procedures will be used for the basic analysis or for advanced issues like control of confounding. In case the help and guidance of a research methodologist or biostatistician will be taken for handling issues of advanced analysis, then the same should be mentioned. In addition, if data management by computerisation is planned, then a brief description of computer packages should be given. In clinical trials, details of stoppage rules and "intention to treat analysis" if applicable, should be clearly brought out.

(n) **Ethical issues :** Most research bodies now need the proposal to be cleared by the Institutional Ethical Committee and this should be ensured and, for animal experiments, separate clearance by Institutional Animal Experiments Ethical committee, should be taken

(o) **Financial Details :** This paragraph is mandatory for any study which seeks "funding" from any Governmental (including AFMRC projects) or Non Governmental organisation. A detailed description of financial requirements, according to instruments, regents, drugs, salaries, office contingencies etc should be made, phase-wise or financial year wise. Work out the financial requirements meticulously, catering to the inflation rates. Contact the various dealers and make an on -ground estimate of prices as well as availability of the equipment, reagents etc. Remember, do not simply go by guessworks or estimates made by some other workers or in the past; such an action has been a cause of major embarrasment for many workers.

## References

This is the last section. The details of writing the references have already been presented in earlier chapter on writing a research paper.

## Annexures

Annexures may be attached to clarify in greater detail, the following

(a) A particular aspect which has not been clarified adequately in the "Material and Method" section because the same would have become unnecessary voluminous.

(b) Detailed description of terms and phrases

(c) Detailed techniques of making clinical measurements

(d) Minute details of the intervention measure to be used in the proposed study

(e) The questionnaire or schedule for recording the data.

(f) Clearance certificate from ethical committee

(g) Minute details of expenses or equipment, instruments etc.

Col RajVir Bhalwar

# Critical Appraisal of a Published Article

The issue of critical appraisal of a published article in a journal is of much importance to every Doctor. As Post-Graduate students in the respective specialities, we have periodic "journal clubs" during which research articles are critically evaluated. As practising Doctors, we need to advance our knowledge constantly, by reading the various articles. Similarly, as senior level health care administrators, we have to keep abreast regarding the contemporary practices in health care administration, therapies, equipment, diagnostics and the financial implications. From the research methodologist's perspective, reading a journal needs a series of well planned sequential steps. The following is a check list proforma :-

**Step 1 : Deciding whether I should read this article**

(a) Look at the title : Is it interesting ? Likely to be useful in your practice? Yes/No.

(b) Look at the Abstract : Will the conclusions (if valid), likely to be useful to you, in your area of clinical practice or research areas? Yes / No.

(c) Quickly browse through the 'Materials and Methods' section. See if the 'settings' are similar to your own settings of practice (may be dissimilar because of different facilities, different technological availability, grossly different demographic profile of patients, or the level of medical care in which the study was done) - Yes / No

If answers to 1 (a), (b) & ( c ) are Yes for two or more question, go ahead and start reading the article. Keep giving your comments as per the following general check-list :-

**Step 2 : Assess the research question of the authors**

(a) Is there a clear cut/specific research question?

(b) Was it feasible for the authors to study this question, given their technical expertise, available facilities etc.

(c) Does the research question has some element of novelty (is likely to add to existing knowledge rather than reconfirming the already well established facts).

**Step 3 : Assess the issues of Internal / external validity and bias in the study**

(a) Have the authors made a mention (explicit or, at least, implicitly) of the :

(i) Total (Whole; Reference) Population ?

(ii) Actual (study) Population ?

(iii) Is the actual (study) population from which sample was drawn likely to be a "representative subset" of the total population (If no, then external validity/generalisability will be restricted)

(b) Have the authors :

(i) Calculated the sample size ?

(ii) Whether they have specified the parametres like Type-I (alpha), Type-II (Beta) errors, OR or RR to be detected, expected P0, or mean and SD, and acceptable deviation (as applicable to the study design), while calculating the sample size?

(iii) Are the above parametres, if specified, likely to be correct / realistic .

(c) Have the authors :

(i) Described the method of sampling ?

(ii) Is the method of sampling based on some random (probability) method ?

(d) Have the authors explicitly mentioned :

(i) The exposure variable(s) (only for an analytic design).

(ii) The outcome variable(s) (for all types of designs).

(e) Have the authors

(i) Clearly identified all the potential confounding factors (PCFs)?

(ii) Have they adequately covered for all PCFs by taking action during designing (Randomisation/ Restriction/ Matching) or during analysis (Standardisation / Stratified analysis/ Mathematical modelling) ?

(iv) What are the PCFs which have either not been considered at all, or else not controlled during design / analysis ?

(f) Have the authors clearly described the following items used by them in this study :

(i) Physical instruments and reagents ?

(ii) Questionnaire ?

(iii) Any other scales (eg, psychological assessment scale) .

(iv) Definitions of terms and criteria for various diseases etc used by them ?

(v) Techniques of using the instruments, questionnaires, scales etc ? Yes/Na/NA.

(g) Have the authors mentioned as to how they have standardized / validated :

(i) Physical instruments ?

(ii) Questionnaires ?

(iii) Any other "scales" used by them ?

(iv) Quality control procedures during the conduct of study ?

(h) Could any of the following biases have occurred in

the study ?

If yes, briefly comment as to how ?

(i) Selection bias
- Referral
- Self selection
- Berksons
- Survivorship
- Healthy worker
- Exposure related

(ii) Information Bias
- Recall / reporting
- Detection
- Observers
- Cross over
- Contamination
- Co-intervention
- Loss to follow up

**Step 4 : Analysis**

(a) Has the data been presented in a simple, intelligible form ?

(b) Are the statistical tests " correct" for the type of variables ?

(i) Have the authors worked out the measures of 'effect' (i.e., RR or OR) (as applicable to the research question ) ?

(ii) Have the authors worked out the 95% CI of the various estimates?

(iii) Have the authors correctly controlled for confounders, in analysis, and worked out the independent, adjusted estimates ( e.g., by stratified analysis)

(iv) Have the authors assessed effect modification?

**Step 5 : Conclusions**

(a) If the findings are `statistically significant', are they also of clinical/ public health significance/relevance?

(b) If the findings are `statistically non significant' is it possible that a real effect may have been missed due to "low study power" as consequence of low sample size (Have the authors back calculated the study power; alternatively calculate it yourself)?

(c) Are the conclusions drawn by the authors based on the actual findings of the study ?

(d) Do you think the study results can be gainfully utilized in your clinical / preventive practice?

**Step 6 : Additional actions for specific situations**

Check the following additional points depending on the type of study objective.

For a study assessing the efficacy of a therapeutic or preventive procedure

(a) Was allocation to the intervention and control groups done by Randomisation' ?

(b) Were the 2 groups similar on baseline comparison ?

(c) Were all the clinical/health relevant outcomes (good as well as bad) considered ?

(d) Was the therapeutic / preventive procedure tried out, described in adequate detail ?

(e) Were all the subjects who entered the study accounted for in the final analysis?

(f) What was the level of control ? Placebo control/Non placebo control/ Uncontrolled.

(g) What was the level of blinding ? Triple / Double/ Single blinding / Unblinded.

(h) Was the trial ethical ?

(j) What was the proportion of "lost to follow up"

For a study assessing the role of a risk factor / causal factors

(a) What was the strength of the design itself ?

(b) Very strong (experimental) / Reasonably strong (Cohort) / Moderately Strong (Case control, Cross sectional analytic) / Weak (Ecological)

(c) What is the strength of association (as seen by RR or OR) ?

(d) Is the association "significant" (as seen by test of significance and 95% CI of RR)

(e) Is the temporal relationship (cause or exposure definitely preceded the effect or outcome) definitely shown?

(f) Does the association stand to reasoning ?

(g) Is there a dose response relationship ?

For a study dealing with clinical course and prognostic factors.

(a) Was an 'inception cohort' assembled ?

(subjects should be identified at an early and uniform point (inception) in the course of their disease, such as when they develop unambiguous symptoms or receive their first definitive therapy)

(b) Was the "referral filter" of the subjects to the present location adequately described ?

(c) Was clinical status of all patients who entered the study accounted for in the end ?

(d) Were the prognostic outcomes clearly defined ?

(e) Was the outcome assessment done by physicians who were blinded' to the other features of patients ?

**For a study on Diagnostic tests evaluation**

(a) Was a proper `Gold Standard' of diagnosis

described and used?

(b) Was the evaluation of test results done by observers who were `blinded' to the results of Gold Standard test?

(c) Were all subjects subjected to both the gold standard as well as test under study?

(d) Did the subject sample contain an appropriate `spectrum' of the target disease?

(mild, moderate, severe, atypical, other closely related diagnoses).

(e) Were the "settings" of study adequately described?

(f) Was the "referral filter" through which subjects passed before reaching the settings of present study adequately defined?

(g) Was the reproducibility of test (the range of variations due to observers, subjects, instruments and techniques) adequately studied and defined?

(h) Were the techniques of carrying out the test under study adequately described?

(j) Was the "utility" of the test determined? Yes/No.

(ie., whether the authors went beyond the issues of validity and reliability to describe the consequences of the test - whether it really contributed to better patient management or favourably changed the disease outcome for which the test is designed).

# Introduction to Biostatistics

Statistics are everywhere. Statistics is becoming increasingly more important in modern society with passing time. We are constantly being bombarded with some fact or figure, charts and graphs quoted in the media or newspaper prints. In order to realistically understand the subject of statistics it is important to appreciate the rationale behind why and how statistics is used at large. Once you collect information in your area of interest you need to carefully study the information to come to valid and rational conclusions. This is where statistics plays an important role.

*Statistics is nothing but learning from data. It guides the way we collect, organize, present and interpret data.* It helps us to weigh the evidences and draw conclusions. It should not be considered as merely pushing numbers through formulas and computers.

Statistics can be broadly split into two categories Descriptive Statistics and Inferential Statistics. Descriptive statistics deals with the meaningful presentation of data such that its characteristics can be effectively observed. It encompasses the tabular, graphical or pictorial display of data, condensation of large data into tables, preparation of summary measures to give a concise description of complex information and also to exhibit pattern that may be found in data sets. Inferential statistics however refers to decisions. Medical research doesn't stop at just describing the characteristic of disease or situation. It tries to relate and determine whether characteristics of a situation are unusual or if they have happened by chance. Because of this desire to generalize, the first step is to statistically analyse the information.

In order to begin our analysis as to why statistics is necessary we must begin by addressing the nature of science and experimentation. The characteristic method used by researcher when he/she starts his/her experiment is to study a relatively small collection of subjects, as complete population based studies are time consuming, laborious, costly and resource intensive. The researcher draws a subset of the population called as "sample" and studies this sample in depth. But the conclusions drawn after analyzing the sample is not restricted to the sample but is extrapolated to the population i.e. people in general. Thus Statistics is the mathematical method by which the uncertainty inherent in the scientific method is rigorously quantified. We have already discussed, in detail, these concepts in the Seventh Building Block (Population and Sample) and the Eighth Building Block (Random Error and Chance) in chapter 1 of the previous section on Research Methodology and it would be desirable that you have a quick revision of that chapter before proceeding with this section on biostatistics and the next section on statistical software.

**Measurement**

Before we start collection of information regarding the characteristic that we want to study in the general population a research hypothesis needs to be formulated. A problem has to be stated clearly before it can be solved. **Your research hypothesis should be specified prior to the collection of any data**. Once the hypothesis is stated with clarity, the researcher starts collecting facts and figures to prove the hypothesis. The facts and figures or the information is called as 'data'. Data can thus be defined as an organized collection of information, containing the 'values' of the various variables, obtained from a sample of subjects, and which would be subsequently used to derive conclusions through the process of scientific analysis and reasoning. The data that we collect can, broadly, be either of the "Quantitative" or of "Qualitative" type. Further quantitative data can be of 3 subtypes (Discrete numerical, continuous numerical and ordered numerical. Similarly the qualitative data can also be of 3 subtypes (Nominal dichotomous, nominal polychotomous and ordinal polychotomous). We have already given detail description of these various types in the third building block of our previous chapter on Research Methodology and in the section on Principles of Epidemiology and you should go through the same.

Mrs. Seema R Patrikar & Col RajVir Bhalwar

# Presentation of Data : From Chaos to Order

The information collected on the subjects one after the other is called as **raw data**. Raw data is often little more than jumble of numbers and hence very difficult to handle. Hence we need to find ways to make sense out of this chaos of data such that we can extract information from the data and communicate it to others. This is possible through data depiction, data summarization and data transformation. The techniques for data depiction and data display are too numerous. However, they generally fall into categories of tables, charts or graphs. The process involves moving from the "chaos" of hundreds and thousands of raw numbers to the relative order of a table or graph. We shall discuss few of the presentations which are important in describing medical data. Tables are used to categorize and summarize the data while graphs are used to provide an overall visual representation.

## Tabular presentation of data

By reducing raw data into tabular form, we can quickly learn a lot about nature of the distribution, the range of values and where the most common values lie. This representation is also called as frequency distribution table.

### Ordered array

When the data is organized in order of magnitude from the smallest value to the largest value it is called as ordered array. For example consider the ages of 11 subjects undergoing tobacco cessation programme (in years) 16, 27, 34, 41, 38, 53, 65, 52, 20, 26, 68. When we arrange these ages in increasing order of magnitude we get ordered array as follows : 16, 20, 26, 27, 34, 38, 41, 52, 53, 65, 68. After observing the ordered array we can quickly determine that the youngest person is of 16 years and oldest of 68 years. Also we can easily state that almost 55% of the subjects are below 40 years of age, and that the midway person is aged 38 years.

### Grouped Data - Frequency Table

Besides arranging the data in ordered array, grouping of data is yet another useful way of summarizing the data. We classify the data in appropriate groups which are called **"classes"**. The basic purpose behind classification or grouping is to help comparison and also to accommodate a large number of observations into a few classes only, by condensation so that similarities and dissimilarities can be easily brought out. It also highlights important features and pinpoints the most significant ones at glance.

To group a set of observations we select a set of contiguous, non overlapping intervals such that each value in the set of observations can be placed in one and only one of the intervals. These intervals are usually referred to as **class intervals.** For example 0-19, 20-29, 40-59, 60-79 and 80-99 are called class intervals. The class interval 0-19 includes the values 0, 1, 2, .....upto 19. The smallest value 0 is called its **lower class limit** whereas the highest value 19 is called its **upper class limit**. The middle value of 0-19 i.e., 9.5 is called the **midpoint or class mark**. The number of subjects falling in this range of 0-19 is called its class frequency. Such presentation of data in class intervals along with frequency is called frequency distribution. When both the limits are included in the range of values of the interval, the class interval are known as inclusive type of class intervals (e.g., 0 – 19, 20 – 39, 40-59 etc.); whereas when lower boundary is included but upper limit is excluded from the range of values, such class intervals are known as exclusive type of class intervals (e.g., 0 – 20, 20 – 40, 40 – 60 etc.). This type of class intervals is suitable for continuous variable.

### How to decide on the number of class intervals?

When data are to be grouped it is required to decide upon the number of class intervals to be made. Too few class intervals would result in losing the information. On the other hand too many class intervals would not bring out the hidden pattern. The thumb rule is that we should not have less than 5 class intervals and no more than 15 class intervals. But to be specific, Sturg has suggested a formula for number of class intervals denoted by k as follows :

$K = 1 + 3.332 \log_{10} n$ rounded to the nearest integer, where n is the number of values or observations under consideration.

For example if n=25 we have, $K = 1 + 3.332 \log_{10} 25$ i.e. approximately 5 class intervals.

Having decided the number of class intervals the next step

$$\text{Width} = \frac{\text{Maximum observed value - Minimum observed value (= Range)}}{\text{Number of class interval (k)}}$$

is to decide the width of the class interval. The width of the class interval is taken as

The class limits should be preferably rounded figures and the class intervals should be non-overlapping and must include range of the observed data. As far as possible the percentages and totals should be calculated column wise.

An advantage with frequency table is that even categorical type of variable can be presented in frequency table. For example Table 1 depicts the findings of a hypothetical research work intended to describe the pattern of blood groups among patients of essential hypertension.

Table - 1

| Blood Group | Number of patients (frequency) | Percentage |
|---|---|---|
| A | 232 | 42.81 |
| B | 201 | 37.05 |
| AB | 76 | 14.02 |
| O | 33 | 6.09 |
| Total | 542 | 100.00 |

### Graphical presentation of data

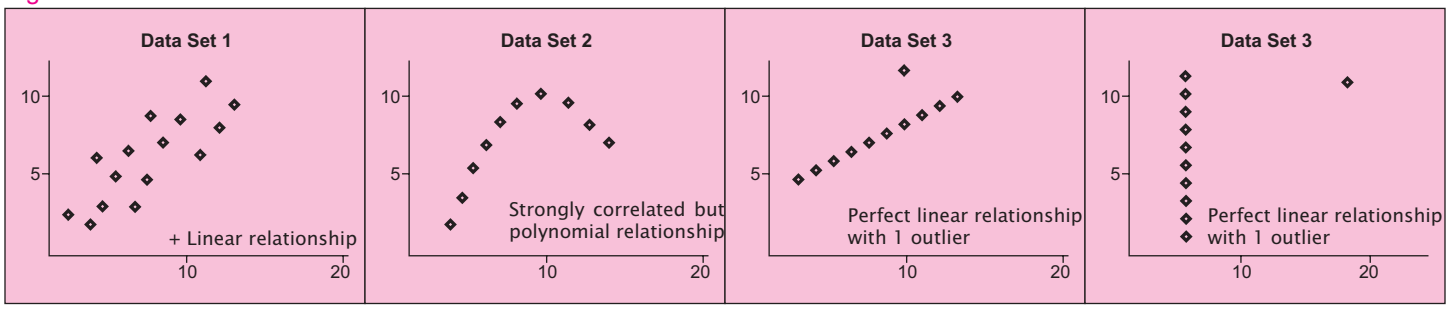
A frequency distribution discussed above shows distribution of subjects in various groups or classes. This tabular representation of the frequency distribution is useful for further analysis and conclusion. But it is difficult for a layman to understand complex distribution of data in tabular form. Graphical presentation of data is better understood and appreciated by humans. Graphical representation brings out the hidden pattern of the complex data sets. To understand the concept of graphical presentation of data let us consider an example where the data is collected on 11 subjects. (Table - 2)

Suppose we have four sets of observation on two variables X and Y. Each of the set has equal number of observations (n=11) with readings as given in Table - 2.

If you observe the data set, each of the set has 11 readings on X and Y. Certain statistical measures like means of X and Y, Correlation coefficients between X and Y along with $r^2$ and regression equation is also provided. Look carefully at the data sets and try to find out the hidden pattern existing in the data.

You will realize that it is difficult to bring out the characteristics of each of the data set or the relationship that exists in the two variables by just looking at the table. Now if we visually depict the same information in the simplest form i.e. scatter diagram representing one variable (X) on X-axis and other variable(Y) on the Y-axis.

Fig - 1



For each of the four sets we have following scatter diagram (Fig - 1).

We now appreciate that all the four data sets have very different pattern of relationship despite the fact that their summary figures (Means, Correlation coefficient, Regression equation etc.) as shown in the tabular form are the same. However, the hidden pattern in each of the data sets is revealed when they are represented by graphs. Thus the reason for displaying data graphically is two fold:

(a) so that as investigators we can have a better look at the information collected and the distribution of data

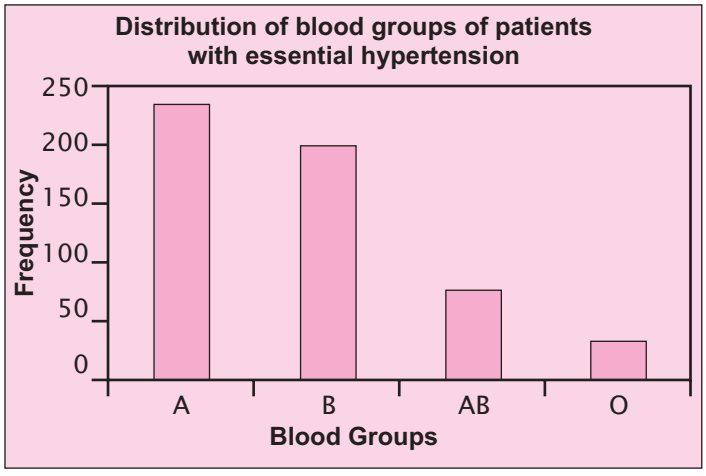
(b) to communicate this information to others quickly

We shall discuss in detail some of the commonly used graphical presentations.

Bar Charts

Bar charts are used for qualitative type of variable in which the variable studied is plotted in the form of bar along the X-axis (horizontal) and the height of the bar is equal to the percentage or frequencies which are plotted along the Y-axis (vertical). The width of the bars is kept constant for all the categories and the space between the bars also remains constant throughout. The number of subjects along with percentages in bracket may be written on the top of each bar. When we draw bar charts with only one variable or a single group it is called as simple bar chart (Fig - 2) and when two variables or two groups are considered it is called as multiple bar chart. In multiple bar chart the two bars representing two variables are drawn adjacent to each other. Equal width of the bars is maintained. Third type of bar chart is the component bar chart wherein we have two qualitative variables which are further segregated into different categories or components. In this the total height of the bar corresponding to one variable is further sub-divided into different components or categories of the other variable.

Fig - 2



A simple bar chart in respect of the data (Table - 1) on blood groups among patients of essential hypertension is represented in Fig - 2.

Pie Chart

Another interesting method of displaying categorical (qualitative) data is a pie diagram. A pie diagram is essentially a circle in which the angle at the center is equal to its proportion multiplied by 360 (or, more easily, its percentage multiplied by 360 and divided by 100). A pie diagram is best when the total categories are between 2 to 6. If there are more than 6 categories, try and reduce them by "clubbing", otherwise the diagram becomes too overcrowded.

A pie diagram in respect of the data on blood groups among patients of essential hypertension (Table - 1) is presented in Fig-3 after calculating the angles for the individual categories as follows

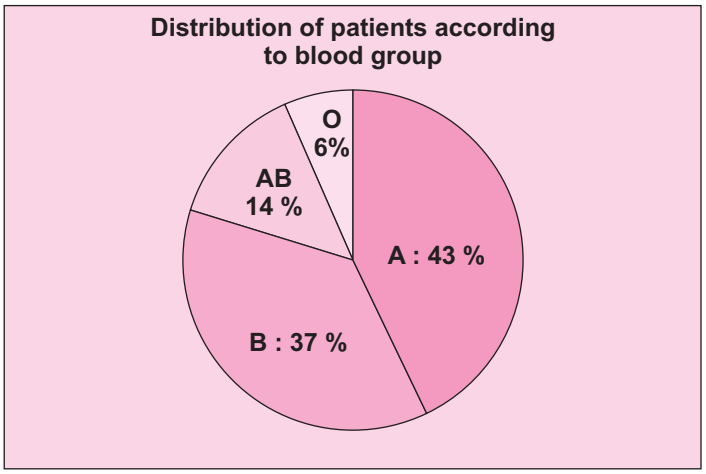
Blood group A = $\frac{42.81}{100}$ X 360 = 154 degrees

Blood group B = $\frac{37.08}{100}$ X 360 = 134 degrees

Blood group AB = $\frac{14.02}{100}$ X 360 = 50 degrees

Blood group O = $\frac{6.09}{100}$ X 360 = 22 degrees

Fig - 3



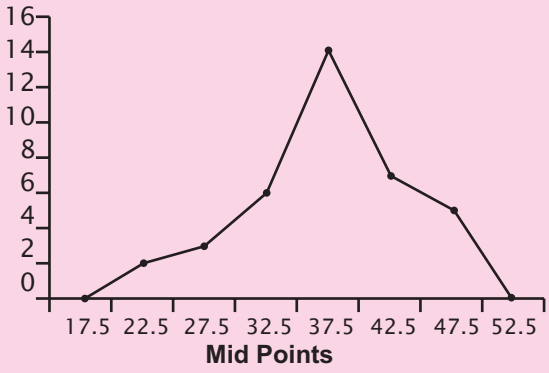
Frequency Curve and Polygon

To construct a frequency curve and frequency polygon we plot the variable along the X-axis and the frequencies along the Y-axis. Observed values of the variable or the midpoints of the class intervals are plotted along with the corresponding frequency of that class interval. Then we construct a smooth freehand curve passing through these points. Such a curve is known as frequency curve. If instead of joining the midpoints by smooth curve if we join the consecutive points by a straight line then it is called as frequency polygon (Fig.-4). Conventionally, we consider imaginary one value immediately preceding the first value

Table - 3

| Age | Number of subjects | Midpoints |
|---|---|---|
| 20-25 | 2 | 22.5 |
| 25-30 | 3 | 27.5 |
| 30-35 | 6 | 32.5 |
| 35-40 | 14 | 37.5 |
| 40-45 | 7 | 42.5 |
| 45-50 | 5 | 47.5 |

Fig - 4



Note that the imaginary frequency of the immediately preceding class interval (15 to 20, mid pt 17.5) and immediately succeeding ( i.e., 50 – 55, mid pt 52.5) has been plotted as zero.

and one succeeding the last value and plot them with frequency = 0 )Table - 3.

Stem-and-leaf plots

This presentation is used for quantitative type of data. To construct a stem-and-leaf plot, we divide each value into a stem component and leaf component. The digits in the tens-place becomes stem component and the digits in units-place becomes leaf components. It is of much utility in quickly assessing whether the data is following a "normal" distribution or not, by seeing whether the stem and leaf is showing a bell shape or not. For example consider a sample of 10 values of age in years:

21, 42, 05, 11, 30, 50, 28, 27, 24, 52. Here, 21 has a stem component of 2 and leaf component of 1. Similarly the second value 42 has a stem component of 4 and leaf component of 2 and so on. The stem values are listed in numerical order (ascending or descending) to form a vertical axis. A vertical line is drawn to outline a stem. If the stem value already exists then the leaf is placed on the right side of vertical line.

0 |
1 |
2 |
3 |
4 |
5

The value of each of the leaf is plotted in its appropriate location on the other side of vertical line as follows.

0 | 5
1 | 1
2 | 1 4 7 8
3 | 0
4 | 2
5 | 0 2

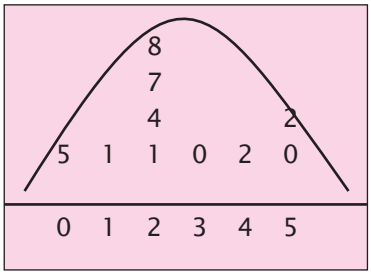
To describe the central location, spread and shape of the stem plot we rotate the stem plot by 90 degrees just to explain it more clearly

8 → Rough estimate of the center or
7 middle observation i.e., median value (27.5)

4 2
5 1 1 0 2 0
0 1 2 3 4 5 → Spread of the data

Roughly we can say that the spread of data is from 5 to 52 and the median value is between 27 and 28. Regarding the shape of the distribution, though it will be difficult to make firm statements about shape when n is small, we can always determine:

(a) Whether data are more or less symmetrical or are extremely skewed
(b) Whether there is a central cluster or mound
(c) Whether there are any outliers



For the given example we notice the mound (heap) in the middle of the distribution. There are no outliers

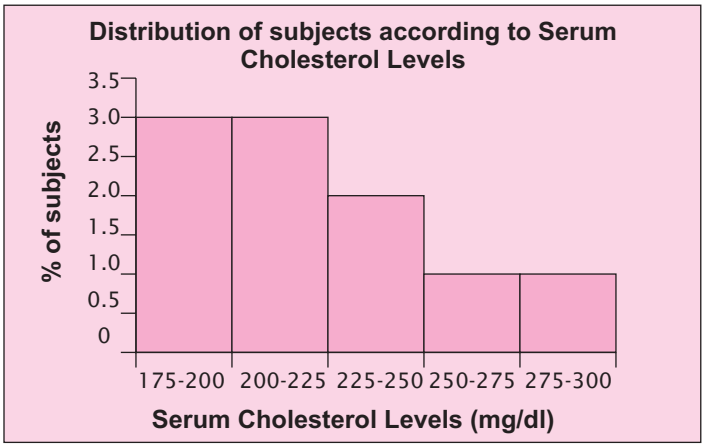
Histogram

The stem-and-leaf is a good way to explore distributions. A more traditional approach is to use histogram (Fig - 5). A histogram is used for quantitative continuous type of data where, on the X-axis, we plot the quantitative exclusive type of class intervals. On the Y-axis we plot the frequencies. The difference between bar charts and histogram is that since histogram is the best representation for quantitative data measured on continuous scale, there are no gaps between the bars. Consider an example of the data on serum cholesterol of 10 subjects ( Table - 4)

Table - 4

| Serum cholesterol (mg/dl) (mg / dl) | No. of subjects | % |
|---|---|---|
| 175 - 200 | 3 | 30% |
| 200 - 225 | 3 | 30% |
| 225 - 250 | 2 | 20% |
| 250 - 275 | 1 | 10% |
| 275 - 300 | 1 | 10% |
| Total | 10 | 100% |

Fig - 5



The Guassian Distribution or Normal Curve

If we draw a smooth curve passing through the mid points of the bars of histogram and if the curve is bell shaped curve then the data is said to be roughly following a normal distribution (Fig - 6). Many different types of data distributions are encountered in medicine. The **Gaussian or "normal"** distribution is among the most important. Its importance stems from the fact that the characteristics of this theoretical distribution underline many aspects of both descriptive and inferential statistics. The normal distribution is defined by following characteristics:

(a) It is a bell shaped symmetric (about the mean) curve.

(b) The mean, median and mode are all co-incident or equal to one another.

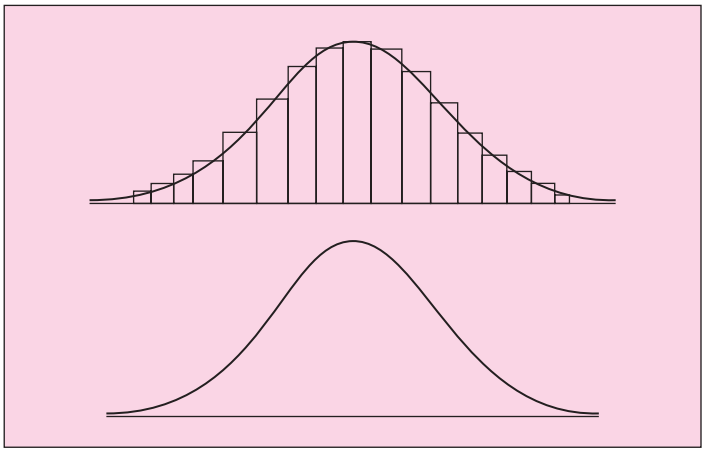
(c) The total area under the curve is equal to 1

(d) It follows the 68-95-99% rule i.e. the distribution is shaped such that 68% of the values fall between ± 1 standard deviation (SD) from the mean, 95% of the values lie within ± 2 SD from mean and 99% lie within ± 3 SD from mean.

If these criteria are not met then the distribution is not a Gaussian or normal distribution.

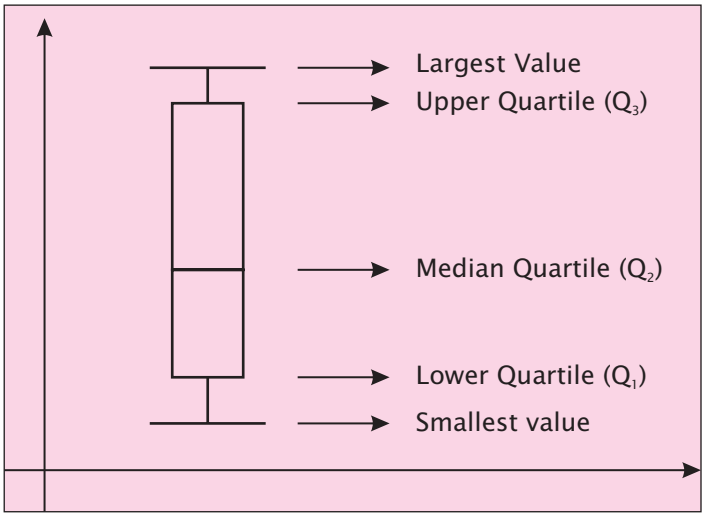
**Box-and-Whisker plot**

Fig - 6



A box-and-whisker plot reveals maximum of the information to the audience. A box-and-whisker plot can be useful for handling many data values. They allow people to explore data and to draw informal conclusions when two or more variables are present. It shows only certain statistics rather than all the data. Five-number summary is another name for the visual representations of the box-and-whisker plot (Fig - 7). The five-number summary consists of the median, the quartiles (lower quartile and upper quartile), and the smallest and greatest values in the distribution. Immediate visuals of a box-and-whisker plot are the center, the spread, and the overall range of distribution.

Fig - 7



Line chart

Line chart is used for quantitative data. It is an excellent method of displaying the changes that occur in disease frequency over time. It thus helps in assessing "temporal trends" and helps displaying data on epidemics or localised outbreaks in the form of epidemic curve. In a line diagram, the rate of disease are plotted along the vertical (y) axis. However, in localised outbreaks, with a well

demarcated population that has been at risk (as sudden outbreaks of food poisoning) the actual numbers can be plotted on Y-axis, during quick investigations. The unit of time, as applicable to the disease in question, is plotted along the "X"-axis (horizontal). This unit of time would be hours-time in food poisoning, days (i.e, as per dates of the month) for cholera, weeks for typhoid, malaria or Hepatitis-A, months for Hepatitis-B and in years (or even decades) for IHD or Lung Cancer.

### Scatter Diagram

A scatter diagram gives a quick visual display of the association between two variables, both of which are measured on numerical continuous or numerical discrete scale. An example of scatter plot between age (in months) and body weight (in kg) of infants is given below. (Fig - 8)

The scatter diagram in fig - 8 shows instant finding that weight and age are associated - as age increases, weight increases. Be careful to record the dependent variable along the vertical (Y) axis and the independent variable along the horizontal (X) axis. In this example weight is dependent on age (as age increases weight is likely to increase) but age is not dependent on weight (if weight increases, age will not necessarily increase). Thus, weight is the dependent variable, and has been plotted on Y axis while age is the independent variable, plotted along X axis.

Fig - 8

# Data Summarization

Compiling and presenting the data in tabular or graphical form will not give complete information of the data collected. The way the disease is described by certain characteristics, the data set is described by summary measures. Summary measures provide description of data in terms of concentration of data and variability existing in data. Thus data is described by two summary measures namely, measure of central tendency and measure of variability.

### Measures of Central Tendency

This gives the centrality measure of the data set i.e. where the observations are concentrating. There are several measures of central tendency.

(a) Mean (average)

Mean is most appropriate measure for data following normal distribution but not for skewed distributions. It is summing all the observations and then dividing by number of observations. It is the simplest of the centrality measure but is influenced by extreme values. When the data is skewed, another measure of central tendency called median is used.

(b) Median

Median is a locative measure which is the middlemost observation after all the values are arranged in ascending or descending order. The mean and median are the most commonly used measures of central tendency, while the third measure mode is used rarely.

(c) Mode

Mode is the most common value that repeats itself in the data set. Mode is used more often as a descriptive term.

### Measures of Variability

In contrast to measures of central tendency which describes the center of the data set, measures of variability describes the variability or spreadness of the observation from the center of the data. One of the simplest measures of variability is range.

**Range** is the difference between the two extremes i.e. the difference between the maximum and minimum observation. One of the drawbacks of range is that it uses only extreme observations and ignores the rest. A better measure than range is mean deviation.

**Mean deviation** is the mean of the difference from a constant 'A' which can be taken as mean, median, mode or any constant observation from the data. The formula for mean deviation is given as follows:

$$\text{Mean deviation} = \frac{\sum |x_i - A|}{n}$$

where

A may be mean, median, mode or a constant

$x_i$ = the value of individual observations

n = the total number of observations

$\Sigma$ = a sign indicating "sum up".

The main drawback of this measure is that it ignores the algebraic signs and hence to overcome this drawback we have another measure of variability called as Variance.

**Variance** is the average of the squared deviations of each of the individual value from the mean ( ). It is mathematically given as follows:

$\bar{x}$

Most often we use the square root of the variance called

$$\text{Variance} = \frac{\sum (x_i - \bar{x})^2}{n}$$

**Standard Deviation** to describe the data as it is devoid of any errors. Variance squares the units and hence standard deviation by taking square root brings the measure back in the same units as original and hence is best measure of variability. It is given as follows:

The larger the standard deviation the larger is the spread

$$\text{Standard Deviation (SD)} = \sqrt{\frac{\sum (x_i - \bar{x})^2}{n}}$$

of the distribution.

Note: When n is less than 30, the denominator in variance and standard deviation formula changes to (n-1).

Besides these measures of variability, we have one more important measure called the **coefficient of variation**

**Coefficient of variation** compares the variability in two data sets. It measures the variability relative to the mean and is calculated as follows:

Any information that is collected by the researcher needs

$$\text{Coefficient of Variability (CV)} = \frac{SD}{Mean} x100$$

to be described by measure of central tendency and measure of variability. Both the measures together describe the data. Measure of central tendency alone will not give any idea about the data set without measure of variability. Descriptive Statistics is critical because it often suggests possible hypothesis for future investigation.

The calculation of mean and standard deviation differ slightly for grouped data. We will consider a hypothetical example to get more familiarized with mean and standard deviation calculations for grouped data. Given in Table - 5 is the weight distribution (in kgs) of 40 faculty members of a department. The data is grouped as below

Table - 5

| Weight ( in kgs) | No. of faculty members |
|---|---|
| 50-55 | 5 |
| 55-60 | 9 |
| 60-65 | 13 |
| 65-70 | 10 |
| 70-75 | 3 |

Since this is a grouped data we cannot use simple mean formula (i.e. $\bar{x} = \frac{\sum x_i}{n}$) .
But, we use the modified formula given as

$$\bar{x} = \frac{\sum f_i x_i}{\sum f_i}$$

where

$f_i$ is the frequency of the class interval

$x_i$ is the midpoint of class interval.

$\sum f_i$ = N (total number of observations)

For the above example we make columns for mid points (class mark) of the class interval and then calculate the mean value.

Table - 6

| Weight (in kgs) | Mid points Class mark($x_i$) | No. of faculty members ($f_i$) | $f_i x_i$ |
|---|---|---|---|
| (a) | (b) | (c) | (b) X (c) |
| 50-55 | 52.5 | 5 | 262.5 |
| 55-60 | 57.5 | 9 | 517.5 |
| 60-65 | 62.5 | 13 | 812.5 |
| 65-70 | 67.5 | 10 | 675 |
| 70-75 | 72.5 | 3 | 217.5 |
| Total | | 40 | 2485 |

Thus, $\bar{x} = \frac{2485}{40} = 62.125$

The standard deviation for the same set of data is calculated by

$$SD = \sqrt{\frac{\sum f_i (x_i - \bar{x})^2}{\sum f_i}}$$

$$SD = \sqrt{\frac{5(52.5 - 62.125)^2 + 9(57.5 - 62.125)^2 + ..... \\ ... + 3(72.5 - 62.125)^2}{40}} = 5.63$$

## Inferential Statistics : From Sample to Population

The second broad category for which statistics is used is Statistical Inference. As we have already said that research most often is conducted using samples of individuals from larger populations. It is impractical if not impossible to study all people, so we select a sample of people for study. We collect data on these subjects, draw conclusions from the data and make inferences to the larger population. Of course, if we did not measure the whole population, there will always be some error in our conclusions regarding the estimates of the population which we call as "error". The concept is best understood by an example of a court decision in a crime case. When a case is presented before a court of law by the prosecution, the judge has to start with the presumption of innocence. The prosecution has to present adequate evidence against the innocence of the person tried. If the evidence is not sufficient the person is acquitted, whether the crime was actually committed or not. Thus, the permutation and combination between the exact reality (or, truth) and our verdict (decision) can be presented in Table - 7.

Table - 7

| Our judgment about Mr. X (based on evidence produced before us) | The reality about Mr.X | |
|---|---|---|
| | Is not guilty | Is guilty |
| Found guilty Reject $H_0$ | Type I error Wrong decision | Correct decision |
| Found not guilty Accept $H_0$ | Correct decision | Type II error Wrong |

When we do medical research, we take a sample of people, representative of the study we wish to do. For example we may wish to study the effect of new drug in reducing cholesterol levels. Any results we get from our research are only estimates of the true effect that medication will have in the population. The participants are called as sample. Since we know our results are just estimates, we may be wrong in giving our conclusions. Statistically these are called as errors. The research question is formally converted into a formal scientific hypothesis, which has two parts : the **null hypothesis** (denoted by $H_0$) and the **alternative hypothesis** (denoted by $H_1$). In case of statistical decision making the assumption initially made unbiasedly is that the new medication is not effective in reducing cholesterol levels which is equivalent to the presumption of innocence in the judicial setting. In the settings where two treatments (new drug and placebo) are administered to two different samples the null hypothesis would be that there is no difference between cholesterol levels in the two groups i.e. "Persons treated with new drug will have same cholesterol levels as persons not treated with new drug". If this null hypothesis gets rejected then the hypothesis that gets accepted is called as alternate hypothesis. Thus the alternative hypothesis is the assertion accepted when null hypothesis is rejected.

The alternate hypothesis would be phrased as, "Persons treated with new drug have different (higher or lower) cholesterol levels than persons not treated with new drug". This alternative hypothesis is called as a **two-tailed** hypothesis. If the alternative hypothesis would have been stated as "Persons treated with new drug have lower cholesterol levels than the persons not treated with new drug", then such an alternate hypothesis, which considers only one direction or effect (either lower or else higher), is called as **one-tailed** alternative hypothesis.

To prove the hypothesis stated by the researcher, he starts accumulating data from the selected sample. The values observed in the sample serve as evidence against Ho. The error of rejecting the true null hypothesis is equivalent to punishing an innocent person. This is serious type of error and is called as **Type I error**, denoted by $\alpha$ and referred to as p-value. Thus p-value is probability that a true null hypothesis is wrongly rejected. The maximum p-value allowed in a research problem is called the level of significance or $\alpha$-level. The type I error is the probability that we reject the hypothesis that there is no difference between the cholesterol levels in the two groups (i.e., we conclude that there is a difference), when actually there is no difference. In other words these are false positive trials; it is like when there is no difference we conclude that there is difference. (An innocent person is hanged). Being serious, this error is kept at a very low level, mostly 5% or 0.05.

There may be other type of error in taking decision called as **Type II error** which is the probability that we accept a false null hypothesis. In other words this is equivalent to letting a culprit go free. This error is denoted by $\beta$. In medical research this is equivalent to false negative trials i.e., though there is significant difference between the drugs we conclude that there is no difference and declare the new drug as ineffective. This error is not as serious as type I error. If today we are not able to prove that the new drug is effective someone else would prove it in some other trial tomorrow. The effect of type-II error is that it may delay the introduction of the new drug, though effective, in the market but not deny it. Type-I error is pre-decided before the research is undertaken. Depending on type-I error and the alternative hypothesis the type-II error is calculated. Type-II error can occur when our sample size is too small to detect the difference that really exists between those treated and those not treated. This brings us to the concept of power.

Power

The complimentary of Type II error is called power (Power = 1 - $\beta$). Thus the power of a test is the probability of correctly rejecting Ho when it is false. In other words power means that we readily detect true difference when it exists. Power of a test is high if it is able to detect a small difference and thus reject $H_0$. You will get more power with a larger sample size.

P - value

P-value is calculated under the assumption that the null hypothesis is correct. R. A. Fisher first proposed the P-

value in the 1920s. Fisher proposed this as an informal index to be used as a measure of discrepancy between the data and the null hypothesis. It is the probability of the test statistic (a function of sample values) as extreme as or more than one actually calculated. Since it is a probability it lies between 0 and 1, (or, from 0% to 100%). If it is 0% it implies that the chances of our having gone wrong from our study sample are absolutely nil and on the other hand, if it is 100% it means that we are absolutely wrong in our conclusions. But how small should we consider the p-value is a difficult question to answer. The answer to this question will vary from one situation to the next, and will depend on many factors. If adopting a new drug would be very expensive, or expose patients to severe side effects, as compared to the already available cheap and low toxicity drugs, then one might demand a very high standard of evidence (that is very small p-value). On the other hand, the shortcoming to adopting the new treatment may be quite low, and may offer advantages over an existing treatment, in which case we may agree to even higher p-value for taking the decision. This could be the situation when we are trying out a vaccine against HIV infection against "no vaccine" against this frightening and potentially fatal condition. Thus what we need therefore is a rule to help us decide if a result is likely due to chance alone, meaning it is not statistically significant, or if it is unlikely due to chance alone, meaning it is statistically significant.

Statistically significant = unlikely due to chance alone

Not statistically significant = likely due to chance alone

To make a decision, you need a point such that any P-value larger than that point will lead to one conclusion and a P-value smaller than that point will lead to the opposite conclusion. That point is most often set at 0.05 and is called as alpha or Type I error.

When alpha is =0.05, a P-value of 0.10, for example, indicates the result of the study are not statistically significant and the conclusion will be that chance is a likely explanation for the observed results. The conclusion will be that the observed results are unlikely to represent real treatment differences.

When alpha is =0.05, a P-value of 0.03, for example, indicates the result of the study are statistically significant and the conclusion will be that chance is an unlikely explanation for the observed results. The conclusion will be that the observed results are likely to represent real treatment differences. Table 8 provides a reasonable interpretation of P-values.

This interpretation is widely accepted, and many scientific journals routinely publish using such an interpretation for the result of test of hypothesis. However, our readers need to be cautioned at this point. Random error or chance which is estimated by p-value is just one type of error that can occur in research. One needs to be more cautious about the other 3 types of errors in research, i.e., error of basic measurement, systematic error (Bias) and Confounding error, all of which have been discussed in detail in the previous section on Research Methodology. Even the most highly significant p-value is of no avail if the data has flaws of measurement error, systematic error or confounding.

Table - 8

| P- value | Interpretation |
|---|---|
| P<0.01 | Very strong evidence against null hypothesis ($H_0$) |
| 0.01 to 0.05 | Moderate evidence against null to hypothesis |
| 0.05 to 0.10 | Suggestive evidence against null hypothesis |

Confidence Level

Most of the research results rely on the premise that what is true for the randomly selected sample from the population will be true for the population from which the sample is selected. The reliability of the results obtained is addressed by Confidence Intervals (CIs). A CI is the range of values that encompass the actual or true population value. They provide information about how precise the estimate is. Wider CIs indicate lesser precision and narrower CIs indicate greater precision. Also P-value and CIs are related to each other. When P-value is less than 5%, the 95% confidence interval will exclude the hypothesized null value. Hence confidence intervals can also tell you whether null hypothesis is rejected or not.

In order to understand the concept of confidence intervals we must understand the concepts expressed in the central limit theorem (CLT). Let us use the example of height of a population of AFMC students. (In reality the population itself is a sample of students). The students in AFMC who graduated in 2006 were asked to draw a random sample of size 5 and another random sample of size 10 each and calculate the mean height of each sample. We then plotted the mean heights from all the students' samples. This plot of mean heights from all the samples is called as "sampling distribution"-because it is the distribution of a statistic (mean) from series of samples. The CLT states that if we take many random samples from a population and then calculate means from each sample and plot the means, then the plot will follow a normal curve. The mean of the sample means is equal to the population mean and the standard deviation of the sampling distribution is dependent on standard deviation and sample size. The standard deviation of the sampling distribution has a special name called as "standard error of mean" (SEM). Since the sampling distribution of mean follows a normal curve, 95% of all AFMC medical students sample means would be expected to fall within 2 SE of true population mean. It implies that the true population mean must therefore fall within 2 SE away from true mean. This information is used to calculate the confidence interval.

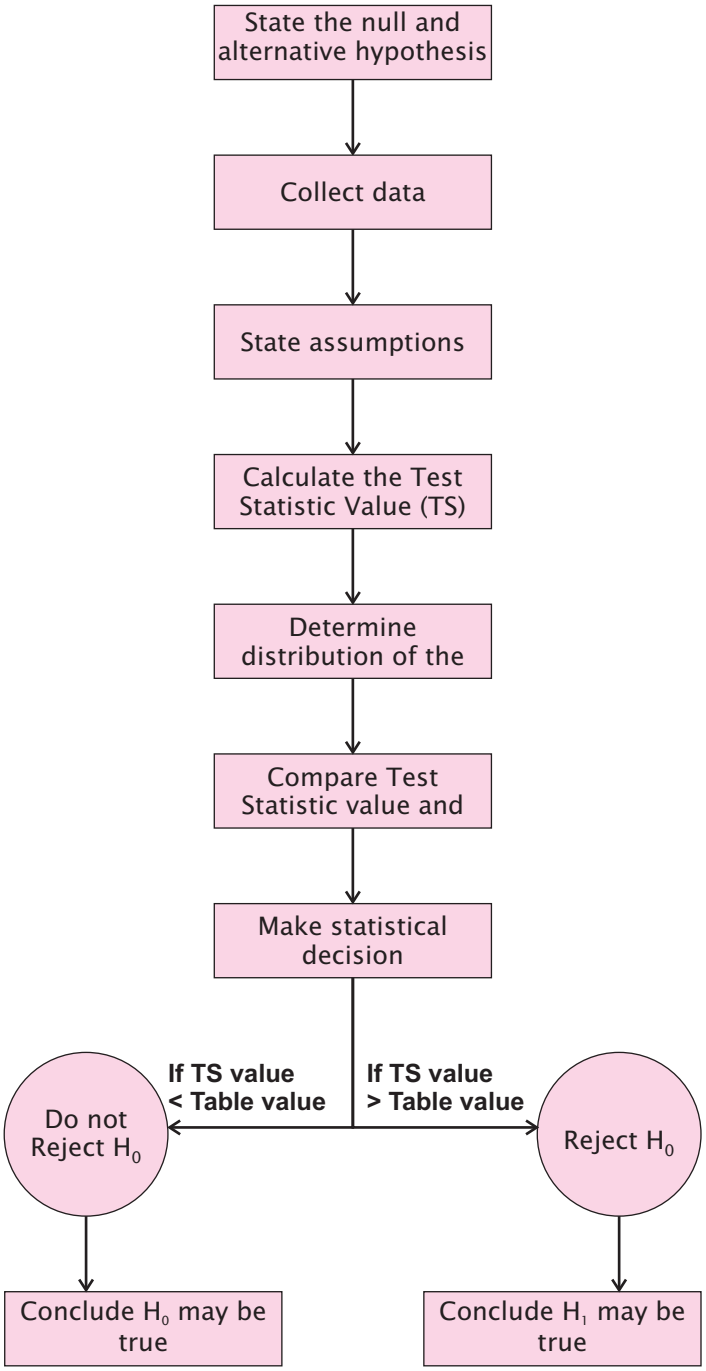
The confidence interval is interpreted by imagining many samples being drawn and many means being calculated. 95% Confidence Interval is that these confidence intervals calculated will have the true population parameter included in the range. In reality we do the study only once, we don't repeat the experiment, but by virtue of CLT we state that despite the random error inherent in our sample, we would expect to be about 2 SE from the true answer in 95% of research studies that we conduct.

Mrs. Seema R Patrikar & Col RajVir Bhalwar

## Statistical Procedures for Hypothesis Testing

'P' values are generated by a formal process called hypothesis testing. Before directly jumping to any conclusions from the sample one should always ask oneself as to what could be the explanations for the findings. Are the findings just due to chance alone or otherwise? The whole of the theory of statistical analysis tries to determine the role of chance as an explanation for our observed findings. This quantification is done by calculating a P-value. Hypothesis testing aids the clinician and researcher in reaching a conclusion concerning a population by examining a sample from that population. At this point the difference between a statistically significant result and a clinically significant result must be thoroughly understood. Statistical decision should not be interpreted as definitive but it has to balance with the clinical and medical significance. Clinical significance relates to the magnitude of the observed effect while statistical significance answers the question of whether or not the results are due to chance alone or otherwise. The hypothesis testing procedure follows certain steps which are as listed in the flow chart (Fig - 9). In this chapter we will explain in detail, the methods of statistical hypothesis testing in the most common situations. Inferences from single mean and proportion, difference between two means (paired and unpaired t test) and differences between two proportions. We will also deal with chi square test. For the remaining situations, we will give a guide as to which test should be used in a given situation and later, in the subsequent chapter on common statistical software (EPI - 2002). We shall demonstrate as to how all these test can be done on computer using EPI 2002 software.

Fig - 9 : Steps in Hypothesis testing



### Hypothesis Testing: A Single Population Mean

Here we consider two situations about a population mean ($\mu$)

(1) When sampling is from normally distributed population and population variance is known. (Population may not be normally distributed but if sample size $\geq$ 30, replace population variance by sample variance)

(2) When sampling is from normally distributed population but with unknown population variance.

#### Situation 1

When sampling is from **normally distributed population** and **population variance is known.** (Population may not be normally distributed but sample size $\geq$ 30, replace population variance by sample variance)

In the first situation the distribution of the test statistic under null hypothesis follows a standard normal distribution. The test statistic value which is a function of null hypothesis and the sampling distribution of the sample mean

$$z = \frac{\bar{x} - \mu_0}{\sigma / \sqrt{n}}$$

.....(Equation 1)

If the sample on which we base our hypothesis test about population mean comes from a population that is not normally distributed but if we have large sample drawn (n≥ 30) then by virtue of central limit theorem we use the test statistic value as

$$z = \frac{\bar{x} - \mu_0}{s/\sqrt{n}}$$

where $s$ is sample standard deviation ..... (2)

which under null hypothesis follows standard normal distribution.

Let us consider a hypothetical example. Researchers claim that the mean age of population having a certain disease 'A' is 35 years. To prove their claim, a researcher collected information from a random sample of 20 individuals drawn from population of interest. Population variance is known and is equal to $\sigma^2 = 25$ with mean age of 20 individuals as 29.

Hypotheses

Null hypothesis is that the mean age of the population is equal to 35. The alternative hypothesis is that the mean age of the population is not equal to 35.

$H_0 : \mu = 35$ against $H_1 : \mu \neq 35$

Data

From the sample the mean age was computed as $\bar{x} = 29$.

Assumptions

It is assumed that the parent population from which the sample is drawn follows a normal distribution. We also assume that $\alpha = 5\%$ and population variance is known and is equal to

$\sigma^2 = 25$

Test Statistic

Since we assume that population is normally distributed and since population variance is known, our statistic will be given by equation (1). Thus

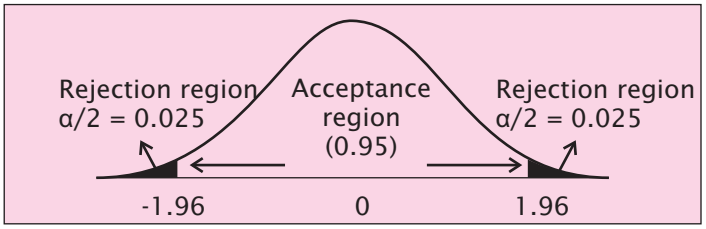
$$z = \frac{\bar{x} - \mu_0}{\sigma/\sqrt{n}} = \frac{29 - 35}{5/\sqrt{20}} = -5.36$$

Distribution of test statistic

The test statistic if $H_0$ is true follows standard normal distribution with mean of 0 and variance of 1.

Decision Rule

The statistical decision is taken by comparing the calculated test statistic value with the table value of standard normal curve against predecided value of $\alpha$ and type of the alternative hypothesis. If the alternative hypothesis is two tailed then $\alpha$ is divided in the two tails of the standard normal curve into equal parts of $\alpha/2$ each.



These areas are called as rejection areas. The decision of rejecting the null hypothesis is taken if the calculated value of absolute test statistic falls in this area i.e. rejects $H_0$ if calculated value of absolute test statistic is = $Z_{1-\alpha/2}$ or = $Z_{\alpha/2}$

From the standard normal table for $\alpha = 0.05$ two tailed the table value is 1.96. Whereas for one tailed alternative hypothesis, $\alpha = 0.05$, $\mu < \mu_o$ type the table value is -1.64 and for $\mu > \mu_o$ type the table value is 1.64. So we may reject $H_0$ if calculated value of the test statistic is ≥1.96 or ≤-1.96 otherwise we do not reject $H_0$. In the given situation we take the statistical decision to reject the null hypothesis since absolute value of test statistic (5.36) is greater than the table value (1.96) Tables are provided at the end of section.

Conclusion

We conclude that the mean age of the population with a specific disease 'A' is not equal to 35 years ($p<0.05$).

**Situation 2**

When sampling is from **normally distributed population** but with **unknown population variance**.

In practice we rarely know the population variance. Quite often we face the situations where the sample size is less than 30 and population variance $\sigma^2$ is not known. In such cases we calculate the sample standard deviation (s) and use this as an estimate of $\sigma$. This adds another element of uncertainty to our inference. Z statistics do not consider this additional uncertainty. Therefore, we use a modification of z procedures based on **Student's** t **distribution**. Student's 't' distribution was discovered by William Gosset who was working for Guinness brewing company. He was not allowed to publish scientific research, so he used the pseudonym "Student" to publish his work. t distributions are similar to z distribution, but have broader tails and less peaked at the center. As 'n' increases, t distribution approaches normal distribution. t tables are set up different than z tables. Each row is for a particular degrees of freedom. Columns show cumulative probabilities.(Tables are provided at the end of the section)

$$t = \frac{\bar{x} - \mu_0}{s/\sqrt{n}}$$

When sampling is from normally distributed population but unknown population variance the test statistic for testing

$H_0 : \mu = \mu_0$ is given as

.....(3)

which under $H_0$ follows Student's t test with (n-1) degrees of freedom (dfs).

Consider a hypothetical situation. Suppose the researcher wants to know as to what extent the diabetics are over weight. He collects information on the body weight in terms of % of ideal body weight in 18 diabetics.

Hypotheses

We convert the claim to null hypothesis. Null hypothesis is that "Diabetics are not overweight". (Not overweight = 100% of ideal body weight). Therefore,

**$H_0$: μ = 100** and alternative hypothesis can be **$H_1$: μ ≠ 100 (two-sided)**

Data

{107, 119, 99, 114, 120, 104, 88, 114, 124, 116, 101, 121, 152, 100, 125, 114, 95, 117}

We calculate sample mean $\bar{x}$= 112.78 and sample standard deviation (s) = 14.424

Assumptions

It is assumed that the parent population from which the sample is drawn follows approximate normal distribution.

We also assume that α = 5% and population variance is unknown.

$$t = \frac{\bar{x} - \mu_0}{s/\sqrt{n}} = \frac{112.78 - 100}{14.424/\sqrt{18}} = 3.76$$

Test Statistic

Since the population variance is unknown and n<30 the test statistic is given by equation (3). Thus substituting the values we get the calculated test statistic value as

Distribution of test statistic

The test statistic if $H_0$ is true follows student's t distribution with (n-1) dfs.

$t_{n-1,1-\alpha/2} = t_{18-1,1-.05/2} = t_{17,.975} = 2.11$ (t table)

Decision Rule

The statistical decision is taken by comparing the calculated test statistic value with the table value of student's 't' distribution. Since our calculated 't' value is more than table value at that particular df (17) and at that particular "two-tailed level of significance" (0.975), we reject the null hypothesis at 5% level of significance.

Conclusion

We have significant evidence against $H_0$. Hence we conclude that diabetics are not having the same weight as normals. (p<0.05)

Consider another situation. We know from our background knowledge that the mean fasting blood sugar level of non pregnant young adult women is 88 mg/dl. With this background, we conducted a study on a sample of 100 ladies in 2nd / 3rd trimester of pregnancy, attending the obstetric department. We found that the mean fasting blood sugar of this sample of 100 ladies was 102 mg/dl with a standard deviation (SD) of 14. Apparently, our sample shows that the fasting blood sugar, on an average is higher by (102-88) = 14 mg/dl among pregnant ladies, as compared to non pregnant ladies. We now want to see, statistically, whether this is a significant finding or simply a matter of chance, i.e, simply due to random (sample to sample) variations. To summarize, this is a situation in which we are studying only one sample and trying to compare the mean from this

$$t = \frac{\bar{x} - \mu_0}{s/\sqrt{n}} = \frac{102 - 88}{14/\sqrt{100}} = 10$$

sample with a known population mean. This is the "single population mean" (or, one sample) situation. The statistical procedure is followed as mentioned above. The test statistic is

The `t' value so calculated is compared with the `t' table value at degrees of freedom = (n-1)

df = (n - 1) = (100 - 1) = 99.

On looking at the `t' table we find that the `t' table value at 0.05 level corresponding to df = 99 is approximately 1.98 and at 0.01 level it is 2.62. Since our calculated `t' value (10) is much higher than this value we say that our results are highly significant (p < 0.01); the higher average fasting blood sugar that we have seen among our sample of pregnant ladies is not likely to have come up simply because of "chance" (the probability of its having occurred simply by chance, i.e., random error is less than 1 in 100). We finally conclude, clinically, that pregnancy definitely leads to a rise in fasting blood sugar level.

## Hypothesis Testing: The Difference Between Two Population Means

One of the commonest situations that a medical researcher faces while testing his/her hypothesis is when his/her interest is to see whether the two samples that he/she has drawn, differ significantly from each other as regards the "mean" of a particular variable of interest. Apparently, the above situation will be possible when we have recorded the data, in respect of that variable, on a "numerical discrete", or on a "numerical continuous" scale. At this point, it would be worth emphasizing that in case the data has been recorded on a "numerical ordinal" scale (eg, dyspnoea scores, cancer grades etc.), we would NOT do testing for difference between "means". This is for the simple reason, that though these figures (eg, dyspnoea score 1, 2, 3 etc.) obviously look like mathematical figures, they are not "mathematically meaningful" numbers. In such cases, we should use non-parametric tests for the differences between "medians". In testing the

hypothesis whether the means of the two populations differ significantly or not we have one of the following hypotheses formulated for our research:

1. $H_0$: $\mu_1 = \mu_2$ against $H_1$: $\mu_1 \neq \mu_2$ which is equivalent to saying
   $H_0$: $\mu_1 - \mu_2 = 0$ against $H_1$: $\mu_1 - \mu_2 \neq 0$
2. $H_0$: $\mu_1 - \mu_2 \geq 0$ against $H_1$: $\mu_1 - \mu_2 < 0$
3. $H_0$: $\mu_1 - \mu_2 \leq 0$ against $H_1$: $\mu_1 - \mu_2 > 0$

Again we consider different situations about difference between two population means ($\mu_1 - \mu_2$)

(1) When sampling is from **normally distributed population** and **population variance is known.** (Population may not be normally distributed but if sample size ≥ 30, replace population variance by sample variance)

(2) When sampling is from **normally distributed population** but with **unknown population variance.**

**Situation 1**

When sampling is from **normally distributed population** and **population variance is known.** (Population may not be normally distributed but sample size ≥ 30, replace population variance by sample variance)

In the situation when both the samples follow normal distribution and population variances are known, the distribution of the test statistic under null hypothesis ibution. The test statistic llowing equation

$$z = \frac{(\overline{x_1} - \overline{x_2}) - (\mu_1 - \mu_2)}{\sqrt{\frac{\sigma_1^2}{n_1} + \frac{\sigma_2^2}{n_2}}}$$

.....(4)

In the situation when the samples do not follow normal distribution but if the samples are large enough (≥30) then the distribution of the test statistic under null hypothesis follows a standard normal distribution for assumed α. The test statistic in this case is calculated by the following equation

$$z = \frac{(\overline{x_1} - \overline{x_2}) - (\mu_1 - \mu_2)}{\sqrt{\frac{s_1^2}{n_1} + \frac{s_2^2}{n_2}}}$$

..... (5)

**Situation 2**

When sampling is from **normally distributed population** but with **unknown population variance.**

$$t = \frac{(\overline{x_1} - \overline{x_2}) - (\mu_1 - \mu_2)}{\sqrt{\frac{s_p^2}{n_1} + \frac{s_p^2}{n_2}}}$$

In this situation the test statistic is calculated by first calculating the pooled variance given by $s_p^2$. The test statistic is then calculated by the following equation.

$$s_p^2 = \frac{(n_1 - 1)s_1^2 + (n_2 - 1)s_2^2}{n_1 + n_2 - 2}$$

..... (6)

Where,

Under the null hypothesis the test statistic follows student's t distribution with $(n_1+n_2-2)$ dfs. Since under null hypotheses there is no difference, $\mu_1$ and $\mu_2$ are assumed to be the same and hence $\mu_1$ minus $\mu_2$ becomes zero.

The following is a hypothetical data set of a research study to answer the question whether the serum cholesterol of healthy adult males, living in hot desert areas is, on an average, different (ie., significantly higher or lower) from the average serum cholesterol of healthy adult males living in temperate climates. The serum cholesterol values of 12 subjects from the deserts and 14 subjects from temperate climate are presented as under :

Serum Cholesterol Values(mg/dl)

Desert group (Total = 12) : 254, 218, 176, 242, 184, 239, 225, 256, 218, 182, 210, 191

Temperate Climate Group (Total = 14) : 210, 176, 194, 250, 219, 207, 162, 154, 258, 166, 219, 200, 176, 182,

Hypotheses

$H_0$: $\mu_1 = \mu_2$ against $H_1$: $\mu_1 \neq \mu_2$ which is equivalent to saying

$H_0$: $\mu_1 - \mu_2 = 0$ against $H_1$: $\mu_1 - \mu_2 \neq 0$

Data

As given above

$$s_p^2 = \frac{(n_1 - 1)s_1^2 + (n_2 - 1)s_2^2}{n_1 + n_2 - 2}$$

$$= \frac{(12-1)(28.2)^2 + (14-1)(31.5)^2}{12+14-2} = 901.95$$

$$t = \frac{(\overline{x_1} - \overline{x_2}) - (\mu_1 - \mu_2)}{\sqrt{\frac{s_p^2}{n_1} + \frac{s_p^2}{n_2}}} = \frac{(216.25 - 198.07) - 0}{\sqrt{\frac{901.95}{12} + \frac{901.95}{14}}} = 1.53$$

Assumptions

Both the populations follow approximate normal distribution with unknown population variances and $\alpha$ = 5%.

Test Statistic

Since population variance is unknown we use equation 6 to calculate the test statistic value.

Distribution of test statistic

If null hypothesis is true then the test statistic will follow student's t distribution with ($n_1$+$n_2$-2). From the t table we get the value against (12+14-2=24) dfs as 2.06.

Statistical Decision

Since the calculated test statistic value lies below the table value we do not reject the null hypothesis (accept $H_0$).

Conclusion

Serum Cholesterol levels of healthy adult males, living in hot desert areas is, on an average, **not different** from the average serum cholesterol of healthy young males living in temperate climates. (p>0.05)

**Paired Comparisons**

The `t' test we have described above deals with situations in which there are two different samples whose means are to be compared. Sometimes, in medical research, we may have either only one sample which gives us two sets of readings (before and after readings) or else, we may have two different samples which are very similar to each other excepting for the factor which is being studied. Let us have a look at the following examples :

(a) To study the efficacy of a drug in reducing the Serum Cholesterol level, we took 10 healthy adult males and measured their Serum Cholesterol levels. These 10 subjects were then given the drug for 1 month and the Serum Cholesterol levels were again measured thereafter.

(b) For evaluating the skin irritant effect of an industrial chemical, we applied the chemical (in paste form, using paraffin jelly as the medium) on the right forearm of 10 subjects, while on the left forearm, only paraffin jelly was applied to serve as control. After 24 hours, we measured the maximum diameter of hyperaemia in millimeters on both the forearms.

(c) For studying the effect of tobacco smoking during pregnancy on the birth weight of the child, we took a sample of 90 pregnant ladies who were tobacco users. For each such lady, we took another pregnant lady of same age, parity, income status and duration of pregnancy but who was a non smoker. In other words, we "pair - matched" each subject (pregnant smoker) with a control (pregnant non-smoker). We then followed up each of the 180 subjects till delivery and recorded the birth weight of the offspring in grams.

All the above three examples have very different objectives and settings; however, they have one thing in common - each data point of the first sample is related to a unique data point of the second sample. These are the situations of "paired samples". Such "paired samples" may represent two sets of measurements on the same subject in a "before and after" fashion (thus, each subject serving as his own control, vide example No. 1 above); or they may be two exactly similar anatomic or physiological points excepting for the factor under study (example No. 2 above); or, measurements on different people who are chosen on an individual basis using "matching criteria", so that they are very similar to each other, except for the factor under study (example No.3 above).

The statistical procedure in such situations is the "paired" `t' test where we first calculate the difference between pairs of observation i.e. difference ($d_i$) between before and after value. The n sample differences then represent a sample from a normally distributed population. The test statistic for testing the hypothesis that the mean difference between the before and after value =0 ($\mu_d$=0) is as follows:

$$t = \frac{\overline{d} - \mu_d}{SD(difference)/\sqrt{n}}$$

.....(7)

Where $\overline{d}$ is the sample mean difference, $\mu_d$ is hypothesized

Table - 9

| Subject No | Serum Cholesterol mg/dl | | Difference (d) (= d1 -d2) |
|---|---|---|---|
| | Before therapy d1 | After therapy d2 | |
| 1 | 306 | 280 | +26 |
| 2 | 254 | 242 | +12 |
| 3 | 198 | 204 | -6 |
| 4 | 242 | 238 | + 4 |
| 5 | 236 | 228 | + 8 |
| 6 | 228 | 202 | +26 |
| 7 | 286 | 264 | +22 |
| 8 | 274 | 258 | +16 |
| 9 | 208 | 209 | -1 |
| 10 | 188 | 198 | -10 |
| | | | |

Hypotheses

$H_0$: $\mu_d = 0$ against $H_1$: $\mu_d \neq 0$

Data

Now, the mean of the differences of the 10 observations (+26, +12, + ----- -1, -10) comes out to + 9.7 and the standard deviation comes out to 12.96 thus.

$\bar{d} = 9.7$, SD(difference) = 12.96, n= 10.

Assumptions

The observed differences constitute a random sample from a normally distributed population and $\alpha = 5\%$.

Test Statistic

Using equation (7) for paired observation we get test statistic value as

Statistical Decision

$$t = \frac{\bar{d} - \mu_d}{SD(difference)/\sqrt{n}} = \frac{9.7 - 0}{12.96/\sqrt{10}} = 2.37$$

df = (n - 1) = (10-1) =9

Now, turning to the t table, we find the t table value at p or $\alpha = 0.05$ and df = 9 is 2.26. Since our calculated `t' value (2.37) is more than the table value (2.26) we conclude that our results are significant i.e. we reject our null hypothesis.

Conclusion

What we are in fact concluding is our sample of 10 subjects shows that there is a reduction on an average by 9.7 mg/dl due to the drug; and the "probability" that in the large reference population (of millions of persons who would be given the drug), the drug will not lead to a reduction in Serum Cholesterol is less than 5 in 100 chances; thus there are 95 in 100 chances that the drug will lead to a reduction in Serum cholesterol in the large reference population ($p<0.05$).

Once again, if we are using "numerical-ordinal" scales then it should not be the "paired t-test" but rather a non parametric test (Wilcoxon's signed rank test) that should be used. For example, if we are comparing the "pain scores" (0,1,2,3 etc) before and after a drug then we should **not** use the paired t test as described above, but the Wilcoxon's signed rank test.

**Which test to use for difference in means of three or more samples?**

If we are comparing the means of 2 samples, then we use the 't' test as described earlier. However if we are testing the difference in means between 3 or more samples then we should not use 't' test. In such situations we should use ANALYSIS OF VARIANCE (ANOVA). For example if we want to see whether the average Hb% level is different among pure vegetarian, ovo-vegetarian and non-vegetarian pregnant women, then we would use ANOVA.

Mrs. Seema R Patrikar & Col RajVir Bhalwar

## Testing for Proportions

In clinical trials one may count the number of times an event occurs. For example number of successful outcomes, number of failures or number of patients recovered after administration of drug etc. This proportion may be compared with a hypothesized value or we may study a two sample problem in which trials are conducted in two independent study groups. Similarly patients in one group may receive new treatment drug and another independent group may receive existing conventional treatment. We may be interested in comparing the proportion of patients attacked by disease after administration of the treatment in the two populations. The population proportion is denoted by 'π'.

The testing of hypothesis about population proportion is carried out in the same way as means.

**Hypothesis Testing: A Single Population Proportion**

In testing a single population proportion denoted by π against a hypothesized value of $\pi_0$ approximate normality assumptions holds true if the sample size is large. The test statistic is given as

$$z = \frac{p - \pi_0}{\sqrt{\frac{\pi_0(1-\pi_0)}{n}}} \quad \text{.....(8)}$$

Which when the null hypothesis is true follows a standard normal distribution. Here p is the sample proportion and $\pi_0$ is the hypothesized population proportion.

Consider a hypothetical example. In clinical studies of an anti-allergy drug, 70 of 781 subjects experienced drowsiness. A competitor claims that 8% of users of his drug experience drowsiness. Use a 0.05 significance level to test this claim.

Hypotheses

Ho: $\pi=\pi_0$ (0.08) against $H_1$: $\pi \neq \pi_0$ (0.08)

Data

The data obtained on drug says 70 out of 781 subjects experienced drowsiness. Hence, p = 70 / 781 = 0.089

Assumptions

The random sample is drawn from a normally distributed population and α = 5%.

Test Statistic

The test statistic is given by equation 8

$$z = \frac{p - \pi_0}{\sqrt{\frac{\pi_0(1-\pi_0)}{n}}} = \frac{0.089 - 0.08}{\sqrt{\frac{0.08(1-0.92)}{781}}} = 0.99$$

Distribution of test statistic

The test statistic, if $H_0$ is true, follows standard normal distribution with mean of 0 and variance of 1.

Decision Rule

For α = 0.05, the standard normal table value is 1.96. So since the test statistic value is less than the table value we fail to reject the null hypothesis.

Conclusion

There is not sufficient evidence to warrant rejection of the claim that drowsiness will be less among users of the competitors drug vis-a-vis the drug used by us (p>0.05)

**Hypothesis Testing: The Difference Between Two Population Proportions**

This is the most common situation in medical research. We test the null hypothesis that the difference between the two proportions is zero or some other value. When the null hypothesis is stated as $\pi_1 = \pi_2$ (two population proportions are same), it means that $\pi_1 - \pi_2 = 0$ we are testing the hypothesis that (difference between two population proportions is zero). The test statistic is given as,

$$z = \frac{(p_1 - p_2) - (\pi_1 - \pi_2)}{SE_{p_1 - p_2}} \quad \text{..... (9)}$$

where,

$p_1$ and $p_2$ are sample proportion values.

$x_1$ & $x_2$ are numbers in the first and second samples possessing the characteristic of interest. The test statistic under null hypothesis follows standard normal distribution.

$$SE_{p_1-p_2} = \sqrt{\frac{\bar{p}(1-\bar{p})}{n_1} + \frac{\bar{p}(1-\bar{p})}{n_2}} \quad \text{and} \quad \bar{p} = \frac{x_1 + x_2}{n_1 + n_2},$$

Consider a hypothetical example where we sampled 55 males in their adolescent ages. 24 of them were obese. Another sample of 149 females had 36 obese ladies. Can we conclude that in the sampled populations the proportion of obese males is higher than that of females ?

Hypotheses

Ho: $\pi_1 \leq \pi_2$ or $\pi_1 - \pi_2 = 0$ against $H_1$: $\pi_1 > \pi_2$ or $\pi_1 - \pi_2 > 0$, $\pi_1$ and $\pi_2$ are proportions of obese in male & female populations respectively.

Data

The data gives the sample proportion values as p1= 24/55 = 0.44 and p2=36/149 = 0.24.$\bar{p}$ = (24+36)/ (55+149) = 0.29

Assumptions

The two independent simple random samples is drawn from a normally distributed population and $\alpha$ = 5%.

Test Statistic

The test statistic is given by equation 9

$$z = \frac{(p_1 - p_2) - (\pi_1 - \pi_2)}{SE_{p_1 - p_2}}$$

$$= \frac{0.44 - 0.24}{\sqrt{\frac{0.29(1-0.29)}{55} + \frac{0.29(1-0.29)}{149}}} = 2.71$$

Distribution of test statistic

The test statistic, if $H_0$ is true, follows standard normal distribution with mean of 0 and variance of 1.

Decision Rule

For $\alpha$ = 0.05, the standard normal table value is 1.645 for one tailed hypothesis. So since the test statistic value is greater than the table value (2.71 > 1.645) we reject the null hypothesis.

Conclusion

There is sufficient evidence that proportion of obese in male population is significantly higher than female population (p<0.05)

# Hypothesis Test for Counts and Non Parametric Tests

The hypothesis testing procedure discussed earlier, whether z test, unpaired t test or paired t test required the population distribution to be normal or approximately normal. In medical research many times we are not sure about the underlying distribution of the population. In such cases we apply non parametric tests which are not based on the assumption of normality of population especially when the sample size is small (n<30). Since they do not assume any distribution they are also called as distribution free tests. Non parametric tests are weaker than parametric tests. Few of the commonly encountered non parametric tests are discussed below.

### Hypothesis Testing for Categorical Data

The previous section of hypothesis testing dealt with situations when we had discrete or continuous, i.e., "quantitative or numerical variables", which could be measured. Apart from above mentioned situations many times medical research deals with situations involved with comparing two groups with the presence and absence of various diseases. Here the qualitative or categorical variables are measured in terms of "counts". The statistical tests used for such variables which do not assume normality of the variable are specific and called as **nonparametric tests**. These are also called as **distribution free test**. These tests are weaker than parametric test and require fewer assumptions. For categorical data the test used is called as chi-square test ($x^2$ test). Chi-square tests have three applications.

(a) $x^2$ **test for independence** to test whether two or more characteristics are associated (independent) to each other.

(b) $x^2$ **test for goodness of fit** to study whether two or more independent populations are similar with respect to some characteristic.

(c) $x^2$ **test for homogeneity** to study whether two study groups independently drawn from two populations are homogenous with respect to some criteria of classification

In all the three situations the test statistic takes the same formula given as follows :

$$X^2 = \frac{\sum (O_{ij} - E_{ij})^2}{E_{ij}}$$

where $O_{ij}$ and $E_{ij}$ are observed and expected frequencies for $i^{th}$ row and $j^{th}$ column.

When the information is collected in counts it is compiled and presented in a table called as **contingency table**. When both the qualitative variables are dichotomous the tabular presentation takes the form of 2 x 2 contingency table (2 rows and 2 columns). In general we can have r x c contingency table where r is number of rows and c is number of columns. Under the null hypothesis the test statistic follows a chi-square distribution with (r-1)x(c-1) degrees of freedom.

Let us illustrate the procedure of Chi-square test using the hypothetical example on the association between maternal age and congenital malformations. Let us say, we started with the research issue as to whether advanced maternal age (>35 years) is associated with congenital malformations among the children. We took a sample each, say, 500 pregnant ladies aged > 35 years and another 1000 pregnant ladies aged upto 35 years and followed them till delivery. We found that out of the 500 children born to ladies > 35 years, 50 had congenital malformations, while out of 1000 ladies upto 35 years, there were again 50 children born with congenital malformations. We would thus proceed to test the research hypothesis that the age of mother and congenital malformations are associated. This research hypothesis would be tested against the **"Null Hypothesis" which states "There is no association between congenital malformation and age of mother". (Age of mother and congenital malformation are independent to each other).** The outcome variable of interest is dichotomous (either malformed child or normal child)

Table - 10 : $X^2$ test for Independence

| Samples of ladies | Number of Children | | Total |
|---|---|---|---|
| | Having Congenital malformations | Not having Congenital malformations | |
| > 35 years | ($O_{11}$)50 (10%) (a) | ($O_{12}$)450 (90%) (b) | 500 (100%) (a+b) |
| < 35 years | ($O_{21}$)50 (5%) ( c) | ($O_{22}$)950 (95% (d) | 1000 (100%) (c+d) |
| Total | 100 (6.67%) (a+b) | 1400 (93.33%) (b+d) | 1500 (100%) (n) |

$O_{11}$, $O_{12}$, $O_{21}$ and $O_{22}$ (Equivalent to a, b, c and d) are the observed frequencies in our sample. To calculate the chi-square test statistic value we are first required to calculate the expected frequencies. Expected frequencies are the one that we expect if null hypothesis is true and is given by

$$\text{Expected frequency} = \frac{(\text{Marginal row total}) \times (\text{Marginal column total})}{n}$$

Thus for the above example we have expected frequencies for each cell as follows :

$E_{11}$ = (500X100)/1500 = 33.33

$E_{12}$ = (500X1400)/1500 = 466.67

$E_{21}$ = (1000X100)/1500 = 66.67

$E_{22}$ = (1000X1400)/1500 = 933.33

### Test Statistic

Test Statistic for chi-square tests is given by

$$X^2 = \frac{\sum (O_{ij} - E_{ij})^2}{E_{ij}}$$

where $O_{ij}$ and $E_{ij}$ are observed and expected frequencies for $i^{th}$ row and $j^{th}$ column.

Substituting the values from the above example we get

$$X^2 = \frac{(50-33.33)^2}{33.33} + \frac{(450-466.67)^2}{466.67} + \frac{(50-66.67)^2}{66.67} + \frac{(950-933.33)^2}{933.33}$$

$$X^2 = 13.39$$

### Distribution of the Test Statistic

Under null hypothesis the test statistic follows a chi-square distribution with (row-1) X (column-1) degrees of freedom. For the above problem we have (2-1) X (2-1) =1 degree of freedom. For 1 df and assumed á level of significance the chi-square table value is 3.84.

### Statistical Decision

If the calculated test statistic value is greater than table value we reject the null hypothesis otherwise accept it. Since our calculated test statistic value = 13.39 > 3.84 we reject null hypothesis.

### Conclusion

On the clinical front we conclude that there is a definite relationship between advanced maternal age (> 35 years) and congenital malformations in the offspring.

Mrs. Seema R Patrikar & Col RajVir Bhalwar

## Advanced Statistical Techniques

The most commonly used statistical procedures in medical research are the "z" test for comparing two means or two proportions, the unpaired and paired 't' tests and the chi-square test, the details of which have been explained in this section. There are certain situations when different statistical techniques are required. The medical researcher should have an orientation to these procedures so that he/she can decide as to which procedure is most appropriate. As regards actual calculations, the same can be easily undertaken with statistical software EPI-2002, details of which are being described in the next section.

**Which test to use**

As we said earlier, in the previous section on Research Methodology, the prototype scenario is to study an association between a given exposure variable and an "outcome" variable. (Please refer to detailed discussion on 2 x 2 table in that chapter). Now, we must first decide as to which "scale" have we recorded the exposure and the outcome variable. (i.e., Quantitative Continuous, Discrete or Ordinal; or, Qualitative- Dichotomous, polychotomous nominal or polychotomous ordinal) Next, depending on the scale on which the exposure and outcome variables have been recorded, the appropriate test can be used.

1. For testing one to one (Univariate) relationship between exposure and outcome variable (Table - 11).

2. One to One (Univariate) Situation of Paired (dependent) samples or 'Before and After' situations

   (a) For Means : Paired 't' test

   (b) For proportion : McNemar Chi square

   (c) For Medians : Wilcxon Signed Rank test.

3. If the outcome variable is dependent on time (as survival)

Use Survival analysis method as Kaplan Meier method

4. For control of confounding (Bivariate or multivariate analysis)

   (a) For one or two confounding variables and when both the exposure & outcome are recorded on qualitative (usually dichotomous) scale: Mantel-Haenszel's stratified analysis

   (b) For one or two confounding variables and when either exposure or outcome are recorded on quantitative (Continuous, discrete or ordinal) scale : - Two way or Multiple way ANOVA.

   (c) When a large number of confounding variables are to be controlled.

      (i) If outcome variable is recorded on quantitative (Continuous or discrete numerical) scale: Multiple Linear Regression Model.

      (ii) If the outcome variable is recorded on dichotomous scale: Use Multiple Logistic Regression

      (iii) If the outcome variable is a dichotomous variable but dependent on some type of time duration, as survival time : Use Cox

Table - 11

| | | OUTCOME | | | | | |
|---|---|---|---|---|---|---|---|
| | | **Continuous** | **Discrete** | **Numerical Ordinal** | **Dichotomous** | **Polychotomous Nominal** | **Polychotomous Ordinal** |
| EXPOSURE | **Continuous** | Pearson Correlation & Regression | Pearson Correlation & Regression | Spearman Rank correlation | 't' test | ANOVA | ANOVA |
| | **Discrete** | Pearson Correlation & Regression | Pearson Correlation & Regression | Spearman Rank correlation | 't' test | ANOVA | ANOVA |
| | **Numerical Ordinal** | Spearman Rank correlation | Spearman Rank correlation | Spearman Rank correlation | Mann Whitney U test | Kruskal Wallis test | Kruskal Wallis test |
| | **Dichotomous** | 't' test | 't' test | Mann Whitney U test | Chi Square for 2X2 table | Chi Square for rXc table | Chi Square for linear trend in proportions |
| | **Polychotomous Nominal** | ANOVA | ANOVA | Kruskal Wallis test | Chi Square for rXc table | Chi Square for rXc table | Chi Square for rXc table |
| | **Polychotomous Ordinal** | ANOVA | ANOVA | Kruskal Wallis test | Chi Square for linear trend in proportions | Chi Square for rXc table | Chi Square for rXc table |

Proportional Hazards Regression model.

Fisher Exact Test for 2 x 2 table

Many times we face the situation where the variables of classification are qualitative but the sample size is too small. **Chi-square test fails when the sample size is less than 30.** In such situations instead of using chi-square test we should use Fisher Exact Test.

McNemar Test for related data

In the situation of a chi square test, as described earlier, if "paired matching" has been done then McNemar test should be done instead of ordinary Chi square test.

Medain based Non Parametric test:

At times when the scale of measurement has been ordinal numerical (as rank achieved, grade of dyspnoea, economic status and so on) we should compare the medians rather than the means, using certain non parametric tests. The following tests are commonly used:-

(a) Mann-Whitney 'U' test : When medians of the two independent samples are to be compared. It is the counterpart of unpaired 't' test.

(b) Wilcoxon Signed Rank test : When the medians of the paired samples are to be compared. It is the counterpart of "paired t test".

(c) Kruskal Wallis test : When medians of three or more samples are to be compared. It is the counterpart of ANOVA.

Regression Techniques

Often in medical research it is desirable to analyse the relationship or association between two quantitative (i.e., continuous, discrete or numerical ordinal) variables. The nature and strength of relationship that exists is examined by regression and correlation analysis. When the objective is to determine association or the strength of relationship between two such variables we use correlation coefficient (r). If the objective is to quantify and describe the existing relationship with a view of prediction we use regression analysis. Before we develop a mathematical model describing relationship we should first plot the scatter diagram of the variables. A scatter plot is a visual description of the relationship between two continuous variables.

Correlation Coefficient(r)

We have two types of correlation depending on whether the variables are continuous variables and joint distribution is following normal distribution or not.

**Pearson Correlation Coefficient**

This correlation coefficient works when variables are continuous variables and joint distribution is following normal distribution.

The correlation coefficient ranges between -1 to +1. A correlation of zero indicates no association whereas a correlation of 1 indicates perfect association. The sign of correlation coefficient provides information on the type of association between the variables. If it is positive then high values of one variable will be associated with high values of the other variable and if the correlation coefficient is negative then low values of one variable are associated with high values of other variable. The interpretation of r is shown in Table - 12.

**Spearman correlation coefficient**

Sometimes the variables are not normally distributed but are ranked in order then the appropriate correlation measure is Spearman rank correlation coefficient. The Spearman correlation coefficient also ranges from -1 to +1

Table - 12 : Interpretation of r

| Value of r | Relationship |
|---|---|
| If 0< r < ±0.25<br>Between 0 and ±0.25 | Little or no linear relationship. |
| If ±0.25= r < ±0.50<br>Between ±0.25 and ±0.5 | Fair degree of linear relationship |
| If ±0.50 = r < ±0.75<br>Between ±0.5 and ±0.75 | Moderate to good linear relationship. |
| If r = ±0.75 | Very good linear relationship. |

and is interpreted in the same way as the Pearson correlation coefficient.

**Coefficient of determination**

Coefficient of determination is defined as square of correlation coefficient. It is the amount of variation in the dependent variable accounted for by the independent variable. In other words if coefficient of correlation (r) between age and blood pressure is 0.8 then coefficient of determination $r^2$ = 0.64. This is interpreted as 64% of variability in blood pressure is accounted by age whereas the remaining 36% is not by age. Other factors such as weight, diet and exercise may account for the 36% variability in blood pressure.

**Simple Linear Regression**

In simple model we have one outcome or dependent variable associated with only one independent variable. The line describes the linear relationship between the variables. We predict the dependent variable by a straight line equation.

**Multiple Linear Regression**

Multiple regression is the extension of simple linear regression except that in this regression model we have more than one independent or explanatory variables, and the outcome (dependent) variable is continuous or discrete numerical scale.

**Multiple Logistic Regression**

In logistic regression, the outcome variable or dependent variable is dichotomous (Died/Alive, Yes/No, Present/Absent). Logistic regression is widely used in medical science since the medical researcher many a times is interested in presence or absence of a condition or disease and also the coefficients derived from logistic regression can be interpreted as odds ratio.

Mrs. Seema R Patrikar & Col RajVir Bhalwar

# Survival Analysis

The various statistical situations that we have considered till now relate to "risk" or to "prognosis" or treatment related outcomes. However, sometimes the research question may be more interesting and somewhat different from the above mentioned situations. For example, the question could be "what are the chances that a case of HIV infection acquired due to blood transfusion would be surviving at the end of 6 years?"; or, "what are the chances that a lady who has been diagnosed as cervical cancer by early screening and treated would be alive at the end of 5 years?" or **in general how long people with a life threatening disease survive following treatment.** The analytical methods used to draw inferences regarding the chances of surviving / dying / getting cured/getting diseased (in short, the chances of developing the "outcome of interest"), over the various points of time are answered by "survival analysis". Thus survival analysis deals with situations where the outcome is dichotomous and is a **function of time.**

Suppose patients suffering from a life threatening disease 'A' are treated with two treatment modalities and followed over specific time period say 5 years. The study continues during which any of the following three situations may occur.

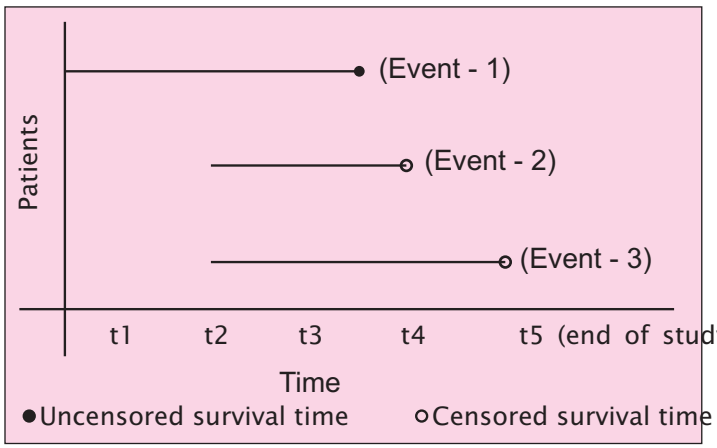
(1) The event of interest (death of patient due to disease 'A') has occurred.

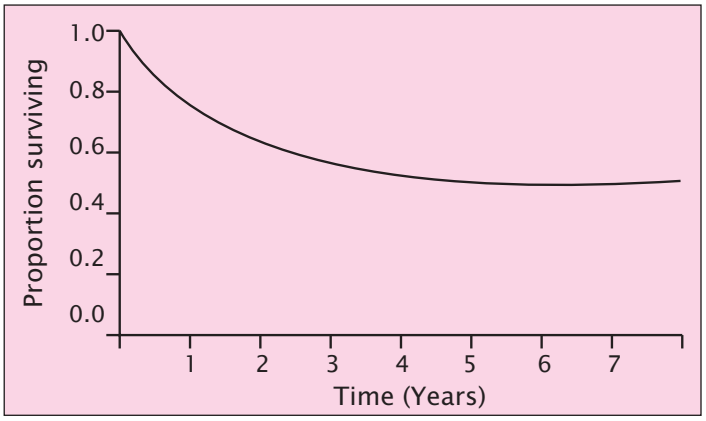
(2) The patient is lost to follow up, from death due to cause other than disease 'A' or has left the study by moving out of area etc.

(3) The event of interest (death of patient) does not occur till the end of study. i.e. the patient is alive when the study is terminated.

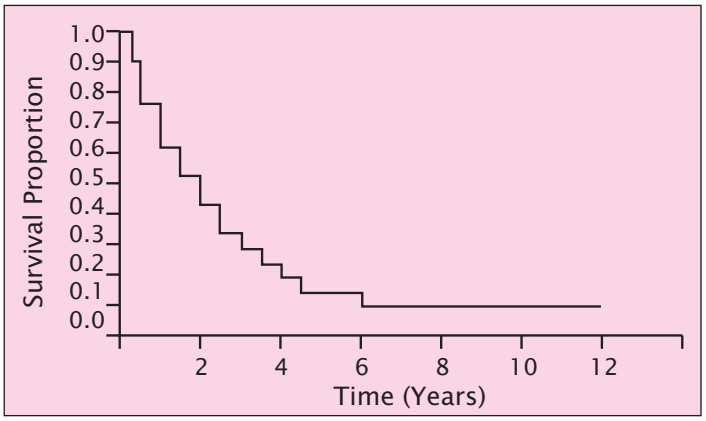
The time from enrollment to experiencing one of the above situations is called survival time. In situations 2 and 3 the survival time of patients is called as **censored survival time**. Thus all those who achieve the outcome of interest are "uncensored" data while those who do not achieve the outcome are "censored" data.

Visual representation of the survival experience of patients against time is represented by survival curves. Thus survival curves show the percentage surviving versus time. The following is a graph depicting survival curve.





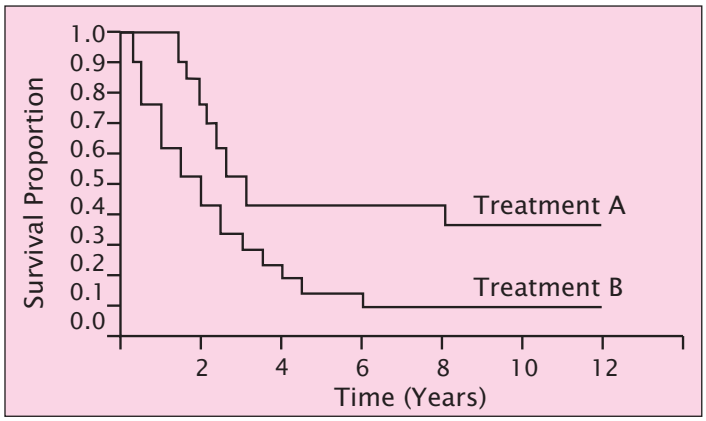
Most real life survival curves are usually shown as staircase curves with a step down each time there is a death. This is because the survival curve represents the actual experience of a particular group of people. At the moment of each death, the proportion of survivor's decreases.



### Comparison between two survival curves

The curves may compare results from different treatments as in the graph shown below. If one curve is continuously "above" the other, as with these curves, the conclusion is that the Treatment "A" associated with the higher curve was more effective for these patients then Treatment "B". The two lines represent the two "survival curves".

The vertical (or Y) axis of the graph is the percentage of patients in the group surviving. The horizontal (or X) axis represents time, starting from the time of diagnosis, or the time that treatment starts. As time goes on, some of the patients die and the curve steps down each time this



happens. Most of the times these curves flatten out at the ends suggesting that some patients in each of the two groups are cured or at least are long term survivors, though the odds of that are obviously much greater for the upper curve.

There are number of methods of analyzing a survival data. Life table method accounts for differences in follow-up time and also account for changes in survival rate over time. It breaks the follow-up period of the study into intervals and then calculates the proportion of people at risk at the start of each interval who survive until the start of the next interval.

There are two methods to calculate life tables.

(a) Actuarial method

(b) Kaplan-Meier method.

The basic difference between the two methods is the interval classification. The actuarial method adopts fixed class intervals which are most often year following the end of treatment given. The Kaplan-Meier method uses the next death, whenever it occurs, to define the end of the last class interval and the start of the new class interval. In both the methods the statistical test applied to test the null hypothesis that there is no difference in survival rates of the patients treated with two different treatment modalities (comparing two survival curves) is the **Log-Rank Test.** Log-Rank test does not control for confounding. To control for confounding we use another test called as **Cox proportional hazards regression.** The mathematical calculation of the two tests is not discussed in detail but we only need to know that in medical research articles when we see Log-Rank test applied, a crude test for difference in survival curves was conducted whereas when we come across Cox proportional hazard model then the comparison in survival curves was conducted

Mrs. Seema R Patrikar & Col RajVir Bhalwar

# Sample Size Determination

In the initial chapters, we have highlighted that the major reason for utilizing statistics is because we study a sample instead of complete population. Research studies (surveys, experiments, observational studies, etc.) are always better when they are carefully planned. Determining sample size is a very important issue and hence must be planned carefully because samples that are too large may waste research time, resources, patient effort and money invested in clinical trial, while samples that are too small may lead to inaccurate results. Also, it may be considered unethical to recruit patients into a study that does not have a large enough sample size for the trial to deliver meaningful information. Thus to ensure that a statistical test will have adequate power, one usually must perform the exercise of calculating how large an 'n' (sample size) is required. It is not possible to compute a sample size for certain types of experiments because prior information is lacking or because the success of the experiment is highly variable. These studies are called as **pilot studies**. Pilot experiments are designed to explore a new research area to determine whether variables are measurable with sufficient precision as well as to check the logistics of a proposed experiment. Usually a pilot study is conducted by taking an approximate sample size of 30 or less. In most of the other research designs (for hypothesis testing) the sample size calculation depends upon the four major components viz the power, the level of significance, the effect size or the expected parameter value in the population and the expected size of the treatment effect sought. We have already discussed that **power of a study** is its ability to detect a true difference in outcome. This is usually chosen to be 80%. If study power is set at 80% it accepts a likelihood of one in five (that is, 20%) of missing such a real difference i.e. the study will have 20% possibility of a "false-negative" result. Level of significance is predefined before we start the experiment. The chosen **level of significance or Type I error** is the probability of detecting a treatment effect when no effect exists (leading to a "false-positive" result) and defines the threshold "p value". Results with a p value above the threshold lead to the conclusion that an observed difference may be due to chance alone, while those with a P value below the threshold lead to rejecting chance and concluding that the intervention has a real effect. The type I error is most commonly set at 5% (or, sometimes at 1%). This means the investigator is prepared to accept a 5% (or 1%) chance of erroneously reporting a significant effect. The **effect size** is the biologically significant difference which is specified from a detailed review of literature, from experts or by conducting a pilot study. This is defined as “minimum detectable RR or OR or Treatment Effect (TE)”. We consider below sample size determination in simple situations of estimation alone and not hypothesis testing. In hypothesis testing along with α, power is also considered.

### Sample Size determination for Estimating a Mean

Sample size 'n' is given by

$$n \geq \frac{z^2_{1-\alpha/2}\sigma^2}{d^2}$$

where,

- d is the precision or margin of error. In other words it is the acceptable deviation between the hypothesized value and the true value of population parameter assuming 95% confidence interval.
- σ is the population standard deviation which is estimated from pilot study or from previous similar study.
- $Z_{1-\alpha/2}$ is the table values for alpha error corresponding to the standard normal distribution. This is 1.96 at 5% (i.e. 0.05) and 2.57 at 1% alpha error (two tailed).

### Sample Size determination for Estimating Proportion

The procedure in estimating sample size for proportion remains same as in case of means. Assuming that

$$n \geq \frac{z^2_{1-\alpha/2}pq}{d^2}$$

population is large we determine the sample size by following equation.

where,

- $p$ is the proportion in population possessing the characteristic of interest and q=1-p. This expected proportion in population is estimated from literature or pilot study. If nothing is known of p then it can be assumed to 0.5.
- $d$ is the acceptable deviation
- $Z_{1-\alpha/2}$ is the value of two tailed alpha error; this is 1.96 at 5% (i.e. 0.05) and 2.57 at 1% alpha error (two tailed). For one tailed alpha error this will be 1.64 at 0.05 and 2.33 at 0.01 levels of alpha error.

### Sample Size determination for Estimating Difference between Means

For comparison of means in two independent samples the sample size calculation remains similar to single

$$n \geq \frac{z^2_{1-\alpha/2}\sigma^2}{d^2}$$

population mean. Here $n_1 = n_2 = n$

where it is assumed that $\sigma_1$ and $\sigma_2$ are same and equal to $\sigma$. If they are not equal their average can be taken as an estimate of the standard deviation.

**Sample Size determination for Estimating Difference between Proportions**

The method of sample size determination for estimating difference between proportions is slightly tedious than for single population proportion. No estimate of standard deviation from previous work or literature is required but the actual proportions in the two populations must be

$$n \geq \frac{z^2_{1-\alpha/2}(p_1q_1 + p_2q_2)}{d^2}$$

specified as well as their difference (d).

where $p_1$ and $p_2$ are proportion in population possessing the characteristic of interest and $q_1=1-p_1$ and $q_2=1-p_2$.

**Sample Size application for hypothesis testing in a case control and a prospective studies**

In a case control study besides giving specifications for acceptable alpha error and acceptable beta error, the proportion of the persons without the outcome who are likely to give a history of the exposure (i.e. proportion of controls who are exposed) and the minimum risk (i.e. the minimum Odds Ratio that our study wants to detect) needs to be specified.

In case of a prospective study besides giving specifications for acceptable alpha error and acceptable beta error, the proportion of subjects those who are not exposed to the exposure but are likely to develop the outcome and the minimum risk (i.e. the minimum Relative Risk that our study wants to detect) needs to be specified.

Once the above specifications have been made, the calculation becomes simple by the following formula :

$$n = \frac{(z_{1-\alpha/2} + z_{1-\beta})^2 * p * q}{(p_1 - p_0)^2}$$

where

n = minimum sample size for each group

$Z_{1-\alpha/2}$= value of alpha error

$Z_{1-\beta}$ =value of beta error;

For the usual situation when

alpha error =0.05 two tailed, the value is 1.96 and for

beta error = 0.20, it is 0.84

$P_0$ =Proportion of those "without the exposure" who are likely to develop the "outcome" (in a prospective study) or Proportion of those without the outcome who are likely to have the exposure (in a case control study).

The value of $P_0$ would have to be specified by us. The methods of obtaining the same are extensive reading into the subject, discussions with experts, or finally, by conducting a pilot study if required. Once $P_0$ is specified $P_1$ is then obtained as follows

In a Prospective study

$$P_1 = \frac{P_0 \text{ X RR}}{(1 + P_0 (\text{RR} - 1)}$$

In a Case-control study

$$P_1 = \frac{P_0 \text{ X OR}}{(1 + P_0 (\text{OR} - 1)}$$

and then calculate $P$ & $q$ as

$$P = \frac{P_0 + P_1}{2}$$

$$q = (1-P)$$

(Please note: Sample size determination is discussed in detail with examples in next section on EPI 2002. Hence it is suggested that the readers also review the details given in that section)

Mrs. Seema R Patrikar & Col RajVir Bhalwar

# Methods of Sampling

To draw conclusions about population from sample, there are two major requirements. Firstly, the sample size should be adequately large, an issue which has been discussed in the previous chapter. Secondly, the sample has to be selected appropriately so that it is representative of the population Sample, should have all the characteristics of the population. In other words a sample is expected to be mirror of the population from which it comes. Sampling techniques is concerned with the selection of representative sample, especially for the purposes of statistical inference. We will discuss few of the important sampling techniques adopted in medical research.

### Simple Random Sampling (SRS)

In this method the individual units constituting the sample are selected at random. Each unit in the population has an equal chance or probability to be selected in the sample. For this reason, it is sometimes referred to as a probability sample. There are two types of random sampling, simple random sampling with replacement and simple random sampling without replacement. In SRS with replacement the selected unit is replaced back to the population and again has the chance of getting selected. In SRS without replacement, which is the usual method in medical research, the selected unit is not put back in the population and hence the population size reduces by one at each selection. Random samples can be drawn by lottery method or by using random number tables. In Lottery method we make small chits of paper for each unit in the population which are folded and then mixed together. From this the required number are picked blindly. For example, if you want to select 10 subjects randomly from a population of 100, you can write their names, fold them up, mix them thoroughly then pick ten. In this case, every name had an equal chance of being picked. The other method of drawing a random sample is by using random number tables. This method is possible only with finite population i.e. when the population size N is known. The technique of selecting random sample with the help of these numbers is very simple. Suppose we have to select a sample (n) of 100 subjects from a population of 500 (N). We first make, a serial list of each and every subject of the 500 subjects in the population. This is called the "sampling frame". Then from the random number table, random numbers are selected row wise or column wise. Since 'N' (500) is of 3 digits, the random numbers selected are also 3 digits. If the selected random number is less than N, then the unit corresponding to that random number from population is selected in the sample. However if the selected random number is greater than N then the remainder after dividing the random number by N is selected in the sample. For example if selected random number is 167 then the unit corresponding to this number in the sampling frame is selected in the sample. But if the random number is 641 then the remainder after dividing 641 by 500 is 141. Thus the unit corresponding to 141 in the sampling frame is taken in the study. Simple random sampling is very scientific but the practical problem is that it may be quite difficult, often impossible to make a complete list of all subjects in the population from which the sample is to be selected.

### Stratified Random Sampling

In this method the complete population is divided into homogenous sub groups called strata and then a stratified sample is obtained by independently selecting a separate simple random sample from each population stratum. This gives equal chance to the units in each stratum to be selected as sample. The total sample is the addition of samples of each stratum. Population can be divided into different groups based on some characteristic or variable like income or education. The advantage of this sampling procedure is that each subgroup, however small, has representation in the total sample. For example, if we draw a simple random sample from armed forces population, a sample of 100 may contain only 7 to 8 officers, 15 to 20 JCOs and 70 to 80 Other ranks (OR). To get adequately large representation for all the three rank structures, we can stratify on rank and select simple random samples from each of the three strata.

### Systematic Random Sampling

A systematic random sample is obtained by selecting one unit on a random basis and then choosing additional units at evenly spaced intervals until the desired number of sample size is obtained. For example, if there are 100 students(N) in a class and we wish to select a sample of 20 students (n) from them by systematic random sampling procedure, than the first step is to write the names of 100 students in alphabetical order or their roll numbers one below the other. In the systematic sampling procedure we divide N by n to get the sampling fraction (k). Thus in the example k=100/20 = 5. Next we randomly select any number between 1 to k i.e., between 1 to 5. Suppose the number we select is 4. Then the student number 4 is selected in the sample. Thereafter every kth student is selected in the sample until we reach the last one. Thus the student's corresponding to numbers 4, 9, 14, 19, .....99 are to be selected in the sample.

### Cluster Sampling

Cluster sampling is used when the population is heterogeneous. Clusters are formed by grouping units on the basis of their geographical locations. A cluster sample is obtained by selecting clusters from the population on the basis of simple random sampling. From the selected clusters each and every unit is included for study. Cluster sampling is very useful method for the field epidemiological research and for health administrators. A special form of cluster sampling called the "30 cluster sampling" has been recommended by the W.H.O. for field studies in assessing vaccination coverage. In this a list of all villages (clusters) for a given geographical area is made. 30 clusters are selected using Probability Proportional to Size (PPS). From each of the selected clusters, 7 subjects are randomly chosen. Thus a total sample of 30 x 7 = 210 subjects is chosen.

**Multistage Sampling**

In this method the whole population is divided in first stage sampling units from which a random sample is selected. The selected first stage is then subdivided into second stage units from which another sample is selected. Third and fourth stage sampling is done in the same manner if necessary. For example in an urban survey in a state, a sample of towns may be taken first and then in each of the selected towns a second stage sample of households may be taken. If needed further from each of the selected household a third stage sample of individuals may be selected. Since the samples are selected at each stage the method is called multi stage sampling.

**Randomization (Random allocation)**

'Randomization' is different from random sampling. Randomization (or, random allocation) is a method used for allocating selected subjects (already selected by random sampling method) into 2 or more than 2 groups with a view to ensure that these groups are similar in all respects excepting for the drug or vaccine etc that we are interested in administrating to them. Randomization ensures that the treatment groups are comparable with respect to other factors (such as age, sex, severity of illness) which might be associated with the outcome. Hence if a difference in response between groups is seen, we can be confident that this is due to the treatment, rather than due to other factors.

Random allocation can be done in many ways from tossing a coin to using random number tables. For example, keep tossing a coin and all patients who get `heads' get drug `X' and all patients who get `tails' get `Y'. If there are 3 groups (drugs X,Y,Z), toss a die and all patients who get 1 and 4 go to X, 2 and 5 go to Y and 3 and 6 go to Z; or, more scientifically, we should use a random table and all subjects getting even numbers go to `X' and all getting odd numbers get Y.

Let us say, we are having an experimental study in which we are studying a new drug 'X' against an existing drug 'Y'. Our sample size calculations indicated that we will need 10 subjects in each of the groups 'X' and 'Y' (total 20 subjects).

Now, the first step is to decide by any "random" (fair play) process as to which all random members so selected will get treatment 'X' and which will get 'Y'. This we can do by keeping two chits, having written 'X' on one and 'Y' on the other. Similarly, place another 2 chits (with "even" written on one and "odd" written on the other) in another box. Now, ask any impartial observer to pick up one chit from each box. Let us say that chits drawn were 'X' from one box and "even" from the other. Thus, we will give treatment "X" to all even random numbers so selected and "Y" to all odd random numbers. Next, make a table, listing all the 20 patients as seen in Table 12.

Now, select any random starting point from the random numbers table by dropping a pencil. Let us say, out of the 35 rows and 36 columns in our random number table, we picked up the intersection of 29th row and 4th column, i.e. number 9. Now note down this number against patient No. 1. From here we proceed down the 4th column, noting the numbers against the patient's serial numbers and ignoring any zero. Once we come to the end of column 4, we continue with column no. 5 Thus, the next number after 9 is zero hence we ignore it; we take the next number i.e. 7, and write it against patient No.2. The next random member is 8 and we write it against patient No. 3. We continue this process till a random number has been allocated to each of the 20 patients. Now, in the next column of our above table we write down whether the random number selected for the particular patient is odd (O) or even (E). Thus, the random number given to the first patient is 9, i.e., odd and we write 'O' opposite it, similarly we write 'O' and 'E' respectively for 2nd and 3rd patient and so on. Now, in the fourth column with the heading "treatment X and Y" write X for all patients getting 'E' and 'Y' for all patients getting 'O'. The final table will look like in

Table - 12

| Patient No. | Random No. | Even or odd | Treatment (X or Y) |
|---|---|---|---|
| 1 | | | |
| 2 | | | |
| 3 | | | |
| 4 | | | |
| ... | | | |
| ... | | | |
| 20 | | | |
| | | | |

Table - 13

| Patient No. | Random No. | Even or odd | Treatment (X or Y) |
|---|---|---|---|
| 1. | 9 | O | Y |
| 2. | 7 | O | Y |
| 3. | 8 | E | X |
| 4. | 4 | E | X |
| 5. | 1 | O | Y |
| 6. | 1 | O | Y |
| 7. | 7 | O | Y |
| 8. | 8 | E | X |
| 9. | 9 | O | Y |
| 10. | 2 | E | X |
| 11. | 8 | E | X |
| 12. | 7 | O | Y |
| 13. | 1 | O | Y |
| 14. | 8 | E | X |
| 15. | 6 | E | X |
| 16. | 8 | E | X |
| 17. | 8 | E | X |
| 18. | 5 | O | Y |
| 19. | 9 | O | Y |
| 20. | 6 | E | X |

## Miscellaneous Topics

### Qualitative research methods

Till now the research and analysis that we have considered falls into the category of Quantitative Research. Qualitative research in contrast deals with the indepth response of the individual with respect to different issues on which the information is gathered. In other words when it is subjective matter it is best answered by qualitative research techniques rather than quantitative research techniques. Qualitative research gathers information from individuals about the issue of interest. In presence of a particular problem qualitative research explores it in depth understanding the issue with respect to the nature of problem, the reasons of the existence of problem, ways and means of solving it. Qualitative research is more of an answer to "why" as against quantitative research which answers "what". Even if your study isn't perfect in every last detail, you'll still get mostly good results from a qualitative method that relies on understanding users and their observed behavior. The most common methods in qualitative research are personal interviews, Focus Group Discussion (FGDs), case studies and "Observation of Subjects". Although procedures and outcomes of qualitative data analysis differ from that of quantitative techniques, the principles are not so different. In both cases, researchers will have to describe the sample and population, compile and summarize the data. Also the summary data needs to be represented in a way that interpretation becomes easy. At the end we need to draw conclusions.

### Standardization of Mortality Rates

As has been mentioned in the section on Principles of Epidemiology, the crude death rate (CDR) could be different among 2 communities simply because their age structures are different. Hence to scientifically compare the 2 CDRs after removing the confounding effect of age structure on mortality, we use the process called as standardization. Standardization can be done by two methods

(a) Direct method

(b) Indirect method.

Direct Method of Standardization

This is simple and preferred method to calculate the age adjusted mortality rates. To perform a direct standardization, one has to first select a standard population. This population is arbitrary, although conventionally one uses either the World Standard Population produced by the World Health Organization, or a census population for the country in which the work is being conducted. Next, one computes the age-specific rates within the study group. Then, one multiplies these age specific mortality rates by the number of people in that age group in the standard population to get the "expected" number of deaths in each age group in the standard population. These expected counts are summed and divided by the total population size of the standard population to yield the direct standardized rate. In other words the standardized crude death rate in direct method is the crude death rate experienced by standard population if it was exposed to the age specific death rate of the study population.

Indirect Method of Standardization

Indirect standardization uses the standard population to provide age-specific rates i.e. the age specific mortality rates of the standard population are applied to the age structure of the study population. Within each age stratum, one multiplies the age specific mortality rates of the standard population by the number of people in that age group in the study population to determine the "expected" number of deaths that would have been expected in each age group of the study population, had the age specific mortality rates of the standard population been applicable to them. These expected numbers are added up across all age groups. We now divide the observed number of deaths by the expected number of deaths. This ratio is multiplied with the crude death rate of the standard population to yield the Standardized Mortality Rates. In other words in indirect standardization, one computes the number of cases of deaths (or disease) that would have been expected if the death (or disease) rates from the standard population had applied in the study population. This is also known as standardized

# Introduction to Statistical Software for Analysis of Epidemiological and Medical Research : Epi - 2002

## Overview of Epi Info

Epi Info is a package which is most suitable for doctors and researchers. It is a package which sufficies for nearly all the usual clinical research and epidemiological settings. Epi Info is a public domain database and statistics program for performing statistical applications in clinical research. Statistics, graphs, tables, and maps can be produced with simple commands. **Epi Info is free, downloadable software provided by the CDC** (www.cdc.gov/epiinfo/) and has been developed as a joint collaboration between WHO and CDC, Atlanta. In our experience Epi-Info 2002 is the best for all the statistical requirements of most clinical researchers and epidemiologists and it would be worthwhile that we master the use of this programme.

We are providing a copy of EPI 2002 in a CD alongwith this book. A file (sample.dbf) is also given in the CD for you to practice analysis with EPI.

A word of caution, however, is required. Statistical software are actually "enlarged calculators", which make easy your problems of calculation. However, they can never substitute for the essential knowledge of epidemiology, research methodology and bio-statistics. In fact, inadvertent use of statistical software without adequate background of research methodology and biostatistics may create more problems than do good. Secondly, please do remember that no statistical software can substitute for accurate, valid and reliable data. In the field of Information Technology, there is an old saying "Garbage In, garbage Out" (GIGO) !

## Installing Epi Info 2002

You will need to uninstall any earlier versions of EPI that may already be on your system.

(a) On your desktop, click **Start**, then **Programs**, then **Epi Info 2000**, then **Uninstall Epi Info 2000**.

(b) Continue to follow the instructions on your screen.

(c) When this is complete, install the new Epi Info.

### Installation from the Internet

**Step 1** : Log on to CDC's website at www.cdc.gov/epiinfo/epiinfo.htm

**Step 2** : Click the **Download** button to perform a Web Install of the latest Epi Info.

**Step 3** : Save the file to a temporary folder on your hard drive (anywhere except where Epi Info will be stored).

**Step 4** : Go to this temporary folder and double click the **Setupweb.exe** icon for a complete installation by following the directions on your screen. You must be connected to the Internet while this installation occurs. Web Install will NOT result in a copy of setup files after the installation is complete. This means that you will not be able to install the program onto another system with these files. To do so, you must download the Complete Installation Package, then save onto a CD-ROM.

**Step 5** : Begin using Epi Info

### Installation from a CD-ROM

**Step 1** : Insert disc in CD-ROM drive.

**Step 2** : Open **My Computer**, click on **(E:) (CD Drive)**

**Step 3** : Click on **Epi Info** folder and select **Full Version** folder

**Step 4** : Click on **Setup** icon. The Installation Wizard should begin. Follow the instructions as they appear. Most of your selections should be **OK** and **Next.**

**Step 5** : Click **OK** to put Epi Info icon on your desktop. Make sure icon is on your desktop; double click to make sure it works.

**Step 6** : Begin using Epi Info.

## How to Run Epi Info

Once Epi Info is installed on your computer, the easiest way to "run" the software is clicking the Epi Info icon on

your desktop. The Epi Info main menu should then appear:

### Main Menu

The main programs of Epi Info can be accessed either through the PROGRAMS menu or by clicking on the buttons. The components of the Main Menu of Epi Info 2002 are -

MakeView, Enter Data, Analyze Data, Epi Map, Nutrition, Epi Info Website and Exit

Though all these programs are being mentioned we would concentrate on two major programs- Statcalc (assessed

through Utilities) and Analyze Data because these are the major requirements for epidemiologists and clinical researchers.

**Statcalc**

Statcalc is assessed through the dropdown menu in Utilities on the top of the main menu. Statcalc is an epidemiologic calculator that gives various statistical analysis of the data entered in the table form which appears on the screen. Three types of analysis are offered.

(a) Tables (2 x 2, 2 x n)

(b) Sample size and power

(c) Chi square for trend

Each option can be assessed by pressing <Enter>.

**Tables**

It provides statistical analysis of tables (from 2 x 2 to 2 x 9 tables) along with the exact confidence limits for odds ratios. Stratified analysis of 2-by-2 tables can be carried out to produce odds ratios and risk ratios (relative risks) with confidence limits. Several types of chi-square tests, Fisher exact tests, Mantel Haenszel summary odds ratios and associated p values are provided.

Single 2-by-2 Tables

2-by-2 tables are frequently used in medical research to explore associations between EXPOSURE (to risk factors or the intervention in a clinical trial) and DISEASE (or other outcomes, if the outcome is not a disease but rather improvement from disease as may occur in a clinical trial). The table in STATCALC is set up with EXPOSURE on the left and DISEASE across the top. STATCALC produces results that test for relationships between EXPOSURE and DISEASE. The 2X2 layout is given in Table - 1.

Table - 1 : 2 X 2 Table

| | Disease present (D+) | Disease Absent (D-) | Total |
|---|---|---|---|
| Exposure present(E+) | a | b | a+b |
| Exposure Absent(E-) | c | d | c+d |
| Total | a+c | b+d | a+b+c+d |

The details of 2 X 2 table have already been covered in detail in the sections on Epidemiology and Research Methodology. When a 2 x 2 table appears on the screen we need to enter four numbers in the table. To do this enter the number in the first cell and press <Enter>, the cursor goes in the next cell. Again enter the next cell entry and press <Enter> to go to the next cell. (If any entry is wrongly entered this option does not allow you to edit hence you have to keep on pressing <Enter> till we are back to the empty 2 x 2 table). After the entry in the 4$^{th}$ cell press <Enter> or <F4> to calculate the single table statistics showing associations between EXPOSURE to the risk factor and DISEASE or other outcomes. Generally an association is suggested by an odds ratio or relative risk. The statistical significance is interpreted by 'p' values for chi square tests.

Pressing <Enter> or <F4> displays the statistical result which gives all the summary statistics i.e. Odds ratio along with the 95% confidence interval, Relative Risk along with 95% confidence interval. Remember that only one of these will be appropriate so don't quote both. You will also get some test statistics, such as $X^2$ values. If the computer says that Cornfield not accurate, you can generally ignore this, but take advice from Epidemiologist or Statistician. Depending on the study design (a case-control or a cohort or a cross sectional design) we should select summary statistics (as either OR or RR). Generally, an association is suggested by an odds ratio or relative risk larger or smaller than 1.0. The further the odds ratio or relative risk is from 1.0, the stronger the apparent association. The significance is assessed by the p value. Whenever $p<0.05$ it is considered to be statistically significant; also when the confidence limits for the odds ratio do not include 1.0 it is significant. Whenever the frequencies entered in the table are very small (<5) the program recommends Fisher Exact Test Results and the Exact confidence limits to be used.

Consider an example where we picked up 100 diagnosed patients of IHD from our Cardiology centre and another 100 subjects from the same centre in whom IHD had been excluded (Total = 200). We took the history from each and every one regarding smoking. Suppose we observed from our data that out of the 100 IHD cases, 80 were smokers and 20 non-smokers; while out of 100 healthy (non-IHD) subjects, there were 20 smokers and 80 non smokers. We would then consolidate our data into a '2 X 2' table. Data is given in Table - 2

Table - 2

| | Disease present (D+) | Disease Absent (D-) | Total |
|---|---|---|---|
| Exposure present(E+) | 80 | 20 | 100 |
| Exposure Absent(E-) | 20 | 80 | 100 |
| Total | 100 | 100 | 200 |

Once we enter this data, press <Enter> or <F4> to get the table statistics.

Analysis of Single Table
**Odds ratio = 16.00 (7.60<OR<34.18)**
Cornfield 95% confidence limits for OR
Relative Risk = 4.00 (2.67<RR<5.99)
Taylor Series 95% confidence limits for RR
Ignore relative risk if case control study.

| | Chi-Squares | P-values |
|---|---|---|
| Uncorrected : | 72.00 | 0.0000000 |
| Mantel-Haenszel : | 71.64 | 0.0000000 |
| Yates corrected : | 69.62 | 0.0000000 |

F2 More Strata; <Enter> No more Strata; F10 Quit

On pressing <Enter> or <F4> following analysis is provided

The output given by the software includes the odds ratio as well as the relative risk along with the 95% confidence interval (which is shown in parentheses after the value of OR or RR. Depending on our study design we select between the two estimates. If the study design is a case control study (as was in this example) then select odds ratio (OR) along with 95% confidence limits. If the study design is a cohort study then select RR and if cross sectional then also select the odds ratio which is approximately equal to the prevalence odds ratio. Whether you select the RR or OR, also select the chi square along with the p value for mentioning in your results. To be on the safer side, select Mantel-Haenszel Chi-square along with the p value.

### Stratified Analysis of 2by2 tables

Associations between DISEASE and EXPOSURE can be missed or falsely detected if CONFOUNDING is present. A confounding factor is one that is associated with both the DISEASE and the EXPOSURE. Age is a frequent confounder. Any factor other than the main EXPOSURE being considered can be treated as a confounder. For details on confounding and its control refer to chapter on confounding in Research Methodology section.

Stratification means making a separate table of DISEASE by EXPOSURE for each possible combination of confounders. In the simplest case, this could mean separate tables for males and females, if SEX is the potential confounder. If AGE, SEX, and CITY are confounders, separate tables would be made for each possible combination of age, sex and city. The Mantel-Haenszel weighted odds ratio, relative risk, summary chi square and p value combine results from different strata to remove confounding caused by the variables used for stratification. Thus, if tables are entered for males and females, confounding by SEX will be removed. The degree of confounding can be judged by comparing the crude and weighted odds ratios; if they are identical, there was no confounding by SEX. The approximate and exact confidence limits provide additional measures. If the weighted odds ratio or relative risk has confidence limits that do not include 1.0, then there is a significant statistical association between the DISEASE and the EXPOSURE, after controlling for confounding by the stratifying factor.

Consider following example. A study was done to see whether consumption of alcohol is a risk factor for oral cancer. 100 cases of oral CA and 100 healthy subjects were asked regarding history of alcohol consumption during past 15 years. The results are shown in Table - 3.

Table - 3

| History of Alcohol | Oral cancer | | |
|---|---|---|---|
| | Present | Absent | Total |
| Present | 80 | 20 | 100 |
| Absent | 20 | 80 | 100 |
| Total | 100 | 100 | 200 |

Analysis of Single Table
**Odds ratio = 16.00 (7.60<OR<34.18)**
Cornfield 95% confidence limits for OR
Relative Risk = 4.00 (2.67<RR<5.99)
Taylor Series 95% confidence limits for RR
Ignore relative risk if case control study.

| | Chi-Squares | P-values |
|---|---|---|
| Uncorrected : | 72.00 | 0.0000000 |
| Mantel-Haenszel : | 71.64 | 0.0000000 |
| Yates corrected : | 69.62 | 0.0000000 |

F2 More Strata; <Enter> No more Strata; F10 Quit

(Also see chapter on Confounding in the section on Research Methodology). Enter the four numbers in the 2 X 2 table on the screen.

Press <Enter> or <F4>. On pressing <Enter> or <F4> the following output is given.

Since above is a case control study we select **odds ratio = 16** which concludes that the risk of getting oral cancer is 16 times higher if a person drinks alcohol.

Now we also know that tobacco use is related to oral cancer. Hence stratifying the data by Tobacco status, we have two tables, one for tobacco users and the other for non-users of tobacco. This becomes stratified 2 X 2 tables with 2 stratums. In this case enter the four numbers for the first stratum and press <F4> or <Enter> to calculate the related statistics. Press <F2> to enter another stratum. Enter the four numbers for this second stratum and press <F4> or <Enter>. Repeat the process for all the stratums available. Pressing <Enter> when there are no more stratums will present the stratified analysis summary for all strata entered. Pressing <Enter> again will then offer an opportunity to do exact confidence limits. Stratified

analysis are not done for tables larger than 2-by-2

| History of Alcohol | Oral cancer | | |
|---|---|---|---|
| | Present | Absent | Total |
| Present | 60 | 15 | 75 |
| Absent | 20 | 5 | 25 |
| Total | 80 | 20 | 100 |

Analysis of Single Table
**Odds ratio = 1.00 (0.28<OR<3.46*)**
Cornfield 95% confidence limits for OR
*Cornfield not accurate. Exact limits preffered.
Relative Risk = 1.00 (0.80<RR<1.25)
Taylor Series 95% confidence limits for RR
Ignore relative risk if case control study.

| | Chi-Squares | P-values |
|---|---|---|
| Uncorrected : | 0.00 | 1.0000000 |
| Mantel-Haenszel : | 0.00 | 1.0000000 |
| Yates corrected : | 0.08 | 0.7728300 |

F2 More Strata; <Enter> No more Strata; F10 Quit

In the example considered the stratums for Tobacco users and non-Tobacco users are as follows. Substituting the values for first stratum and pressing <Enter> or <F4>

| History of Alcohol | Oral cancer | | |
|---|---|---|---|
| | Present | Absent | Total |
| Present | 5 | 20 | 25 |
| Absent | 15 | 60 | 75 |
| Total | 20 | 80 | 100 |

yields the following output

**Stratum I : Tobacco users**

Since we have one more stratum of non-Tobacco users we press <F2>.

**Stratum II : Non users of Tobacco**

On pressing <F2> another 2 X 2 table appears on the screen. Enter all the four cell values for non-Tobacco users and press <Enter>. The following output appears on the screen.

Analysis of Single Table
**Odds ratio = 1.00 (0.28<OR<3.46*)**
Cornfield 95% confidence limits for OR
*Cornfield not accurate. Exact limits preferred.
Relative Risk = 1.00 (0.40<RR<2.47)
Taylor Series 95% confidence limits for RR
Ignore relative risk if case control study.

| | Chi-Squares | P-values |
|---|---|---|
| Uncorrected : | 0.00 | 1.0000000 |
| Mantel-Haenszel : | 0.00 | 1.0000000 |
| Yates corrected : | 0.08 | 0.7728300 |

F2 More Strata; <Enter> No more Strata; F10 Quit

Stratified Analysis
**Summary of 2 Tables**
Crude odds ratio for all strata = 3.45
Mantel-Haenszel Weighted Odds Ratio = 1.00
Cornfield 95% Confidence Limits
0.41 < 1.00 < 2.37
Mantel-Haenszel Summary Chi Square = 0.04
P Value = 0.83907676
Crude RR for all strata = 1.86
Mantel-Haenszel Weighted Relative Risk
Of Disease, given Exposure = 1.00
Greenland / Robins Confidence Limits =
0.77 < MHRR < 1.29
<Enter> for more; F10 to quit

Since no more stratum are available press <Enter>. On pressing <Enter> the stratified analysis or the summary of 2 tables appears on the screen as follows:

**The odds ratio for each table is 1.0 and the Mantel-Haenszel summary odds ratio is 1.0.** The crude odds ratio and the Mantel Haenszel summary odds ratio are quite different, leading to the conclusion that use of tobacco was a confounding factor and that there appears to be no risk of cancer due to alcohol after considering the effect of tobacco.

### Sample Size & power

Determining sample size is a very important issue, as already emphasized in the section of biostatistics. In the sample size calculations, an initial screen explains the data items and allows input of a single set of values.

Pressing <F4> then shows the results on the second screen. On pressing Sample size & power three options are

made available

(a) Population Survey

(b) Cohort or cross-sectional

(c) Unmatched case-control

**The screen is as follows**

Sample size calculations are possible by both **Statcalc** as well as **EpiTable**. However if you are calculating the sample size for population survey, we recommend that you use EpiTable programme that is separately given for sample size calculations, and not Statcalc. For cohort, cross sectional and unmatched case-control design you can calculate by either EpiTable or Statcalc. For matched pair case-control design calculate sample size using Epi Table.

Population Survey

We recommend the use of EpiTable, described later.

Cohort or cross-sectional studies

For this type of study the proportion of disease in the unexposed group and the relative risk that the study anticipates to detect needs to be specified. Also the confidence interval along with desired power of the study requires to be specified. Once all the specifications are filled up, pressing <F4> calculates the minimum required sample size for our study.

Consider following study. We want to try acetazolamide as a prophylactic therapy against the development of High Altitude Pulmonary Oedema (HAPO). Our background information based on available data tells us that till now people have not been taking Diamox (i.e., are `not exposed' to Diamox) and 10 out of every thousand such persons develop HAPO; thus proportion of `outcome' (HAPO) among those who are `not exposed' (i.e., not taking Diamox) is 10/1000 = 0.01 or 1%.

Considering the cost and problems of logistics, we would say that putting this prophylactic therapy into routine preventive use will be worthwhile only if Diamox reduces the load of HAPO by at least 50%; thus the minimum detectable RR = 0.5. We specify an alpha error of 0.05 (two tailed) (i.e., confidence level of 95%) and beta error of 0.20 i.e. power of 80%.

Substituting the required values as above the required minimum sample size is obtained by pressing <F4>. The result screen is as follows.

Thus we would require a total of 10130 subjects to be studied, 5065 subjects who would get Diamox and another 5065 subjects who would not get any drug.

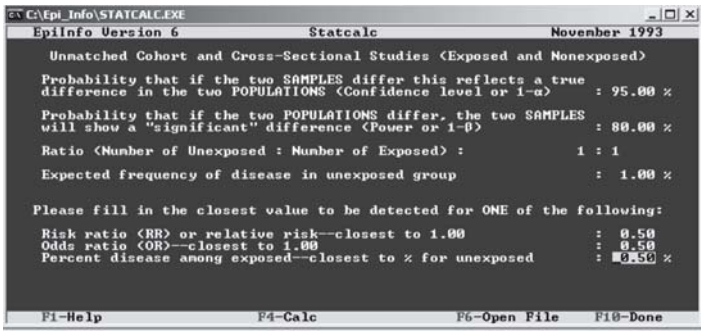
Case-control study

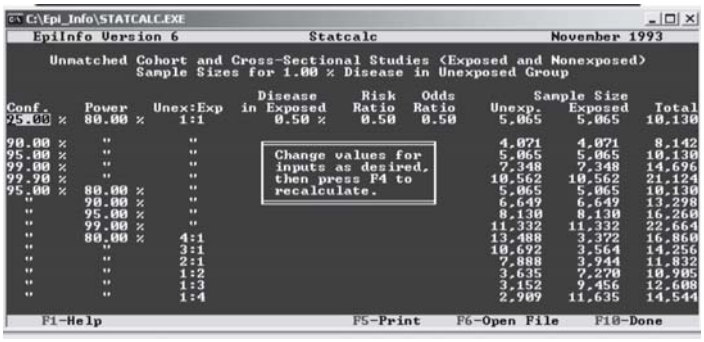
This option deals with the sample size determination when the study design is case control study. For this type of study the proportion of exposure in the not ill group (control) and the odds ratio that the study anticipates to detect needs to be specified. Also the confidence interval along with desired power of the study requires to be specified. Once all the specification is filled up pressing <F4> calculates the minimum required sample size for our study.

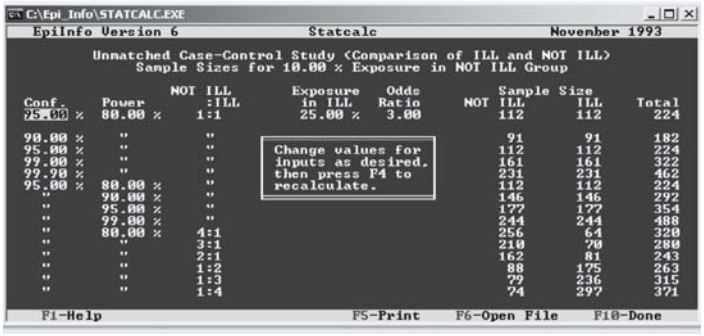
Continuing the same situation of HAPO, a research study wanted to find out whether even a slight physical exertion during first 24 hours of entry into high attitude may be associated with the development of HAPO. To proceed with this question as a case-control study, we want to take up cases of HAPO admitted to the hospital and healthy subjects who did not develop HAPO as a control group. Our background information from pilot study gives an indication that out of the healthy persons who did not develop HAPO (i.e., in whom outcome is absent), about 10% did engage in physical exertion within 24 hours after entry into high altitude (i.e., had the `exposure' to physical exertion); thus percentage of exposure among controls is 10% or 0.1. We think that physical exertion during first 24 hours should carry at least 3 times higher risk for developing HAPO; a risk less than this may not have public health significance since the administrators may not agree to “waste” so many man-days in rest if the risk is not really high (3 times). Thus, the minimum detectable OR that we choose is 3.

Once all the required information is substituted in the Case-control study screen and press <F4> the required minimum sample size is displayed on the screen as under.

Thus a total of 224 subjects are needed. In other words we



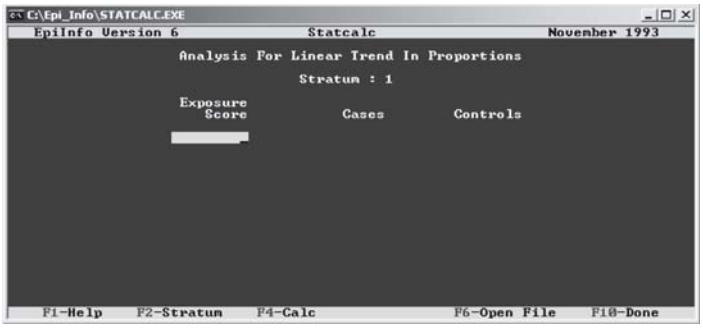




will we will need 112 cases OF HAPO and another 112 healthy controls to do this study.

**Chi Square for Trend**

Many times the variables of interest are measured on qualitative polychotomous ordinal scale, i.e., there are more than two exposure categories and these multiple



categories have a definite common-sense ordering . In such situations, it is advisable to do the chi-square test for linear trend in proportions and not a simple chi-square test for rXc contingencey table. The Chi Square for trend tests whether the odds (risk) increase or decrease in each group with respect to the first group, which is taken as the baseline for comparison. Epi calculates the chi-square for trend there are at least three or more exposure levels and which have a sensible ordering of categories. For this we have to choose Chi square for trend and press return (<enter>). The screen looks as under

You have to choose an exposure score. The first category should be your unexposed (or least exposed) group. Choose 1 as their exposure score, then go on to fill in the cases and controls columns, which refer to the outcome. Fill in your next group as the next least exposed. Typically their exposure score would be 2 and the next group's 3 and so on. When you have entered all your data, press F4 which will calculate the $X^2_{trend}$

This statistic always has 1 degree of freedom. Also the p value is given to you. When finished press F10 to exit.

Consider an example to understand this concept in detail. Suppose we have a hypothetical cohort study, which was undertaken to assess whether smoking by mothers during pregnancy is a possible determinant of congenital malformations in the foetus. Let us assume that a total of

| Exposure Category (Exposure | Smoking habits during pregnancy (Exposure score) | Status of delivered child | |
|---|---|---|---|
| | | Congenital Malformation (cases) | Normal (controls) |
| 1 | Non-smokers | 81 | 1995 |
| 2 | 1 to 10 cigg/day | 10 | 162 |
| 3 | 11 20 cigg/day | 28 | 115 |
| 4 | > 20 cigg/day | 21 | 50 |
| | Total | 140 | 2322 |

2462 pregnant ladies were taken up and their average daily cigarette consumption was assessed. 2076 ladies

**Analysis for Linear Trend In Proportions**

Chi Square for linear trend : 128.167
p value : 0.00000

| Exposure Score | Odds Ratio |
|---|---|
| 1.00 | 1.00 |
| 2.00 | 1.52 |
| 3.00 | 6.00 |
| 4.00 | 10.34 |

were non smokers, while 172, 143 and 71 were smoking upto 10 cigarettes, 11 to 20 and more than 20 cigarettes per day respectively. It was observed that 81 (i.e. 3.09%) of the non-smoker mothers delivered congenitally malformed children. The proportion of such malformed children increased progressively. It was 10, 28and 21 as the smoking category increased respectively. Putting the following information in a table form we have the following, which is clearly an qualitative, ordinal, polychotomous data :

After entering all the numbers in the table, pressing <F4> gives the following output

Interpretation

There exist highly significant linear trend in the odds of successive levels of the smoking and congenital malformation. The odds of congenital malformation in ladies who are smoking 11-20 cigg/day increases by 6 times and in ladies who smoke > 20 cigg/day the odds increases by more than 10 times as compared to non

smokers. In addition with a p value of < 0.0001, this overall 'trend' (of increasing risk of congenital malformation with increasing smoking) is statistically very highly significant.

## Epitable

EPITABLE is statistical calculator with many statistical functions and graphs which you should become acquainted with to carry out various research analysis. EPITABLE is separately given in the CD with this book. This programme can be accessed by first pressing on the EPI6 icon and then subsequently pressing EPITABLE calculator through Programs. The EPITABLE appears as below.

The components of Epitable are:

(a) Describe
(b) Compare
(c) Study
(d) Sample
(e) Probability
(f) Setup

**Describe**

This option calculates confidence intervals around an estimate of a proportion, a mean, or a median.

Proportion

| **Simple random sampling** | |
|---|---|
| Numerator | : 12 |
| Total observations | : 997 |
| Proportion | : 1.2036% |
| Fleiss quadratic 95% CI | [0.6534 2.1552] |
| Exact binomial 95% CI | [0.6234 2.0930] |
| Mid-p 95% CI | [0.6538 2.0372] |
| **Select the Exact binomial 95% CI** | |

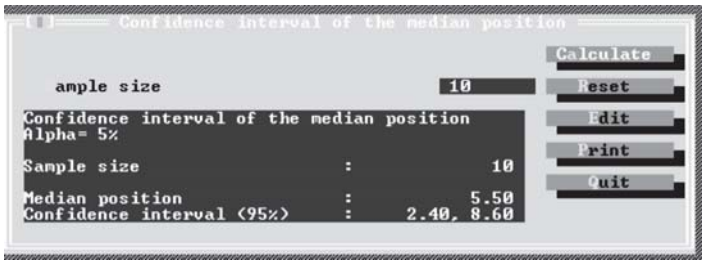
Confidence interval is calculated for proportions estimated from simple random samples or cluster samples. Three methods for calculating confidence intervals of a proportion are presented. These are Fleiss quadratic, exact binomial and mid-p.

**Example :** Suppose in a survey we wish to detect the seropositivity for HIV in blood donors. Total of 997 cases are considered. Out of these 12 are found to be positive. In the describe dropdown menu select the proportion option and then select Simple random sampling. Substitute 12 in the numerator and 997 in the denominator. On pressing calculate, the following output is given.

Mean

This command provides the confidence interval of a mean using the alpha risk specified in the setup option. The inputs required are the mean and the standard deviation values for the given data. If the size of the population from which the sample is taken is not known, we should use the default maximum value of 999999999.

Let us consider an hypothetical example where 10 volunteers are weighed in a consistent manner before they start consuming an experimental diet. Weights in kg for these 10 volunteers are as follows, 81, 79, 92, 112, 76, 126, 80, 75, 68, 78. We calculate the mean in the usual manner by adding all the observations (weights) and then dividing by 10 to give us the mean weight as 86.7. Similarly we calculate the standard deviation which is equal to 18.33. Now if we wish to calculate the 95% confidence interval for mean we select 'Mean' and substitute the requisite information, i.e. value of mean as 86.7, Sample standard deviation as 18.33 along with the sample size as 10. On pressing calculate following output

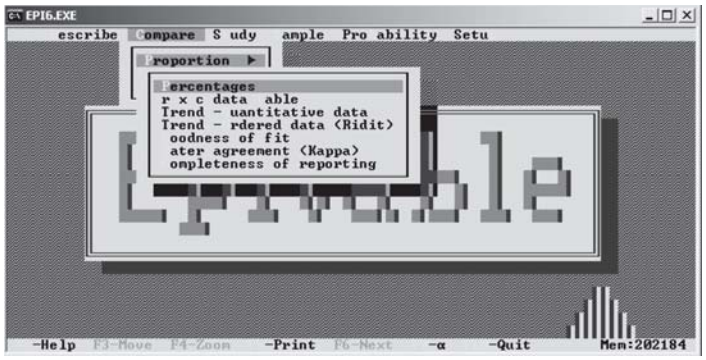


renders the 95% confidence interval.

Median

This option gives the confidence interval of a median using the alpha risk specified in the setup option. The inputs required are the median and the sample size for the given data. For example we ask the 10 patients attending OPD to evaluate his pain on a scale of 0 (no pain) to 10 (the worst pain). The scores given by the patients are 3,4,2,6,1,8,1,9,3,6.

**Note that the package gives the median position along with 95% confidence interval for median position and not the median value.**



The median score of pain after arranging the patients in ascending order is 3.5 which is the middle most position i.e. 5.5.

**Compare**

This menu compares the **proportions**, **means** and **variances** using various statistical methods. Under proportion menu following components are available:

Proportion

This option compares several proportion expressed either as percentages, rows or columns, quantitative or qualitative manner using the chi square test. The various

| | | |
|---|---|---|
| $Chi^2$ | : | 7.34 |
| Degrees of freedom | : | 1 |
| p value | : | 0.006748 |

options available are as follows.

**Percentages**

When we have the percentages in the two groups which we

are interested to compare we use this option. The program requires the percentage values along with the sample sizes for each group. On analyzing it gives the chi-square statistics along with the significance value i.e. p-value. Consider an hypothetical example where we sampled 55 males in their adolescent ages. 44% of them were obese. Another sample of 149 females had 24% obese ladies. To test whether from the sampled populations the proportion of obese males was comparatively higher than that of females, we use the Percentage option of Proportion in Epitable.

**Since p<0.05 we reject the hypothesis i.e.** we can conclude that there is significant difference in proportion of obese. In other words we say that the percentage of obese males is greater than percentage of obese females in the sampled population.

**Chi square for r x c data table**

This is applicable when we have qualitative data in terms of counts which can be compiled in terms of rows and columns. The procedure is as follows. First indicate the number of rows and the number of columns. Then enter the data for each cell. Chi square calculation will be performed when the calculate button is selected. The percentage of cells with an expected value <5 is returned if any such cells are found. When more than 10% of the cells have expected values <5, chi square calculation is no longer recommended. The chi square calculation is not

| Mothers | Status of delivered child | |
|---|---|---|
| | Congenital Malformation | Normal |
| Upto 35 years of age | 50 | 950 |
| > 35 years | 50 | 450 |

valid if there are expected cells with values <1. In this case, an error message is displayed.

| Chi square calculation | | |
|---|---|---|
| $Chi^2$ | : | 13.39 |
| Degrees of freedom | : | 1 |
| p value | : | 0.000253 |

Let us illustrate the procedure of Chi-square for r x c table using the hypothetical example on the association between maternal age and congenital malformations. Let us say, we started with the research issue by taking two groups of mothers, one group upto 35 years of age and other above 35 years of age. We took a sample each, 500 pregnant ladies aged > 35 years and another 1000 pregnant ladies aged upto 35 years and followed them till delivery. We found that out of the 500 children born to ladies > 35 years, 50 had congenital malformations, while out of 1000 ladies upto 35 years, there were again 50 children born with congenital malformations. Converting it into a 2 x 2 table.

Substitute all the observed frequencies and press calculate. The following output is displayed.

Since p<0.05 we can conclude that there is statistically significant association or that there is a definite relationship between advanced maternal age (>35 years) and congenital malformations in the offspring.

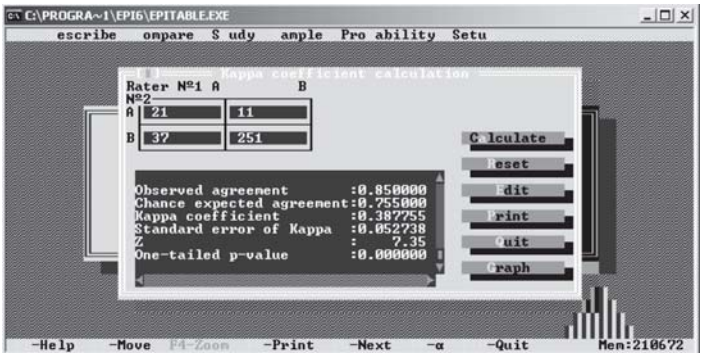
**Trend Quantitative data**

This is same as discussed under chi square for trend in 'Statcalc' and hence is not repeated here.

| Lab Technician's Diagnosis | Microbiologist's Diagnosis | | |
|---|---|---|---|
| | Positive | Negative | Total |
| Positive | 21 | 11 | 32 |
| Negative | 37 | 251 | 288 |
| Total | 58 | 262 | 320 |

**Two rater agreement (Kappa)**

This allows us to measure the inter observer reliability. The consistency of measurement by different observers is



assessed by kappa coefficient. This measure is carried out only for categorical data upto 6 categories. Each cell of the table corresponds to the count of observation classified by rater 1 and rater 2. For example we may be desirous of undertaking a study on Pulmonary TB, with AFB on sputum smear as the method of measurement. Let us say we are using Laboratory technicians to examine the sputum slides after training given to them by microbiologist. For doing an inter observer reliability assessment (between the microbiologist and Lab technician) we took 320 stained slides and eah slide was examined by both of them. The results are as follows:

On pressing Rater Agreement (Kappa) and substituting the values as given above the following output is rendered.

The Kappa coefficient of 0.38 is interpreted as moderate agreement.

**Means**

This option performs a test (F test), which is equivalent to a student's t test for 2 samples. This test is not valid if all samples come from

| | |
|---|---|
| Variance between samples : | 2135.62 |
| Residual variance | : 901.95 |
| F Statistic | : 2.37 |

normally distributed populations with variances not statistically different.

Consider a hypothetical data of a research study to answer the question whether the serum cholesterol of healthy adult males, living in hot desert areas is, on an average, different (ie., significantly higher or lower) from the average serum cholesterol of healthy young males living in temperate climates. The serum cholesterol values of 12 subjects from the deserts yielded a mean value of 216.25 mg/dl with variance of 795.24 mg/dl. Similarly 14 subjects from temperate climate yielded a mean value of 198.07 mg/dl with variance of 992.25 mg/dl.

The details of the two population means along with variance ($SD^2$) and sample size are substituted to give us following output.

Since p>0.05 we accept the null hypothesis i.e. we can conclude that Serum Cholesterol levels of healthy adult males, living in hot desert areas is, on an average, **not different** from the average serum cholesterol of healthy young males living in temperate climates.

**Study**

This option gives methods of measuring association for cohort and case control studies. Different methods for measuring vaccine efficacy are also presented. There are various methods available. The control method uses the proportion of population vaccinated and the proportion of cases vaccinated. Methods based on the estimation of attack rates in cohort study, estimation of odds ratio in case control and matched case-control study is given. Also measures of parameters in screening studies are performed using this module. Examples are not carried out for each.

It is expected that students solve few modules on their own with real life data set.

The screen appears as given below.

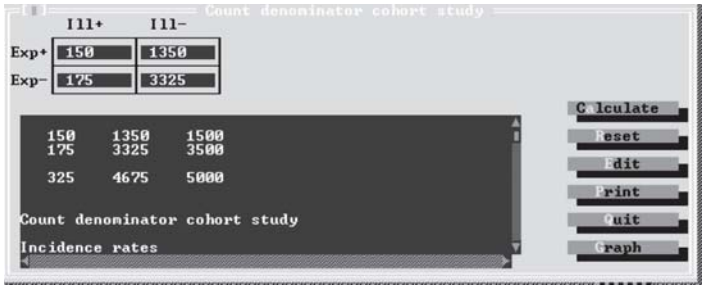
Cohort / cross sectional

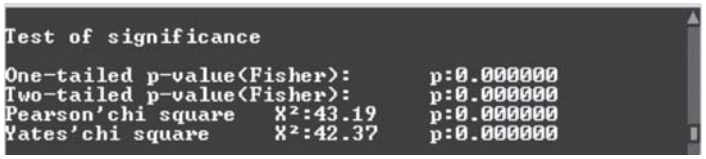
Cohort/cross sectional (In cohort study, associations are measured for data tables with cumulative incidence and incidence density). In stratified cohort studies, after specifying the number of strata, associations are measured on cumulative incidence and incidence density

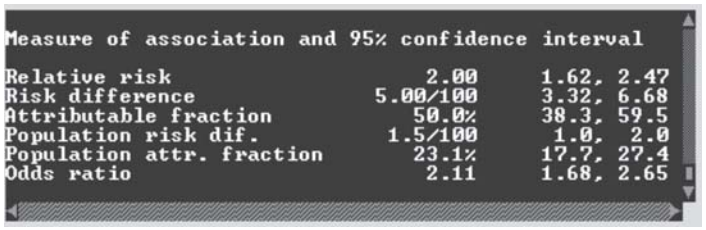
(a) Cumulative incidence

(b) Incidence density

| | III+ | III- |
|---|---|---|
| Exp+ | 150 | 1350 |
| Exp- | 175 | 3325 |







(c) Stratified, cumulative

(d) Stratified, density

Please compare the results as they are shown in the above screen with the calculations of RR, AR and PAR% which were calculated for the same example in the chapter on "Measurement of Risk" in the section on epidemiology.

Case-control

(a) Unmatched

(b) Matched 1:1

(c) Matched 1:2

(d) Stratified

For example, if we take 5000 healthy adult males in whom IHD was excluded based on history of smoking and resting/exercise ECG. Then, on asking them about history of smoking we found that 1500 were smokers and 3500 non-smokers. We followed up these 2 groups (1500 smokers and 3500 non-smokers) for 20 years and observed that during this period there were 150 cases of IHD among smokers and 175 cases of IHD among non-smokers.

Thus substituting the values of this 2 x 2 table on the screen as

Depending whether the cases and controls are unmatched or matched in the ratio of 1:1 or 1:2 (1:2 means number of controls will be twice the number of cases) we select that particular option

On pressing Calculate following output is given. Again depending on the type of study carried out the correct statistics is selected.

Please refer to our example on odds ratio in the chapter on "Measurement of Risk". We observed from our data that out of the 100 IHD cases, 80 were smokers and 20 non-smokers; while out of 100 healthy (non-IHD) subjects; there were 20 smokers and 80 non smokers. Substituting the values in a 2 x 2 table and pressing calculate gives the following output on the screen.

Vaccine efficacy

| Output | | |
|---|---|---|
| **Measures of association and 95% confidence interval** | | |
| Odds ratio: | 16.00 | 8.00, 31.99 |
| Attributable fraction | 93.8% | 87.5, 96.9 |
| **Exact confidence limits of the odds ratio** | | |
| Fisher: | 7.6013 | 34.0195 |
| Mid-p: | 7.9638 | 32.1333 |

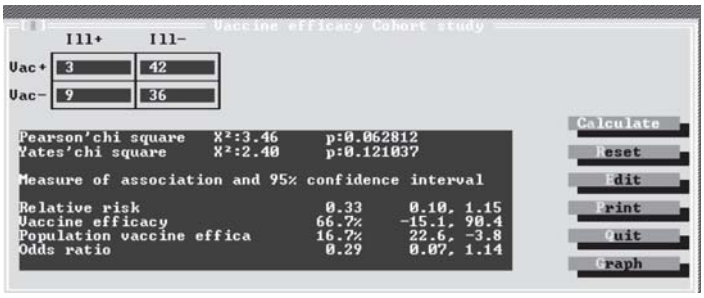
(a) Control method
(b) Cohort study
(c) Case-control study
(d) Matched case control study 1:1
(e) Matched case control study 1:2

Vaccine efficacy is measured by comparing Attack Rates among Vaccinated and Attack Rate among Non vaccinated people. There are four different methods presented which corresponds to different approaches for measuring or estimating Attack Rates among Vaccinated and Attack Rate among Non vaccinated people. The first method i.e. control method is not very precise method. Also confidence interval cannot be calculated unless denominators are known for calculation of various proportions. Other methods are used depending on the study design.

Let us take an hypothetical example where isoniazid chemoprophylaxis and development of tuberculosis is studied. The information gathered is set in the form of a 2 x 2 table.

| Exposure | Outcome | | |
|---|---|---|---|
| | Developed TB | Did not develop TB | Total |
| Given isoniazid (intervention group) | 3 | 42 | 45 |
| Not given isoniazid (Control group) | 9 | 36 | 45 |
| Total | 12 | 78 | 90 |

Substituting all the four cell values of the cohort study with the aim to find beneficial effect of the drug or vaccine we press Calculate.



This yields us the efficacy of 66.7% and hence we conclude that insoniazid chemoprophylaxis reduces the occurrence of TB in close contacts by 66.7%.

Screening

This option is used to evaluate the performance of a diagnostic test. On substituting the true+ and true- values (Gold standard + and - values) and the test+ and test- values the option gives the sensitivity, specificity along with the Predictive value positive and predictive value negative.

Consider an example on evaluating the performance of ELISA as a diagnostic test for HIV infection as compared to the gold standard as PCR. We took 1,00,000 subjects and subjected each and every one of them to both, the ELISA as well as the PCR tests. After substituting the values of a=990, b=9900, c=10 and d=89100 in the table the following output is given.

| Screening | | |
|---|---|---|
| **Measures of association and 95% confidence interval** | | |
| Sensitivity | 99.0% | 98.1, 99.5 |
| Specificity | 90.0% | 89.8, 90.2 |
| Predictive Value Positive | 9.1% | 8.6, 9.7 |
| Predictive Value Negative | 00% | 100.0, 100.0 |

The interpretation of each of the parameters listed above is explained in detail in the section on Research Methodology.

**Sample**

On pressing sample following options are made available.

(a) Sample size
(b) Power Calculation
(c) Random number table
(d) Random number list

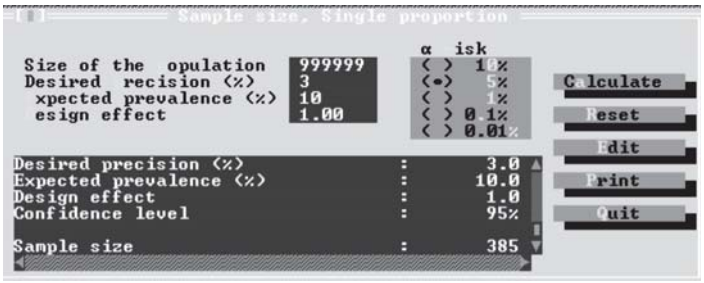
Sample size

The first option gives the desired number of minimum sample size required for the various studies. The parameter under consideration can be single proportion or two proportions. Also sample size can be calculated for cohort and case-control studies.

**Single proportion**

Let us understand this with an example. Suppose a study on gestational diabetes is undertaken. The expected proportion is p=10% with the desired precision or acceptable deviation as 7% to 13% i.e. 3% on either side.(d=0.03). We specify the alpha error as 5%. To estimate the minimum sample size for the above proposed study we first have to press sample and then select the first option single proportion which displays the screen requesting the information on the size of the population, desired precision (%), expected prevalence (%) and design effect. Design effect is a bias introduced in the sampling design and is taken as 1 which means that there is no design effect. (Note: In case of cluster sampling the

design effect is taken as 2). After substituting the required

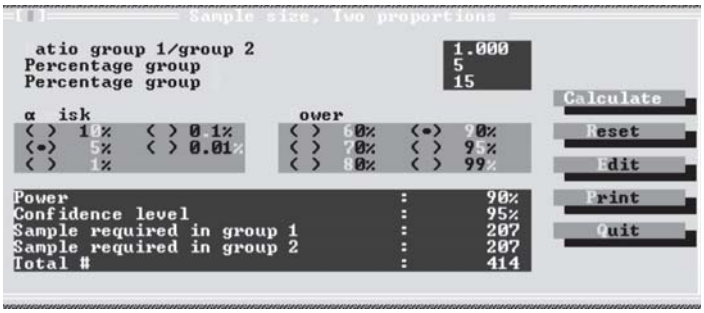


information press calculate.

The required minimum sample size is calculated as 385.

**Two proportions**

This option is used when we are interested in comparing two groups with respect to variable of interest. The specifications required are the anticipated or expected proportions in both the groups along with the alpha error and power of the test. Let us calculate the sample size for the following situation. Suppose the proportions of patients who develop complications after a particular type of surgery is 5% while the proportion of patients who develop complications after another type of surgery is 15%. We wish to test whether the second surgery has more complication rate than the first type of surgery with a power of 90%. The level of significance or type I error is assumed to be 5%. In this given situation to arrive at the number of patients that would be required in each group we first press sample size from the menu sample. From the sample size select Two Proportions. After specifying the requirements as given above and then pressing



Calculate the results on the screen appear as follows:

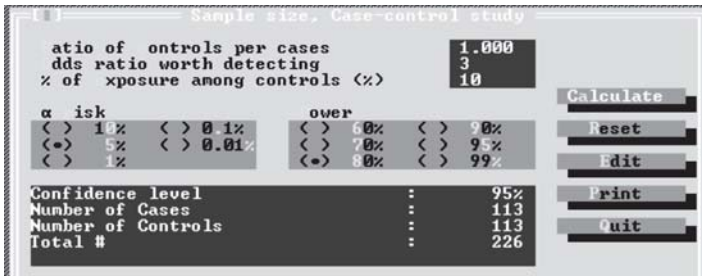
Thus a total of 414 i.e. 207 patients in each group are required to study.

**Cohort study**

Refer back to the example on HAPO which was considered for sample size determination using Statcalc. Substitute the required values of attack rate among non exposed as 1% and the detectable RR as 0.5. Also substitute the alpha error and power as 5% and 80% respectively. After pressing Calculate the minimum required sample size is 10134. In other words we would require to study 5067 subjects who would get Diamox and another 5067 subjects who would not get any drug.

**Case control study**

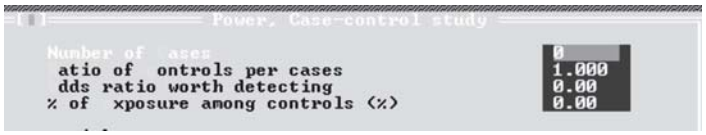
Refer back to the example on HAPO which was considered for sample size determination using Statcalc. Substitute the required values of percentage of exposure among controls as 10% the OR worth detectable as 3. Also substitute the alpha error and power as 5% and 80% respectively. After pressing Calculate the minimum required sample size rendered is 226. In other words we will we will need 113 cases OF HAPO and another 113



healthy controls to do this study. (Note that the sample size determined are almost same when calculated by sample size option of Statcalc)

Power calculation

The power calculation option calculates the power of the study. It is the complement of the beta error. In other



words it is the probability of making the correct decision. It can be calculated in both the cohort studies and case-control studies. The specifications required in both the situations are as under.

Substitute the sample size along with alpha error and other information of the study. Pressing Calculate reveals the power of the study.

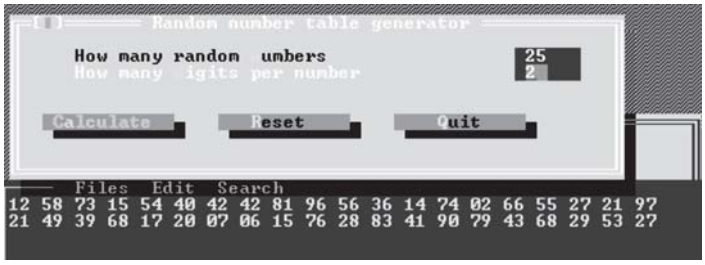
Consider the two examples that we have discussed above in the sample size determination option for cohort and case-control study. If we substitute retrospectively all the specification (except power) taken into consideration including sample size which was calculated. On pressing Calculate the power of the study is detected as 80% for cohort study and 84% for case-control study.

Please note that the calculations for sample size and power by the package differ from the manual way of calculations by slight margin. Hence it is recommended that for calculation of sample size and power the reader preferably uses the ready tables from WHO manual.

Random number table

This option generates a table of random numbers with a specified number of digits. Available options include the number of digits of generated numbers, as well as the total number of random numbers generated.

**Example :** Let us consider a hypothetical study where we require selecting 25 subjects by simple random sampling technique using random number method. Thus we want to generate 25 random numbers. On the screen we specify



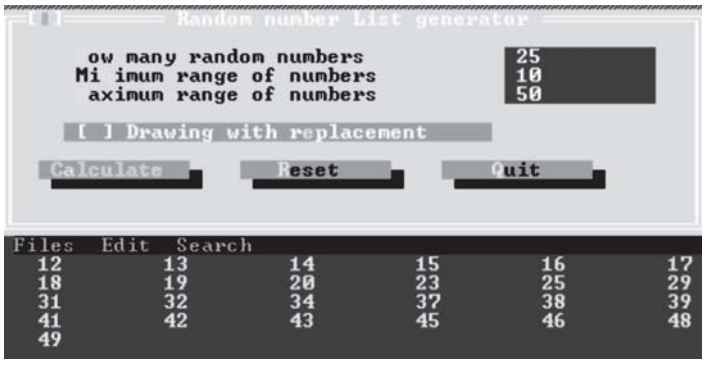
the number of random numbers as 25 and the digits per number as 2 (Since we have population which consists of subjects numbered in two digits). Pressing calculate gives a list of 25 two digit random numbers as follows.

Thus from the population we will choose the subjects with numbers 12, 58, 73 and so on, to form our study sample.

Random number list

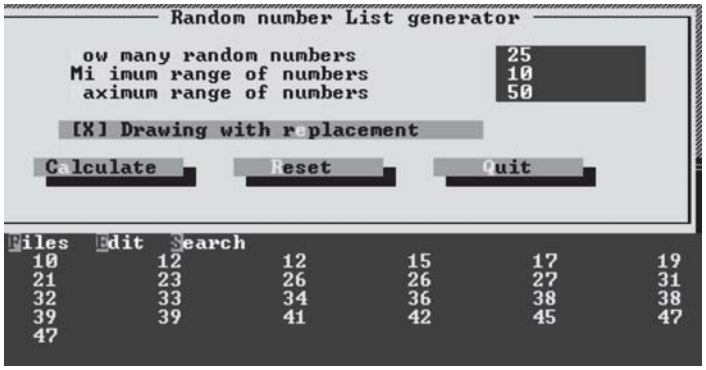
This option generates a list of random numbers ranging from a minimum to a maximum value. These random numbers can be drawn with or without replacement. In without replacement duplicate are not allowed whereas in with replacement duplicates are allowed. The random numbers generated are presented in sorted order.

The difference between random number table and random number list is that the random number table generates the specified number of random numbers from all the available digit number that we have specified. For example in the above example the 25 random numbers



are generated from 01 to 99. Whereas the random number list gives us a list of numbers where the range can be specified by us. For example if we want a list of 25 random numbers from 10 to 50 without replacement then the output is as follows

**Note that none of the random number repeats itself in the list.**



Let us draw the same number of random numbers (25) but now if we specify with replacement then the output is as follows.

**Note that the random number 12, 26 38 and 47 are repeated in the study**

## Analysis of data

Let us once again revert back to the main menu of Epi 2002. One of the most important component of Epi 2002 is Analyze Data. This program allows access to data entered in 20 data formats (e.g. Epi Info data files, Foxpro data base files, Excel files, Access data base files, etc) to perform statistical analysis. Though you can directly enter data in the EPI INFO we strongly recommend that the data be first entered in Excel, Foxpro or Access and then imported to EPI. To understand this option in detail a practice data file named "SAMPLE.dbf" is provided to the readers in a CD, alongwith this book. It is suggested that the readers use this file and try out all the options available in the Analyze Data menu of Epi 2002. The description of the data set in "SAMPLE.dbf " is given at the end of the Epi section.

Using this menu following statistical analysis can be carried out.

(a) It produces tables, epidemiologic statistics & graphs.

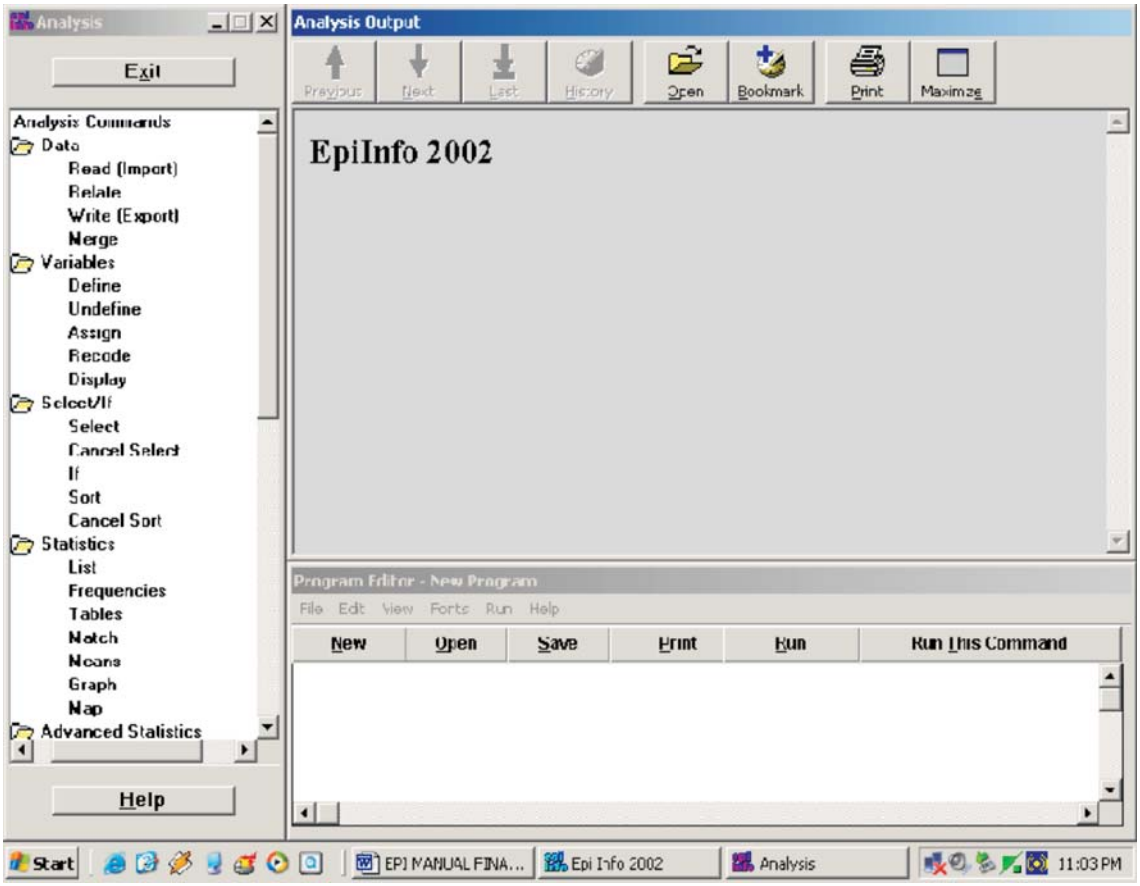
(b) It can also produce lists, frequencies, cross tabulations, and other epidemiologic statistics, such as odds ratios, relative risks and p-values.

(c) Graphing and mapping are also available using this component

First, to activate the analysis screen, click on the "Analyze Data" button on the main screen of EPI - 2002. The menu appears on the screen as shown on next page.

**Read**

By using READ command, located in the left hand column we can tell EPIINFO which file or table to analyze. The Data Formats requires the format in which the data is entered. In our case the data set enclosed in the CD is of type "foxpro" named "SAMPLE.dbf". Hence to read this particular file we should type dBASE IV in Data format. The Data Source requires the source destination of this file from where it can be extracted to read.



**List**

List does a line listing of the current dataset. If variable names are given, List option will list only these variables whereas List * will list all variables of all active records, using several pages across to accommodate all the variables, if necessary. The simplest and sometimes the best way to analyze data are to produce a line listing, using the List command.

**Frequencies**

The Freq command is used to determine the frequency of values for numeric character. The output shows a table of the values for a variable, the number and percent of records having each value, and the confidence intervals for each value as a proportion of the total. For numeric data only, descriptive statistics such as mean and standard deviation are also shown. On selecting the variables and clicking OK the results appear in the browser window. The yellow bars accompany each table to the right which indicates the frequencies. Statistics will be displayed below the table if the value of the variable is numeric.

Example

Suppose in the example "SAMPLE.dbf" we want to find the frequencies of the personnel of different rank structure. The variable we have used for rank is RANK. Click frequencies and specify RANK in the drop down menu of Frequency. Pressing OK yields the Frequencies, Percent, cumulative percent along with 95% confidence intervals

| RANK | Frequency | Percent | Cum Percent |
|---|---|---|---|
| JCO | 105 | 17.1% | 17.1% |
| OFFICER | 25 | 4.1% | 21.2% |
| OTHER_RANK | 484 | 78.8% | 100.0% |
| Total | 614 | 100.0% | 100.0% |

**95% Conf Limits**

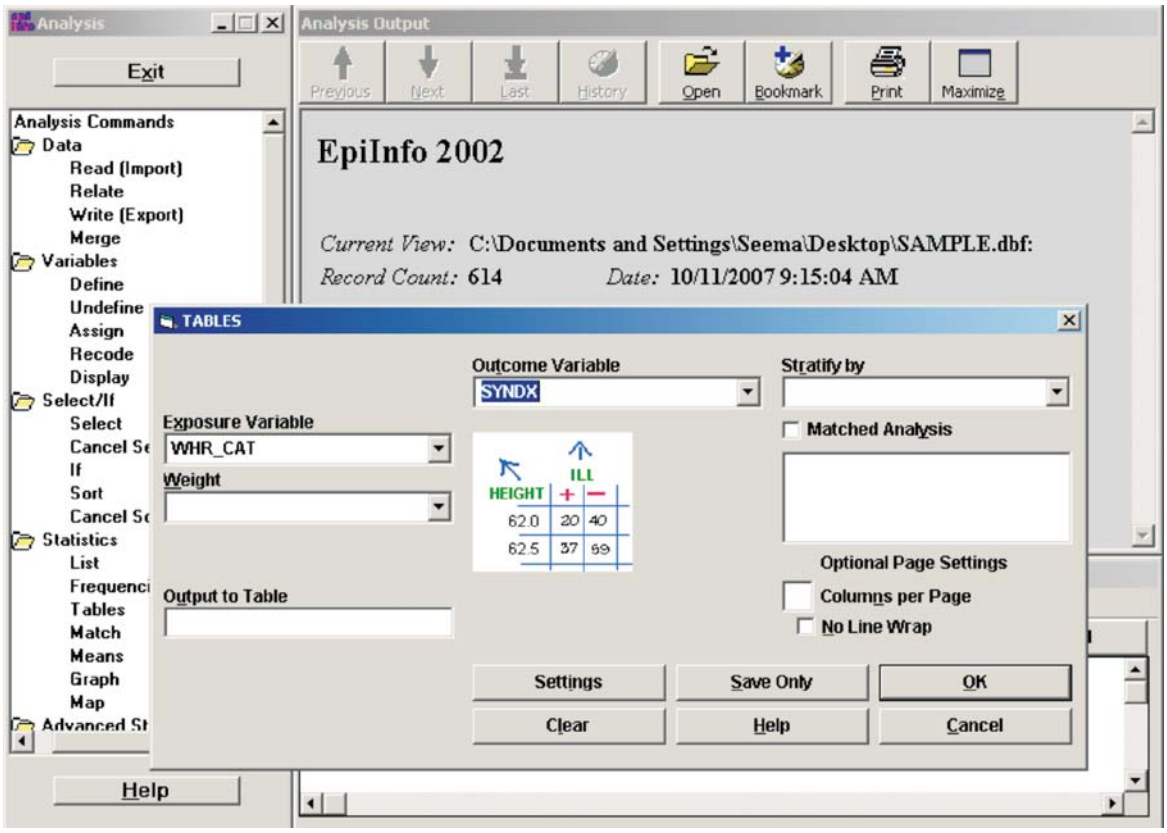
| | | |
|---|---|---|
| JCO | 14.3% | 20.4% |
| OFFICER | 2.7% | 6.0% |
| OTHER_RANK | 75.3% | 82.0% |

for the frequencies in the following manner. The yellow bars also indicate the frequencies for each category.

Tables

The Tables command is used to create a table of categorical data, often called as cross-tabulation. Two variables can be compared using Tables. This is similar to the 'Tables (2 x 2, 2 x n)' option of "Statcalc". In Statcalc when 'Tables' option is used either for analyzing a single table or carrying out stratification analysis for confounding effect, we make use of the readymade 2 x 2 tables. The disease status as well as the exposure status cross classification cell values are directly entered by

counting them separately from raw data. In the "Tables" option of "Analyze Data" the difference is that we do not count the frequencies manually but the raw data file is accessed through the 'Read' (Import) command in "Analyze Data". The computer counts the cell frequencies.



On clicking the command Tables, we select the Exposure (Independent variable) and the Outcome (Dependent variable) variables. Exposure variable is that variable in the database which is to be considered as the risk factor. Outcome variable is the variable in the database considered as the Disease of consequence. Click on OK when done. A single table of 2 or more rows and 2 or more columns can be provided, which is called as an R x C table (Row by Column). In addition to the row and column variables, the user can stratify on additional variables, which is then called as an R x C x S table (Row by Column by Strata). This is used for control of confounding and is equivalent to stratification in Statcalc. The output gives frequency tables accompanied by confidence limits on the proportions and 2x2 tables by odds ratios, risk ratios, and several types of confidence limits on these ratios, as well as chi square and Fisher exact tests. Stratified analyses result in Mantel-Haenszel summary odds ratios and confidence limits.

We will understand the usage of this command by considering our hypothetical data set of "SAMPLE.dbf". Let us say that we are interested in exploring association between SyndromeX and central obesity. Central Obesity (WHR_CAT) is considered to be a risk factor for development of SyndromeX and hence is selected as exposure factor and SyndromeX as our variable of interest as Outcome. We select these variables and then press <OK>.

| | SYNDX | | |
|---|---|---|---|
| WHR_CAT | 0 | 1 | Total |
| **0** | 233 | 7 | 240 |
| Row % | 97.1 | 2.9 | 100.0 |
| Col % | 41.5 | 13.5 | 39.1 |
| 1 | 329 | 45 | 374 |
| Row % | 88.0 | 12.0 | 100.0 |
| Col % | 58.5 | 86.5 | 60.9 |
| Total | 562 | 52 | 614 |
| Row % | 91.5 | 8.5 | 100.0 |
| Col % | 100.0 | 100.0 | 100.0 |

## Single Table Analysis

| | Point Estimate | 95% confidence interval | |
|---|---|---|---|
| | | Lower | Upper |
| **PARAMETERS: Odds-based** | | | |
| Odds Ratio (cross product) | 4.5528 | 2.0176 | 10.2735 (T) |
| Odds Ratio (MLE) | 4.5438 | 2.0979 | 11.0869 (M) |
| | | 1.9874 | 12.1557 (F) |
| **PARAMETERS: Risk-based** | | | |
| Risk ratio (RR) | 1.1036 | 1.0567 | 1.1526 (T) |
| Risk difference (RD%) | 9.1154 | 5.1906 | 13.0403 (T) |
| (T=Taylor series; C=Cornfield; M=Mid-P; F=Fisher Exact) | | | |
| **STATISTICAL TESTS** | Chi-square | | 1-tailed p 2-tailed p |
| Chi square - uncorrected | 15.6 | | 6 9 8 0.0000765860 |
| Chi square - Mantel-Haenszel | 15.6443 | | 0.0000776106 |
| Chi square - corrected (Yates) | 14.5160 | | 0.0001401431 |

Let us now consider another variable BMI. We now wish to explore whether BMI is a confounding variable in the observed association between central obesity and syndromeX. Hence along with exposure and outcome variable we also give the variable BMI in the Stratify By on the screen.

The procedure is to click on Tables in Analyze Data after the data file is imported through 'Read' command. In the exposure dropdown we select the exposure variable as WHR_CAT and the outcome variable as SYNDX. Along with these we also select the confounding variable (BMICAT_01) from the dropdown list of "Stratify By". This is equivalent to stratification in Statcalc. On pressing <OK> the output is rendered as a single 2 x 2 analysis of WHRCAT and SYNDX but taking into consideration BMICAT_01 as 0 and 1. In other words the cross tabulated frequencies are only for the group having BMICAT as 0 (<25) and another single 2 x 2 analysis for the group having BMICAT_01 as 1 (=25). A SUMMARY TABLE provides the summary statistics after removing the effect of confounder. The output is given as under.

WHR_CAT : SYNDX, BMICAT_01 = 0

| | SYNDX | | |
|---|---|---|---|
| WHR_CAT | 0 | 1 | Total |
| **0** | 213 | 5 | 218 |

| Chi square - Mantel-Haenszel 0.2169343585 | | 1.52 | 245 |
| Chi square - corrected (Yates) | | 0.89 | 26 |

Warning : The expected value of a cell is <5. Fisher Exact Test should be used.

Summary

Summary information

| Parameters | Point Estimate | 95%Confidence Interval | |
|---|---|---|---|
| | | Lower | Upper |
| Odds Ratio Estimates | | | |
| Crude OR (cross product) | 4.5528 | 2.0176, | 10.2735 (T) |
| Crude OR (MLE) | 4.5438 | 2.0979, | 11.0869 (M) |
| | | 1.9874, | 12.1557 (F) |
| Adjusted OR (MH) | 2.9415 | 1.2562, | 6.8881 (R) |
| Adjusted OR (MLE) | 2.9617 | 1.3062, | 7.4701 (M) |
| | | 1.2285, | 8.2237 (F) |
| Risk Ratios (RR) | | | |
| Crude Risk Ratio (RR) | 1.1036 | 1.0567, | 1.1526 |
| Adjusted RR (MH) | 1.0614 | 1.0188, | 1.1057 |
| (T=Taylor series; R=RGB; M=Exact mid-P; F=Fisher exact) | | | |

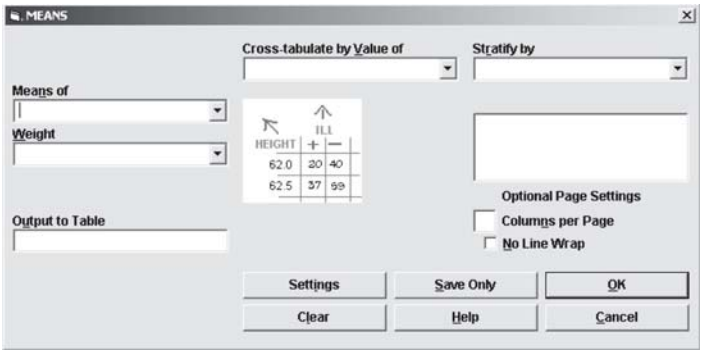
| STATISTICAL TESTS (overall assoc) | Chi-square | 1-tailed p | 2-tailed p |
|---|---|---|---|
| MH Chi square - uncorrected | 6.7724 | | 0.0093 |
| MH Chi square - corrected | 5.8796 | | 0.0153 |
| Mid-p exact | | 0.0039 | |
| Fisher exact | | 0.0060 | |
| In the following two tests, low p values suggest that ratios differ by stratum | | | |
| Chi-square for differing Odds Ratios by stratum (interaction) | 0.0630 | | 0.8018 |
| Chi-square for differing Risk Ratios by stratum | 0.9671 | | 0.3254 |

Since Chi-square for differing Odds Ratios by stratum (interaction) is not significant. We conclude that BMI_CAT_01 is a confounder variable as the crude odds ratio and adjusted odds ratio differ. Based on Adjusted OR(MH) of 2.94, we conclude that the risk of syndromeX due to high WHR, after controlling (adjusting) for the confounding effect of raised BMI, increase the risk by almost 3 times.

**Means**

The Means command can compare mean values of a variable between the groups. The Means command can also compare mean group values before and after the event. This method, however, ignores the matching that occurs from using the same student or subject for both tests. A better method is to subtract the before score from the after score to find the difference for each student, and then to see if the average difference is significantly different from zero, using Students t-test. Epi Info performs the t-test every time the Means command is given with a single variable, just in case the variable represents a difference and you would like to know if it differs, on the average, from zero. If there are only two groups, the equivalent of an independent t-test is performed. If there are more than two groups, then a one-way analysis of variance (ANOVA) is computed. Thus Means provides the equivalent of ANOVA for two or more samples. "One way" means that there is only one grouping variable. If there were two grouping variables, then that would be a two-way ANOVA, which Epi Info does not perform. The one-way ANOVA can be thought of as an extension of the independent t-test to more than two groups. Because the ANOVA test requires certain assumptions about the data and the underlying population, another test (Kruskal-Wallis, also known as the Mann Whitney/Wilcoxon test if there are only two groups) is also provided. This is a non-parametric test, meaning that it does not require assumptions about the underlying population. We will discuss in detail each of the output section separately.

Consider again the example of "SAMPLE.dbf". One of the numeric variables considered is age of the person. If we wish to test whether there is any significant difference between the three ranks of the personnel as regards to the age parameter, we use one way ANOVA. For carrying out this analysis we first click on Means. The following screen



will appear.

In the **Means of** we substitute the continuous numeric age variable and in the **Cross Tabulate by values of** substitute groups which is given in the column of Rank i.e. press Rank and then Press OK. The output is provided in 5 different sections:

(a) A table of the two variables with the continuous variable forming the rows and the grouping variable forming the columns.

(b) Descriptive information of the continuous variable by each group such as number of observations, mean, variance, and standard deviation; minimum and maximum values; the 25th, 50th (median), and 75th percentiles; and the mode values are described.

(c) An Analysis of Variance (ANOVA) table and a p-value for whether or not the means are equal.

(d) A test to determine whether the variances in each group are similar (Bartlett's test for homogeneity of variance).

(e) A non-parametric equivalent, Kruskal-Wallis test instead of the independent t-test and one-way ANOVA is also provided.

For the example considered from SAMPLE.dbf following

**Descriptive Statistics for Each Value of Crosstab Variable**

| | Obs | Total | Mean | Variance | Std Dev |
|---|---|---|---|---|---|
| JCO | 105 | 4652.0000 | 44.3048 | 18.6947 | 4.3237 |
| OFFICER | 25 | 1133.0000 | 45.3200 | 45.4767 | 6.7436 |
| OTHER_RANK | 484 | 18191.0000 | 37.5847 | 8.9804 | 2.9967 |

| | Minimum | 25% | Median | 75% | Maximum | Mode |
|---|---|---|---|---|---|---|
| JCO | 36.0000 | 41.0000 | 45.0000 | 48.0000 | 53.0000 | 46.0000 |
| OFFICER | 35.0000 | 40.0000 | 46.0000 | 51.0000 | 55.0000 | 36.0000 |
| OTHER_RANK | 35.0000 | 36.0000 | 37.0000 | 38.0000 | 55.0000 | 35.0000 |

output is given on the screen.

**ANOVA, a Parametric Test for Inequality of Population Means** (For normally distributed data only)

| Variation | SS | df | MS | F statistic |
|---|---|---|---|---|
| Between | 4921.3197 | 2 | 2460.6599 | 203.9088 |
| Within | 7373.2145 | 611 | 12.0675 | |
| Total | 12294.5342 | 613 | | |

P-value = 0.0000

**Bartlett's Test for Inequality of Population Variances**

Bartlett's chi square= 64.7890 df=2 P value=0.0000

**Mann-Whitney/Wilcoxon Two-Sample Test (Kruskal-Wallis test for two groups)**

Kruskal-Wallis H (equivalent to Chi square) = 183.0437

Degrees of freedom = 2

P value = 0.0000

A small p-value (e.g., less than 0.05) suggests that the variances are not homogeneous and that the ANOVA may not be appropriate.

The overall one-way ANOVA results are said to be significant (p= 0.0000) so we conclude that the mean age in the three ranks (groups) are not same.

Note that All statistical methods require assumptions

(a) ANOVA requires distributional assumptions of

(i) Independence

(ii) Normality

(iii) Equal variance

**(b) Bartlett's Test for Inequality of Population Variances** test for the assumption of equal variances. It also advices you as to whether ANOVA results are appropriate or Non-parametric test are more appropriate.

**(c) Kruskal-Wallis Test**

The Kruskal-Wallis test is the nonparametric analogue to one-way ANOVA. It can be viewed as ANOVA based on **rank-transformed data**. The initial data are transformed to their ranks before submitted to ANOVA. The p-value suggests the significance. The null and alternative hypotheses for the K-W test may be stated in several different ways. We choose to state:

$H_0$: the population medians are equal

$H_1$: the population medians differ

(d) In case when the ANOVA results are significant ($p<0.05$), multiple comparisons between two groups at a time should be carried out. Since in our case results are significant ($p<0.05$) we now compare two means at a time. This is a **post hoc (after-the-fact) comparison**. In other words it means that after rejecting $H_0$ we conduct the following three tests:

Test 1: $H_0$: Group1 = Group 2 vs. $H_1$ Group 1 ≠ Group 2

Test 2: $H_0$: Group1 = Group 3 vs. $H_1$ Group 1 ≠ Group 3

Test 3: $H_0$: Group2 = Group 3 vs. $H_1$ Group 2 ≠ Group 3

This is carried out by the procedure explained in **EPITABLE section of COMPARE.**

### Match

MATCH performs a matched analysis of the specified exposure and outcome variables, which are assumed to be yes/no variables. One table is produced for each number of cases in a match group. The first variable will appear on the left margin and will contain values from zero to the number of cases in the match group. The second variable will appear on the top margin and will contain values from zero to the number of cases in the match group. The cells contain the number of match groups showing the combination of positive exposures and positive outcomes shown in the margins. The output table produced by the command is similar to that produced by TABLES.

### Graph

The GRAPH command in Analysis offers many types of charts for displaying the values of one or more fields in a data table. A toolbar within the graphing module can be activated to allow customization of the resulting graphs. Settings can be saved as templates and used again from Analysis.

### Advanced Statistics

Linear regression

Regression analysis deals with developing a mathematical relationship between two variables of interest. Regression is used when the primary interest is to predict one dependent variable (y) from one or more independent variables (x1, ... xk). When only one independent variable is used to predict the dependent variable then it is termed as simple linear regression. When multiple independent variables are used to predict the dependent variable it is defined as multiple linear regression and for quantifying the relationship between two variables we calculate correlation. To analyse the relationship between the independent and dependent variables we click on Linear Regression. From the dropdown menu in Outcome Variable select the outcome or dependent variable. In the Other Variables select the multiple independent variables and press OK. On pressing OK the output is visible on the screen.

Consider the example SAMPLE.dbf given separately in the CD. Suppose the outcome variable is diastolic blood pressure (DIA_BP). Let the independent variables or predictors be BMI (BMICAT_01), Waist-hip ratio (WAIST_HIP), serum cholestrol level (S_CHOL) and heart rate (HR_CAT_0_1). Follow the instructions given above

and arrive at the solution.

[Hint: In the above example, the regression line is:

$DIA\_BP = a + b_1x_1 + b_2x_2 + b_3x_3 + b_4x_4$

DIA_BP = 58.892 + 6.216(BMICAT_01) + 2.141(HR_CAT_0_1) + 0.047(S_CHOL)+ +18.3(WAIST_HIP)

For any given value of independent variables, diastolic blood pressure (DIA_BP) value can be predicted.]

### Logistic Regression

Logistic regression shows the relationship between an outcome variable with two values (i.e. dichotomous) and explanatory variables that can be categorical or continuous. In Epi Info 2002, either the TABLES command or logistic regression (LOGISTIC command) can be used when the outcome variable is dichotomous (for example, disease/no disease). Analysis with the TABLES command in Epi Info is possible if there is only one "risk factor." Logistic regression is needed when the number of explanatory variables ("risk factors") is more than one. The method is often called "multivariate logistic regression." A model might predict the probability of occurrence of a myocardial infarction (MI) over a 5-year period, given a patient's age, sex, race, blood pressure, cholesterol level, and smoking status. Please note that the outcome variable has to be of YES/NO type or logical (TRUE/FALSE). The latest version of EPI 2002 can take the outcome variable in logical form as 0 & 1. Epi Info 2002 uses a process called "maximum likelihood estimation" to arrive at the best estimate of the relationships based (usually) on a follow-up study. The results include values for the beta coefficients 'ß' but more important for epidemiologists, can produce an odds ratio (OR) for each value of a risk factor compared with its baseline ("absent" or "normal") state.

Consider in SAMPLE.dbf the dependent outcome variable as having IHD(which is coded separately as FINAL_IHD and is logical type) given the different risk factors as BMICAT_01(categorized 0 for BMI<25 and 1 for BMI = 25), weekly exercise (WK_EX_CAT categorized 0 for no exercise and 1 for exercise), waist-hip ratio, (WHR_CAT categorized 0 for having normal waist i.e. = 0.90 and 1 for having central obesity i.e. >0.90), heart rate (HR_CAT_01 categorized 0 for heart rate =72 beats/min and 1 for >72 beats/min) and SyndromeX (categorized 0 for all those who did not qualify as having syndrome X and 1 for all those who qualified as having or presence of syndrome X). Follow the instructions given above and arrive at the solution.

### Survival Analysis

Survival Analysis deals with situations where the outcome variable is dichotomous and is a function of time. The analytical methods used to draw inferences regarding the chances of surviving / dying / getting cured / getting diseased (in short, the chances of developing the "outcome of interest"), over the various points of time are answered by "survival analysis". The accompanying CD gives data set for survival analysis named as "SURVIVAL.dbf". This is a HYPOTHETICAL data of a new drug which was being tried out for treatment of Leukemia. 100 patients of confirmed leukemia was randomized into two groups. One group of 50 subjects which continued with the existing standard therapy (Group1) and another 50 subjects (Group2) were given the trial modality. All subjects were followed up for maximum period of 7 years (84 months) from the point of starting treatment or else till they died due to leukemia or lost to follow up or died due to some other disease. If subject died because of leukemia they are called as uncensored data (0) whereas subjects who died of some other cause and not leukemia or were lost to follow up or were still alive by the end of 7 years are called as censored data (1). The defined outcome of interest was the subject who was living at the end of followup. (This includes those who were loss to followup assuming that they would have lived).

There are three columns. The first column named "Time_since" represents the time in months of the event (death) taking place. The second column, named "Outcome" represents the status of the patient, whether the patient is alive or has died, and the third column, named "Group" represents the group to which the patient belongs, with 1 = existing treatment given and 2 = new trial treatment given. Press Kaplan-Meier Survival from Advanced Statistics and give input of all the required variables. The Censored Variable is the Outcome variable, Time Variable is Time_Since and Group Variable is Group respectively in our example. Value of uncensored is 0 whereas Time Unit is taken as months. Once you press OK the survival curve along with statistical difference between the two survival curves are provided. (The details on Survival Analysis are given in the section of Biostatistics). Follow the instructions given above and arrive at the solution.

#### Description of the data set : SAMPLE.dbf

SAMPLE.dbf file is a HYPOTHETICAL data meant for practicing only. It was a cross sectional study in which 614 healthy army subjects aged more than equal to 35 years were randomly selected from various army units in a very large cantonment. General particulars included age, rank, native state. History was recorded of details of physical exercise, alcohol consumption and tobacco use. Clinical measurements included measurement of height, weight, waist circumference, hip circumference and systolic & diastolic blood pressure. Biochemical measurements included fasting and 2 hour PP blood sugar, lipid profile and fasting insulin levels. Resting ECG was recorded and assessed for evidence of coronary insufficiency (CI) as per the standard Minessota code criteria. Syndrome X was defined as per standard international code criteria. A total of 52 persons out of 614 studied were found to have syndrome X as per defined criteria.

The description of various variables coded in the data sheet is as follows

| | |
|---|---|
| AGE | : Actual age in completed years. |
| RANK | : Self explanatory - Officers/ JCO/Other ranks |
| STATE | : The state of native residence of the subject. |
| WK_ALC | : Average amount of alcohol (in terms of |

gms
of ethanol) consumed in one week as a routine

TOBACCO : Coded as 1 for Users of Tobacco: 0 for non users

WK_EX_CAL : The number of K-calories spent on an average in one week in structured physical exercise (as PT, Games, Walking or sports under own arrangements)

EXCAT : NIL-undertaking no exercise; Similarly MILD,
MODERATE & HEAVY INTENSITY EXERCISE.

WEIGHT : Weight in kgs to the nearest whole number.

HEIGHT : Height in cms to the nearest whole number.

BMICAT_01 : 0 means < 25 and 1 ≥ 25

WAIST : Waist circumference in cms.

HIP : Hip circumference in cms.

WAIST_HIP : Waist-Hip ratio (WHR)

WHR_CAT : 0 = Having normal waist, normal WHR ≤ 0.90; 1= Having central obesity i.e. WHR>0.90

SYS_BP : Systolic Blood pressure in ml/mercury

DIA_BP : Diastolic Blood pressure in ml/mercury

BL_SUG_F : Fasting Blood sugar mg/dl

BL_SUG_PP : 2 hours post prandial blood in mg/dl

S_CHOL : Serum total; cholesterol mg/dl.

INSULIN_F : level of fasting insulin in mIU/ml

HYPERINSUL : 1 = Having hyperinsuliniea as per defined criteria of fasting insulin in uppermost quintile; 0 for Normoinsuliniea

HR : Heart Rate in beats/min

HR_CAT_01 : 0 Heart Rate =72 beats/min, 1 for Heart Rate>72 beats/min

IHD_EVI : Evidence of coronary insufficiency (CI) on resting ECG; 1=CI present; 0=normal

SYNDX : 1= SyndX present as per defined criteria; 0= SyndX absent

FINAL_IHD : TRUE=evidence of CI present; FALSE=No evidence (Normal)

**Using SAMPLE.dbf answer the following questions:**

Q1: Write the scales of measurement for all the variables considered in the SAMPLE.dbf

Q2: If the investigator is interested in assessing whether there exist any association between the occurrence of IHD and systolic blood pressure as risk factor. How will the investigator proceed to test this association?

Q3: In the above situation how will the investigator check whether age is a confounder variable or not?

Q4: Describe the following variables along with the 95% confidence interval.

a) Heart Rate
b) Serum Cholesterol Level
c) Tobacco consumption.
d) Age

Q5: Test whether there is any difference in the proportion of subjects consuming tobacco in the two groups with presence of IHD and absence of IHD.

Q6: To test whether there is any correlation between Waist Hip Ratio and BMI (taking both as dichotomous variables) what type of statistical analysis will be carried out?

Q7: Taking Fasting Insulin as a continuous variable and age as dichotomous variable (0 for = 35 years of age and 1 as > 35 years of age) test whether there is any difference between the insulin levels in the two age groups.

Q8 Carry out analysis to find out whether there is any association between the exposure variables WK_EX_CAL and the outcome variable FINAL_IHD with and without considering the confounder variable BMI

Q9: If we wish to test whether there is any significant difference in the proportion of people of different ranks (RANK) with outcome of "SyndromeX" using EPITABLE and ANALYZE DATA, what would be the difference?

Q10: Which statistics will be used to predict the outcome of SyndromeX in subjects, considering the risk factors as Age, Exercise (WKEXCAT01), TOBACCO consumption (categorized as 0 and 1)?

Q11: Correlate Fasting Insulin and Fasting Sugar using 'Graph' from "Analyze Data"

# Effects of Hot Environment

The term "heat stress" is applied to any degree of environmental heat that causes physiological thermoregulatory mechanisms to get activated. Human beings are homoeothermic creatures whose physiology attempts to maintain a constant core body temperature of 37°C (range 36 to 38°C). Obviously, this requires balancing of the body heat production with heat loss which is achieved by a combination of physiological mechanisms (as peripheral vasodilatation or vasoconstriction, changes in heart rate, sweating or shivering) and behavioural mechanisms (increase or decrease in voluntary physical activity, seeking appropriate shelter etc). In addition, environmental conditions viz., temperature, humidity and speed of air also greatly determine whether a person will be subjected to thermal stress. Prevention and management of thermal stress disorders therefore requires an understanding of these physiological, behavioural and environmental mechanisms and manipulating them appropriately. For the purpose of thermoregulation, the human body can be conceived of having two "layers" - an outer periphery or "shell" consisting of skin, subcutaneous tissue and muscles, and an inner "core" consisting of brain, heart and viscera.

## Magnitude of the Problem

Epidemiological descriptions provide evidence of diseases and deaths due to hot environment since Biblical and Alexandrian times (1-4). Medical descriptions of heat related Illnesses have been made in relation to various human activities, ranging from adventure and sports to industries, occupation, pilgrimages and, of course, military operations (5-9).

In terms of the burden of mortality, hyperthermic brain injury is the third largest cause of brain-injury related deaths, next to Cardiovascular and traumatic diseases (10, 11). Scientific published data on the magnitude has described the death of almost eleven thousand people in the month of July, in China, during the eighteenth century due to hot weather conditions. The adversities faced by Napoleon's army in 1798, during his Egyptian campaign, were poignantly summarized by Larry. Another description by Marshall enumerates the death of thousands of soldiers due to physical exertion in hot environment, during the Arab-Israeli war of 1956 (12). Again, very high incidence of heat illnesses has been reported from the Middle East, among the Haj pilgrims (13). It has been estimated that the massive heat wave that swept over Europe in 2003, claimed more than 35,000 lives, with France accounting for 14,000 deaths (14). Even in developed countries like United States, heat illness is a major public health issue (15). Data from Centers for Disease Control and Prevention (CDC) indicates that during the period 1979 to 1997, as many as 7000 deaths in the USA were attributable to excessive heat (16). Reports of high incidence of heat illnesses from various other developed countries have appeared recently (17-20).

In India, more than 1600 heat related deaths were reported during the year 2003 (14). A report by Larsen, on behalf of Earth Polity Institute, as quoted by Sri Ramachari (14) makes a pointed reference to India, as "where heat related fatalities in thousands are no longer uncommon", thus exhorting all professionals concerned with human development towards addressing this problem. More recently, apprehensions have also been raised regarding the world wide climatic changes and global warming, which may increase the incidence of heat related illnesses in the human populations (21-23). In India, 3,194 deaths due to heat-stroke have been recorded over the 5-year period 1999 to 2003; the actual magnitude may be much more. The central and northern plains, western deserts and tropical forest areas of North - East have environmental conditions causing heat stress during the months of April to September.

## Epidemiological triad in heat illnesses

In the conventional "Epidemiological triad" of agent, host and environmental factors, the "agent" is "heat". However, who would get adversely affected by this agent is determined by a complex interplay of various factors in the human host or the environment.

Human (Host) Factors

A wide array of host factors have been implicated in increasing the risk of heat illnesses, as summarized in Box 1.

**Box - 1 : Persons at high risk of heat stress**

- Extremes of age (<5 years or >65 years)
- Pregnancy
- Occupation: Workers in military, agricultural, construction & industrial settings, labourers, sports-persons and miners.
- Low level of physical fitness
- Lack of acclimatization to environmental heat
- Obesity
- Alcohol use (acute and chronic)
- Skin diseases: Extensive prickly heat, psoriasis, pyoderma
- Sleep deprivation
- Co-existing febrile illness, renal, thyroid, cardio-vascular and metabolic diseases.
- Previous history of heat-illness

### a) Age

Children upto five years of age and the elderly (aged more than 65 yrs) are at a higher risk and need special

preventive efforts. A considerable portion of such decline in heat tolerance with increasing age may be actually due to reduction in physical fitness, increase in body weight and chronic diseases, which all accompany advancing age (24).

**(b) Gender**

Earlier workers had been of the general opinion that females are less able to work in hot environment and hence more susceptible to heat illnesses. However, more recent evidence suggests that if women are fully acclimatized and physically conditioned, the differences between males and females as regards susceptibility may not be significant. On the other hand, hospitalization data may show a preponderance of males since, in most parts of the world, males are more employed in hazardous heat-illness-prone jobs (25). There is indication that women may be less tolerant to exercise in hot environment during the luteal phase of menstrual cycle as compared to follicular phase (26). There is an indication that pregnant women may be at higher risk of heat illness.

**(c) Racial and genetic factors**

Morbidity and mortality data from the US, British and British- Indian Army, during the world wars, tends to indicate a paradoxical situation that while the overall incidence of heat related illnesses were higher among the whites as compared to soldiers with black colored skin the incidence of severe forms of the disease and death was higher among the latter. More recent evidence, however, indicates that race, per se, may not be an important determinant and any observed differences between racial/ethnic groups may be actually due to socio-cultural reasons. Further studies are required in this field (14). It is also being increasingly realized that certain genetic factors may determine the susceptibility to heat stroke, as those which encode cytokines coagulation proteins and heat shock proteins (HSPs) involved in the process of adaptation to heat stress (27-33).

**(d) Level of physical fitness**

Low level of physical fitness (as indicated by lower levels of $VO_2$ max), in relation to the occupational or recreational requirements, reduce the heat tolerance (25, 34). Similarly, hot environment also has an effect on physical performance in that maximal exercise capacity, as measured by $VO_2$ max, is reduced in hot environment, as compared to temperate environment (35-37).

**(e) Overweight and obesity**

Overweight/obesity (body mass index >25) is also a well accepted risk factor, predisposing to heat illness (38-42). From ergonomics point of view, obesity translates into "additional load" being placed on the body, and hence increases the heat production in a geometrical manner, especially when moderate or heavy exertion is being undertaken. In addition, obesity is often associated with reduced physical fitness which, in turn, is a risk factor for heat illness (43). In fact, there seems to be an interactive effect between obesity and poor physical fitness, with the risk of heat illness multiplying if both are present (38).

**(f) Occupation**

There are certain groups who are well documented to be at high risk by virtue of their occupation or indulgence in certain recreational habits. These include military personnel, mine workers, industrial workers especially those employed around furnaces and foundries, farmers and labourers, especially in tropical countries, fire fighters, sports persons, hazardous waste site workers (particularly due to their impervious clothing ) and adventurers especially when carrying load. Not only sports persons, even spectators may be often at risk (44)

**(g) Physical activity**

Physical activity in a hot /humid environment is a major determinant of heat illness. Within the broad group of "physical activity", certain variables determine the occurrence and severity as follows:

(i) Nature of physical activity

The nature of physical activity and its strenuousness, at a given time is one of the most important determinants since it directly determines the metabolic heat being produced by the body which, in turn, reflects the intrinsic heat load of the body. It also needs to be noted that running or jogging at fast pace leads to very high metabolic heat production and may be particularly hazardous during hot weather.

(ii) The amount of load being carried

For every additional kilogram of "load", an additional 2 kcal / hour of additional heat will be produced, when walking at ordinary pace. This would further increase as the pace increases.

(iii) The type of terrain

As compared to walking on an ordinary black topped road, the metabolic heat production will progressively increase when walking (at the same speed), on a cross country track, on recently ploughed fields, on snow or over heavy sand. In the last case the heat production may be almost two times when compared to walking on road.

(iv) The Inclination (Gradient)

Heat production increases, at a given pace, as the gradient increases. Even a 10% increase in the gradient may substantially increase metabolic heat production.

(v) The duration of physical activity

In harsh, hot & humid environment even well trained persons may suffer from adverse effect of hard physical activity if continued for more than half an hour unless adequate rest pauses are interspersed.

**(h) The type of clothing being worn**

There are 3 aspects, in relation to clothing, which determine the dissipation of metabolic heat, being produced in the body.

(i) The insulation, measured in Clo units (45). The insulation should be, ideally, as low as possible in a hot environment.

(ii) The permeability to moisture, which should be as high as possible.

(iii) Absorption of "radiant energy" which is quite high for dark clothing.

Synthetic material has poor permeability and should be avoided. Similarly multilayered clothing, which 'trap' layers of still air between them tend to increase the insulation even if they have good permeability. Thus the correct approach would be to use light colored loose fitting clothing, in one or two layers, and made of 'breathable' material as cotton.

**(j) Acclimatization to hot environment**

Acclimatization implies physiological adaptation so as to be able to work in the given hot environment without being adversely affected by hot weather. The details of acclimatization are discussed subsequently. Lack of acclimatization is a risk factor for being affected by adverse affects of heat, particularly for exertional heat illness (EHI) which is more common in certain occupational groups as described earlier.

**(k) Lack of concurrent hydration**

It needs to be noted that adequate water has to be replenished, hour by hour, when working in hot environment. The concept of "hardening" the persons to hot environment so that they drink less water on exposure to hot environment (known as "water discipline" or hard scale water rationing") is scientifically incorrect and is likely to do more harm. In fact, dehydration reverses the advantage which is conferred by physical fitness and heat acclimatization (46-48). As would be appreciated subsequently, one of the major pathways through which acclimatization itself works is by increase in sweating. Dehydration will therefore negate the very physiological basis on which acclimatization works. Similar to inadequate replenishment of water, diuretics which are often used by sports persons to reduce their weight before competitions, can have the same adverse effects on heat tolerance, as is caused by dehydration due to drinking less water (49). There is also some evidence that drinking some water, say half to one liter, before physical exercise (pre hydration) may provide some additional advantage as compared to normal (euhydrated) state (50,51).

**(l) Alcohol intake**

It is generally agreed that alcohol intake, in acute or chronic forms, is a definite risk factor for developing adverse effects of hot environment. Kilbourne et al (52), in a case control study, observed that history of alcoholism was associated with a very strong (OR=15.02) and statistically significant risk of fatal form of heat stroke. It is quite likely that the dehydration caused by even moderate amounts of alcohol, as well as the inhibition of secretion of anti-diuretic hormone (thus leading to diuresis and further dehydration) may be the main reasons. The adverse effect of alcohol on heat tolerance may continue for many hours, even for a day, after consumption.

**(m)Skin diseases**

Any impairment of the functioning of sweat glands due to unclean skin, exposure to chemical agents, absence of sweat glands or skin diseases involving a large area, will reduce heat tolerance. The commonest skin disease which interferes with sweat function, thereby reducing heat tolerance, is prickly heat (milaria rubra) (53), which, interestingly, is itself a heat related illness. Similarly, Psoriatic lesions also increase the risk of heat illness (54). Even sunshine may adversely affect tolerance to exercise in a hot environment. The adverse effects of rashes may persist for almost a week after resolution of rash (55, 56).

**(n) Sleep Deprivation**

Sleep deprivation leads to impairment of heat tolerance and also reduces the tolerance built up by acclimatization. The possible mechanism are alteration of thermoregulatory responses during exercise, as also disruption of the cyclical mechanism by which minimum body temperature is achieved as a part of normal circadian pattern (57-60). Available evidence strongly suggests that peaceful sleep of at least 7 to 8 hours in the night and cooler hours of early morning is a good adjunct for preventing heat illness.

**(o) Febrile illness**

Febrile illness, as a consequence of infection or following immunization, increases the "heat load "of the body, as well as the heart rate. It is always a good practice not to exert in hot climate, till 48 hours have elapsed since full recovery from short term febrile illness. For long term febrile illness, re-acclimatization after full recovery should be undertaken. Similarly, gastroenteritis increases the vulnerability by causing dehydration.

**(p) Other illnesses**

Chronic diseases which affect the haemodynamics of circulation, particularly cardio vascular, renal and thyroid diseases or diabetes mellitus will affect heat tolerance mechanism and such persons should be careful when exposed to hot environment (61). In this regard, care should be exercised for providing cool environment in hospitals and nursing homes since it has been shown by Machenbach et al (62) that patients admitted to nursing homes (for different diseases ) are at a higher risk of mortality during hot months vis-à-vis general population.

**(q) Medications (Drugs):**

A number of pharmacological substances reduce tolerance to heat. These include substances often present in "over-the-counter" (OTC) drugs. The important pharmacological agents include tranquilizers of phenothiazine group, anti-cholinergics, anti-histaminics, anti-depressants, beta blockers, ACE inhibitors, diuretics, MAO inhibitors and thyroid hormone preparations (63-66). Kilbourne et al also observed that taking major tranquilizers and anti-cholinergics was an important risk factor for fatal heat stroke (52). Besides pharmacological agents in medications, as above, use of additictive drugs/substances as cocaine, cannabis and amphetamines is also an important risk factor for increased susceptibility to heat illness.

**(r) Previous history of heat illness:**

For reasons which are not still clearly understood, persons who have suffered from heat injury previously are at an increased risk of recurrence (67-69). Moreover, another interesting finding is that there is approximately 40% increased risk of overall (all cause) mortality (mainly due to IHD and cerebrovascular disease), among those who have history of prior hospitalization for heat illness. Thus, being affected by heat illness may also serve as a marker for increased susceptibility to death from others causes. (70).

**(s) Resumption of physical activity without adequate recovery**

Bout of physical activity, followed by another bout, which is likely to be more strenuous than the previous one and undertaken before proper recovery (in terms of stabilization of heart rate), is likely to increase the risk of heat-related illness (71). Similarly, the "last minute dash" in sports events indulged in by sportsperson / military personnel, wherein all available physical energy is used during the last few minutes of a strenuous event may be particularly hazardous (72).

**(t) Type of residential building**

In an earlier study by Parries et al (73) it was observed that a disproportionately large number of heatstroke victims lived on the top floors of buildings. Similarly, in a case control study, Kilbourne et al (52) found out that people staying on floors above the second floor were at 60% increased risk. The same results were observed by Semenza et al (74) who found more than four fold risk for people staying on top floor. It is plausible that heat illness would be greater on the higher floors of building because hot air rises within a building, or else, because of close proximity to a roof heated by the sun. In general, it seems that the higher one stays from the ground or if one stays in the top floor house, the chances of being affected by heat illness are higher, and hence such persons should be more careful regarding prevention.

**(u) Cool environment at home / work place**

Earlier workers had felt that air conditioning at home might actually increase the chances of heat illness, by inhibiting proper acclimatization to hot weather (75). However, Kilbourne et al (52) found quite different results, in that they observed that absence of air conditioning had significant, independent and strong risk for both fatal as well as non fatal heatstroke as compared to persons who had 24 hours air conditioning at home. The workers also observed that spending increased time in air conditioned places (out side the place of residence) also reduced the risk of fatal as well as non fatal heatstroke by one fourth. Similarly Semenza et al (74) have also reported a significant protective effect of residential air conditioning during condition of heat wave.

**(v) Rural-Urban Differences**

It has been observed in western countries that, during heat -wave conditions, the morbidity and mortality in urban areas tends to be higher as compared to rural areas. In fact, urban areas tend to have a 'heat island effect'. The higher effect of heat in urban areas may be due to the higher temperature in cities as a result of increased retention of solar heat by concrete buildings and pavements, increased heat production by motor vehicles, factories and increased concentration of human beings, and, decreased heat loss due to lower wind velocity. In addition, other as yet undefined economic and social differences between city and rural residents may contribute to the higher adversity of heat in cities (76-78).

**(w) Vegetation around places of residence.**

Kilbourne et al (52), in their case- control study, observed that presence of trees and shrub growth around the residence was a strong and significant protective factor, reducing the risk of non-fatal heat stroke by almost half. It is quite logical, since trees and shrubs may shield a residence from direct sunlight.

**(x) Social and religious conglomerations**

A simple epidemiological reason for the observed increase in the incidence of heat illnesses during social and religious conglomerations could be because the "affected" people are much more, hence more cases. However, even when the numbers of the cases are converted to rates by relating them to the population size, it is seen that during such collections in hot / humid weather, the risk of heat illnesses increases. Public Health authorities should therefore keep this aspect as a priority while planning preventive activities during such gatherings (79-81).

**(y) Other social factors**

It has been observed that persons who are living and being cared for, in organized family groups, those who have social contacts and support and who have access to transportation are relatively protected against adverse effects of heat (74).

Environmental Factors

While various attributes of the human host, as described earlier, play an important role in determining who will ultimately get affected by heat illness, a major role in these health issues is played by the physical environment.

From the physical environment point of view, the major factors which emerge as determinants of heat illness are, the temperature of ambient air (usually determined by dry bulb thermometer, DBT), the relative humidity (usually determined by using psychrometric charts and the reading of both the DBT and the wet bulb thermometer, WBT), the Mean Radiant Temperature (MRT) whose main source is either solar radiation or radiations from hot objects as furnaces, and which is usually determined by the globe thermometer (GT), and the speed of the air (usually determined by anemometers or specialized thermometers). Based on the permutation and combination of these parameters, certain indices of environmental heat illness have been developed. A brief description of these indices is as follows:-

**(a) Effective Temperature**

ET is defined as the subjective feeling of warmth (or cold) at a given temperature of air (DBT), when RH is 100%, the air is almost still (minimal air movement) and the subject

is ordinarily clothed. In general, when a person is at rest with a body metabolic heat production of 100 kcal/ hour, in an environment of 100% RH and minimal air movements, an air temperature (DBT) of 36$^0$C marks the upper limit of heat tolerance. If heat productions increases, by strenuous activity to about 425 kcal/hour, under the same environmental conditions, a DBT of 31$^0$C is the upper limit of ET for 4 hourly tolerance (82). For the outdoor setting, the preferred index is Corrected Effective Temperature (CET), where Globe thermometer temperature (GT) is used in place of DBT.

**(b) Oxford (syn: Wet-Dry: WD) Index:**

The Oxford Index is a simple and quite effective Index, based on DBT and WBT

WD Index = 0.85 WBT + 0.15 DBT.

**(c) Wet bulb globe temperature (WBGT)**

WBGT index is most commonly used index of thermal stress. It takes into account the effect of MRT (as measured through globe thermometer (GT) in addition to WBT and DBT as follows:

Outdoor WBGT = 0.7 WBT + 0.2 GT + 0.1 DBT

Indoor WBGT = 0.7 WBT + 0.3 GT

WBGT levels of 30$^0$ C and above indicate definite thermal stress and care needs to be exercised (83). From May to August, most of the Indian subcontinent (except the northern hilly areas) tends to have WBGT values of more than 30$^0$C.

## Prevention of Heat Related Illness

No country, particularly the armed forces and industries, can ignore the potential dangers of sustained heat wave. Every community should assess its resources and develop a contingency plan. Although heat stroke is amenable to medical treatment, control can best be achieved by applying the principles of public health. Sentinel Surveillance, public education, outreach to vulnerable persons and enlistment of the help of the entire community can save lives (81).

A structured approach towards prevention and control of Heat illnesses in communities consist of

(a) Health measures directed towards communities and large populations groups

(b) Specific preventive measures directed towards individuals/small groups identified to be at high risk of heat illnesses due to certain occupational characteristics

(c) Early detection and first aid.

**Public health measures directed towards communities and large populations groups:-**

In tropical countries like India, millions of people among the general population are at risk during the hot/humid months, especially when spells of heat wave strike. In such settings, heat related casualties may occur in large numbers in short duration (84-86) creating almost a disaster like situation and hence the need for public education, provision of evacuation and treatment facilities, and quick first aid. From the public health point of view, the following aspects need to be addressed:

(a) Public education on various preventive measures

Creating public awareness should be high on the list for the public health administrators. Studies have revealed that subjects who listen to media messages through radio or television are less prone to developing heat illness, hence full use of audio-visual and print mass media must be made during the onset of hot weather and also well before the expected heat wave. In Armed Forces settings,

Box - 2 : Education for prevention

- Do not venture out in the sun, especially between 10 am to 4 pm unless the same is necessary
- Avoid strenuous physical exertion between 10 am to 4 pm during the hot weather unless the same is necessary for reasons of occupation.
- Drink at least 4 to 5 liters of cool water in a day even if not feeling thirsty. If undertaking strenuous physical activities, drink a quarter to half liter of water after every half hour, as long as strenuous activity continues.
- Do not wait for 'thirst' to develop. Keep drinking water regularly even if not thirsty.
- If exposure to sun is necessary, place a wet hand towel around your neck.
- Put on a wide brimmed hat of light colour when going out. Simple caps as golf cap may not give enough protection.
- Put on sunglasses when going out in the sun.
- Apply a sun screen ointment with a sun-protection-factor (SPF) of at least 15, which should be able to protect against both UVA and UVB rays , when going out in the sun,.
- Avoid alcohol consumption during hot humid months. If consumption becomes necessary, keep the same within limits of less than 2 small drinks of hard liquor or one bottle of light beer.
- Keep children less than 5 years and elderly (aged 65 years and above) away from sun as far as possible.
- Never leave children (or pets) in a closed, parked car. Try and park your car in cool, shaded place
- Use a car-sun visor to minimize the effect of direct radiant heat produced by the sun.
- Dress for hot, humid weather should be 'breathable' i.e. Loose fitting, light weight, light colored, preferably of cotton material and in one or two layers only.
- Carry a water bottle with cool drinking water whenever you go out in summer months.

all Medical Officers, especially RMOs should endeavour to educate the troops and families regarding these points, as shown in Box - 2.

In addition to providing the messages for simple Dos and Don'ts, the general public should also be made aware of whom to contact during an emergency (telephone numbers and addresses). In addition, messages should also tackle certain myths which need to be busted (Box - 3).

**Box 3 : Myths that need to be removed**

- Alcohol especially if chilled is good (or harmless) during hot weather.
- Track suits or windcheaters should be worn while doing sports or physical training.
- Tough people do not need to drink water.
- After acclimatization (getting used to) to heat, one can do well with only limited amounts of water.
- Drink water only when you are thirsty.
- Sports drinks are better than water.
- Salt tablets are good for preventing dehydration.

(b) Provision of basic preventive amenities at vantage points on a large scale basis, during high risk periods:-

There are four basic amenities which all public health managers must strive to provide to the general public during the hot weather or else, if some high risk activity as sports events or religious/social gatherings are likely. They are:-

(a) Cool drinking water at vantage points.

(b) Covered/shaded areas for taking rest pauses.

(c) Facilities for first aid in a way that they are early accessible to all, particularly the high risk groups.

(d) Public information system to make all aware about the facilities and the telephone numbers/addresses of persons / first aid facilities who may be contacted during need.

(c) Identification of high risk groups and enlistment of community support

Studies have revealed, there are certain high risk groups like agricultural workers, manual laborers, young children, old people, those who are unable to care for themselves or do not have a family to care for them, those staying on higher floors of high rise buildings, people staying in "concrete jungles" of urban areas without much vegetation around, and those using major tranquilizers, anti-cholinergic, alcohol, cocaine or cannabis, and those who form part of large social or religious gatherings/festivals, are more vulnerable to the effects of heat. Enlistment of community support as part of voluntary services with outreach efforts towards these high groups can be of much utility in minimizing the public health impact of heat.

(d) Public Health Surveillance, Early Warning Systems and Disaster Plan

The need to have a good epidemiological surveillance system for heat illnesses as well as various environment conditions that determine those illnesses, need not be over emphasized. This should be established not only for specialized groups like armed forces or industries, but also for the general community as well. It is only through ongoing collection of data and monitoring of trends of occurrence of illness and environmental factors, that proper policy decisions on public health aspects of heat illnesses can be taken (44,87, 88). An effective heat illness surveillance system must include reporting of all heat illness cases according to diagnostic categories, both for inpatient and OPD cases separately. It should include the time and place of exposure, basic clinical data, the antecedent / precipitating factors, personal risk factors and the essential meteorological data (WBT, DBT, GT) according to time and for various locations. The data should be analyzed in an ongoing manner and a "Heat and health early warning system" should be developed to issue early warnings to the physician as well as to the general community. Simple warning criteria for outdoor exercises or events as running, cycling, for general public can be that if the WBGT is >28°C or else if the oxford (WD) index is >26.5°C than the event should be preferably cancelled (87). It should be noted that the Dry bulb / wet bulb / Globe temperature should be recorded as near the place of event and at about the same time when the event is scheduled. More detailed guidelines for use by medical officers in Armed forces are given in Table -1. For combination of DBT and RH which fall in moderate risk category, medical officer should advise the commander to be extra cautious. If the combination fall in high risk zone medical officer should advise the commander to consider canceling the event unless operationally required.

Table - 1 : Rough Guide For Outdoor Physical Exercise based on DBT and RH

| Dry bulbs temp (DBT) °C | Moderate risk of heat effects | High risk of heat effects |
|---|---|---|
| | Relative Humidity | (RH) levels (%) |
| 29.5°C | 100% | - |
| 32.2°C | 70-99% | - |
| 35.0°C | 50-70% | >80% |
| 37.8°C | 40-50% | 60-80% |
| 40.6°C | 20-40% | 50-60% |
| 43.3°C | 10-30% | 40-50% |
| 46.1°C | 10-20% | 30-40% |
| 48.9°C | 1-10% | 20-30% |

**Note**

(a) These meteorological parameters should be recorded as near the place of outdoor exercise as possible and around the same time.

(b) Calculation of RH based on DBT and WBT readings is described subsequently in the chapter on

meteorology in this section.

**Specific Preventive Measures Directed Towards Individuals and Small Groups**

Specific preventive measures directed to individuals or specific high risk groups as industrial workers, military personnel, sports persons etc, are set out to achieve the following objectives :-

(a) To reduce the "heat load":-This is achieved by

(i) Proper protective measures in the industries as isolation of furnaces, air conditioning of works areas, and spray with cold aerosols.

(ii) Seeking shade and wind to the extent possible.

(iii) Frequent rest pauses interspersed between phases of physical activity.

(iii) Putting on proper clothing of low insulation, low energy absorption and high permeability.

(iv) Reducing the amount of exercise in terms of duration or intensity or both especially during hot part of the day.

(v) Avoiding carrying of load or reducing the load.

(b) Improving and maintaining the individual capacity to dissipate heat

This is achieved through acclimatization to heat and proper hydration, as described later.

(c) Avoiding antecedent factors which increases the risk : These include

(i) Avoidance of obesity.

(ii) Avoidance of alcohol and other habit forming agents as cocaine, cannabis and caffeine.

(iii) Avoidance of self medication.

(iv) Avoiding physical activity and exposure to hot environment during febrile illness, until fully recovered.

(v) Ensuring proper sleep of 7 to 8 hours in the night and cooler parts of early morning. An afternoon rest in a shaded place may be of further protective value.

(vi) Avoiding exposure to heat for extremes of age (less than 5 years or more than 65 years) and during pregnancy.

(vii) Maintenance of general hygiene and sanitation, regular bath and care of skin, proper immunization and food/water hygiene to avoid GIT infections.

(viii) Nutritious and palatable meals with plenty of drinking water.

(ix) Treatment of skin conditions as prickly heat, psoriasis, sun burns etc.

(d) Acclimatization to heat

Acclimatization to heat is a process of undertaking gradually increasing physical exercise in gradually increasing hot environment with a view to develop physiological changes, so that the individual, so acclimatized, is able to perform physical activities in the hot environment for which he/she has been acclimatized, with much less risk of suffering adverse effects of heat (88, 89).

The individuals to be acclimatized are subjected to physical exercise in a hot environment in which they are ultimately required to work. The schedule should be in a graded manner, starting with lower intensity of physical exercise for lesser duration (about an hour) in less hot environment. This is gradually increased, both in intensity and duration (to about 90 -120 minutes) and to the required hot environment, by the $6^{th}$ or $7^{th}$ day and continuing thereafter for another 7 days. It takes about 10 to 14 days for status of acclimatization to be achieved.

During the process of acclimatization, individuals should be encouraged to drink plenty of water/oral fluids and additional salt may be given with meals (not as salt tablets). The dictum should be to replace water loss hour by hour and salt loss day by day.

The physiological changes consequent to acclimatization are increased sweating in response to exercise, lowered threshold for exercise induced sweating, lesser rise in heart rate and lesser rise of skin and rectal temperature in response to exercise. In addition, the amount of salt excreted in sweat decreases with acclimatization; there is increased ability to sustain sweat production during prolonged exercise and redistribution of sweating from truncal region to the extremities. Use of heavy or impervious clothing will negate the advantage achieved by acclimatization. It is important to ensure proper hydration to compensate for the water loss.

Secondly, it must be noted that acclimatized people are rendered "heat-fit" only for the particular level of hot environment for which they have been acclimatized; sudden requirement to work in a harsher environment will need further acclimatization.

There is some evidence that physical exercise programme of 2 months, undertaken in temperate environment may lead to improvement in exercise heat tolerance. However, for achieving the ideal state of exercise heat tolerance, acclimatization should ideally be undertaken in hot environment (89). It has also been reported that while acclimatization in a hot and dry (desert like) environment also provides adequate protection in hot and humid (jungle like) environment the reverse may not be completely true, since acclimatization in humid heat produces physiological changes which are more specific for hot and humid conditions (90, 91). Hence, personnel moving to hot and humid areas, even from hot & dry areas, need to be additionally acclimatized.

The tolerance which results from acclimatization may be reversed by use of alcohol, dehydration, sleep deprivation, infections and by salt depletion and hence these aspects must be taken care of, even after individuals have been fully acclimatized (92-94). Moreover, without ongoing heat exposure, it is likely that nearly all the beneficial changes of acclimatization may be lost in about two-and-a-half to three weeks time, although partial losses due to non-exposure for few days can be made up by the body on re-exposure to hot environment. Hence,

acclimatized subjects should continue to exert ohysically in the hot environment once thay have been acclimatized, to retain the acclimatized state. Physically fit subjects are likely to retain the beneficial effects of acclimatization for a longer time (90, 91, 95, 96).

As regards the role of supplemental salt, for a fully acclimatized person, the same may not be required. This is because, with acclimatization, the secretion of sodium in the sweat is greatly reduced so that healthy, acclimatized persons can secrete up to 9 liters of sweat in a day and live in perfectly well salt balance, with 5 to 6 grams of dietary salt per day. However, subjects who are not acclimatized or are in the process of acclimatization in unusually hot environment or else are not consuming normal diet, an additional 10 grams salt may be given in the diet (not as salt tablets) till they are fully acclimatized, taking care that adequate hydration is maintained. Corticoids (Aldosterone, deoxycorticosterone) sometimes administered during or before the process of acclimatization do not seem to be having any useful role. The role of heat shock proteins (HSPs) which are released as a result of exposure to heat, in assisting during acclimatization is still in the preliminary studies (97).

(e) Maintenance of Hydration

During the process of acclimatization and also after acclimatization it is imperative that adequate hydration be maintained, other wise the entire process of acclimatization will be negated. In certain settings particularly in military and industries, there is a general feeling that once fully acclimatized; persons can do with greatly reduced amount of water (the so called water rationing or hard-scale of water or water discipline). Medical persons must explain to commanders that this feeling is scientifically unfounded and can, in fact, lead to disastrous results. It needs to be noted, and explained, that there is no substitute to adequate hydration even after full acclimatization since acclimatization itself works on the principle of increasing the sweating. One can acclimatize to physical work in heat but there is nothing like acclimatization to dehydration.

Persons should be encouraged (even, at times, forced or ordered) to drink water regularly, while working in hot environment, even when not thirsty. It must be explained clearly that thirst is quite a poor index of dehydration and should not be relied upon (98-100). Drinking only when thirsty will result in inadequate replacement of water losses and result in dehydration of more than 2% of body weight, which may be dangerous. A very rough but useful guide for the RMO / MO functioning at isolated areas is to notice the colour of urine of the subject; increasingly yellow shades of urine colour indicate increasing dehydration.

The best fluid for drinking is cool, hygienic water. There does not seem to be any scientific rationale for the so called 'Sports Beverages' which contains large amounts of electrolytes and glucose. Of course, the only advantage of sports beverages seems to be their greater palatability, so that subjects drink more as compared to plain water (101-104). Glucose and electrolytes in such drinks do not increase the intestinal absorption of water, compared to plain water as often claimed (103). There is no place for supplemental salt tablets as has already been emphasized earlier. There is, however, some evidence that providing carbohydrates, in the forms of oral 5% or 10% glucose or sucrose solutions or oral "glucose polymer solutions" (available commercially) can improve the exercise performance and can be used in sustained sports activities (soccer, hockey and tennis) or sustained military operations (105,106).

It would be worthwhile to drink half a litre of water, about an hour before starting physical activities in hot weather, as a 'prehydration' method and to correct any pre-existing water deficit (107). Thereafter, every person should drink 300 to 350 ml water (equal to the usual steel tumbler) every half hourly, during the exercise, without waiting for thirst. In fact, more frequent intakes of smaller amounts (250 ml i.e., one ordinary size glass tumbler every 20 minutes) may be even better. At the same time, care should be taken not to drink so much that it leads to abdominal distension (108-109). A safe upper limit can be a maximum of 500 to 600 ml at a sitting. There is no harm in drinking cold water; there is no evidence that it causes cramps. In-fact, cold water increases the motility of gastric smooth muscle leading to rapid empting and hence faster absorption of water from proximal intestine (110).

**First Aid**

This is described subsequently under management of heat effects

## Clinical features of effects of heat & their management

**Pathophysiology**

As a part of thermoregulatory process, even an increase of 1˚C in the temperature of blood generates signals to the hypothalamic thermoregulatory center leading to increase in heart rate and cardiac output, which, coupled with the sympathetic cutaneous vasodilatation, greatly increases the skin blood flow. Sweating is activated and its evaporation cools the body surface, unless the air surrounding the body is fully saturated with water, i.e., having relative humidity (RH) of 100%.

Increasing the movement of air in contact with the body also increases cooling by promoting evaporation of sweat. Sweating, however, leads to loss of water and salt, which may be as high as 2 liters per hour under conditions of high humidity and physical exertion. If the water and salt are not replaced adequately and concurrently, the fluid reserves would be depleted, even though the body core temperature may not be very high. This condition is called "Heat Exhaustion" (HE).

However, at times, the thermoregulatory response may be overwhelmed by the hot environment, even though the fluid and salt reserves of the body may be adequate. Such thermoregulatory failure, coupled with exaggerated acute phase response (increased production of inflammatory cytokines & endothelium derived vasoactive factors and activation of coagulation process) and alterations in the expression of Heat Shock Proteins (HSPs), leads to "Heat

Stroke" (HS). For these reasons, a number of cases of HE, if not properly managed, would also pass on to HS. Following HS, a Multi-Organ- System-Damage (MOSD) results from a complex interplay between the cytotoxic effects of heat and the inflammatory and coagulation responses of the host.

**The Clinical Syndromes Of Adverse Environmental Heat**

Heat Stroke (HS) :-

The classical clinical description of HS is the triad of hyperpyrexia (rectal temperature > 40°C), CNS dysfunction and anhidrosis. Anhidrosis, however, is not a diagnostic requirement since it may appear later when volume depletion is severe. Moreover, in cases which initially start as HE or cases of HS which occur among young people who have been exerting physically, the skin may be moist. Brain dysfunction is usually severe (coma, stupor or delirium), but may sometimes be subtle, manifesting as inappropriate behaviour or impaired judgment. In fact, any person who develops irrational or confused behavior following exposure to heat stress either with or without a history of physical exertion, should be treated as a potential HS patient. Other clinical features include evidence of dehydration, shock, convulsions and, sometimes, mild icterus. Two forms of HS are recognized, viz. the classical (CHS) and the

Table - 2

| | CHS | EHS |
|---|---|---|
| Age group | Elderly | 15 to 45 years |
| Previous health status | Usually compromised | Healthy |
| Concurrent activity activity | Sedentary | Strenuous |
| H/O drug use | Often present | Usually present |
| Sweating | Often absent | May be present |
| Skin | Dry | Frequently moist |

exertional (EHS) form. The clinical differences between the two forms are shown in Table - 2.

**Differential Diagnosis**

Heat stroke should be considered as a possibility in any patient who presents with elevated body temperature and altered mental functions. Important and common diseases which need to be excluded are tropical infectious diseases like cerebral malaria, encephalitis and meningitis. Other diseases which need to be considered are thyroid storm, pheochromocytoma, status epilepticus, cocaine and amphetamine abuse, delirium tremens and CVA especially pontine hemorrhage. The diagnosis of HS is usually one of exclusion and the typical history of exposure to hot environment during the immediate past is a strong indication towards heat stress hyperthermia.

**Laboratory Investigations**

Blood should always be drawn for a peripheral blood smear for malarial parasite as well as for other infectious causes of hyperpyrexia with CNS dysfunction. Laboratory findings of HS include haemoconcentration, mild leukocytosis, elevation of blood urea and, in some patients of EHS, hypoglycemia. Impaired blood coagulation with lowered prothrombin, low platelet counts, hypofibrinogenaemia and features of DIC may be seen. Serum electrolytes studies generally show normal or high chlorides, hypokalaemia, hypocalcaemia, and hypophosphataemia. Enzyme studies show increase in CPK, SGOT and SGPT levels. If rhabdomyolysis or acute renal failure (secondary to acute tubular necrosis) has set in, urine will show myoglobinuria, proteinuria, and hyaline and granular casts, and there will be increase in BUN levels.

**Complications**

The most serious complication of HS is Multi-Organ-Systems-Damage (MOSD), manifesting as hepatic failure, renal failure, cerebellar damage, cerebral oedema and

Box - 4 : Heat Stroke : Management at First Aid Level

- Record rectal temperature. If it is not possible to record rectal temperature, record oral temperature and add 0.5°C.
- Try and move patient to a cooler, shaded place.
- Remove the clothes.
- Spray skin with water at 25 to 30°C or wrap the patient with a sheet soaked in water at 25-30°C.
- Continue fanning manually or with an electrical fan.
- Keep vigorously massaging the skin to prevent cutaneous vasoconstriction during cooling.
- If available, place ice packs or towel soaked in cold water around the neck, axillae and groin.
- Nurse in the comatose position; clear oral secretions.
- Transport to the medical facility as an emergency.

Box - 5 : Heat Stroke Management at the Level of Solo-Physician or at Primary Health Care Level

- Initiate measures outlined under first aid if not already initiated
- Establish Intravenous line; take blood sample for investigations.
- Continue cooling measures as outlined in first aid.
- In case temperature is not reducing, immerse the patient in tub containing cold or iced water, keeping the head and neck outside the water surface.
- Start normal saline (or Ringer lactate) drip at 20-25°C. Give a challenge of 1 litre fluid in 15 to 30 minutes. Add other electrolytes such as $K^+$, as guided by subsequent investigations.
- If any evidence of seizures, give IV Diazepam 5-10mg over 10 minutes
- If facilities are available, intubate the patient and initiate ventilatory support.
- If rectal temperature is not coming down or there is evidence of cerebral, hepatic or renal complications transfer the patient to a hospital with adequate facilities.

arrhythmias. Rhabdomyolysis and DIC are other serious complications.

**Prognosis**

HS must be treated as an emergency. Mortality may be as high as 30% to 50% among cases in which treatment is delayed. Mortality is directly proportional to the level of core temperature and its duration. Prolonged coma of more than 2 hours is a poor prognostic indicator. Among survivors, neurological recovery generally occurs but some deficit may persist in upto 20% of the cases.

**Treatment**

HS must be treated as a serious medical emergency. Delay in institution of appropriate therapy by even few minutes may make all the difference between life and death. The treatment objectives are, firstly, rapid cooling to bring down the core temperature to below 39°C, reducing it by approximately 0.2°C per minute; secondly, rehydration and care of comatose patient; and, thirdly to support the organ system function. Cooling measures should be stopped once core temp falls below 39°C. The steps in management at the first aid level, and primary care / solo physician level (RMO / OC ADS / MO at peripheral hospital in context of armed forces) are shown in Box 4 & 5 respectively.

**Heat Exhaustion (HE)**

The features which differentiate HE from HS are that core temp is less than 40°C and there is no evidence of CNS dysfunction, though some patients may be anxious or irritable. The main features are feeling of exhaustion, nausea, headache or light headedness, features of dehydration, hypovolaemia (tachycardia, loss of skin turgor, dry mucous membranes and thirst) and syncope. Sweating is usually profuse and skin is moist. Rectal temperature is usually between 39°C to 40°C, though some patients may have a normal temperature. In fact, HE may actually be a point along the continuum which, if not managed energetically, may move on to HS. Urinary output is reduced and urine may be light to dark yellow in colour. Depending on how energetically the patient has been replacing either water or salt, two subtypes, viz. Water Depletion HE and Salt Depletion HE may occur. In water Depletion HE, as compared to Salt Depletion HE, vomiting and muscle cramps are not a prominent feature, while thirst is prominent, and serum $Na^+$ is normal or raised. However, mostly a mixed picture, as described earlier is seen.

Treatment consists of shifting the patient to a cool, shaded and ventilated place. The clothing should be loosened, patient placed in recumbent position and feet should be elevated. If patient can drink, give one liter of water (or, preferably, "Oral Rehydration Solution" 1 packet dissolved in one litre water or else a solution of 2.5g common salt and 2.5g baking soda in 1 liter water) orally in about 30 minutes Give a total of 2 liters in about one to one-and-a-half hours. Simultaneously, measures for cooling, as described under heat stroke, should be initiated. Keep monitoring rectal temp; if rectal temp goes beyond 39°C, the patient may be passing on to heat stroke and should be shifted to a medical facility for appropriate management.

**Other Adverse Effects Of Hot Environment**

Heat Cramps

These manifest as spasms of muscles, especially lower extremity and shoulder, following heavy muscular exertion in hot environment, with associated intake of hypotonic oral fluids. Treatment consists of oral administration of 0.1% to 0.2% salt solution. Severe cases or those with vomiting should be given IV normal saline.

Heat Tetany

Symptoms include carpopedal spasms and paraesthesiae following short exposures to excessively hot environment, leading to hyperventilation and respiratory alkalosis. Treatment consists of removing the patient to a cool environment and asking him to slow down the respiration.

Heat Syncope

This manifests as syncope following exposure to heat stress as a result of peripheral vasodilatation. One should exclude other serious causes of syncope. Treatment consists of removal of patient to cool environment and oral rehydration.

Heat Oedema

This presents with pitting oedema of hands and feet, usually in the elderly, following exposure to heat stress. Other causes of oedema should be excluded. Treatment consists of reassurance, elevation of affected limbs and, if required, compression bandage.

Prickly Heat (Lichen Tropicus, Milaria Rubra)

It manifests as erythematous, pruritic, maculopapular rash. If the condition is allowed to progress, extensive prickly heat that can progress to chronic dermatitis and superinfection can occur. Prevention consists of regular baths with cool water after gently scrubbing the skin, and wearing loose, light weight clothing. Local application of calamine lotion or chlorhexidine lotion alongwith oral antihistamines is helpful. In case of severe forms, local application of 1% salicylic acid cream and antibiotics for superinfection (usually S. aureus) should be given.

## Global warming & ozone attenuation

Increased human activity inclusive of rapid industrialisation, urbanisation and increased burning of fossil fuels coupled with deforestation has lead to Global warming affecting the earth's ecosystem through the changing climatic & environmental conditions.

The earth's mantle of atmosphere, consisting of various gases, acts like a Green House allowing the passage of short wavelength solar radiations in to the biosphere, trapping longer wave length infrared radiations. Presence of these atmospheric gases acts like an insulator for the earth and prevents excess of heating and cooling during the day and night respectively. Otherwise the mean temperature of the earth would have varied from 49°C to (-) 40°C during the day & night as compared to the existing global mean temperature variation of 14°C to 15°C. This phenomenon is known as Green House Effect. Increased

combustion of petroleum fuels through ever increasing automobiles, accelerated by global industrial and commercial development are adding many pollutant gases in to the atmosphere in large quantities. About 6 billion metric tonnes of carbon dioxide are being added to the troposphere annually which is ever increasing. Tropical rain forests, an important carbon sink, are being rapidly depleted & unicellular phytoplankton present in sea, another carbon sink, is damaged by increased ultra violet radiation flux due to depletion of stratospheric ozone resulting in increased concentration of carbon dioxide in the green house which would trap more solar radiation in the biosphere leading to Global Warming. The annual average global temperature has risen gradually from 14.5°C in 1886 to 15.4°C in 1995 which closely relates to the increase in atmospheric heat trapping green house gases. It is predicted that the mean temperature of the globe might increase by 1°C to 3.5°C in the twenty first century with all its adverse effects.

Ozone ($O_3$) is formed by combining of an $O_2$ molecule with oxygen atom under the influence of solar radiations. The average concentration of ozone is about 300 parts per billion by volume in the atmosphere of which 90% is present in stratosphere. Ozone even in such quantities plays a vital role in supporting life on earth. The conversion of Ozone into oxygen molecules and reforming into ozone under the influence of solar radiations helps in conversion of solar energy to heat. Ozone exerts its protective effect by absorbing ultra violet radiations of wave lengths from 290 to 315 nm . Ultra violet radiations are partially shielded by clouds, dust and other air pollutants. Reduction in ozone concentration with clear sky will have adverse effects.

The chlorofluorocarbons (CFCs) are used in refrigeration industry, as propellants in aerosol sprays, as blowing agents for plastic foam and as cleansers in electronic industry. Over 7 lakh metric tonnes of CFCs are not removed by rainfall as they are not soluble in water and further their half lives are over 100 years and thus can exert their influence for a long time. Chlorofluorocarbons like each carbon monoxide molecule can destroy 10,000 ozone molecules other compounds like halocarbons, oxides of nitrogen can also destroy ozone.

**Effects**

The effects of global warming on human health are both direct and indirect which include the following :-

(a) Heat Stress

An increase in average global temperature will result in experiencing of irregular heat waves in mid latitude levels. Minimum temperatures in night and winters would increase more rapidly than average temperatures. A warmed atmosphere holds more water vapour (6% more for each degree celsius) resulting in increased humidity in heat waves.

(b) Weather Disasters

Global warming would result in frequent and more severe storms with heavy precipitation and flooding. The increased temperature of air and oceans result in more evaporation , clouds and rains mainly in coastal areas.

(c) Rising Sea Levels

In the preceding 100 years, sea levels have risen by 10 to 25 cm. Even the expected rise of sea levels sea level by 50 to 100 cm due to thermal expansion of the oceans, melting of glaciers and ice caps will inundate large population centres and much fertile land, resulting in 50 million environmental refugees world wide. Mainland coastal regions and low islands will be in danger. In addition, adjacent land would be rendered unfit for agriculture by the rising salinity of water table. In India 5.7 Lakh hectares and 7 million peoples are at the risk of inundation.

(d) Climate change & Infectious Diseases

Outbreaks of vector borne diseases which are dependent on climatological factors would be common as temperatures coupled with increased humidity would help the vector to develop early and live longer and thus could transmit the disease for longer duration.

Ozone attenuation would adversely affect the life on earth by allowing the ultra violet radiations in the biosphere and their consequent ill effects are as skin diseases, varying from simple sunburn like lesions to cancers (squamous cell & basal cell carcinomas and other malignancies); Keratitis, cortical / subcapsular cataracts and lowering of general immune response.

# Adverse Effects of Cold Environment : Epidemiology and Prevention

Annals of warfare history have recorded cold injuries as a major problem in military operations. Descriptions of Xenophon's march of Ten Thousand in 400 BC in Armenian region, and Hannibal's loss of large numbers of his Army of half a lakh, while crossing the Alps in 218 BC, are quite vivid (1,2). Deleterious effects of extreme cold are inherent in the atmospheric environment at high altitude, but they also occur at low altitudes as in the Polar Regions. Even sub tropical areas like the plains of Northern India experience severe winters, where such illnesses do occur.

Human exposure to extreme cold produces significant physiologic and psychological challenges. Cold is considered as an important environmental stressor, in view of its potential lethal / serious consequences (3). The human body becomes even more susceptible to the adverse effects of cold when chronic exertional fatigue, sleep loss, and inadequate nutrition are also co-existent (4). Initially, the relevance of cold was limited to the militaries with operational deployment of troops at high altitude and extreme cold areas; the effects of cold climate get further complicated and aggravated due to hypoxia. Thereafter, the medical fraternity got further interested in this field, following the expeditions to the Polar Regions. As of now, cold injuries have become a matter of study, not only in context of military or polar expeditions, but because of increased participation by the general population in such outdoor activities as mountaineering, ice skating, ice fishing, cross country skiing, snow-games, etc.

Extreme cold conditions occur in India in the Himalayan, Sub - Himalayan and the northern Indian plains with cold waves and deaths being recorded every year. Over the 5-year period of 1999 to 2003, a total of 3,524 deaths due to cold exposure have been reported; the actual magnitude may be higher. Groups at particularly high risk include military personnel, agriculturists, mountaineers and persons engaging in adventure or winter sports. From socio - economic aspect, persons with low income, poor housing and inadequate clothing are at particularly high risk especially during the cold wave conditions. Extremes of age (<5yrs or >65yrs), physical exhaustion, pre - existent malnutrition or starvation, use of alcohol and underlying diseases (hypothyroidism, hypoadrenalism, diabetes and CV Disease) increase the risk.

## Adverse Health Effects of Cold

Adverse effects of cold environment can manifest as either generalized effects (hypothermia) or local "tissue-freezing" effects as frost bite, or non-freezing cold injuries (NFCI) as trench foot and chilblains. Besides, local effects due to UV rays predispose to solar keratitis (snow blindness) and sunburns, while exposure to cold, dry air predisposes to rhinitis. Local effects on dental fillings due to cold lead to bacterial invasions and dental problems.

## Pathophysiology

The physiological protective responses to generalized cold involve, firstly, peripheral vasoconstriction, which tends to act as an "insulator" for the inner body core, in an effort not to lose the core heat, and, secondly, increased thermogenesis by shivering. Coupled with behavioural factors as seeking shelter, putting on clothes and increased muscular activity, the body physiology tries to normalise the core temperature. In the initial stages, there is increase in metabolism, heart rate and cardiac output. However, as exposure to cold increases, the overall metabolism slows down and there is reduction in heart rate, cardiac output and respiratory rate.

Local cold induced injuries are due to formation of "Ice - crystals" within the cells followed by rupture of cells due to endosmosis or due to tearing by ice crystals. Distal areas of the body and areas with high surface-to-volume ratio (ears, fingers, toes, nails and cheeks) are more susceptible.

## Generalisied Hypothermia

### Clinical Features

Early symptoms of generalised adverse effects of cold become apparent as the "core" (rectal) temp. drops below 36˚C and are clearly evident once it is below 35˚C. Depending on the core temp, hypothermia may be classified as borderline (36 to 35˚C), mild (35 to 32˚C), moderate (32 to 28˚C) and severe (<28˚C). One of the earliest symptoms of hypothermia is change in behaviour but, unfortunately, the victim is the last person to notice such changes himself. There are mild mood changes, lack of affect, apathy, uncoordinated movements, ataxia, confusion and decreased ability to sense cold. Initially, there is tachycardia, tachypnoea & shivering which can be voluntarily controlled. However, as hypothermia becomes more severe, (32 to 35˚C) there is bradycardia and decrease in respiratory rate. Higher reasoning becomes impaired (e.g., the person may not be able to count backwards from 100, subtracting 9 every time). Shivering becomes violent and cannot be stopped voluntarily. Lack of appreciation of cold may lead to "paradoxical undressing" (the person starts removing the clothes rather than putting on more clothes). Gait becomes stuporous. As the core temp falls below 32˚C, shivering stops. Skin becomes blue and puffy. Patient becomes semiconscious and muscles start becoming rigid. Trismus is often present. There is marked bradycardia and lowering of respiratory rate. ECG shows the 'J' (Osborn) wave at the junction of QRS complex with ST segment in about 80% cases and this may be confused with myocardial ischaemia. Cardiac dysrythmias are very common, especially atrial / ventricular fibrillation. Once the core temp drops to 28˚C or less, the patient is completely unconscious with severe bradycardia. Radial

pulse may not be palpable and carotid pulse may reveal as low as 2 to 3 beats per min. Respiratory rate is also reduced to 1 to 2 per min. Muscles become rigid and pupils dilated. At this stage the patient may appear dead but may not be so. Carotid pulse must be carefully palpated in all such cases.

### Investigations

The most important investigation in a patient of hypothermia is to accurately monitor the core temperature. If possible, an X-ray of the chest or other regions may be taken, primarily to rule out other traumatic injuries since coexisting trauma, haemorrhage and shock may worsen the manifestations of hypothermia. Blood biochemistry usually shows metabolic acidosis, azotaemia and haemoconcentration. ECG may show the 'J' wave as described above, bradycardia and dysrhythmias.

### Treatment

Hypothermia should be treated as a medical emergency. Early recognition and institution of therapy may make all the difference between life and death. The basic principle of management is quick warming of the "core" without causing simultaneous vasodilation of the periphery, from the level of first aid till the most elaborately equipped critical care facility. The steps in management at the first aid level, and at the primary care/ solo physician level are shown in Box - 1 & 2, respectively.

During the process of rewarming, one should be very careful as regards the phenomena of "after-drop". This happens if the extremities are also rewarmed or else the patient starts exerting again, leading to vasodilation of peripheral vessels in arms and legs, thus releasing extremely cold blood as well as acidic metabolites (which were trapped in this part of the vasculature). Once this cold blood and metabolites are shunted back, it further cools the brain, heart and viscera as well as making the myocardium more susceptible to dysrhythmias. Hence, during rewarming, do not warm the extremities and do not let the patient exert even if consciousness has been regained.

One also needs to be careful while instituting cardiopulmonary resuscitation (CPR) in a patient of hypothermia, who may appear dead with dilated, fixed pupils and no discernible pulse or respiration. Such patient may be still alive, in a "metabolic icebox". Instituting CPR in such a patient may precipitate an "after drop" and dangerous dysrhythmias. Hence, in such a patient, one should carefully check the carotid pulsation and respiration to detect very low heart rate (2 to 4 min) and low respiratory rate (2-3/min). If there is evidence of life, one should start rewarming and not institute CPR. CPR should be started only if it is confirmed that pulse is absent. Once started, CPR should be continued as the patient is being rewarmed. There have been cases when patients with severe hypothermia have been given CPR for as long as 3 hours and finally revived. The patient should be declared dead only after he has been rewarmed to core

**Box - 1 : Management at First Aid Level (Nur Asstt. / RMO)**

- Remove wet clothing only when patient has reached a warm, dry and sheltered environment and not in the open.
- Immediately wrap the patient all around, including head, with warm clothes, blankets, quilts, sleeping bags - whatever insulatory material is available, even news papers or rags. Make an "insulatory wrap" of about 4 inches thickness all around the patient. Provide a wind and water proof outer most layer, as polythene sheets.
- Make hot packs with warm water bottles covered with a cloth, or warm pads, at 42°C to 45°C, and apply them to axillae , groin and neck.
- Do not warm the extremities at this juncture. Place arms and hands on the sides and not on the abdomen or in axillae.
- Do not let patient do any physical activity. Treat as a "stretcher case".
- If patient can take orally give warm, sweetend tea or milk to provide "fuel".
- Do not massage the limbs.
- Do not give alcohol or tobacco
- Evacuate to a sheltered place preferably to a medical facility at the earliest.

**Box – 2 : Management At Solo Physician / Primary Care Level (RMO / OC ADS/ MO Peripheral Hospital)**

- Check rectal temp and other vital parameters.
- Quickly open up the insulatory layer, remove wet clothing (if not already removed at first aid level). Change patient to dry clothing.
- Apply warm packs at axillae, groin and neck. Reapply the "insulatory layer" around the patient, as described under first aid.
- Establish IV line and start 5% dextrose (or any other crystalloid) preferably warmed to 37 to 41oC. Initial fluid challenge should be 500 ml to 1 litre in half to 1 hour.
- Start oxygen inhalations with face mask, 4litres/min, preferably warm and humidified oxygen, if equipment is available.
- If facility exists, pass an indwelling bladder catheter. Start monitoring urinary output.
- Keep monitoring core temperature. The rectal thermometer should be inserted to at least 15 cm into rectum. If there is no increase in core temp despite rewarming efforts in more than an hour or else if patient is not shivering and unresponsive, consider evacuation to a well-equipped hospital. Evacuate as a stretcher case.

temp of 36˚C and CPR fails at that temp. The dictum is "A patient of hypothermia, in finality, is never "cold and dead" but is "warm and dead".

### Localized Effects Of Cold

Frost Nip and Frostbite

Frost nip involves freezing of top layers of skin tissue. It is generally reversible and manifests as numbness and white, waxy or rubbery feeling of the affected skin but the deeper tissue is still soft. Frostbite is the more severe form and affects all layers of the skin and often the deeper tissue also. Frostbite is of four degrees, depending on the depth of the tissue involved. As an urgent first aid measure, remove any constrictive clothing or bands. Start local warming by placing the affected part in a warm water bath at 40-42˚C. If nothing is available, place the affected part in the axiliae or on the stomach of another healthy person. Analgesics and sedatives should be given for relief of pain. Initiate immunisation with tetanus toxoid and evacuate to a surgical facility at the earliest opportunity. If generalised hypothermia and local frost bite both are present, first treat the patient for generalized hypothermia. Local rewarming for frostbite should be undertaken only after core temp has returned to normal.

Non - Freezing Cold Injuries

These include chilblains and trench (immersion) foot, occurring due to prolonged exposure to cold environment with wet conditions. Chilblains manifest with initial pallor of affected area (usually fingers, toes, cheeks or earlobes) followed by erythema, pruritus and intense pain. Prevention by way of avoidance of exposure to cold and wet conditions among susceptible persons is the most important. Otherwise, there is no specific treatment, though symptoms may be ameliorated by oral nifedipine in some cases.

Trench foot is caused by prolonged exposure of feet to cold and wet conditions. The skin is reddened with tingling pain and itching. Gradually the skin becomes pale, mottled and finally dark purple, gray or blue. If the circulation remains impaired for more than a few hours, permanent damage to the affected part can occur. Treatment consists of gentle drying, elevation of the affected limb and keeping it at an environmental temperature of 18 to 22˚C while keeping rest of the body warm. NSAIDS may be given for relief of pain. The patient should not walk on the affected limb till fully cured. Prevention is, once again, very important and consists of keeping the feet clean and dry, dabbing the feet with aluminium hydroxide powder thrice daily, and changing into dry socks and shoes at the earliest .

## Epidemiology

### Environmental Factors

Cold may exist in conjunction with very low atmospheric humidity, or with high humidity. It may alternate with very hot summers as in continental environs of the plains or with mild summer as in the mountains. There may be blizzards associated with it. The exact nature of the effects of cold may vary from one type of cold environment to another. The following major environmental factors determine the severity of cold induced diseases :-

Severity of Cold

Severity of atmospheric cold and its abrupt occurrence increases the liability of incidence of cold injuries among non-acclimatised, non-resident individuals.

Duration of Exposure

It is an important factor determining the final injury. About 10 hours of exposure to minus 10˚C is needed to cause the cold injury, but may occur in shorter period of time, in intense cold.

Wind Movements

These hasten tissue cooling. The combination of ambient low temperature and wind movement is termed as the 'wind-chill factor'. The probability of cold climate to cause cold injuries is directly proportionate to the 'wind-chill' factor rather than its temperature alone. Increased wind velocity, by increasing the 'wind-chill' factor, increases chances of generalised and localized injuries due to cold. Wind makes a substantial difference; air currents on a windy day magnify heat loss because the warmer insulating air layer surrounding the body continuously loses heat to the cooler ambient air. For example, at 0˚C ambient temperature, the conditions become equal to minus 18˚C, if the wind is blowing at a speed of 40 km per hour. The danger zones, based on combinations of ambient temperature (in degrees Celsius) and wind velocity (in Km per hour) are as highlighted in table - 1.

Table - 1 : Danger zones for cold illnesses, based on Combinations of air velocity & ambient temperatures

| Ambient air temperature (°C) | Wind velocity (Kmph) at that temperature which will indicate danger zone |
|---|---|
| - 10 | 40 |
| - 12 | 32 |
| - 15 | 24 |
| - 18 | 24 |
| - 20 | 16 |
| - 23 | 16 |
| - 26 | 8 |
| - 29 | 8 |
| - 32 | Even minimal wind movements |
| | |

Moisture

Moisture is a good thermal conductor and its presence in contact with the skin interferes with the natural insulating action of the sebaceous material on the skin. Presence of moisture in the clothing increases its thermal conductivity, obliterates air-containing meshes in clothing, thereby decreasing its insulating action and extracts body heat by evaporation. Wet clothing, either due to external wetting or internal wetting due to sweat, is therefore dangerous.

Hypoxia

High altitude hypoxia deprives the cardiac muscle of oxygen and thereby decreases the cardiac output, lowering the peripheral blood and oxygen tension and reducing the tissue oxygen saturation. Hypoxia also devitalises the capillary endothelium and increases exudation into tissues. All these increase the proneness of the extremities to get cold injuries; skin, being the least vital organ, suffers the most.

Clothing and shelter

An extremely important determinant of cold illnesses and their prevention is the adequacy of clothing and shelter in such weather. Clothing insulates the body from its surroundings. It can also cause radiant heat gain (mainly from solar radiations) as well as retard conductive and convective heat loss in cold climate. The index of thermal resistance of clothing is measured in 'Clo'units. It indicates the insulative capacity provided by a layer of the clothing. A value of 'one Clo' means that for a person at rest in an environment of 21˚C and Relative Humidity (RH) of 50%, and absolutely still air (no air movement), clothing of one clo unit will maintain the core temperature of such person, under such circumstances, for indefinite periods. Thus, to maintain a person in comfort, clothing with higher clo units will be required if metabolic heat production decreases, or ambient temperature decreases, or RH decreases, or air movement increases. The values required to maintain core temperature according to various physical activity levels and at various ambient temperature are given in Table-2. The clo values of certain commonly used clothing are given in Table-3.

These values are for routine clothing used in cold climate areas; special cold climate clothing have different and higher values.

Table - 2 : Clo values required to maintain core temperature according to various physical activity levels at various ambient temperatures.

| Level of activity | | Temperature °C | | |
|---|---|---|---|---|
| | | 0 | -20 | -50 |
| | | Clo values of clothing | | |
| Heavy work | (6 MET) | 1.0 | 1.6 | 2.2 |
| Moderate work | (3 MET) | 1.6 | 2.8 | 4.2 |
| Light work | (2 MET) | 2.6 | 4.0 | 6.2 |
| Very light work | (1.5 MET) | 3.4 | 5.6 | 8.2 |
| Rest | (1 MET) | 5.4 | 8.3 | 12.4 |
| Sleep | (0.8 MET) | 6.7 | 10.6 | 15.5 |

Table - 3 : The Clo values of certain commonly used clothing

| Garment | Clo value |
|---|---|
| Brief | 0.04 |
| T shirt | 0.09 |
| Full sleeve shirt | 0.25 |
| Half slip, nylon | 0.14 |
| Flannel full sleeve shirt | 0.30 |
| Ordinary trousers | 0.28 |
| Thick long socks | 0.10 |
| Inners (full sleeve vest and pyjama) | 0.50 |
| Sweater | 0.28 |
| Thick sweater | 0.35 |
| Thick sweater, full neck | 0.37 |
| Dinner Jacket | 0.37 |
| Full Coat | 0.60 |
| Parka | 0.70 |
| Boots | 0.05 |
| Fibre coveralls | 1.03 to 1.13 |
| | |

**Human (Host) Factors in cold illnesses**

Age and Sex

People at extremes of age (less than 5 years or more than 65 years) are known to be more susceptible. Women seem to be protected possibly due to the increased subcutaneous fat. There is preliminary evidence from laboratory studies that dark skinned people may be more susceptible to adverse effects of cold as compared to whites. Circulatory Stagnation: Local circulatory stagnation allows local temperature to be lowered, increases liability of exudation through the already damaged vascular endothelium and also deprives the tissues of nutrition and oxygen, thereby increasing devitalisation. This may be caused by forced immobility due to being pinned down in shelters or vehicles, or during conditions of prolonged bad weather. Tight fitting clothes, boots or socks may also cause constriction.

Physical Inactivity

It increases risk of cold injuries. Activity increases the metabolic heat production and is an important prophylaxis against cold injuries.

Nutrition

Adequate, or even increased, calorie intake is necessary to sustain the increased heat production and the increased work required to function in a cold environment (5). It plays an important part in resisting cold effects, and malnutrition predisposes a person to cold injuries. Vitamin A deficiency increases liability to infections especially of mucous membranes. Vitamin C deficiency increases capillary permeability and decreases healing power of tissues. It also plays a part in ameliorating the cold stress and helps in the General Adaptation Mechanism. The presence of adequate subcutaneous fat definitely increases the insulation and hence protects against cold (6, 7).

Poor Physical Health

Intercurrent /chronic diseases, convalescence and physical exhaustion decrease the general tissue vitality, physical activity and also power of acclimatisation, and hence increase the liability to cold injuries.

Poor Mental Health

Mental apathy, fatigue, fear and anxiety which are common in a cold climate, especially under hypoxic conditions at high altitude, cause neglect of precautions and increase in physical inertia, thereby increasing liability to cold injuries.

### Local diseases

Local injury or skin infection predisposes the particular part to cold injuries.

### Tobacco

Use of tobacco increases the risk of frost bite due to severe vasospasm induced by it and definitely aggravates the injury itself when once established.

### Alcohol

Alcohol has been universally regarded as a very important and avoidable risk factor in cold illnesses. Its consumption, especially if followed by exposure to cold, or excessive physical activity or lethargy after alcohol consumption, increases risk of general hypothermia and also local cold injuries.

### Cold Adaptation

Adaptation to cold, although not as good as acclimatisation to heat or high altitude, is nevertheless an important factor determining individual vulnerability to cold injuries.

## Prevention of cold illnesses

### Clothing

Special attention should be given to clothing in cold weather, in a scientific manner. In providing insulation from the cold, the mesh of the cloth fibres traps air that then becomes warm. This establishes a barrier to heat loss because both, the cloth as well as the trapped air conduct heat in a poor fashion. Several layers of light clothing or garments lined with animal or artificial fur, feathers or synthetic fabrics (with numerous layers of trapped air) provide better insulation than a single, bulky layer.

The clothing layer in contact with the skin should effectively "wick" moisture away from the body's surface to the next insulating clothing layer for subsequent evaporation. Wool or synthetic (e.g. polypropylene) that insulate well, as well as dry quickly, serve this purpose. A woollen cap very effectively contributes to heat conservation since nearly a third (33%) of all body heat loss is from the head region alone. If clothing becomes wet either due to external moisture (snow or rains) or due to condensation from sweating, it looses as much as 90% of its insulating properties; this may actually start facilitating heat loss from the body rather than conserving heat. Hence, wet clothing should be changed at the earliest opportunity in cold environment. Secondly, it must be ensured that while the clothing should provide adequate insulation (by way of adequate material and layers, as described above), it should, at the same time, allow for water vapour to escape through the clothing, if sweating occurs. If this does not happen and sweat accumulates near the skin layer, its condensation may become another hazardous situation, which was faced by the expeditions to Polar Regions. Hence, scope must be left to allow some layers to be removed if required, without exposing the body to cold. Thus, the undergarments and inner layers should move the moisture (mainly from sweat) away form the skin by wicking action (by use of artificial fabric material), the outer layers should prevent the outside moisture (from rain or snow) from penetration of the clothing but at the same time allowing for sweat to move away (by using directional-flow nylon and polytetrafluorethylene material). The basic rules for dressing in a cold climate are

(a) Keep the clothing clean otherwise the wicking / moisture repelling action will be compromised.

(b) Do not sweat unnecessarily; undertake activities in a way that sweating is kept to the minimum.

(c) Keep the clothing dry; wet clothing will grossly reduce the insulatory power.

(d) Dress in layers (as explained above).

It must be noted that clothing must be worn in sequence, with undergarments and thermal inners being the innermost layer, followed by shirt, trouser, sweaters, and finally the jackets / thermal or feather coveralls. The fit of each item is very important; each item should be tried in its correct sequence. If clothing is too tight, it will restrict the blood flow and increase the predisposition to cold injury.

### Boots

In cold weather when two pairs of socks are worn, boots become tight and this may compel the individual to discard them. Therefore, boots should be a loose fit, kept soft and water proof and every person should have an extra dry pair of socks and boots to change into, if feet get wet. It is always advantageous to have "thermal lined" snow boots. If activity requires work in water or slush, gum boots are of advantage. Boots should always be purchased / issued after the individual has tried them out with thick woollen socks and walked about for some distance. As far as possible, while moving, one must try to wipe dry the inside of the boots with a cloth kept in the haversack for this purpose, after every few hours. One must remember never to sleep with boots on; before going to sleep, boots should be removed and dried. Socks: A pair of thin nylon / polypropylene socks should form the inner layer, being worn next to the skin and the next layer should be the heavy woollen socks to absorb moisture. These should not be tight. Every person exposed to intense cold should have at least four pairs of woollen socks. Socks should be inspected daily and mended if found to be torn / damaged. Badly darned socks become dangerous by adding an element of trauma. Damp socks should be changed immediately.

### Shelters

An effective shelter should meet the requirements of protection from wild life, heat retention, protection from wind, ventilation and some facility for drying the clothes. Shelter from strong wind is essential, especially when resting or sleeping. Facilities for drying clothes should be available in each camp. Shelter used in cold environment should be designed on the same basic principles of layering as for cold weather clothing. The tents should have a strong, tightly woven outer shell, which should be

impervious to rain and snow. The inside liner is a lighter weight fabric and is hung to provide an air space along the outer shell. Ideally the tent should have a floor made of impervious material.

### Precautions for Carbon Monoxide Poisoning

If ever a stove is burnt inside the tent for heating purposes, the potential dangers of Carbon Monoxide poisoning and fire hazards is to be kept in mind. Arrangements for ventilation must be ensured in such circumstances. Such hazard of CO poisoning can also occur when people sleep in vehicles whose engine has been left running and vehicle parked downwind. Alcohol can further aggravate the risk of CO poisoning and fires by decreasing consciousness and causing inebriation. Similarly, chronic smokers are more susceptible to CO poisoning, due to lowered threshold because of high baseline carboxy-haemoglobin levels in a smoker. One person of the party should always be awake when any stove is placed inside a shelter for heating purpose, to watch out against any fire.

### Nutrition

Energy requirement in the cold environment is more due to higher metabolism. In general, for civilian population, who are also likely to be indulging in some sort of winter or mountain sports activities, the energy requirement may be 3000 to 3500 Kcal for women and 3500 to 4000 Kcal for men. Provision of adequate hot and appetising meals should be ensured. Well cooked, nourishing hot foods and drinks increase resistance to cold, promote mental and physical well being and fortify the body against infection, fatigue, hazards of privations and climatic extremes. Vitamin C is also necessary for the cellular reformation, vascular endothelial integrity and as a steroid sparer. It may be given in the form of multivitamin tablets. For armed forces rations and feeding at cold climate areas, the details are given in the section on nutrition and dietetics.

### Exercise

Regular moderate exercise to keep up the circulation without causing any exhaustion or excessive sweating should be undertaken frequently. When climatic conditions do not permit movement in the open, static physical activity by frequent vigorous movements of limbs, movements of neck and back, wriggling of toes and moving of fingers should be continuously practised. Face muscles should be wrinkled to keep up the circulation.

### Venous Congestion

People should not sit for long periods cramped up in enclosed places or upon the railing with feet hanging down and especially over the edge of seats as this leads to venous congestion. Too tight clothing also causes venous stagnation.

### Alcohol

Alcohol is best avoided when confronted with harsh, cold environment. In any case, it should never be consumed in excess over a short duration and none at all when likely to be exposed to cold wind, required to undertake excessive exertion or trekking / marching, or when proper shelters for sleeping are not likely to be available.

### Smoking

It is advisable not to smoke at all. Those who cannot avoid smoking should do so in moderation. It should be definitely prohibited once the cold injury occurs.

### Buddy System

For small parties on adventures / expeditions, it is always a good practice to have a “buddy system”, i.e., to pair up people and make them responsible to look after each other, in harsh cold or wilderness type of environment. It is practised by watching each other's face and feet for observing any early tissue damage. Buddies also watch out for each other’s personal hygiene, nutrition, and behaviour so that any aberration is identified at the earliest and first aid is given. For the buddy system to be effective, the buddies must communicate very effectively with each other.

General Personal hygiene should be maintained at the highest level. Besides ensuring local cleanliness and preventing infections, it will enhance the general feeling of well being, so essential in tough, cold environment. Proper bathing is preferred; however, even a basin of water for a sponge bath will help. When no water is available, simply rubbing the body, preferably with a wool rag, is worth the effort. It is recommended that such a procedure be followed weekly. Changing to clean or even airing of soiled socks and underwear periodically will help to maintain body cleanliness. At least two or three hot baths in a week in snowbound and cold environs are necessary. Bathing places should be sheltered from wind and snowfall. However, too frequent use of too much soap is not good as it removes the greasy sebaceous material and decreases insulation.

Foot Hygiene The feet should be inspected before going to bed every night, for any swelling, ulcer or numbness. Wriggling the feet and toes before going to sleep and even within the boots, while walking, should be an inculcated habit. It is much better to make two partners responsible for inspecting each other's feet. Feet must be washed with warm water, thoroughly dried and smeared with a little Vaseline, before sleeping. This helps prevent frost bite. An individual with ulcers and abrasions on the foot should not move around until they are healed. Talcum powder should be used before wearing socks in the morning to decrease dampness during exertion and reduce friction with socks.

### Oral Hygiene

By daily cleaning the teeth with a piece of gauge or other cloth wrapped around a finger is an effective practice in the absence of toothbrush. “Feel Good” :- Keeping well is especially important when one is stranded. While physical fitness of the body decides survival, yet a positive mental attitude is just as important. Personal cleanliness, dry clothing, ventilated shelter without drought, a warm bed, and adequate recreational activities are helpful. Provision of sufficient latrine accommodation and proper disposal of all wastes must be ensured. Re-exposure: Persons who have once suffered from cold injury should be very careful when getting exposed to cold environment again.

### Adaptation to Cold

Adaptation to cold is slower and less efficient than

acclimatisation to heat or high altitude. It is automatically effected when human beings are inducted to cold areas in summers and allowed to stay on over one or two winters or gradually move up the mountains in stages. When, however, they are suddenly inducted to cold areas in winter, the effects of cold may appear in a large number of persons. Systematic acclimatisation to cold can be carried out under such circumstances by exposing newly inducted people to the atmospheric temperature of 0˚C to 5˚C for three or four hours a day for three consecutive weeks. During the first week people should be dressed in vest cotton, full sleeves flannel shirt, pullover, woollen trousers, balaclava or fleece lined cap, gloves and boots with only one pair of woollen socks. Outside the exposure hours, people can put on the additional clothing as jackets, coveralls, etc. During the next two weeks, jersey pullover is also removed, so that people stay in flannel shirt and trousers for 3 to 4 hours. The site selected for exposure should be sheltered from wind. If there is any wind or breeze, people should wear a thin nylon wind-cheater. Since physical exercise warms the body and hence impedes the acclimatisation process, during the hours of exposure, therefore, physical exercise should not be allowed; however, normal sedentary recreational work as reading, knitting, playing cards etc., which do not involve much physical activity, may be carried out. People should be assured that exposure to cold for cold acclimatisation will cause no harm. If any complaints like rhinitis, pharyngitis, fever, excessive shivering or cramps are noticed, the exposure should be discontinued for the day or until cured. It can be restarted and gradually increased day by day when the individual has recovered.

### High Altitude Acclimatization

Often, cold environment co-exists with high altitude environment. Adverse effects of high altitude will worsen the physical and psychological adversities due to cold and vice-versa. Proper acclimatization to high altitude should be therefore undertaken, as described in the chapter on high altitude.

### Prevention in Relation to Some Basic Survival Problems

In harsh, extreme cold climate, often co-existing with wilderness type of environment, one may be faced with an emergency at any time, especially when traveling. Hence, survival techniques should be a major element of preparation. Skills pertaining to shelter construction, first aid, map and chart orientation and sanitation provide a good foundation on which to base success in an emergency. Detailed guidelines from technical point of view (8 - 11) as also of general nature (12, 13) are available in various texts and websites and those interested may refer to them. Similarly, serious accidents are often the result of incompetence, ignorance or overconfidence arising from inexperience. Success and survival depends on planning, timing, common sense, and the intelligent use of supplies and equipment.

### Protection against Snow Blindness

Humans can make no natural adjustments to the reflection of bright sun from snow. Dark glasses are, therefore, a must. One must not wait until eyes start hurting. If the glasses are lost, improvised eye protection, by either wearing a muffler or stockings over one eyes through which one can barely see, or, better yet, one can make a “slit goggles” out of leather, cardboard, or any other similar material. Cut a horizontal slit 1.5 to 3 millimetres high by 25 to 40 millimetres wide in the material. Keep the goggles approximated around the head with a string, cloth or leather strip, or slung around the neck so that you donot lose them. Treat snow blindness by getting the victim to a dark place. Apply eye shades to both eyes, if required. Cool compresses may help to relieve the pain. Time is the only cure for temporary snow blindness.

### Protection against Sunburns

Sunburn can occur even at temperatures below freezing

# Adverse Effects of High Altitude

High Altitude illness is a collective term for the syndromes that can affect unacclimatised travellers, shortly after ascent to high altitude (1) (The term "unacclimatised travellers" also includes the native highlanders who are re-inducted into high altitude after a sojourn to lower altitude or if they move to a still higher altitude from the normal place of stay in high altitude). The term "high altitude illness" encompasses the cerebral syndromes of Acute Mountain Sickness(AMS) and High Altitude Cerebral Oedema (HACO) as also the pulmonary syndrome of High Altitude Pulmonary Oedema(HAPO).(1)

With the present body of knowledge, there does not seem to be any clear cut demarcation as to the height above sea level that constitutes " High Altitude(HA)". The general opinion varies and is dependant on the altitude at which definite manifestation of high altitude illness are likely to occur in a noteworthy proportion of the subjects. Generally, an altitude of 2700 m and above defines high altitude, with increasing grades of high altitude as 2700 to 3600 m, 3601 to 4500m and 4501 to 5400m. Altitudes above 5400 m in are often referred to as "extreme high altitude" wherein permanent successful acclimatization becomes very difficult. However, the above levels cannot be sacrosanct boundaries; in fact high altitude illness is being increasingly recognised at "moderate" altitudes of 2200 to 2500m (2)

Around 140 million people over the globe live permanently at altitudes of over 2500 m (3) and approximately another 40 million enter high altitude area every year for reasons of occupation, sporting or recreation. Miners in South America go for work to altitudes as high as 6000 m, while Indian soldiers are deployed at even higher altitudes. Persons who are at a definitely increased risk of being affected by high altitude illness include Native highlanders who re-enter high altitude after stay at lower altitudes; Mountaineers; Soldiers; Trekkers; Adventurers; Miners at high altitude; and, Pilgrims and porters (4, 5).

## The High Altitude Environment

Effects of high altitude are encountered among troops deployed at high altitudes and in high altitude aviation. The environmental conditions at high altitudes which influence physiological processes are:- the lowered atmospheric pressure and partial pressure of oxygen, lowered temperature and humidity, increased intensity of sunshine and cosmic electrical conditions and the isolation under monotonous mountain conditions. The chief hazards on health, however arise from the low atmospheric pressure, coupled with low partial pressure of $O_2$ in the alveolar air leading to low oxygen tension in the blood and low ambient temperature, all of which worsen as the altitude increases. The Effects of hypothermia have been described in the preceding paragraphs. There is no difference in their aetiology, manifestation, prevention and first aid at high altitude, except that they are aggravated due to atmospheric and tissue hypoxia.

The main problem with high altitude terrestrial environment is, in fact, the declining atmospheric pressure. For instance, the atmospheric pressure which is 760 mm Hg at sea level drops down to only approx. 500 mm Hg at Leh, which is at around 11000 feet above Mean sea Level (MSL). Now, as we know from a very basic law of physics (Boyle's Law) that the partial pressure of a mixture of gasses is equal to the sum of the partial pressure (pp) of these gasses; and the partial pressure of these individual gasses is proportional to their concentration in the gaseous mixture. For all practical purposes, air is mainly a mixture of Nitrogen (N) and Oxygen (O) in the proportion of 80% and 20% respectively. Thus the pp of N will be four fifth and that of O will be one-fifth that of the atmospheric pressure at a given location. Hence, at sea level, where the atmospheric pressure is 760 mm Hg, the partial pressure of 'N' is 4/5 of 760 i.e., approx 608 and that of 'O' is approx. 152 mmHg.

Now as the atmospheric pressure drops with ascent from sea level (by very roughly, 25 mm Hg for every 1,000 feet ascent), hence at Leh (11,000 feet) it would be approx. 500 mm Hg; and, by Boyle's law, at this height, the partial pressure of Nitrogen would be (4/5 of 500) i.e., 400 mm and that of Oxygen will be 100 mm Hg. It is this progressive decline in partial pressure of oxygen in ambient air (commonly referred to as "thinning or air" or, "rarefied air') that results in reduction of alveolar oxygen pressure, with all the resultant pathological issues of high altitude. Thus, though the concentration of oxygen in atmospheric air at high altitude is still one-fifth, the net result because of such reduction of partial pressure of oxygen is as if there were a lack of Oxygen in the air. Thus, at Leh, at around 11,000 feet, the effect is as if oxygen in the air were 13.8% instead of 21% normally seen at sea level. The details are depicted in table-1. This is the basic environmental issue that triggers a massive cascade of physiological responses, intended to be protective, once a human being is inducted into high altitude.

## Physiological Adaptation

The lowered atmospheric oxygen partial pressure at high altitude causes alveolar and arterial hypoxia leading to tissue hypoxia. As described earlier, the oxygen partial pressure in alveoli is decreased at high altitude and hence, to compensate for this, more blood has to flow into the alveolar capillary bed in a given unit of time, and also, more air needs to be sucked in by the luings in a given unit of time, as compared to sea level. In order to meet the tissue oxygen demand at high altitude, in the face of such altered alveolar oxygen pressure, the cardiac output per minute has to increase and in order to ensure adequate oxygenation of the blood, the pulmonary ventilation has to increase. These requirements are initially achieved by hyperpnoea and tachycardia arising out of hypoxic drive.

As the stay at high altitude continues, the increased pulmonary and cardiac frequencies are replaced by increased amplitudes. A series of further physiological adjustment take place depending on the rate of ascent, the altitude attained, and the period of stay at that altitude, by adaptation of the haemopoietic, cardio-vascular, respiratory and nervous systems. Gluco-corticoids and vasopressin are poured in the blood stream to counteract stress of hypoxia. The number of circulating RBCs, haemoglobin concentration in RBC, the size and volume of red cells, pulmonary ventilation, vital capacity, pulse rate, circulating blood volume, circulation rate, cardiac output all undergo changes.

Circulatory and haemopoietic adjustments are variable and do not normally occur to an appreciable extent among Indians up to an altitude of 2500 m. Over that height the variation in haemodynamics and concentration of available RBCs in the peripheral circulation appear first; the increased frequency of respiratory and cardiac rhythm closely follow; haemopoietic response brought about by the erythropoietin (produced by kidneys) comes next; and finally the increased amplitude of respiratory and cardiac movements gradually replaces the increased frequency. This completes the early process of adaptation. Interstitial fluid is diverted to the vascular compartment which alters the haemodynamics and cause hypervolaemia, thereby overloading the pulmonary circulatory system and cardiac function. Due to increased pulmonary ventilation, the tissue $CO_2$ is washed out, alkalosis occurs and the $CO_2$ tension in the blood is decreased. Hypocapnia (lowered $CO_2$ tension in the blood) due to hyperventilation leads to shifting the oxygen dissociation curve to the left, and decrease in cerebral and coronary flow thus leading to other complications. The altered pH (alkalosis) of the blood is partially rectified by increased excretion of alkaline urine thus restoring the left shift of oxygen dissociation curve as the acclimatization process continues. But the major readjustment in the respiratory system is brought about by increased 2-3-diphosphoglycerate of RBC which in turn offsets the effects of left shift of $O_2$ dissociation curve and thus restores oxygen delivery to the tissues, increased sensitivity of respiratory centre to lower $CO_2$ tension and by increased diffusion coefficient of oxygen at the alveolar level. The cause for Pulmonary hypertension which is a common observation in high altitude is not known. At the initial phases it is relieved by oxygen inhalation.

Stimuli for adaptation becomes operative when the atmospheric pressure is decreased by 30 percent, which

Table - 1 : Altitude, pressure, temperature, oxygen partial pressure and percentage

| Altitude | | Pressure | Temperature | | $O_2$ partial | Equivalent $O_2$ |

occurs at the height of 2500 m. These mechanisms are usually uneventful and insensible up to about 3000 m; however, above that height when pronounced physiological mechanisms are called to action, the symptoms of 'early mountain sickness' which in reality are the symptoms of 'rapid acclimatization', become manifest. If acclimatization is inadequate, or if it breaks down, or if the ascent to higher altitude is too rapid, the essentially beneficial adaptive responses become aberrant and the disease processes occur.

The variable factors which determine the direction taken by the responses are the rapidity of exposure to atmospheric low pressure, severity and duration of oxygen lack and the physical condition of the body. The various symptoms of high altitude sickness essentially arise from the lag in adjustment of the body to increasing hypoxia and partial lack of cardiopulmonary co-ordination to meet the challenge of tissue hypoxia in the face of atmospheric hypoxia coupled with the altered haemodynamics. The symptoms are, therefore, more severe and frequent during rapid ascent and also at night time owing to the dumping of blood in the lungs due to the horizontal position of the persons. Cerebral hypoxia causes mental symptoms. The most frequent and important clinical problems encountered at high altitude are shown in box-1.

**Box-1 Clinical Syndromes At High Altitude**

- Acute mountain sickness (AMS).
- Acute pulmonary oedema of high altitude (HAPO).
- Chronic pulmonary hypertension.
- Coronary and cerebrovascular insufficiency.
- Seroche- Monge's disease.
- Flare up of precontracted infections.
- Manifestations of diabetes mellitus.

## Acute Mountain Sickness (AMS)

### Latent period

The latent period of AMS (time elapsing from entry into high altitude to onset of first symptom) is usually 6 to 12 hours. Sojourns to high altitude which last for less than 6 hours are not likely to be associated with AMS.

### Incidence

AMS is quite uncommon below the altitudes of 2000 m. The incidence of AMS has been quite variable in different studies and primarily depends on the altitude reached, the rate (speed) of ascent to high altitude and physical exertion after entry into high altitude, besides other variables. Thus, Hackett and Rennie reported an overall incidence of as high as 43% among trekkers reaching an altitude of approximately 4200 m (6). A serial and proportionate increase occurs in the incidence, as reported by Maggiorini et al, who observed the incidence to be 9%, 13 % and 34% at altitudes of 2850 m, 3050 m and 3650 m respectively (7). In another study among tourist at Colorado, arriving at altitudes between 1900 to 2940 m, the overall incidence was 25% (8). It seems that at altitudes of 4000m and above, the incidence is almost universal among the new entrants, especially if those with mild symptoms are also taken as AMS. Thus, the incidence was observed to be as high as 85% among tourists who are directly inducted, by air, to an altitude of approx 3700 m. (9). Garlland et al (10) reported that among trekkers in Nepalese Himalayas, tracking up to an altitude of 5400 m, the frequency of AMS was 29% in the year 1998, which was a clear decline as compared to the incidence of 43 % as was observed in 1986. The authors attributed this decline in AMS occurrence to better awareness which has developed among the trekkers about AMS so that they climb slowly and observe the necessary preventive measures. In another study among pilgrims, at an altitude of 4300 m in Nepal, Basnyat et al reported an incidence of as high as 68% (4) while in another study the incidence was observed to be 20 % at 4243 m as compared to 6% at 3499 m (11).

One of the reasons for the widely differing incidence rates of AMS at corresponding altitudes could be due to disparities in diagnostic criteria used by different workers. In fact, the more recent “Lake Louise consensus” on diagnostic criteria could streamline and standardize the procedure, thus ensuring comparability of data.

### Risk factors for AMS

Age

The evidence regarding susceptibility of any particular age group to AMS is equivocal. The results may be confounded due to the increase in volitional activity on arriving at high altitude among the younger people, particularly young soldiers, besides various other socio-behavioral factors. In general, it seems that children and adults seem to be equally affected, as reported by Yakon et al who observed no difference between children and adults as regards incidence of AMS. (12) On the other hand, some studies indicate that young persons are probably at greater risk (10,13 & 14) while Pollard observed that people aged more than 50 years may be more susceptible to AMS(15)

Gender

Kayser, in a study in Nepal at an altitude of 5400 m concluded that the incidence was higher (69%) among women trekkers as compared to 57% among males (16). Similarly, Basnyat et al (4) observed that the risk of AMS was much higher among women (OR-4.39, 95% CI= 1.83 to 10.68). Murdoch et al also found a higher risk among women (9, 17). However, one must consider the possibility of information bias, since women may more easily report their symptoms. At present, it may be apt to conclude that while women may be at a slightly higher risk, more studies using stronger epidemiological methodology and increase study power need to be undertaken to answer this issue.

Obesity/Overweight

There is some evidence that subjects who are slim have lesser susceptibility to AMS as compared to subjects who are overweight (or even towards the higher side of normal BMI of 25)(16,18). On the other hand Garland et al did not

find any association between body Mass index (BMI) and AMS (10). It is possible that increase in body weight, particularly the "dead weight" of obesity may impose additional load on the body during physical activity and may increase the predisposition to AMS. Though more evidence needs to be collected, it is in any case desirable that obesity be avoided for various other health reasons also.

Altitude reached

One of the most important determinants is the altitude which has been negotiated. The condition is very infrequent below the altitude of 2000 m; as the altitude reached is around 4200 m, a large majority will have the symptoms, while it is almost universal at 5000m. Even the native highlanders who return to their high altitude residence after a stay for few days at low altitude, or else the highlanders who move to higher altitude from their usual residences in high altitude are also at risk.

Speed of ascent

Next to the altitude reached, the speed of ascent becomes a major factor determining the risk. A much larger population of subjects who move to high altitude by air are likely to be affected, as compared to subjects who get inducted by road transport to the same high altitude locations. Level of Physical fitness:Prior physical fitness seems to provide no immunity against AMS; similarly pre-existing infection or disease may not be a necessary predisposing factor. It is a common-place and repeated observation in epidemiological descriptions that young, strong and healthy men may be overcome by AMS while people with lung diseases may not even get headache. This was pointed out in one of the earliest scientific descriptions on AMS, in 1913 by Ravenhill (19) and has been consistently noted thereafter. Various workers as Milledge, Brucher et al and Sowouney et al have not found any correlation between occurrence of AMS and various parameters of physical fitness, as VO2 max or physical work capacity (20-22).

Exercise

In a study conducted under controlled circumstances in a chamber, Roach et al produced simulated altitude of about 4500m for 10 hours. Subjects were subjected to physical exercise on one occasion and not subjected on the other occasion. The results clearly showed that exposure to physical exercise in high-altitude simulated environment carried a significant risk for causing symptoms of AMS (23). The finding is further supported by observations of other workers that faster rate of ascent on mountains among trekkers (indicating strenuous exercise) is related to higher incidence of AMS and vice-versa (14, 24, 25). Thus, it would be prudent to avoid strenuous exercise on arrival to high altitude for prevention of not only AMS but other high altitude illnesses as well.

History of Previous episode

It has been shown by Forster that the rank scores (or AMS score), achieved by subjects on induction to an altitude of 4200m showed strong correlation with the rank score achieved by the same subjects when they were de-inducted and then re-inducted at the same altitude after 5 days(26). However, other case series do not seem to show such consistency and, with the present status of available evidence, it seems very difficult to predict the probability with which a subject is likely to develop (or not develop) AMS, given that he/she has (or has not) developed AMS during earlier inductions to high altitude.

Dehydration

In the study by Basnyat (25), higher fluid intake (up to 5ltr per day) was found to be associated with a lower incidence of AMS. However, in an earlier controlled, experimental design, Aoki and Robinson did not observe any relationship between dehydration and AMS incidence (27). Similarly Cumbo et al (28) did not find any definite association between dehydration and AMS. At present, there does not seem to be a clear evidence-based answer to this issue and more studies are needed. Till then, a reasonable scientific practice would be to ensure proper hydration, in view of the various other physiological benefits it provides vis-à-vis a dehydrated state.

Tobacco Smoking

In an experimental design undertaken in a simulated chamber it was observed that smokers tend to have fewer symptoms than non-smokers (29). The plausible explanation is that smokers seems to be habituated to a pre-existing, modest level of carboxy-hemoglobin and hence may be having a physiological state equivalent to "pre-acclimatization". On the other hand, Garland et al did not find any association between AMS and smoking habit (10). In general, it would be prudent to avoid smoking / tobacco use, in any case, for various documented health resaons, if not for prevention of AMS.

High Carbohydrate diet

There seems to be no significant difference between normal or high carbohydrate diets as regards susceptibility to AMS (30).

## High Altitude Pulmonary Oedema (HAPO)

### Epidemiology

The first scientific description of HAPO, in English language, was provided in 1960 by Houston (31). However, there are earlier descriptions too, though the disease was not precisely identified as HAPO. For instance, the description of the death of a Doctor at an altitude of 15000 feet during a rescue mission was most probably due to this condition, (32). Similarly, Ravenhill's description (19) in 1913, of cases of cardiac failure at high altitude would have actually been cases of HAPO. It is also likely that the experiences of Hultgren and Spickard in Peru, in 1959, of cases of pulmonary oedema actually referred to description of HAPO (33). Since then, the condition has become widely recognized. Pioneering work in this field has been undertaken by Medical Officers of the Indian Armed Forces, especially after the rapid induction of thousands of troops into high altitude areas following the Sino-Indian war of 1962 and subsequently during the Indo-Pak conflict on Siachen Glacier which is considered as the highest battle field in the world.

### Incidence

The incidence of HAPO has been found to be quite

variable, as reported by various workers. In general, the incidence can be taken to be in the range of 0.1% to 4% (1) In a study on Indian Soldiers in North Western Himalayas, Menon found that the incidence was 5.7 per 1000 (34). However, in a subsequent study on the same general population in the same location, using more precise information on the number of 'inductions' into high altitude areas of 3600 m and above, Bhalwar et al, in their nested case- control study, found that the incidence was 1.42 per 1000 inductions (95% CI 1.11 to 1.73 per 1000 inductions) (35). A much higher incidence of 3.4% has been reported by Hultgren et al from the Western world (36), while a study in Nepal put the incidence of HAPO to be 2.5% among trekkers (14). In another study in Peru, at an altitude of 3750 m, the incidence of well diagnosed HAPO was 0.6% among adults, while Basnyat et al (4) observed that among pilgrims at an altitude of 7300 m, the incidence was 5%.

**High Risk Groups**

Broadly, any person irrespective of age, gender or race, who enters into a high altitude terrestrial environment, is at risk of HAPO, including native highlanders who enter into high altitude after a stay at lowlands. However, certain groups seem to be at a higher risk due to Socio-behavioral or occupational reasons. These include soldiers, mountaineers trekkers, adventurers, mountain-sports persons, miners working at high altitude, porters, and land pilgrims to high altitude shrines.

**Induction Time**

Most of the epidemiological studies indicate that the 'latent period' or 'induction time" (period elapsing from entry into high altitude to the onset of first manifestation of HAPO) is usually between 6 to 96 hours. Onset beyond this range is quite uncommon. Bhalwar et al found the induction time, among soldiers at 3600 m, to be 6 to 96 hours with a median of 54 hours (35). Similarly, in the series by Menon, (34) Singh et al (37) and Kleiner (38) it was observed that large majority of cases occurred within 3 days of entry into high altitude. From foregoing epidemiological evidence, it is logical to conclude that, firstly, if a subject, following exposure to high altitude returns to low altitude within 6 hours, the risk of HAPO would be quite low. Secondly, the period of first 72 hours following induction into high altitude seems to be important, with the initial 48 hours being most crucial for enforcing preventive measures regarding acclimatization, especially avoidance of any physical activity (except for self-care activities of a routine nature). It may be noted that though the induction time of 6 to 96 hours encompasses a very large majority, rare cases can occur as late as ten days also.

**Recurrence Rate**

The recurrence rate of HAPO i.e., occurrence for a second time on a subsequent occasion in a subject who has suffered from HAPO earlier, over a follow up period of 18 months, was worked out by Bhalwar et al, based on a well established and scientific central registry for HAPO. The workers reported that out of 152 cases who had the first attack and followed up of 12 to 18 months, a total of 5 cases occurred for the second time during the follow up period, giving a cumulative incidence of 3.29 % (95% CI 0.46% to 6.1%) and incidence density of 1.83 per 1000 person months (95% CI 0.53 to 3.13). The time period between the first and second attack was 115 to 208 days. All the five recurrent cases occurred within 48 hours of the second entry in high altitude (39).

**Risk Factors for HAPO**

Age

Case series have reported a preponderance of young adults among cases of HAPO. However, this may not represent a true cause-effect relationship. Younger people tend to visit the high altitude areas more often, besides being more inclined to exert physically after arrival to high altitude. In fact, in their nested case control analysis, Bhalwar et al (35) did not observe any significant association between age and HAPO; however, this study was conducted in a narrow age zone, mainly in the group of 20 to 40 years. There is also no evidence to indicate that children are protected; in fact, children aged 1 to 4 years are at considerable risk (40).

Gender

Basnyat et al observed that at an altitude of 4300 m, women had higher risk of HAPO (OR = 5.2, 95% CI 1.24 to 24.73) (4). However, as pointed out by Heath and Williams, it is the young male who is at higher risk (40). It is possible that males are more likely to exert physically soon after arrival to high altitude, thus making them more vulnerable. With the present body of knowledge, it may not be possible to comment with authority as regards the gender differences unless comparison of proper cumulative incidence rates between men and women, controlling for potential confounders, is undertaken. Ethnic /Racial differences:There does not seem to be any particular ethnic or racial group which is specifically predisposed to or protected from HAPO. (35).

Fresh inductees/Re-inductees

Re-exposure to high altitude environment has been described to be an important determinant of HAPO. (40). In the study by Menon, much more numbers of cases gave history of having been exposed to high altitude environment earlier, while a smaller proportion of cases were those who had come to high altitude for the first time (34). Similar findings were observed by Hultgren (36) and Marticorena (41). However, it needs to be appreciated that case series are based on simply numerator analysis and, from epidemiological point of view, suffer from the flaw that they do not compare incidence rates. It is quite likely that a smaller proportion of cases of HAPO would give a history of entering high altitude for the first time (fresh inductees) simply because, as such, of all the people who enter high altitude, a much smaller proportion is likely to be fresh inductees while a larger proportion will be those who would be entering high altitude after having been exposed to high altitude at least once earlier, i.e., re-inductees. In fact, Bhalwar et al, using valid 'denominator bases', compared the incidence rates between inductees and re-inductees, and did not find any significant difference (35). Singh et al, in their case series, also found that almost two third of their cases were fresh inductees (37). Anecdotal reason has been cited to support the

increased predisposition of re-inductees, by mentioning that the native highlanders who returns to high altitude after a sojourn to low altitude are quite likely to develop; However this only suggests that the highlanders re-entering high altitude is at risk but not that the risk is comparatively higher among re-inductees. To summarize, firstly it will be apt to treat all entrants into high altitude, whether fresh (first time) entrant or re-entrant with equal concern and apply the laid down acclimatization procedures to all with equal vigor. Previous acclimatization or previous successful sojourn to high altitude does not guarantee protection during subsequent exposure. Re-entry into high altitude, even after an absence of only few days at low altitude, may make a person susceptible to HAPO and complete acclimatization schedule must be undertaken if a person has gone down for more than 4 weeks. If the absence from high altitude has between 11 to 28 days, acclimatization should still be undertaken though in a "modified" (less strict) manner. Secondly, it must be noted that the native highlander re-entering into high altitude is in no way protected and should follow similar acclimatization procedure as that for the residents of low altitude. Thirdly, there is a need to undertake scientific epidemiological studies, by comparing 'incidences rates' (and not number of cases) between fresh entrants and re-entrants to answer this issue.

### Tobacco and Alcohol use

Tobacco smokers do not seem to be at any significant risk (35, 42). Similarly moderate consumption of alcohol after entry into high altitude does not seem to increase the risk (35). However, keeping in view the other health hazards, it would be prudent to advise avoidance of tobacco and alcohol use.

### Genetic Factors

There are some indications that susceptibility to HAPO may be, to some extent, determined by genetic drive. In a study by Hanoka et al, an association was observed between HAPO and certain HLA types, notably HLA-DR6 and HLA-DQ4 (43). Similarly Morrell et al also observed an association between pulmonary hypertension and 'D' Allele of ACE genes among native highlanders of Central Asia (44). At present only limited data are available. Candidates for further studies in this field include endothelial nitric oxide synthase gene polymorphisms, angiotensin-converting enzyme gene polymorphisms and genetic determinants of primary pulmonary hypertension (45-49).

### Previous history of high altitude illness

Persons who have earlier suffered from an episode of high altitude illness (AMS, HAPO or HACO) during their earlier sojourns to high altitude seem to be at a slightly higher risk of HAPO during subsequent sojourns. It has also been observed that if both, previous history of AMS as well as physical exertion within 24 hours of entry into high altitude are present, these two factors tend to "interact", there by multiplying the risk of HAPO. As such, a past history of AMS during earlier sojourns significantly increases the risk of HAPO (OR =2.74, 95% CI = 1.12 to 6.77) (35).

### Cold weather

Observations based on case series indicate that cases are more during the cold weather, particularly in January. It is still not clear whether this is due to an interactive effect between extreme cold weather and high altitude, because the two, in any case, often coexist. It is also likely that during cold weather, the roads leading to high altitude areas may be snow bound and hence most of the entries into high altitude are by air, thereby speeding up the "rate of ascent", a well known risk factor for HAPO. It is also possible that volitional physical activity soon after arrival into high altitude may be more during cold weather, as a part of generating body heat.

**The three most important risk factor predictors of HAPO are:-**

- The altitude reached
- The speed of ascent to high altitude.
- Physical exercise on arrival to high altitude.

### Existing physical condition

Most of the persons are young and of athletic disposition, and have to undergo a mandatory clinical examination before entering high altitude area. However, there is no way to predict that even after a meticulous clinical examination at low altitude, the person will not develop HAPO or AMS (40).

### Physical exercise after induction into high altitude

Physical exercise even of moderate intensity, undertaken within 72 hours of arrival into high altitude is an important determinant of HAPO, and is almost universally upheld by all experts. The risk has been observed in nearly all the studies (31, 35, 37, 38, 50, 51), at various places in the world, and the estimates show a strong and significant association. Thus, the association fulfils the required epidemiological parameters of strength of association, temporality, consistency, dose response and plausibility. In the study on Indian Soldiers, a very strong and significant effect was observed, of physical exercise during first 24 hours of entry into high altitude and HAPO (OR=3.19, 95% CI 1.23.to 8.51). In addition, physical exercise during first 24 hours was also strongly and significantly associated with the severity of HAPO (35). Similarly Singh et al (37) and Kliener et al (38) also reported that a large majority of cases gave history of undue physical exertion within 3 days of arrival into high altitude. Thus, it seems that physical exertion in the first 72 hours of arrival into high altitude is important, the first 24 hours being crucial as a determinant for developing HAPO. However, it is noteworthy that physical exercise is not an 'essential' determinant, since the condition can occur even among persons who have not exerted/are

**The key to prevent HAPO is to ensure acclimatization; in particular, no physical exertion (except activities of daily life) during first 48 hours of entry into HA**

asleep/are at rest, especially if ascent to high altitude has been rapid, as by air.

Lack of Acclimatization

HAPO commonly affects subjects who have not properly acclimatized themselves to high altitude environment soon after arrival. Acclimatization is a gradual process by which the body physiology gets adjusted to high altitude environment. In general, acclimatization is undertaken by 1 to 2 days of complete rest, followed by gradually increasing physical effort for next 2 to 4 days at a particular level of high altitude and the process should be repeated for every 900 m (3000 feet) gain in altitude. Armed Forces acclimatization schedule is described later on.

**Altitude of ascent**

The "critical altitude" at which the risk of developing HAPO is very high has been reported as 3350 m in the Himalayas, 3660m in the Andes and somewhat lower (2590m) in the Rocky mountains(40). This is not to be confused with the definition of "high altitude" which is generally taken as > 2500 mtrs, and, in context of Indian Armed forces, >= 2700 mtrs (9000 feet).

**Rate of ascent**

Epidemiological studies have clearly shown that the speed with which an individual reaches high altitude, especially into a crucial altitude of 3000m and above, seem to be an important determinant in causing high altitude illness. Observations have shown that both among soldiers as well as tourists who move to high altitude areas by air, ascending almost 3000m (or even more) within less than an hour, the incidence rates are much higher when compared to the same location being reached by road transport over 3 to 4 days. The slow ascent by road over a few days may allow some acclimatization.

While negotiating high altitude areas, gradual ascent, thereby giving time for acclimatization to develop, is the key strategy in prevention. In general, at altitude greater than 3000 m, each night should be spent at an altitude of not more than 300 m above the previous night, with a rest day after every 2 to 3 days (i.e., after every 1000 m of ascent) (24). In certain situations, this rate of ascent may be considered to be slow and unrealistic and may be modified so that the altitude difference between two consecutive "sleeping sites" should not be more than 600 m per day (52). All recommendations emphasise "sleeping altitude" which means that it is permissible to ascend more than the recommended daily rate as long as descent is made for sleeping, i.e., the time tested maxim of "climb/work high but sleep low". A night spent at moderate altitude of 1500 to 2500 m before ascent to high altitude, is also likely to aid in acclimatization process (1).

Other risk factors

There is preliminary evidence that neck irradiation or surgery (53) and pre-existing respiratory tract infections (54, 55) may be some of the newly described potential risk factors for HAPO which need further study. On the protective side, there are indication that ingestion of anti-oxidant vitamins prior to induction may reduce the severity and incidence of high altitude illness (56). The role of "Gingko Biloba" (80 mg of the extract twice daily for 5 days before induction) also seems to be useful by virtue of its antioxidant properties. Besides Gingko, the role of sildenafil and gaube as preventive measures has been postulated and needs further studies (57, 58). The role of acetazolamide (250mg BID orally, starting from one day before ascent) and dexamethasone 8mg per day in divided doses in prophylaxis (mainly for AMS) has been studied with convincing results (1).

## Epidemiology of HACO and other high altitude illness

**High Altitude Cerebral Oedema (HACO)**

HACO was scientifically described as early as in 1913 by Ravenhill (19), but it was only after half a century that the importance of this condition was recognized (59,60). There is very little published data on the incidence of HACO, except the study of Hackett et al (14) in which the incidence was found to be 1.8% among trekkers at an altitude of 4243 m. In another study in Nepal, among pilgrims at an altitude of 4300 m, Basnyat et al observed that the incidence of HACO was as high as 31%. Women were found to be at higher risk (OR= 3.15, 95% CI 1.62 to 6.12) (4). Experts agree, in general that HACO is a severe form of AMS. The risk factors for HACO are same as for AMS and HAPO; however, at present it seems difficult to predict who will, and who will not, develop HACO.

**Chronic Mountain Sickness (CMS) and Sub-Acute Mountain Sickness (SAMS)**

SAMS is characterized by pulmonary hypertension and right ventricular hypertrophy/ failure, either among infants or else among adults who have stayed at high altitude for few months. CMS is characterized by excessive erythrocytosis and hypoxemia, reversible on descent, among people who have stayed at high altitude for very long.

Very little published data is available on the epidemiological aspects of CMS and SAMS excepting for isolated case reports and few case series. There is paucity of data related to population denominator base for the purpose of calculating incidence rates or making analytic comparisons.

The occurrence of infantile SAMS was well known to the Spaniards who first colonized the Andes. Knowing that their infants would not thrive if born at high altitude, they used to arrange the deliveries at low altitude and did not bring the new born to high altitude till they were one year old (61). A case series from Tibetan region of fifteen infants, who died of the condition, was described by Sui et al. Majority of these infants were born at low altitude (62). There is a strong possibility of genetic determinants since infants of highlanders seem to be relatively protected, while children of lowlanders born at high altitude or else born at low altitude but moving to high altitude during infantile period seem to be at particular risk.

Epidemiological descriptions of adult form of SAMS have been provided in the form of case series among Indian

Army Personnel who had stayed at extreme altitudes for prolonged periods of many months (63, 64). A similar type of condition called as "Brisket disease" among cattle manifesting as oedema in the dependant part of the neck has been described (65). Adult SAMS could be the human counter part of Brisket disease. The condition manifests with pulmonary hypertension, right ventricular hypertrophy and /or failure and dependent oedema.

Chronic Mountain Sickness (CMS) was first described in 1925 by Monge, followed by case series in 1928, and also known as Monge's Disease (66). Thereafter another case series was reported by Hurtado (67). Descriptions from Tibet indicate that lowlanders migrating to high altitude are at much higher risk vis-à-vis the native highlanders. Males and tobacco-smokers are likely to be at higher risk (68). However, the condition is now being reported among the native Tibetans highlanders also (69). Among the native highland populations, it seems that the native Tibetans highlanders have lower hemoglobin values and are less likely to be at risk of CMS as compared to the native Andean highlanders, possibly due to certain (still unknown) genetic determinants (70).

#### Flare-up of Precontracted Infections

Viral and amoebic hepatitis in individuals who had contracted the infections at lower altitudes run a considerable risk of a more fulminating course with increased fatality, at high altitude. The course is otherwise prolonged, resolution seems to be difficult and unless evacuated to sea level, chronic protracted hepatitis may result. However, serum biochemistry pertaining to Liver Function is not altered in normal individuals located at thigh altitude and do not indicate any adverse effects on the normal liver except that the glucose tolerance may be slightly impaired and a lag curve may be seen. Cases of amoebiasis, who have been successfully treated by all measures even before five years, may flare up into frank amoebic hepatitis within 3 to 4 weeks of their arrival at high altitude. An abscess may form without evidence of liver tenderness, fever or leucocytosis and may even rupture before the patient reports sick. The initial response to emetine is satisfactory but a cure becomes extremely difficult or impossible if the patient is treated at high altitude. Infections of malaria which have been kept suppressed with chemoprophylaxis regime at lower altitudes also break through when the drug is withdrawn and the person is exposed to cold and hypoxia at high altitude. An acute diabetes mellitus may be precipitated at high altitude, more so among the patients who have been stabilized at sea level. The condition remits completely within a few days of return to sea level.

#### Other Effects

Prolonged exposure to hypoxia after acclimatization may produce other minor effects insidiously after a long latent period. Dimness of vision, loosening of teeth, progressive diminution of work capacity, loss of weight, flatulence, indigestion, loose bowels, anemia, thyroid deficiency and increased severity of infections may be encountered. These symptoms usually disappear within 3 to 4 weeks of move to the plains. A very long stay at high altitude somewhat habituates the tissue to low oxygen tension, but causes subnormal tissue metabolism. A high protein diet is thus essential. The atmosphere being cold, the air has very low atmospheric moisture content. The exhaled air on the other hand is at body temperature and hence contains more moisture. Much water is thus lost from the body through the breath. Lack of interest, irritability, insubordination and irrational reaction and lengthening of reaction time may occur. There is no increased incidence of frank psychiatric disease at high altitude in comparison with the plains. Lack of concentration and mental impairment, which may occur on arrival at high altitude, as part of acute mountain sickness, usually subsides within a few days. Some individuals may take a few weeks to acclimatize. In general, there is no scientific evidence to indicate that long term decline in memory or decrease in libido / sexual functions would occur either during stay at high altitude or after return to sea level.

### Prevention of adverse effects of high altitude

Individual tolerance to hypoxia varies and has no correlation with physical fitness in its ordinary sense. Complacency or bravado which in itself is one of the symptoms of hypoxia, encourages excessive physical activities without proper and adequate acclimatization. Rapid ascent without acclimatization followed by physical activity increases the risk of effects of hypoxia. As said earlier, even after acclimatization physical activity of even the most robust persons is less at high altitude than in the plains. Therefore, commanders may be reminded that more man-hours or more personnel are required to perform similar physical tasks at high altitude than in the plains (see next paragraph). Lack of appreciation of this fact can result in expectation of a high output of heavier tasks in short duration or desire on the part of men themselves to show off their prowess. Due to this, many casualties have occurred. Adequate details of prevention of adverse effects of high altitude and cold are laid down in concerned Army Order and DGAFMS Medical Memorandum (cited under "Further suggested readings" at the end of this chapter) and armed forces medical officers should consult these documents. The

**Box - 3 Preventive measures for adverse effects of high altitude**

- Ensure acclimatization (details given subsequently).
- Measures against adverse effects of cold (given in previous chapter).
- Education and motivation of Comanders and troops about acclimatization and planning of manpower for given tasks. Avoidance of tobacco; moderation in alcohol
- Adequate hydration
- Hot palatable meals
- Adequate shelter
- Maintain morale and psychological well-being

cornerstone of preventive measures is "ACCLIMATIZATION", which should be supplemented with general measures as outlined in box-3.

**Physical performance at High altitude**

It needs to be noted that even after complete and successful acclimatization, the capability to perform any given exercise or physical task will be reduced at high altitude in comparison to lower altitudes. This was clearly evident during Mexico Olympics of 1968, held at an altitude of 2300m wherein most of the world class athletes experienced as much as 13% reduction in their performance. Leaving aside the world class sports persons, evidence suggests that for normal, healthy and properly acclimatized subjects, the physical capability will be just about 70 to 75% at an altitude of 3100 m (Compared to capability at sea level altitude) and would be about 50 to 60 % at 4000 m. Care should be taken, therefore, by all subjects moving to high altitude, to make realistic readjustment in their expectations regarding task performance. Medical officers of armed forces should also impress this aspect on their respective commanders, so that they can make realistic estimates of requirements of manpower for a given operational task at high altitude. Available evidence also does not suggest that there would be any definite, especially long term increase in performance at sea level, among people who have trained at high altitude (71).

**Acclimatization**

It is important that troops when posted above 2700 m should be systematically acclimatized. It should be on the pattern followed by mountaineers, i.e. the individual works at a higher altitude than one at which he sleeps during the period of acclimatization. When the troops have acclimatized to a certain height, they can operate at those heights or even at slightly higher heights without any ill effect. This initial acclimatization is enough as long as the individuals do not go beyond 3600 m. If they are required to be stationed at a height of more than 36000m they will require a further period of acclimatization. For individuals who return to high altitude after a period of stay in plains for more than 10 days at a time, re-acclimatization is necessary. The tenure of stay should be such that an individual remains in an excellent state of health and physical fitness during his stay. It has been found that the desirable maximum period of stay should be 24 months between 2700-4200 and 12 months above 4200 m but below 4800 m, and about 2 months at a stretch for staying at altitudes beyond 4800 m. However, these recommendations need to be guided by operational requirements. Medical Officers of armed forces should advise the commanders regarding needful rotation of personnel, with a view to maximize the performance and minimize the ill-health.

Acclimatization Procedure

In Indian Armed Forces it is done in three stages.

**First Stage Acclimatization**

Applicable to individuals posted above 2700m and upto a height of 3600 m. The acclimatization period of 6 days will be as under: -

(a) 1st and 2nd day - rest except for short walks in the unit lines only, not involving any climb.

(b) 3rd and 4th day - walking at slow pace for 1½ -3 km, avoiding steep climbs.

(c) 5th and 6th day - can walk up to 5 km and climb up to 300 m at a slow pace.

**Second stage Acclimatization**

This applies to heights above 3600 and up to 4500 and is carried out for 4 days and is as under :-

(a) 1st and 2nd day - slow walk for a distance of 1½ -3 km avoiding steep climbs.

(b) 3rd day - slow walk and climb up to 300 m

(c) 4th day - climb 300 m with equipment.

**Third stage Acclimatization**

This is for height above 4500 m, lasting for 4 days and is on the same lines as second stage acclimatization.

**Re-entry**

Individuals who have left high altitude area will require acclimatization again if they were away for more than 10 days. Individuals away for more than 4 weeks will require complete acclimatization in 3 stages, as described above, while those who have been away for more than 10 days but less than 4 weeks, will have acclimatization for 4 days at each stage as under: -

(a) 1st and 2nd day - rest except short walk.

(b) 3rd day - walk at slow pace for 1-2 km, avoid steep climb.

(c) 4th day - walk 1-2 km with climb upto 300 m.

**Notes**

(a) If an individual is directly taken to a higher stage, the complete acclimatization as applicable for first stage should be recommended. For example, if a person is inducted by air, from plains, directly to a height of 14,000 feet (4200 mtr), he should have six days of first stage acclimatisation (and not only 4 days of schedule normally recommended for this height, for second stage).

(b) For induction via Road axis Pathankot - Manali-Upshi - Leh, specific instructions of Northern Command regarding acclimatization for persons inducted by this route are given in the succeeding paragraphs and may be further checked form Headquarters Northern Command (Medical Branch).

(c) The role of Acetazolamide, Aspirin, Ascorbic acid and oral antioxidant vitamins is under study but no evidence based proof is available for their introduction for mass prophylaxis.

**Acclimatization schedule : Leh-Manali Axis**

Details of acclimatisation schedule to be followed with base at "P1" for all 6 days ( with entire day to be spent at "G" hts (9000 ft) and night at "P1" transit camp will be as per AO 110/80 with modifications as under:

**New inductees**

(a) Day 1 & 2 : 12 hrs at 9000 ft and 12 hrs at 8000 ft. Troops to be taken up to "G" in vehicles for rest at HAA at 9000 ft during the day for 12 h and

brought down to transit camp, "P1" for night for 12 hrs

(b) Day 3 & 4: Walking 3 km. Troops taken up to "G" stay there for 12h. Only activity is to walk for 3km without much climb during their stay of 12 h at "G" and brought down to transit camp, "P1" for night for 12 h

(c) Day 5 & 6 : Walking 5 km with climb up to 300 mtrs. Troops taken upto "G" stay there for 12h.Walk up-hill for 2.5 km (Climb should be upto 300 mtr) and men walk down hill for distance of 2.5 km during their stay of 12h at "G" and brought down to transit camp, "P1" for night for 12h.

(d) Day 7 : Adm halt at "P2"

(e) Day 8 : Adm halt at "P3"

**Re-entry in HAA. (Away from HAA more than 10 Days but less than 4 wks).**

(a) Day 1 & 2 : 12 Hrs at 9000 ft and 12 hrs at 8000 ft. Troops to be taken up to "G" in vehicles for the Rest at HAA at 9000 ft during the day for 12 h and brought down to transit camp, "P1" for night for 12 h.

(b) Day 3 : Walking 1-2 km. Troops taken up to "G" to stay at 9000 ft for 12 h. Walk for 1-2 km during their stay of 12 h at"G" and brought down to transit camp, "P1" for night for 12 h.

(c) Day 4 : Walking 1-2 km with climb upto 300 mtrs.Troops taken upto "G" stay there for 12 h walk up-hill for 1-2 km (Climb should be 300 mtr) during their stay of 12 h at "G" and brought down to transit camp, "P" for night for 12 h.

**Box - 4 : Essential first aid for HAPO / HACO at forward post**

- Complete rest; no physical activity; manage as stretcher case
- Reassure the patient
- Oxygen inhalations 4 – 5 ltrs / min
- Establish intravenous line
- Call for evacuation

**Note**

Exact names of locations "P1", "P2", "P3" and "G" may be checked from HQ NC (Med Branch)

## Early Diagnosis, Treatment and First Aid

Adverse effects of high altitude, particularly HAPO and HACO should be managed as medical emergencies; prompt first aid and evacuation would be life saving. Medical officers should be familiar as to how to distinguish between AMS on one hand and HAPO / HACO on the other; Unnecessary evacuation in case of AMS may unnecessarily deplete the manpower while not evacuating a case of HAPO / HACO could be disastrous for the patient.

The mainstay of quick management is immediate evacuation of a case of HAPO / HACO to sea level or to as low an altitude as possible, with minimal exertion. If this is not possible, artificial recompression in a "Portable HAPO Bag" (see below) or else in recompression chamber at the dependent hospital should be undertaken. At the level of RMO / Nursing Assistant at the periphery, the essentials of first aid are outlined in box-4.

If evacuation is not possible, a viable alternative is to place the patient in recompression chamber which, in effect, deinducts the patient to lower altitudes. The pressure is maintained at 1 atmosphere. Hyperbaric pressure, beyond 1 atmosphere, is not indicated. Severe cases of HAPO, and the patients with evidence of cerebral oedema should definitely be treated in recompression chamber, if not evacuated to sea level. The average duration of treatment in a chamber is 16 hrs. In forward areas where a portable one-man recompression bag is available, all

# Meteorology

Weather forecasting helps us in planning for the prevention and control of diseases, predict the level of human efficiency, forecast the dangers of climatic extremes and vagaries on men and plan for the prevention of their effects. Weather forecast and knowledge of climate conditions at particular places in particular periods of the year are necessary for the Armed Forces medical officers so as to enable them to advise the commanders on preventive aspects and also plan the control and therapeutic measures. Forecasting of weather and climate is done by correlating the present and previous meteorological observations with norms observed over considerably long retrospective period i.e. the 'climatic habits' of the place.

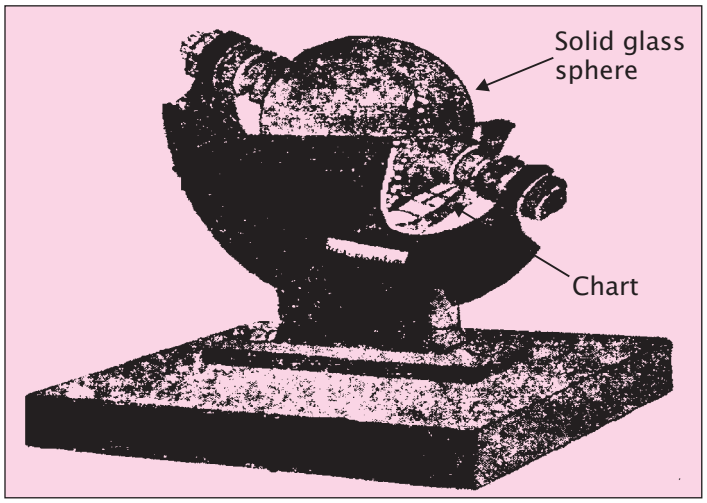
The important data required to be collected for weather forecasting are the atmospheric temperature, atmospheric humidity (wet bulb reading), the barometric readings, the directions and velocities of wind, the presence, type and direction of movements of clouds, the rainfall or snowfall, and the solar radiation. Out of these, the atmospheric temperature and pressure remains the most valuable data for weather forecasting. Various instruments are used to measure these meteorological factors; various modes of expressing the quantitative degree and qualitative types of these factors have been evolved; and various scales of expressing their total effect on human sensation have been innovated. These are briefly described in the succeeding paragraphs.

### Measurement of Solar Radiation

(a) Campbell- Stokes Sunshine Recorder

The number of hours of sunshine is estimated by the Campbell-Stokes Sunshine Recorder (Fig.1) in which sunrays are brought to a focus on a charted paper by means of a glass globe. The charred line gives the total number of hours of sunshine.

Fig - 1 : Campbell stokes sunshine recorder



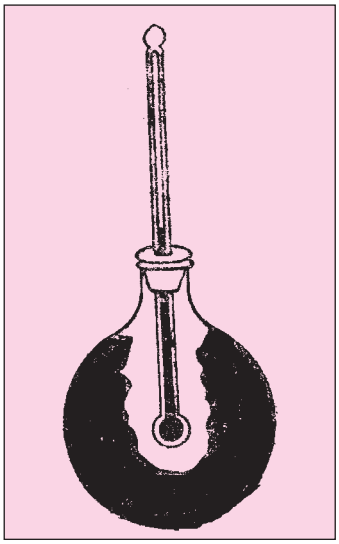
(b) Solar Radiation Thermometer

The intensity of solar radiation is measured by a solar radiation thermometer. It is a black bulb thermometer enclosed inside a glass shield devoid of air. The difference between the black bulb reading taken when exposed to sun rays and the maximum thermometer reading taken inside the Stevenson Screen denotes the intensity of solar radiation.

(c) Black Globe Thermometer

A black globe thermometer (Fig. 2) records the mean radiant temperature of the environment. It consists of a hollow copper globe of 15 cm diameter whose outer surface is coated with matt-black paint, which absorbs the radiant heat from the surroundings. If the place is windy, a black globe with 20 cm diameter should be used. The sphere has circular opening through which a mercury thermometer is inserted into the globe. The instrument is placed in the environment for about 20 min and the temperature is recorded. The mean radiant temperature (M.R.T.) is calculated from the chart provided. A modification called the wet Globe Thermometer consists of a dial thermometer enclosed by a blackened copper sphere which is commonly covered with wet, black cloth (1).

Fig - 2 : Black Globe Thermometer.



### Measurement of Atmospheric Temperature

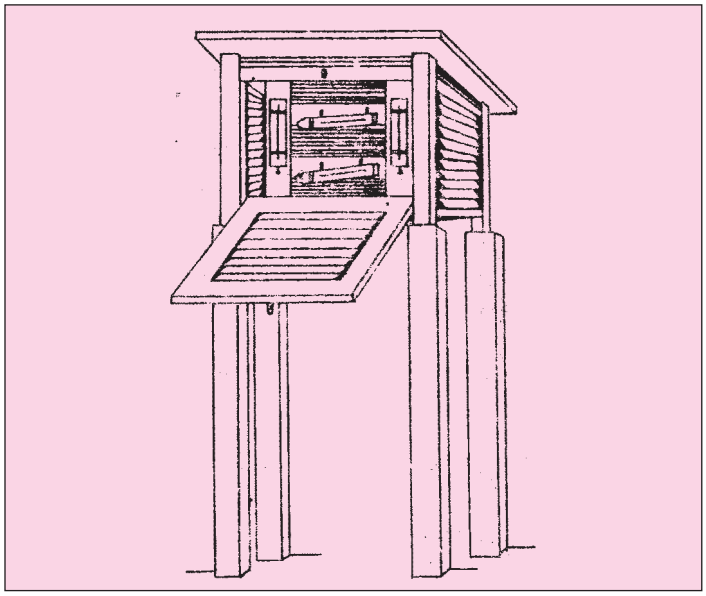
Atmospheric temperature is recorded in the shade by mercury thermometer.

(a) Stevenson Screen

To ensure free access of air to the bulb of the thermometers and their protection from the sun and rain, the thermometers are mounted in a box of approved pattern called the 'Stevenson Screen' (Fig. 3). It is a double louvered box, internal dimensions being, length 76 cm, width 45 cm and height 48 cm. It has a double roof, the upper one projecting 5cm beyond the sides of the box and sloping from front to back, and has an open base. At the front is a hinged door opening downwards. The box is mounted on four posts with its door opening to the North (South in the Southern hemisphere), at such a height that the bulbs of the thermometers are 138 cm from the

ground, and at least 6m away from buildings, large trees and other obstructions to prevailing wind. The thermometers are hung up inside the box so that they can be read without being touched and moved, and arranged

Fig - 3 : Stevenson screen



in such a way that no bulb comes within 8 cm of the roof or sides.

(b) Maximum Thermometer

It records the highest temperature attained at any given time of observation. It is hung up almost horizontally with the bulb end slightly lower than the other end. Maximum thermometer is a mercury thermometer, in the capillary stem of which there is a small metal indicator which is pushed along by the mercury and fits tightly enough to remain behind when the mercury recedes. The lower end of the indicator gives the highest temperature reached during the period of observation. To reset the instrument the indicator is pulled down by means of a magnet until it comes in contact with the mercury.

(c) Minimum thermometer

It is a spirit thermometer with a small metal pin-shaped indicator, which lies free in the column of spirit in the stem. To set the thermometer it is held with the bulb-end uppermost so that the indicator runs down the stem until stopped by the surface tension of the spirit. It is hung up similarly as the maximum thermometer without disturbing the indicator. As the temperature falls, the indicator is dragged down by the contracting spirit; when it rises the spirit flows past the indicator. At the end of any period of observation, the position of the end of the indicator farthest from the bulb shows the lowest temperature reached during the period.

(d) Combined Maximum and Minimum Thermometer

It comes in several types. The commonest of these is the James Six's Thermometer. This instrument consists of a glass tube bent into three limbs and combines the principles of the maximum and minimum thermometers described above. It is convenient for ordinary routine purposes but it is not accurate enough for exact meteorological observations.

**Means of Temperatures**

To convey a proper idea of the prevailing warmth of a locality, a full range of 'normal' data for the whole year and extending over a number of years should be given. They are as under:-

(a) Daily Mean Temperature.

It is the mean of the maximum and minimum temperatures recorded during the day; or at stations equipped with self-recording instruments for temperature, the mean of the twenty-four hourly values from midnight to midnight.

(b) Weekly Mean Temperature

It is the mean of seven consecutive daily mean temperatures.

(c) Monthly Mean Temperature

It is the mean of daily mean temperature of the number of days in the month in question.

(d) Yearly Mean Temperature

It is the mean of 12 monthly means.

(e) Diurnal Range of Temperature

It is the difference between the maximum and minimum temperatures of any day. The mean weekly, monthly and annual ranges of temperatures are obtained in the same way as the mean daily range of temperature.

**Measurement of Atmospheric Humidity**

Absolute humidity is the amount of water vapour actually present in the air expressed as g/l of air, as estimated by means of absorption hygrometers. Relative humidity is the ratio of the amount of water vapour actually present in the air at any given temperature to the amount that would be present in the air, were the air saturated at the same temperature. It indicates the percentage of saturation. Amount of water vapour necessary to cause saturation of the air varies directly with the temperature; the higher the temperature of the air more the water vapour it can hold before saturation point is reached. When atmospheric saturation is reached, evaporation ceases altogether. The relative humidity (RH) can be estimated by first finding out the dry and wet bulb temperatures by means of a self-recording hygrometer and then by calculating RH from the standard tables. Mason's hygrometer and whirling or sling psychrometer are used for this purpose.

(a) Mason's Hygrometer

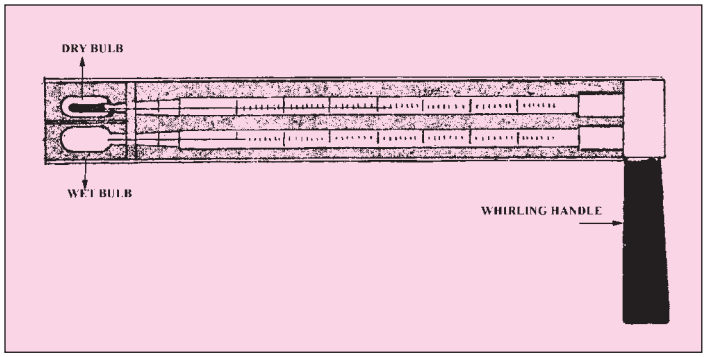
It has two mercury thermometers mounted side by side on a frame in the Stevenson Screen. The dry bulb is exposed in the ordinary way and the wet bulb has its bulb covered with muslin kept moist by a cotton wick, which dips in distilled water. The wet bulb thermometer records air temperature as influenced by the rate of evaporation from the muslin cloth. The drier the air the greater the rate of evaporation and the lower will be the wet bulb readings. In a saturated atmosphere the readings of the dry and wet

thermometers coincide. The difference between the dry and wet bulb readings, known as the 'depression of the wet bulb', is inversely proportional to the amount of atmospheric moisture. Hygrometric tables enable the relative humidity, the vapour, and the dew point to be read directly for any reading of Mason's hygrometer. This hygrometer is used for meteorological purpose at permanent meteorological stations.

(b) Whirling or Sling Psychrometer

It has the dry and wet bulb thermometers mounted side by side on a metal strip, which is pivoted to a frame with a handle. A small cylindrical water container is provided for soaking the piece of a wick. This is whirled by hand until the wet bulb reaches the lowest value. Successive observations are made to get a constant reading. The wet bulb reading should be taken first (2). An aspirating

Fig - 4 : Sling Psychrometer



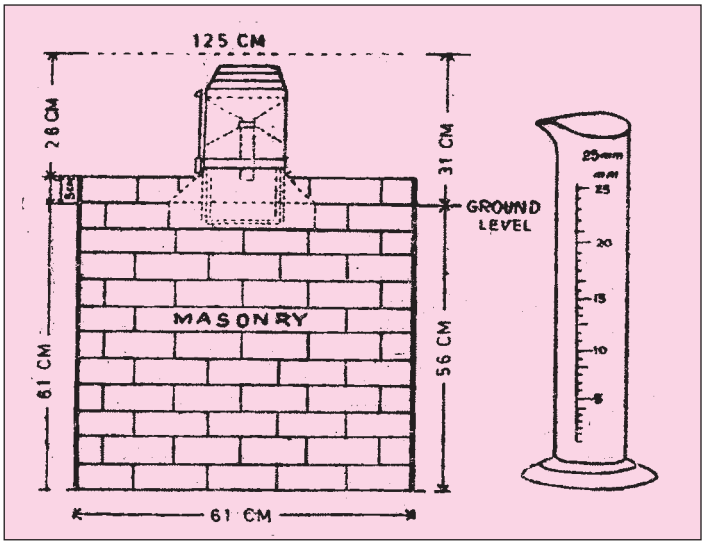
psychrometer is rotated by a motor and is more accurate but expensive. The sling psychrometer is used in physiological studies in enclosed places, to assess the occupational environment. (Fig 4).

**Measurement of Atmospheric Pressure**

The atmospheric pressure is estimated by the use of a mercury barometer of which there are several types, or by an aneroid barometer which, however, is not so accurate as the mercury barometers. Pressure observations are expressed in inches or millimeters of mercury, or more correctly as millibars. Barographs are also available which can make continuous records of barometric pressure, during a 24-hour period. The instrument is supplied complete with recording device and spare recording charts. Highly sensitive barographs are also available which are called microbarographs. The working of this apparatus is simple but for field work aneroid barometers are the instruments of choice. They should, however, be calibrated with a standard mercury barometer at frequent intervals.

**Measurement of Rainfall**

Rainfall is expressed in terms of inches or millimeters. A rain gauge consists of a collecting funnel, a receiving vessel and measuring glass. The funnel, which is made of copper, is cylindrical in its upper part with a diameter of 20.3 cm; in some instruments it is 12.7 cm. The receiving vessel is a small copper can, which fits inside an outer casing. A measuring glass graduated for the particular instrument is provided with each gauge. To take an observation, the outer casing of the instrument with the receiving vessel and collecting funnel in situ is sunk into the ground in an open space so that the top of the receiving funnel is about one foot above the ground. After



the desired time has elapsed the collecting funnel is removed, the receiving vessel lifted out, and its contained water poured carefully into the measuring glass and read off. Snowfall is also measured with the similar apparatus and method (Fig 5).

Fig - 5 : Erection of Rain Gauge

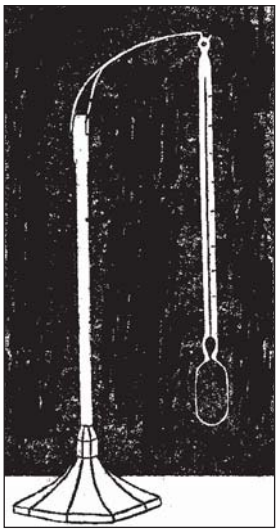
**Measurement of Air Movement**

The instruments that can be used are the kata-thermometers rotating vane or propeller anemometers, thermoanemometer and hot wire anemometer.

(a) Kata-thermometer.

The standard silvered kata-thermometers are of three types with appropriate cooling ranges:-

Fig - 6 : Kata Thermometer



(i)The standard Kata (Red coloured) Cooling range between 100ºF - 95ºF.

(ii)The high temperature Kata ( Dark blue coloured) - cooling range between 130ºF - 125ºF.

(iii)The extra high temperature Kata (Magenta coloured)- cooling range between 150ºF-145º F

The Kata thermometers are alcohol thermometers with a glass bulb 4 cm long and 1.8 cm in diameter. The kata thermometers are useful for measuring air velocities upto 250cm per sec. When air currents are mainly horizontal, vertical air

movements cause error due to convection currents from the large heated bulb. Each kata-thermometer has a given kata-factor and is provided with standard charts with instructions for use. Immerse the silvered bulb of kata into a flask containing hot water. The coloured fluid from the bulb will rise up into the stem upto small upper bulb. Remove the kata-thermometer from the flask and suspend it on a stand 60 cm away from the observer so that his respiratory air current does not vitiate the result. Wipe out all moisture from the surface of the thermometer with a clear chamois leather piece. Note with a stop watch the time in seconds for the fluid column to traverse the marked distance while cooling. Take five readings and estimate the mean value. The wind velocity is calculated from kata- factor and kata-charts available with instruments (3). Fig - 6 depicts the Kata-thermometer.

(b) Anemometer

Anemometer of the rotating vane or propeller type are used to record the speed of a unidirectional air current. For low air velocities and for measuring the combined air movement of eddies, the kata-thermometer is, however, preferable. Moreover, for biometeorological studies omnidirectional air movement is more important than unidirectional air current .

(c) Thermo-anemometer and Hot Wire Anemometer

These are used in laboratories for precision experimental work

(i) A thermo-anemometer is a mercury thermometer with an electrically heated metallic coil round its bulb. A rheostat regulates voltage. The velocity of air can be measured upto 5000 cms per sec or more by suing suitable voltage and a calibration chart.

(ii) A hot wire anemometer is made of three pieces of electrically heated fine platinum wires. The change in resistance produced by the cooling effect of the air current is measured by a potentiometer or a galvanometer. This instrument is sensitive to very low air movements below 100 cms per sec.

# Water Supply

> "We shall not finally defeat AIDS, tuberculosis, malaria, or any of the other infectious diseases that plague the developing world until we have also won the battle for safe drinking water, sanitation and basic health care."
>
> **Kofi Annan, United Nations Secretary-General**

Water is a prime natural resource, a basic human need and a precious national asset. Water is the most important of all the necessities for sustenance of life. Water is essential for drinking, cooking, bathing and washing, laundering, ablution, domestic sanitation, domestic animals and industries. The first two uses require very pure water and the remaining require relatively pure or clear water. Water for industries should be chemically suitable. However, water can become a vehicle for transmission of faeco-oral group of infections, because the faecal contamination of water is extremely common and its avoidance and subsequent purification is very difficult. Therefore, a strict water vigilance and control is to be maintained at all times. Water may also create unhealthy conditions if some organic or inorganic poisons such as lead or arsenic are present; excess of fluorides causes osteofluorosis and mottling of dental enamel; deficiency of fluorides causes dental caries and deficiency of iodine may cause goiter.

### Global Situation

Present estimates suggest that nearly 1. 1 billion people lack access to improved water supply and 2. 4 billion without access to any sort of improved sanitation facility and that at least 5 million deaths per year can be attributed to waterborne diseases. Eighty percent of all sickness in the developing countries, as stated in the International Conference on Primary Health Care at Alma Ata in 1978, was attributable to contaminated water supply. To tackle this global problem, the United Nations Conference on Human Settlement held at Vancouver in 1975 and the Water Conference held at Mar del Plata, Argentina in 1977, had earlier declared the period from 1981 to 1990 as International Drinking Water Supply and Sanitation Decade. Efforts within the countries were directed towards giving higher government priority to Decade activities, changing the technology mixed with a shift towards lower cost solutions; mobilizing community based resources through maximum participation by the beneficiaries and use of local materials; increasing manpower and taking all opportunities to couple water sanitation with health education programs and other developmental efforts, e. g. , agriculture and irrigation projects.

### National Situation

In India, the main sources of water supply are the perennial rivers and ground water resources. Because the annual precipitation is concentrated during monsoons, only a portion of this water is harvested; the bulk of it flows down to the sea and is lost as a source of supply. The groundwater is the principal source of water supply for personal, agricultural and industrial uses. Due to rapid increase in agriculture, industry and population, there has been consistent depletion of groundwater sources. This coupled with deforestation affecting water retention has resulted in depletion and receding water tables.

#### Availability and Demand

Total annual rainfall over India is 4000 cubic kilometers (CKM). Out of this, surface flow is only 1880 CKM annually. Due to topographical, hydrological and other constraints only 700 CKM of surface water per year can be put to beneficial use. The quantity of annual replenishable groundwater is 600 CKM, but only 420 CKM is usable. The estimated annual requirement of fresh water for the year 2000 and 2025 are 750 and 1050 CKM respectively. The present quantity of usable water is just sufficient to meet the demand of the country by 2025 AD.

#### Groundwater

In our country, the groundwater is consumed directly, without any sort of treatment and disinfection, therefore its quality is a cause of concern. Almost all highly industrialized areas in the country have contaminated their groundwater due to industrial wastes and agricultural run-offs (CPCB, 1994). Even all the villages too, do not have access to safe water. A "problem village" is defined as one where no source of safe water is available within a distance of 1. 6 km or where water is available at a depth of more than 15 meters or where water source has excess salinity, iron, fluorides and other toxic elements or where water is exposed to the risk of cholera and guinea worm.

**In India, under the International Drinking Water Supply and Sanitation Program the laid down target was 100 percent safe water supply, in both urban and rural areas.** As per available reports, till 1994-95, 85 percent of the target has been achieved (3 - 5).

## Importance of Water in the Armed Forces

Since Armed Forces personnel are particularly vulnerable to the danger of water related disease because of the nature of their duty under adverse conditions beyond their control, strict water vigilance and control is to be maintained at all times. The provision of adequate and safe water supply for use of Armed Forces personnel is an important responsibility of every Commander as it is important in the maintenance of health and fighting efficiency of troops. The Engineers are responsible for the supply of wholesome water and the Medical Services for the advice as to its safety and procedure to render it safe for consumption. In the field, all untreated water should be regarded as polluted but practically all waters can be made safe by modern methods; however, the better the initial supply the better is the final result. In every instance it must always be properly treated to render it fit for drinking. All units are responsible to maintain the following number of men trained in water and sanitation duties (AO 339/74 Course of training in sanitation and water duties) (See Table 1)

They will work under the supervision of the unit Quarter Master. Their duties consist of :

(a) Sanitation of source/storage of water supplies
(b) Supervision of sanitation within the unit lines
(c) Sanitation of cook houses and canteen
(d) Disinfection
(e) DDT spraying
(f) Anti fly, anti-mosquito and anti-rodent measures. Men previously trained are required to be sent on refresher courses annually. Necessary courses for the training of personnel are organized and conducted by RMOs / SEMOs / SHOs / Fd Ambs.

## Safe and Wholesome Water

Drinking water should be safe as well as wholesome. Water is termed safe when it does not harm the consumer even when ingested over prolonged periods. Safe water, however, need not necessarily be wholesome. It may be unsightly in appearance and unpleasant to taste and smell.

Water for drinking and cooking purposes, therefore, should be safe as well as wholesome. Such water is also termed potable water. Water is called polluted when it contains infective and parasitic agents, poisonous chemicals, industrial and other wastes or sewage.

**Safe and wholesome water thus, must be**

(a) Free of pathogenic organisms
(b) Free harmful chemical substances
(c) Acceptable to taste and appearance
(d) Usable for domestic purposes

## Water Requirements

The supply of water must be satisfactory in quality and adequate in quantity, readily available to the user, relatively cheap, and easily disposed after it has served its purposes. The water requirement depends upon climate, extent of physical activity, its availability, standard of living and habits of the people. In an urban area having water carriage system of sewage disposal, about 150 to 200 litres per head per day supply is considered adequate.

Man's requirement of water is known to depend upon the thermal stress resulting from the heat production in him due to physical work as well as due to heat gained by the body from the environment. It is well known that when the severity of this total stress increases the water requirement also increases.

Many studies have been conducted by Defence Institute of Physiology and allied sciences (DIPAS), Delhi Cantt, to find out qualitatively the optimum and minimum water requirements for troops under various environmental conditions. Based on the findings of these studies the optimum and minimum daily requirement for different activity patterns of troops under varying weather conditions in desert where the air temperature ranges from 41° to 44°C and the wet bulb temperature is about 26 °C to give a heat stress equal to 35 ° C WBGT (Wet Bulb Globe Temperature) are recommended as follows :

(a) When the troops are engaged in sedentary activities the optimum daily fluid requirement as drinking water and beverages is 6. 8 litres and the minimum requirement is 5. 5 litres.
(b) When the troops are engaged in 3 hrs of route march with 12 Kg load in open sun the optimum daily water requirement is 8. 3 litres with minimum of 7 litres.
(c) When troops are engaged in strenuous military exercises like digging of trenches, route marches, bayonet fighting, battle exercises like advance to contact, counter attack, withdrawal etc for a period of six hrs per day the optimal daily requirement is 10 litres and the minimum 8 litres.

Table - 1 : Men trained in Water and Sanitation duties

| Unit | Water and Sanitation Duties | | |
|---|---|---|---|
| | NCO | OR | |
| Major units commanded by Lt Col and above | 4 | 6 | Plus 20% as reserve |
| Minor units commanded by Major and below | 2 | 3 | |

To prevent occurrence of heat causalities or ill effects of heat, the above scale of water for troops in desert should be ensured (Auth : AHQ letter No A/46032/AG Coord dt 10 Dec 81)

The scales of water consumption in the Armed Forces are given in Table - 2.

## Sources of Water

The ultimate source of all natural potable water on the earth is rain. When rain falls, it runs off into streams, in the case of heavy rains, or soaks into the ground, percolating through porous strata until it reaches an impervious stratum, upon which it collects, forming groundwater. Groundwater is the source of wells and of the springs that feed streams, rivers, and lakes. In its course, groundwater dissolves soluble mineral matter, and often the surface waters of rivers and lakes are polluted by the influx of sewage or industrial wastes. The water is impounded by a system of dams, and flow by gravity, or is pumped, to the local distribution system. The quality of water from these sources varies greatly. Surface waters generally contain larger quantities of turbidity and bacteria than ground waters, but groundwater contains higher concentrations of dissolved chemicals

### Rain Water

Rainwater is used as a direct source on islands, such as Bermuda, where the rain is collected and led into cisterns to serve as the only available water supply. Catchment areas for direct capture of rainwater are also useful for

Table - 2 : Scales of water consumption (litres per head per day)

| Class | Married | | Single | | Military Area | | | | |
|---|---|---|---|---|---|---|---|---|---|
| litres | No of family members | Servants and families | No. | Servant | With water borne sanitation | | Without water borne sanitation | | Add for garden conservancy in per day |
| | | | | | Plains | Hills | Plains | Hills | |
| Officers Mil/ Civilians | 5 | 5 | 1 | 1 | 225 | 160 | 160 | 90 | 225 L per married Officer and 135 L per single officer |
| JCOs and their equivalents in the Navy & Airforce | 5 | - | 1 | - | 205 | 145 | 145 | 80 | 115 L per married JCO and 70 L per single JCO |
| NCO & equivalents | 5 | - | 1 | - | 205 | 145 | 145 | 80 | 45 L each for married and single |
| OR & equivalents | 5 | - | 1 | - | 205 | 145 | 145 | 80 | - |
| Followers (Non-Combatants) | 5 | - | 1 | - | 205 | 145 | 145 | 80 | - |
| Regimental shops | - | - | - | - | 7 | 45 | 45 | 45 | - |

| Office/Schools with water borne sanitation | - | - | 1 | - | 45 | 25 | 25 | 15 | - |

individual households as in South West USA or small communities as in Gibraltar where paved catchments are used. Historical sources mention the use of rainwater for domestic water supply some 4000 years ago in the Mediterranean region. In the hills near Mumbai, the early Buddhist monastic cells had an intricate series of gutters and cisterns cut into the rock to provide domestic water on a year-round basis. Bird droppings in rain water have been reported to cause salmonellosis in Jamaica. Rain water is usually soft, plumbosolvent and mildly acidic due to its reaction with carbon dioxide in the atmosphere to form carbonic acid. Acid Rain is a form of air pollution, which occurs when oxides of sulphur and nitrogen combine with atmospheric moisture to yield sulphuric and nitric acids, which may then be carried long distances from their source before they are deposited by rain. The pollution may also take the form of snow or fog or be precipitated in dry forms. The problem of acid rain originated with the Industrial Revolution, and it has been growing ever since. The widespread destructiveness of acid rain, however, has become evident only in recent decades as it has been found to erode buildings and other structures, injure crops and forests, and threaten or deplete life in lakes.

**Surface Water**

It includes rivers, streams, upland reservoirs and lakes. Surface water is moderately soft and contains variable degree of pollution from human and animal excreta. The extent of contamination at a particular time and place will depend upon the proportion of pollution to the amount of water available, from the feeding streams, upstreams or springs, the extent of stagnation or outflow over a given time and the extent of natural self purification.

Upland Waters

These are the collections of water harnessed in the impounding reservoirs by constructing earth, concrete or masonry dams across at convenient places in the valleys in the mountainous regions. These collections are relatively pure in general but may get polluted due to grazing of animals and human activity. During storage, sedimentation takes place and the number of faecal coliforms and faecal streptococci are considerably reduced. Destruction of organic matter by atmospheric

oxygenation, solar radiation and aquatic flora and fauna also occurs. Algal growth and loss of water through evaporation are the chief drawbacks. Storage in reservoirs and lakes may degrade water quality through eutrophication, biomagnification, and thermal stratification. Eutrophication (over-nourishing) occurs due to the influence of nutrient materials, particularly phosphorus and nitrogen which support the growth of algae. These nutrients accumulate in algae, which settle and tend to fill the lake. The increasing amounts of algae impart unpleasant taste and odours to the water. Biomagnification :There is also bioaccumulation of chemicals and contaminants taken up by aquatic life like fish whose quality is affected. Thermal Stratification: During summer, the warmer, lighter water accumulates at the top and the density difference prevents mixing. Microorganisms tend to accumulate at the thermocline, the zone of rapidly changing temperature and density that separates upper and lower layers.

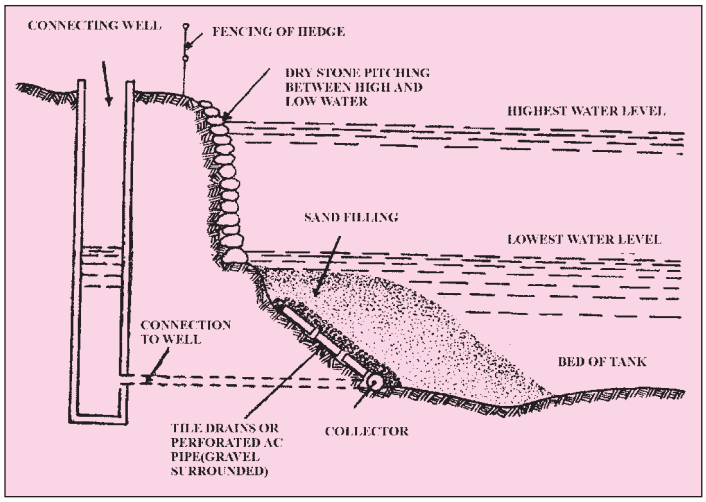
### Lakes

Lakes are increasingly becoming vulnerable to pollution as they are quite accessible for human activities. Eutrophication of lake waters is also common due to runoffs of chemical fertilizer from cultivated fields. The process of eutrophication can produce aesthetic problems such as bad tastes and odors and unsightly green scums of algae, as well as dense growth of rooted plants, oxygen depletion in the deeper waters and bottom sediments of lakes, and other chemical changes such as precipitation of calcium carbonate in hard waters. Another problem, of growing concern in recent years, is acid rain, which is leaving many lakes totally devoid of life.

### Ponds

Surface ponds without inflow of fresh water from upland streams or natural springs are stagnant. The degree of pollution and contamination is very high due to surface inflow and seepage from the surroundings. The concentration of pollution increases as water evaporates. The degree of self purification is negligible and the amount of pollution added to it each day is unpredictable.

Fig - 1 : Slow filteration of tank water



Therefore, water from fresh water lakes, which are properly protected, fenced and patrolled is generally pure and can be made potable whereas that from a pond is never recommended for human consumption. Unfortunately, it constitutes one of the main sources of water supply in the rural areas of this country. Research at national and international level has now come out with plans for improvement of village tanks as a source of relatively safe water supply. The improvement can be achieved as shown in figure - 1 by applying the basic techniques of modifying a part of the pond into a filter bed. The filtered water is then drawn into gravity fed well and finally chlorinated before supply.

### Rivers and Streams

These are natural drainage channels of the land. The quality of river water depends upon the geological strata through which it has travelled, the seasons of the year, and the amount of pollution that has occurred during its course. Generally it is moderately hard and holds organic and inorganic pollutants. Some river waters are brackish and may have an aperient effect and except in rivers arising directly from snow or mountains above human habitations, they are grossly contaminated and traversing long distances, they collect more pollution from sewage discharge from habitations located along their course. Other sources of pollution are the industrial effluents, carcasses and human dead bodies. Rivers, however, have considerable powers of self purification through the physical and biological processes. The degree of self purification depends upon the length, breadth and depth of the river, velocity of the water, nature of river bed, presence of saprophytic organisms, volume of water, presence of aquatic and animal life, and exposure to sun's rays. It should be ensured that water supply is procured upstream and that the industrial and other effluents discharged into a river downstream conform to the laid down standards and that the place around is properly protected. The inadequacy of traditional methods of water treatment to tackle gross river water pollution may be indicated by the outbreaks of viral hepatitis in New Delhi in 1955-56, when there were 30,000 cases, and in 1958, at the time of the outbreak, drought conditions prevailed, and the water abstracted from the river was estimated to contain about 50% of wastewater. Some rivers carry such a high proportion of treated and untreated wastewater that their use as a water source can be considered as essentially wastewater reuse. However, quite often, the same body of water serves both as a source of water and as a recipient of sewage and storm drainage. In wet periods, the water in rivers and streams may be low in dissolved solids content but often of a high turbidity. In dry periods, river flows are low and the load of dissolved solids is less diluted.

### Sea Water

The most appropriate method for desalination of sea water is thermal distillation as done in Middle East and the West Indies. Several different processes, including electrodialysis, reverse osmosis, and direct-freeze evaporation, have been developed for this purpose. With

brackish waters, where the salt content is much less than that of sea water, reverse osmosis or electrodialysis may be used. An additional problem is that with almost 80 percent of the planet covered by oceans, people have long acted as if those bodies of water could serve as a limitless dumping ground for wastes. Raw sewage, garbage, and oil spills have begun to overwhelm the diluting capabilities of the oceans and most coastal sea waters are now polluted.

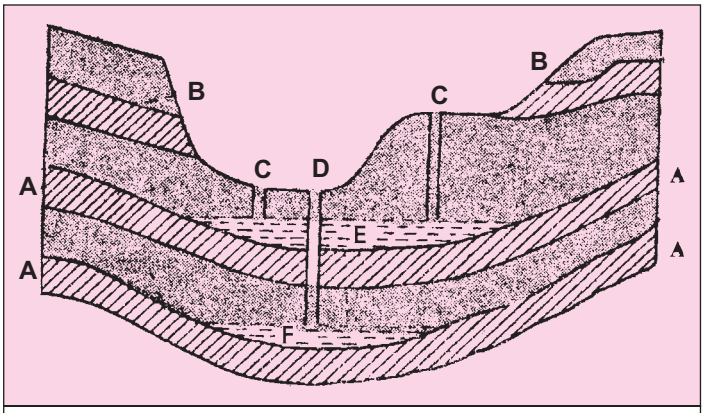
**Underground Water**

Underground water (Fig. - 2) is of major importance to civilization, because it is the largest reserve of drinkable water in regions where humans can live. Underground reservoirs have the following major advantages :

(a) They do not lose water through evaporation

(b) Their quality is not so likely to be affected by natural, urban or industrial pollution

Fig - 2 : Underground Water



(A) Impermeable layers (e.g. Clay) (B) Land springs (C) Shallow wells (D) Deep wells (E) Superficial water table (F) Deep water table

(c) They do not require expropriation of large areas of land

(d) They may be located nearer to the points of use than are surface impoundments.

Although groundwater is a renewable resource, reserves are replenished relatively slowly. Because groundwater is recharged and flows so slowly, once polluted it will remain contaminated for extended periods. Contamination arises from leaking underground storage tanks, poorly designed industrial waste ponds, and seepage from the deep-well injection of hazardous wastes into underground geologic formations. When groundwater is depleted in coastal regions, oceanic salt water commonly intrudes into freshwater supplies. Sometimes, withdrawal of water from a new well may cause an appreciable reduction of the yield of existing wells nearby. When heavily populated or highly irrigated arid areas withdraw water from the ground at too rapid a rate, the water table in such areas may drop so drastically that it cannot be reached, even by very deep wells. Excessive abstraction of groundwater has not only lowered the water table in many places but also has resulted in subsidence of the ground above in some places, threatening structures and increasing the potential for flooding.

Shallow Wells

These tap the 'superficial water table' i. e. the water table above the first impervious layer of the earth. Their yield fluctuates according to the subsoil water percolating to it during the year. The quality of water depends upon the geological formation and the degree of pollution by seepage from the adjacent area, which is unpredictable. Shallow wells are, therefore, inferior to deep wells as sources of water for human consumption. The Cholera outbreaks in Delhi in 1988 were due to contamination of shallow wells. For improvement of the existing shallow wells which are usually 'kutcha' and are most commonly used in rural areas, the Planning, Research and Action Institute (PRAI) Lucknow has developed a modification plan at nominal cost. Such a well can be made sanitary by deepening the bottom, installing a handpump with screen and then filling the well with coarse sand upto water level; clay is then put over sand till it reaches a little above the surface level and then left for consolidation. When the material used for filling is consolidated a platform and drainage may be constructed. Samples of water from such wells are found to be satisfactory. In the well-watered regions of the world, successful wells of moderate depth and diameter in hard rock may be expected to yield from 1 to 50 gallons per minute (1 gpm = 1440 gpd), whereas similar wells in coarse sand and gravel and in coarse sandstone will deliver 50 to 500 gpm.

Deep Wells

These tap the deep water table lying between the two impermeable strata and their yield is constant. Water in a deep well is usually cool, pure and sparkling but likely to have a lot of mineral contents. Normally it forms a very good source of water supply if it is well protected. A deep well is also liable to pollution if there are cracks in the impermeable layer especially in chalky strata. Faulty staining also makes them liable to surface pollution as in the case of shallow wells. An ideal deep well is the one which is sunk to a sufficient depth below the first impermeable geological stratum, well stained with stones or bricks set in cement concrete provided with a covered parapet with a coping or sloped platform around and fitted with a pump. The depth of water should be sufficient to ensure an adequate quantity and sedimentation. Wells in deep aquifers may yield 100 gpm or more in favourable circumstances.

Tube Wells

These are made by boring into the ground. These wells could be shallow or deep. A lot of emphasis is presently being given nationally as well as internationally to provide safe water through tube wells in rural areas. The hand pumps are so constructed that their levers can withstand reasonable degree of rough handling. Boring and inserting a tube and fitting a pump are works of some magnitude. The difficulties lie in the apparatus required for construction, the uncertainty of striking water and,

when found, its suitability. Such water when tapped is often brackish or heavily charged with magnesium salts. The capacity of tube wells varies over a wide range, from less than 1 litre/sec for shallow small-diameter wells in fine sand aquifers, to over 100 litres/sec for large diameter deep wells in coarse sand or sedimentary rock deposits. A tube well has a casing consisting of pipes (tubes) - plain pipes opposite non-water bearing ground formations, and perforated or slotted screen sections opposite the aquifer. Tube wells can be drilled to over 200 metres deep, even through hard rock.

### Artesian Wells

Artesian groundwater is groundwater, that is, by an overlying impervious layer, prevented from rising to its free water table level, and therefore is under pressure. The name is derived from French Artesian of Artois, a province where such wells were first drilled in modern times. Artesian wells are not common in India.

### Step Wells

These are a kind of 'pucca' wells where steps are constructed leading to these wells to fetch water. There is considerable contact between the user and the water. Guineaworm infestation was a public health problem in areas having such wells. Fortunately, these wells are now becoming obsolete.

### Springs

These are natural wells formed when for some reason the underground water over flows upon the surface where the geological formation is favourable for an outcrop. Springs can be 'shallow springs' and 'deep springs' depending upon whether the water comes from the superficial or the deep water tables. They may be intermittent or constant. Intermittent springs are merely the reappearance of upland surface water, which has temporarily passed underground. Until it is made certain that the water is from the deep spring its purity should be viewed with suspicion. Water from a deep spring is generally hard and less suitable for washing and cooking but is passable for drinking. Deep springs can be turned into well like reservoirs by building parapets around them.

### Driven Wells

Driven wells are essentially suitable for soft, sandy formations, which are readily penetrated by the well point. They are usually limited to shallow wells of less than 10-15 metres depth. The diameter is also about 5-10 cm only. The yield is only about 0. 1 to 1. 0 litre/sec.

## Selection and Protection of Water Sources

It is important that in order to expect a purified and safe water supply for human consumption, the proper source and tapping site should be selected keeping in view the liability and degree of pollution and its dilution, power of self purification, daily yield, duration for which available, wholesomeness of water, and the approach to the area. The area around the source, tapping point and delivery point should then be protected against pollution by fencing and prohibiting entry of animals and unauthorized men, bathing and washing. No sanitary installation should be allowed in the vicinity. Water pumped out of wells, when that is the source of water, should be received in a reservoir and chlorinated. The storm water should be led away by a channel constructed around the outer platform to a garden or a large soakage pit. The well should be fenced and no unauthorized persons should be allowed into the area. Periodic inspection, repairs and desilting of the well should be carried out. Springs should also be provided with a coping and parapet. They should be fenced and bricked in. The surface storm water should be diverted away by means of channels dug around the spring.

Water from streams and lakes should be drawn from the upstream side of the township and as far from the banks as possible and pumped into the treatment tanks. In the field several alternative sources and sites should always be examined and the best of them selected for immediate use. The others should then be graded according to merits and improved upon for use in an emergency. When there is no freedom of choice, the only available source and site should be improved upon. Consideration must always be given to yield, extent of pollution, extent of dilution, power of self purification and the outflow of water from the selected or available source and site. Personnel attending to the water treatment/distribution should be protected against typhoid and medically inspected.

## Water Pollution

Natural water, from a chemical point of view, is never pure. The impurities could be either natural, derived from atmosphere or catchment area and soil or due to human activities. Water pollution may come from point or non-point sources.

Point sources discharge pollutants at specific locations from, for example, factories, sewage treatment plants, or oil tankers. Technology is available for point sources of pollution to be monitored and regulated.

Non-point sources run off water containing pesticides and fertilizers from areas of agricultural land, for example are much more difficult to control. Pollution arising from non-point sources accounts for a majority of the contaminants in streams and lakes. The pollutants may be classified as under :

### Natural Pollutants

(a) Dissolved gases Carbon dioxide, ammonia, hydrogen sulphide and nitrogen.

(b) Dissolved minerals Salts of calcium, magnesium and sodium.

(c) Suspended impurities Clay, silt and mud washed by storms and floodwater from croplands, unprotected soils, strip mines, roads, and bulldozed urban areas.

(d) Microscopic plants and animals Plankton, algae, saprophytes and insects.

### Manmade Pollutants

(a) Sewage and other oxygen-demanding wastes (largely carbonaceousorganic material, the decomposition of which leads to oxygen depletion) and infectious agents

(b) Plant nutrients, including fertilizers, that can stimulate the growth of aquatic plants, which then interfere with water useand, when decaying, deplete the dissolved oxygen and produce disagreeable odours

(c) Exotic organic chemicals, including pesticides and herbicides, various industrial products, surface-active substances in detergents, and the decomposition products of other organic compounds.

(d) Petroleum, especially from oil spills

(e) Inorganic minerals and chemical compounds, metal salts and synthetic organic chemicals.

(f) Radioactive substances from the wastes of uranium and thorium mining and refining, from nuclear power plants, and from the industrial, medical, and scientific use of radioactive materials.

(g) Heat may also be considered a pollutant when increased temperatures in bodies of water result from the discharge of cooling water by factories and power plants.

**Hazards**

Health may be affected either directly by consuming contaminated water or indirectly through food chain and also by use of water for recreational, agricultural, trade and other purposes. The health hazards of water pollution may be classified as follows :

Biological

The diseases related to water supply and caused by biological agents of disease are summerised in Table - 3

Chemical

These pollutants are of diverse nature and are derived from industrial, trade and agricultural wastes that are being discharged increasingly into bodies of water. The chemical pollutants include detergents, solvants, cyanides, heavy metals, minerals, organic acids, nitrogenous substances, dyes, pigments, bleaching agents, sulphates, ammonia and many such other toxic substances. Acute toxic effects on human health by these pollutants presently are presumably of less concern than their long term low level exposures. Some of these substances are either known or suspected of having carcinogenic, mutagenic or teratogenic effects. Deficiency of some substances such as iodine and fluorine may cause goitre and dental caries respectively. Excess of some of them may also cause harmful effects; excess fluorides may cause fluorosis; excess of nitrates & nitrites may cause methaemaglobinaemia in infants.

Radio active substances

In modern world with radio active substances being used in wide range of fields, extending from peaceful use such as medical diagnostics and treatment to its wide use in Armed Forces. In future these substances may pose a major health hazard due to water contamination by its residues.

## The Water (Prevention and Control of Pollution) Act 1974

This Act was passed by the Parliament in 1974 to counter and contain ever growing pollution of natural water resources. This Act is comprehensive in providing the

Table - 3 : Diseases related to water supply

| Group | Diseases |
|---|---|
| **Water borne diseases**<br>Diseases transmitted by water where water acts as a passive vehicle for infecting agent. All these depend also on poor sanitation | Cholera, typhoid, bacillary dysentery, viral hepatitis, leptospirosis, giardiasis, gastroenteritis |
| **Water washed diseases**<br>Diseases due to lack of water. Poor personal hygiene favours spread. Intestinal infections depend on lack of proper human waste disposal. | Scabies, skin sepsis & ulcers, yaws, leprosy, lice, typhus, trachoma, conjunctivitis, bacillary and amoebic dysentery, salmonellosis, worm infestations |
| **Water based diseases**<br>Infecting agents spread by contact or ingestion of water. An essential part of life cycle of agent takes place in aquatic animal. | Schistosomiasis, dracunculiasis |
| **Water related vectors**<br>Transmitted by insects living close to water | Yellow fever, dengue, encephalitides, filariasis, malaria, onchocerciasis, sleeping sickness |
| **Faecal disposal diseases**<br>Caused by infecting agents - by eating uncooked fish and other food | Clonorchiasis, diphyllobothriasis, fasciolopsiasis, paragonimiasis |

legal basis for prevention and control of water pollution, maintenance and restoration of wholesomeness of water sources in the country. To execute the aforesaid purposes the Act provides for the constitution of Central, State and joint Boards having prescribed powers and functions. The main function of the Central Board shall be to promote cleanliness of watercourses in different areas of the States. The Board has been conferred the power to perform several functions i. e. , advisory to the Central Govt; co-ordinating the activities of the State Boards; provide technical assistance and guidance to the state board, carry out and sponsor investigations and research relating to problems of water pollution and their abatement; plan and organize training of persons engaged or to be engaged in programmes for prevention and control; collect, compile and publish technical and statistical data related to the subject; to lay down, modify or annul the standards for a water course; plan and cause to be executed nationwide programmes and so on. The Board may establish or recognize laboratories to enable it to perform its functions including the analysis of samples of water, sewage or trade effluents. The State Boards, under the guidance of Central Board, are similarly responsible to plan and execute comprehensive programmes in their respective territories. They have also been conferred the powers of entry into any premises after giving due notice to the owner and collect samples of water, sewage and trade effluents for analysis and recommend necessary legal steps. The State Governments, under advice from the Board, are also authorised to take emergency measures when pollutants have entered or threatened to enter the watercourse due to accidental or unforeseen event or act of omission or commission. A joint Board is set up on subjects of common interest by mutual agreement either between adjacent states or between the states(s) and the Central Govt. when the latter has been appointed as the executing agency for the Union Territories.

## Water Purification

Comprehensive details of water treatment processes in settings of small scale communities, as well as large scale community supplies are laid down in standard publications (6 - 9). Reference No. 6 is generally accepted as a standard reference by various Public / civil engineering agencies in our country. Medical Officers dealing with water supply systems are advised to refer to these manuals.

**Water purification may be required to be carried out either on**

(a) Large scale

(b) Small scale

### Purification of water on a large scale

Aim

The aim of water purification is to diminish

(a) Organic and inorganic suspended matter

(b) Pathogenic organisms

(c) Deleterious salts and poisons in solution

The method of treatment to be employed depends upon

(a) The nature of raw water

(b) The desired standards of water quality

For example, ground water may need no treatment, other than disinfection. Surface water which tends to be turbid and polluted, requires extensive treatment. The components of a typical water purification system comprise one or all of the following measures :

(a) Storage

(b) Filtration

(c) Disinfection

Clarification followed by sterilization by various methods generally renders water safe for human consumption. Clarification removes suspended matter and sterilization kills pathogenic organisms. The elimination of deleterious salts is a difficult problem and no simple practicable method has yet been devised for employment in the field. Sterilization without clarification may be practiced if water is beyond any doubt free of pollution and is visibly clear, or under extreme urgency.

### Clarification

Even when water appears very clear, clarification should be insisted upon particularly for surface water. Minute particles of suspended organic matter which usually give lodgment to microbes particularly the viruses are not usually destroyed by the usual dosage of chlorine. Efficient clarification, therefore, eliminates besides the suspended matter, harmful organisms, cysts, ova, mollusc and Cyclops, and thus reduces the chlorine demand of water. The two methods available for clarification are sedimentation and filtration. Filtration is superior to sedimentation provided that the suspended matter is not too dense. Sedimentation requires more time (several hours) than filtration and the amount of water that can be dealt with is limited by the size of tanks available. Sedimentation less efficiently eliminates ova and cysts than filtration. However, efficient sedimentation prior to filtration definitely results in a better final clarity of water, and relieves the filters of the clogging debris.

### Sedimentation

It is carried out by allowing water to stand in concrete, masonry or canvas tanks over a variable period from 2 to 6 hours for settling the coarse suspended matter. This process can be hastened and improved in quality by coagulation and flocculation, which precipitates particulate and colloidal matter.

(a) Coagulation

The chemical coagulants employed are pure aluminium sulphate (alum) or more commonly alumino ferric, which is an impure form of alum containing about 1 percent of ferric sulphate. Both salts are readily soluble in water and being acid in reaction, tend to lower the pH of the water in which they are dissolved. When either is added to water with a pH of not less than 6, a precipitate of aluminium hydroxide is formed which engulfs and precipitates with it the minute particles of suspended matter. If the pH is less than 6, no precipitate forms and if it is above 8 the

precipitate becomes too gelatinous and sedimentation is delayed. The optimum reaction for rapid and efficient sedimentation is about pH 7 at which the addition of 35 g of alum or aluminoferric per 1000 l will rapidly clarify any but very turbid water. If water is exceptionally turbid, as much as 70 g per 1000 l may have to be used. To immediately disperse the entire dose of chemicals throughout the mass of raw water, it is necessary to agitate the water violently and to inject the chemical in the most turbulent zone. Generally large sludge volumes are produced with alum which requires frequent desludging operations at the treatment plants causing increased wastage of water. There is also the possibility of aluminium carry over in water treated with alum. High levels of aluminium in potable water are reported to cause Alzheimer's disease, a form of senility. However at present there is no clear evidence to suggest a link between aluminium and Alzheimer's disease (Cole, 1990). Poly aluminium chloride (PAC) has been developed as an alternative coagulant for alum by an Indian manufacturer.

PAC hydrolyzes with great ease as compared to alum, emitting polyhydroxides with long molecular chains and greater electrical charge in the solution, thus contributing to maximize the physical action of the flocculation. Better coagulation is obtained with PAC as compared to alum at medium and high turbidity waters. Floc formation with PAC is quite rapid. The sludge produced by PAC is more compact than that produced by alum.

(b) Flocculation

Flocculation is the process of gentle and continuous stirring of coagulated water for the purpose of forming flocs through the aggregation of the minute particles. After coagulation, the individual floc particles are easily observed by the naked eye, being of the order of 1-2 mm in diameter. In practice, the velocities in flocculation tanks vary from 1 m/s at the entrance, decreasing to about 0. 2 m/s near the outlet, with a retention time of 30 minutes. Flocculation is designed to accommodate the worst situation, which generally occurs in winter.

In actual practice this quantity of alum or aluminoferric brings the natural alkalinity of the vast majority of waters down to a pH of 7 and no other treatment is required. If sedimentation does not occur the water may be too acidic and the addition of half the quantity of lime as that of the coagulant is generally enough to correct the pH. For very turbid water sedimentation may be better carried out in two stages; initial settling of the bulk of the coarse debris followed by chemical flocculation. Leading the flow of water through long tortuous broad channels at slow velocity and storage in large reservoirs before its entry into the sedimentation tanks helps to achieve better sedimentation. This also exposes water to the natural purifying effects of the sun's rays and fresh air, and the biological effect of minute aquatic fauna and flora. These processes render the water highly suitable for filtration and bring down the bacterial content of water considerably.

### Filtration

It is almost universally adopted in a large scale purifying process of water in municipal, cantonment, garrison or base areas where permanent water works exist. Storage and sedimentation, with or without flocculation depending upon the quality of water, almost always precede the process of filtration. Filters are slow and rapid sand filters and mechanical filters. Mechanical filters are used in small, more sophisticated water plants and also in the water tank trucks and trailers.

### Slow Sand Filters

These are large masonry tanks 2. 5m -4 m deep containing sand supported on gravel and the water is passed through them slowly from above downwards. As the filter plants need extensive tracts of land these are usually situated on the outskirts of town located on the bank of a river. To avoid choking of the media preliminary sedimentation is necessary, chemicals may be used for hastening up clarification if the water is too turbid. The filter beds are usually rectangular in shape, arranged side by side in rows and may be either open on top or covered. Each bed usually covers an area from one tenth of an acre to one acre land.

The filter bed from below upwards consists of

(a) Under drainage system
(b) A bed of graded gravel
(c) Sand
(d) Supernatant raw water.

The **underdrainage system** which is about 16 cm in depth, consists of porous or perforated pipes which serves the dual purpose of providing an outlet for filtered water as well as supporting the filter media above.

A layer of **graded gravel** of about 30 cm thickness is placed over the perforated pipes.

Above the gravel is the **sand bed** having a thickness of about 1. 2 m.

The depth of **supernatant raw water** varies from 1-1. 5m. It provides a constant head of water to overcome the resistance of the filter bed.

Slow sand filter acts primarily biologically by forming a slimy 'zoogleal' layer also known as 'Vital Layer' containing algae, plankton and other minute plants and protozoa formed in two or three days time over the surface of the sand bed. Till the vital layer of the filter bed is fully formed, the filtrate is run to waste. To obviate cracks in the biological film, the rate of filtration should not exceed 100 $m^2$ of filter surface per hour. After several months of running of the filter, the bed resistance increases necessitating cleaning. This is done manually by scraping the vital layer. After several years of operation when the thickness of the sand bed reduces to about 0. 5 to 0. 8 m, the plant is to be closed down and a new bed is to be constructed.

#### Mechanism of Action of Slow Sand Filters

In a slow sand filter, due to the fine grain size, the pores of the filter-bed are small. The filter is capable of reducing the *Esch. coli* content and the total bacteria count. It will remove protozoa such as *E. histolytica* and helminths

such as *S. haematobium* and *A. lumbricoides.* Trouble free operation is only possible when the average turbidity of the raw water is less than 5 nephelometric turbidity units (NTU) with occasional peak values below 20 NTU permissible.

Removal of impurities is brought about by different processes such as

(a) Straining
(b) Sedimentation
(c) Adsorption
(d) Biochemical and microbial actions.

In straining, suspended particles that are too large to pass through the pores are retained at the surface or top layer of the filter.

In the upper part of the filter-bed, sedimentation of fine suspended solids also takes place. Settling efficiency is very high due to the large surface area (10, 000 to 20, 000 sq. m per cu. m of the filter sand) and slow rate of filtration.

Most of the remaining suspended solids with colloidal and dissolved impurities are removed by adsorption onto the sticky gelatinous coating formed around the sand grains or through physical mass attraction and electrostatic attraction. Clean quartz has a negative charge and so are the particles of bacteria and colloidal material. Initially positively charged ions are adsorbed over the sand grains and over saturation occurs after which negatively charged ions are adsorbed after ripening of filter bed. Then, there is a varied series of negative and positive charged grains that are able to adsorb most impurities from the passing water.

Organic matter is partly oxidized providing energy for bacteria and partly transformed into cell material used for their growth. Since the organic matter is limited, there will be a simultaneous die-off of bacteria releasing organic matter. Gradually, the organic matter is broken down and transformed to inorganic compounds like carbon dioxide, nitrates, sulphates and phosphates which are released with filter effluent. In practice, it is seen that full bacterial activity extends for a depth of about 0. 6 m of filter-bed. For intestinal bacteria, the filter-bed provides unfavourable conditions because the water is generally colder than their natural habitat, and usually does not contain sufficient organic matter of animal origin for their living requirements. The microorganisms in the filter also produce antibiotics and other agents that kill or at least inactivate intestinal bacteria.

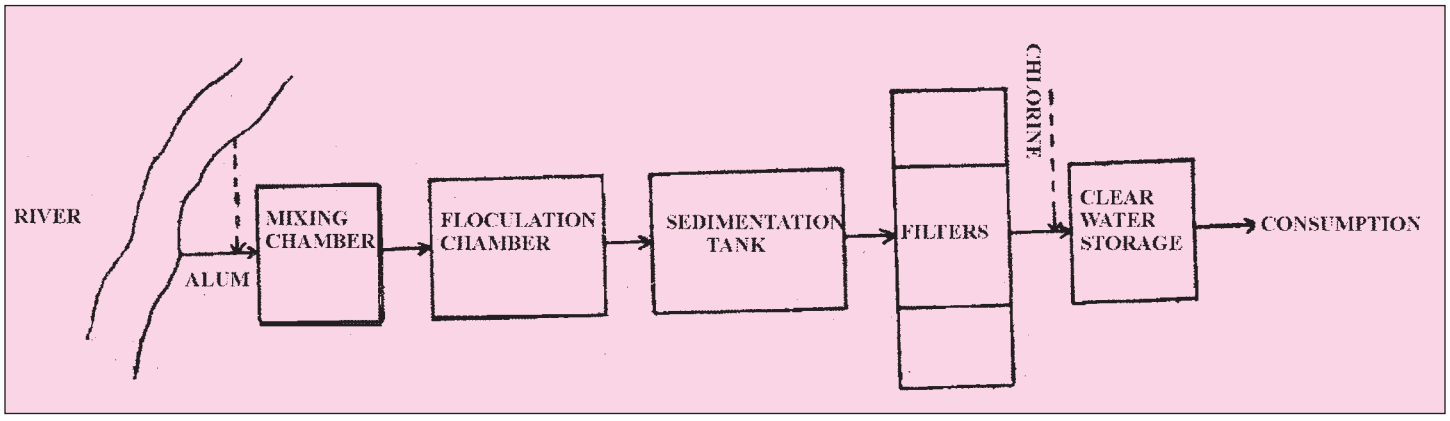
## Rapid Sand Filters

These are of two types 'gravity type' (Paterson's filter) and the 'pressure type' (Candy's filter). While the former is usually used in large installations, the latter is used in smaller installations such as swimming pools. The various steps in the working of a gravity type rapid sand filter are shown in figure - 3. The raw water is first treated with calculated dose of alum or aluminoferric and is then subjected to violent agitation in a mixing chamber for a few minutes. It is then allowed to move gently for half an hour in a flocculation chamber by mechanically operated paddles. A thick floc is formed which entangles suspended matter and bacteria. The coagulated water is then taken to sedimentation tanks where it is detained for 2-6 h when flock settles down. About 95 percent of flock is removed and then the partly clarified water is taken to the filter bed. The filter bed is a watertight rectangular chamber with a surface area of about 90 $m^2$. The depth of the sand bed is usually one meter having sand particles whose sizes are bigger than the ones used in slow sand filters. Below the sand bed is a layer of graded gravel of about 40 cm thickness. The under drainage is below the graded gravel layer. The supernatant water height is about 1 to 1. 5m. The alum floc makes a tough slimy layer (chemical) over the sand bed, which acts mechanically. In this system there is no time wasted for ripening of the bed. When the bed gets clogged after use for a day or so, it is cleaned by back washing by reversing the flow of filtered water. Backwashing is usually preceded by loosening of the sand bed by passing compressed air through it. After backwashing, the filter bed is put to use immediately and not after 24 hours or so as is required for the formation of biological film in a slow sand filter. The rate of filtration in a rapid sand filter is about 100 times faster than of slow sand filter

## Mechanical Filter

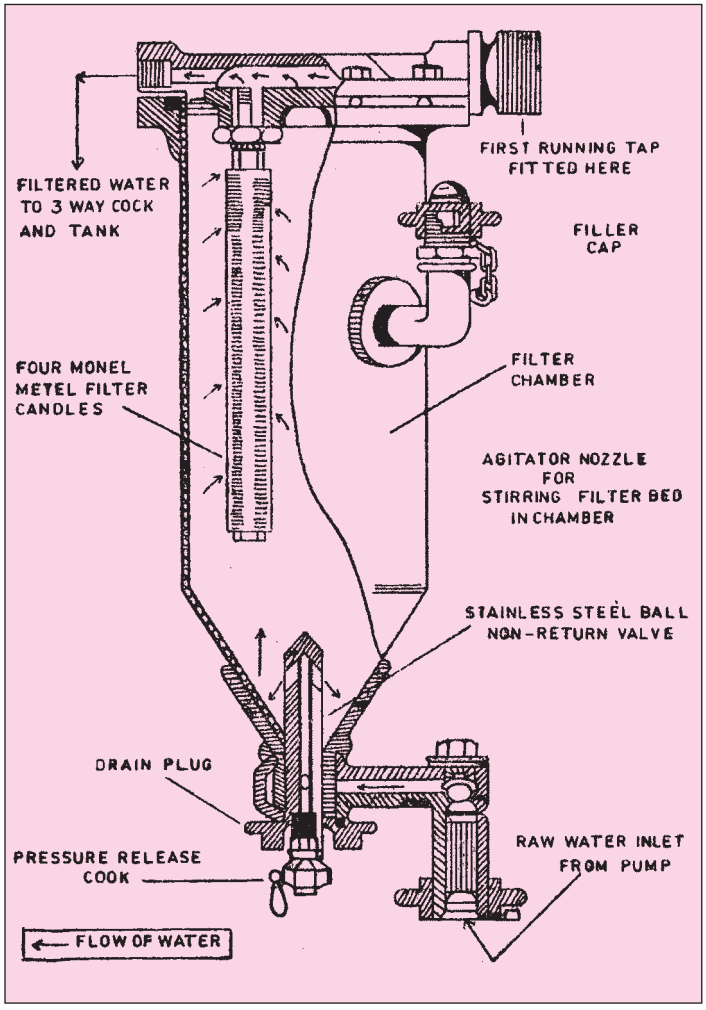
It consists of a cylindrical metal chamber surmounted by a filterhead. Into the undersurface of the filterhead are

Fig - 3 : Flow diagram of a rapid sand filtration plant



screwed four to six filter elements (candles). There are two types of filter candles used in the Armed Forces-meta filter and the stellar filter. The meta filter consists of thin monel metal discs with embossed faces. When these discs are superimposed on each other and held in position by clamping rods they form a column of a candle. Each disc has a central hole. As the discs lie on one another, a central channel through the column is formed. The embossed faces leave a space of 8 m in between each pair of discs. The stellar filter candle, on the other hand, consists of brass former with a central channel and a spiral thread on its outer surface round which a monel metal wire is wound so as to allow a space of 8 m between the adjacent coils of wire. Water from outer side of the meta or stellar filter candles can only pass through the interstices. To increase the filtering efficiency and to reduce chocking of interstices, filter powder is introduced to form a filter bed around the filter candles in the chamber. The powder is mixed in water and then poured onside the filter

Fig - 4 : Mechanical filter (Stellar filter)



chamber. Water is then pumped by using engine power of the water tank truck or trailer into which are mounted these filters. Under field conditions when regular water points cannot be established, these filters could be used as mobile water plants (10). (Fig. - 4)

## Hardness of water

Hardness of water may be defined as its soap destroying power. It is due to presence of bicarbonates, sulphates, chlorides or nitrates of calcium and magnesium in water. Hardness is undesirable because it wastes soap as stated already, retards washing, causes encrustation of the water carrying system and heating utensils resulting in wastage of fuel and even explosion of boilers, although rarely**(6 - 10).** . Vegetables cooked in very hard water may be less digestible. It reduces the life of fabrics also. Hardness is expressed in terms of milliequivalents per litre (m Eq/L) One m Eq/L of hardness producing ion is equal to 50 mg ($CaCO_3H$) (50 ppm) in one litre of water. Based on this scale the degree of hardness of water is classified as soft water (less than I m Eq/L), moderately hard (1-3 m Eq/L), hard water (3-6 m Eq/L) and very hard water (above 6 m Eq/L). Softening of water is recommended when hardness exceeds 3 m Eq/L. Drinking water should be moderately hard. It has been observed that in some localities supplied with soft drinking water death rates due to arteriosclerotic heart diseases and IHD were higher.

### Carbonate Hardness (Temporary)

It is due to the presence of bicarbonates of calcium and magnesium which can be removed by boiling that drives out carbon dioxide and precipitates carbonates, or by the addition of 60 g of quick-lime to 1000 L of water for each degree of hardness (Clark's process). If hardness is due to magnesium bicarbonate, double this dose is required, thorough mixing and filtration are necessary, as complete sedimentation may not occur even after 12 hours.

### Non-Carbonate Hardness (Permanent)

This is due to sulphates, chlorides and nitrates of calcium and magnesium, which is removed by the addition of a calculated amount of sodium carbonate (Soda ash). In the case of water, which contains temporary hardness as well, use of lime and sodium carbonate will remove both. This is followed by sedimentation and filtration. Base exchange silicious zeolites are used for removing permanent hardness in large establishments. Zeolite is a mineral having a complex formula of Sodium Aluminium Silicate. It exchanges the sodium cation for calcium and magnesium ions of the water. When hard water is passed through Zeolite, calcium and magnesium ions are entirely removed by the sodium ions of the Zeolite. As the filtered water has zero hardness it is mixed in appropriate proportion with hard water before its supply. Regeneration of sodium Zeolite takes place when the so formed Ca and Mg Zeolite is washed with sodium chloride.

### Sodium Chloride

Many waters in the desert and elsewhere contain excessive salt making it undrinkable. Below 1000 ppm of salt, the taste is not appreciable. Sodium chloride can be eliminated from water by condensation or by the ion exchange demineralization process. The condensed water should then be blended with the brackish water in

such proportion that the salt content of the mixture falls below 1000 ppm.

#### Bitter Aperient

Water having them can be treated by the gradual addition of lime at the scale of 2 to 3 kg per 1000 L of water and stirring vigorously. From time to time a small quantity is filtered in a cup and few drops of silver nitrate solution are added to the filtrate. If a brown colour appears the process is stopped. 50 L of raw water is added to precipitate excess lime. After complete settling of lime, water becomes free from aperient action.

#### Other elements

Iron

A trace of iron is almost always present in water. Iron upto 0. 3 mg/L is acceptable. Above that it causes constipation, colic and results in the colouration of vegetables while cooking and staining of linen. It also causes deposits in the distribution mains and reservoirs and leads to the growth of iron bacteria. Iron in water is commonly found as bicarbonates and rarely as oxides and sulphates. Exposure to air causes oxidation of ferrous salt, which makes the water opalescent, discoloured and produces a deposit. The usual clarifying processes and Clark's lime process of softening water remove iron to a certain extent. A special manganese Zeolite removes iron more efficiently.

Fluoride

Its removal is necessary when the concentration in drinking water is more than 1. 5 ppm. The optimum concentration in countries like India where people consume a lot of water should be between 0. 5 to 0. 8 ppm. Fluoride concentration over 1. 5 ppm causes dental fluorosis. A still higher concentration causes skeletal fluorosis. Some Armed Forces Establishments in the States of Rajasthan and Punjab are presently facing this problem of water supply. The excess quantity of fluoride in water may be removed by 'Nalgonda technique'. On the other hand if fluoride content of water is less than 0. 5 ppm fluoridation is necessary for prevention of dental caries.

## Disinfection

Disinfection of water means making it fit for drinking by destroying all pathogenic organisms that may be present in it. To be used in water treatment, an ideal disinfectant must possess the following properties :

(a) It must destroy bacteria, viruses and amoebic cysts in water within a reasonable time despite all variations in water temperature, composition and concentration of contaminants.

(b) It must not be toxic to humans and domestic animals, unpalatable or otherwise objectionable.

(c) It must be reasonable in cost and safe and easy to store, transport, handle and apply.

(d) Its residual concentration in the treated water must be easily, and preferably automatically determinable.

(e) It must be sufficiently persistent so that the disappearance of the residual would be a warning of recontamination.

Boiling is of course the best method of destroying all organisms, but it is impracticable to boil water for urban populations or communities like the Armed Forces in the Field. Moreover, the objective aimed at is not the total sterility of water in a strictly scientific sense but to ensure safe water for human consumption and domestic use by eliminating pathogenic organisms, ova and cysts.

## Chlorination

Chlorine has been found to be very efficient to achieve this objective. Disinfection of water is therefore, usually carried out by the use of chlorine. When chlorine is added to water it forms hydrochloric acid and hypochlorous acid ($Cl_2 + H_2O = HCl + HOCl$). The hypochlorous acid further ionizes to $H^+$ and $OCl^-$ (hypochlorite ion). The disinfection action of chlorine is mainly by hypochlorous acid and partly by hypochlorite ion. Chlorine acts best when pH of water is around 7 because of predominance of hypochlorous acid. When pH exceeds 8. 5 hypochlorite ion mostly acts. Fortunately most waters in India have a pH between 6 to 7. 5. However sporing organisms, protozoal cysts, helminth ova, molluscs, cyclops and cercariae are not affected by the usual dosage. Organic matter or reducing salts deviate chlorine which results in uncertainty of its action. Therefore, for efficient action of chlorine, freedom from such organic matter, resistant organisms and reducing salts is essential. Efficient clarification is, therefore, necessary to render the final results predictable and certain, to economize chlorine expenditure and to estimate the quantity of chlorine needed for water disinfection.

#### Chlorine Demand

0. 5 parts of chlorine per million in well clarified water, free from reducing organic matter is normally adequate to render it safe for drinking after 30 minutes. Thereafter persistence of free chlorine in water is essential as a safeguard against any incidental entry of pathogenic bacteria prior to its actual consumption. Therefore, for effective treatment a concentration of above one part of chlorine in a million parts of water which is procured from a safe source and has been well clarified, is necessary so as to leave adequate residual chlorine after destroying all the pathogenic bacterial fauna. However, the sporing organisms like the welchii group, the protozoal cysts like those of *E. histolytica*, helminth ova, moluscs, cercariae and viruses of infectious hepatitis and poliomyelitis in water require a higher concentration of chlorine maintained over a long time. Water must, of course, be very efficiently clarified to achieve attenuation of these organisms even with such a high dosage.

When estimating the chlorine requirement of water, therefore, the chlorine absorption by oxidizable organic matter and the free chlorine desired after 30 minutes have to be taken into consideration. While the amount of chlorine absorbed by the oxidisable matter is called chlorine demand of the water, the sum of chlorine demand and the amount of free chlorine desired after a

specified time of contact, viz 30 min is the total chlorine requirement of the particular sample of water. The chlorine demand, is therefore calculated by subtracting the amount of free chlorine present from the actual amount of chlorine added to the water. The point at which chlorine demand of water is met is called 'breakpoint chlorination'. If chlorine is added further, it only increases free chlorine.

### Chlorinous Taste

A high chlorine dose creates unpleasant chlorinous taste in water. Initial high organic contamination, imperfect clarification or presence of reducing salts necessitates increase in the 'disinfection dose'. An uncertain dose of chlorine application resulting from a doubtful clarity of the water or the uncertain chlorine content of the unstable bleaching powder used may also result in excessive chlorine application. Free chlorine in the strength of 0. 5 ppm in water is imperceptible; over 0. 5 ppm the chlorine taste becomes faintly noticeable; whilst above 1 ppm a definite chlorine odour and taste are apparent. Chlorinous taste can be prevented by :

(a) Careful selection of a good source of water, which should remain qualitatively constant

(b) Efficient clarification

(c) Administration of a minimum 'disinfecting dose' adequate to permit the desired free chlorine persistence.

### Dosage of Chlorine

Under conditions assuring efficient clarity of water a minimum 30 min of contact with the 'disinfecting dose' and persistence of 0. 2 to 0. 5 parts of free chlorine per million parts of water is considered adequate to achieve health safety with freedom from chlorinous taste. On active service in the field or under less efficient conditions, however, persistence of 1 ppm of free chlorine after 30 min of chlorination is considered as a safe standard. Under worse conditions or in the presence of actual or potential danger of outbreak of intestinal infections 2 ppm persistent chlorine i. e. superchlorination is considered necessary. The period of contact with the disinfecting dose may be reduced to 15 min instead of 30 min when superchlorination is resorted to, and dechlorination should be carried out before consumption of water.

## Methods of Chlorine Application

Disinfection of large quantities of water with chlorine may be achieved by one of the following chlorine preparations :

### Chlorine Gas

In the modern water works application of gaseous or liquid chlorine with the help of mechanical injector called 'Chloronomes' is the method of choice. In this process the charging of the water supply with chlorine, ascertaining persistence of free chlorine content are all carried out automatically. The standard of chlorination to be aimed at when chlorinating through chloronomes with an efficient quality control of water is carried out is the persistence of 0. 2 ppm free chlorine at the consumers' end. This can be achieved by ensuring 0. 5 ppm of free chlorine at the plant provided that the delivery of water is not delayed for more than 6 hours. If quantity of water to be treated is more than 500, 000 litres per day, chlorine gas has been found to be the most economical.

### Chloramination

Chloramines are loose compounds of chlorine with ammonia. They impart less chlorinous taste in water and give a more persistent type of residual chlorine. This prolonged residuum confers the power of long resistance to contamination during the flow of water through the pipe system and hence may be advantageously used in large urban water plants where the pipeline runs for several million meters. Their drawback is that they have slower and inferior action than chlorine.

### Bleaching Powder

Since neither of the above mentioned highly efficient but sophisticated methods can be adopted in less developed urban areas or rural areas or under field service conditions, use of bleaching powder for sterilization of water is resorted to in these situations. Bleaching powder also known as chlorinated lime ($CaOCl_2$) was first introduced for sterilization of water by Horrocks in 1914. It is a white amorphous powder with pungent smell of chlorine. When freshly made it contains about 33 percent of available chlorine. It is, however, very unstable and its chlorine is readily set free by the action of moisture, $CO_2$, heat, light, and possibly even by continued vibration sustained during long journeys. As a result it has been frequently delivered in the field with very scanty chlorine content. Estimations to determine the amount of available chlorine in each tin of bleaching powder has to be made before dosing the water involving considerable labour and much error. Bleaching powder is also difficult to introduce in accurate doses into large quantities of water, leading to further error in the dosage and finally to taste trouble. Bleaching powder is stored in corrosion free containers made of wood, ceramic or plastics.

### Water Sterilising Powder (WSP)

Bleaching powder is considerably improved in its keeping quality by the addition to quicklime in the proportion of 80:20 when it is known as water sterilising powder. Its available chlorine should not be less than 25 percent. WSP is usually used for disinfection of water under field service conditions. It is an ASC Store item supplied by the Supply depot (POL Sec) along with Hygiene chemicals in packs of 50 g, 100g, ¼ kg, ½ kg, 1 kg and 25 kg. WSP is soluble in about twenty times its weight of water, yielding an insoluble precipitate consisting mostly of Calcium Hydroxide $Ca(OH)_2$, silica etc. This settles quickly, if too thick a paste is not made; otherwise a gelatinizing action takes place and great difficulty in settling is encountered. It is not necessary or desirable to grind or break up the lumps thoroughly and too much agitation is detrimental to prompt settling. 500 g of WSP mixed with 5:1 water contains approximately 2. 5 percent available chlorine if the powder is of 25 percent strength. Chlorine solution can maintain its strength for weeks if properly corked in

brown bottles.

## Agents Other than Chlorine

### Ozone

It is a powerful oxidizing agent. It removes undesirable odour, taste, colour and organic matter. It even inactivates viruses in a few seconds and hence can be used most advantageously for destruction of enteropathogenic viruses. Since ozone decomposes and disappears within short time there is no residual germicidal effect. Hence, a minimal dose of chlorine may be added to the ozonised water before distribution. In this combined treatment, the two methods complement each other. The ozone dosage required for potable water treatment varies from 0. 2 to 1. 5 mg per litre. Ozonisation of water is presently practiced in the advanced countries. The combination of ozone for pretreatment while providing some disinfection, to be followed by chlorination, has become a popular sequence in Europe and is beginning to be used in USA to reduce the level of trihalomethanes in finished water.

### Ultraviolet Irradiation

Germicidal effect of this method is limited due to its expense, non-residual germicidal effect and its somewhat lesser effect in presence of turbidity. A mercury vapour arc lamp emitting invisible light of 25-37 Angstrom units applied to a water free of light absorbing substances, particularly suspended matter that will protect microorganisms against the light, is a useful method of disinfection used in the Soviet Union.

### Other Halogens

In view of the formation of organochlorine compounds by chlorine which are either known or suspected carcinogens, many chlorine alternatives such as bromine and iodine substances are receiving renewed interest. These substances for the present, however, do not seem to be a viable alternative to chlorine.

## Chlorination on Field Service

Practice of sterilizing water adopted on field service and in some semi-permanent or even a few permanent camps where chloronomes are not available, is by use of WSP, added manually or by dosers. The standard procedures in the field are 'chlorination' and 'superchlorination,

The 'chlorination' aims at obtaining 1 part of free chlorine in a million parts of water after half an hour's contact. The quantity of water sterilizing powder required is estimated by Horrocks' test. The number of scoopfuls (of two grammes) of water sterilizing powder required to chlorinate the given quantity of water are calculated and added to water. The water must be allowed to stand at least 30 min after addition of the requisite amount of WSP before it is taken into use.

Superchlorination' of water aims at obtaining the free residual chlorine of 2 parts per million parts of water. This is achieved by adding one scoopful of water sterilising powder per 500 l of water more than that required for 'chlorination'. A contact of 15 min instead of 30 min is allowed. This method of treatment is adopted when efficient clarification is not possible; safety of source and initial purity of water is doubtful; outbreak of any water-borne disease is threatened; or water is required for use in a very short time.

Superchlorination by a 'fixed dose' of 4 scoopfuls of WSP per 500L of water is carried out when the clarity of water is doubtful and the Horrocks box is not available 30 min contact is allowed before consumption.

In all these processes the required amount of water sterilising powder is first mixed in a little water and made into a strong solution in a bucket and then this solution is evenly added to the whole bulk of the water to be treated and mixed thoroughly. The cadmium iodine starch colour test is then carried out at the end of 30 min for chlorination and 15 min for superchlorination. If a blue colour is not obtained, one scoopful of WSP per 500 L for chlorination and two more scoopfuls per 500 L for superchlorination must be further added to the water. After mixing and allowing a 30 min or 15 min lapse as the case may be, the colour test is repeated. Except in water containing schistosome or cercariae, these doses should not be exceeded.

### Dechlorination

It may become necessary to remove the chlorinous taste after superchlorination. This is done by adding 2 tablets of 0. 5 g each of sodium thiosulphate (taste removing tablets or TRT) per 500 L of water. A contact with chlorine for a minimum of 15 min should be allowed before dechlorinating, but preferably contact time should be prolonged as long as possible until just before the consumption of water. The danger of a premature use of the taste removing tablet and its use in un-superchlorinated water must be appreciated and guarded against.

Sometimes rain water or water recently polluted with organic matter contains ammonia, which forms chloramines on the addition of water sterilizing powder. Chloramines are not deviated by organic matter as chlorine is and hence give the blue colour even in the presence of oxidisable organic matter when a cadmium iodide starch indicator solution is added. Moreover, there will be a lag in disinfection owing to the slower bactericidal action of chloramine. Therefore, while superchlorinating water of this nature it is better to extend the contact time to a minimum of 30 min or even more.

### Prechlorination and Rechlorination

Sometimes prechlorination has to be employed before filtration of water by a water tank truck in order to decrease the organic matter load on the filters and to reduce its subsequent chlorine demand, specially in a newly occupied area in field service. At times the chlorinated water obtained from local civil sources needs to be rechlorinated before consumption by troops if there is a longer lapse of time between chlorination and consumption.

### Horrock's Test

The object of this test is to determine the quantity of the

particular sample of WSP required to sterilize any particular sample of water. The test is carried out by means of the 'case water testing sterilization' (HORROCK'S BOX). The Horrock's box contains six white cups of 200 ml capacity each and one black cup of 240 ml capacity; two metal scoops, each of which holds 2 g of WSP when filled level with the brim; a bottle of stock cadmium iodide-starch solution; a bottle containing 85 ml of 50 percent glacial acetic acid; 25 sodium thiosulphate tablets 100 mg each; six glass tubes; and four glass stirring rods. The test should be carried out while the water receptacle is being filled with clarified water(10).

A standard solution of the particular sample of WSP is prepared in the black cup. First a thin paste with one level scoopful of the WSP and a little clarified water is made and then gradually more water is added up to the mark on the inside of the cup and the mixture is stirred with a clean glass rod. The lime in suspension gradually settles down.

The six white cups are then filled with clarified water to within half a centimetre from its top.

Drops of the standard WSP solution from the black cup are added to each of the white cups by the pipette, so that the first cup receives one drop; the second cup receives two drops and so on serially increasing until finally the sixth cup receives six drops. One drop represents one part of chlorine in a million parts of water when added to the white cupful of water. The pipette must be held vertical when delivering the drops.

The contents of each cup are stirred with a clean stirring rod, starting at the first cup, and allowed to stand for half an hour, shading them from sunlight.

After that time three drops of the starch-cadmium iodide indicator solution are added to each cup from the drop bottle and stirred with a clean stirring rod.

Some of the cups will show a blue colour. This indicates that the water in those cups contains one or more parts of chlorine per million parts of water.

The serial number of the first of the cups showing definite blue colour indicates the number of scoopfuls of the particular sample of water sterilizing powder required to sterilize 500 L of water and to leave 1 PPM of chlorine after chlorine demand of that sample of water is satisfied during half an hour contact with chlorine.

For example, if cups 3, 4, 5 and 6 show a definite blue colour, then three scoopfuls of WSP are required to sterilize 500 L of the particular water sample and leave I ppm residual free chlorine after half an hour contact. If superchlorination is indicated one more scoopful of WSP per 500 L of water is required to be added. This will give 2 ppm of free chlorine in water after 15 min contact. In the example given above a total of 4 scoopfuls of WSP per 500 L will be needed for superchlorination. The WSP used for chlorination or superchlorination should be from the same tin from which the WSP for Horrock's test was used.

An indicator solution is made by first preparing a uniform paste of 1. 5 g of starch in 25 ml of distilled water and then adding it slowly to 75 ml of boiling distilled water and continually stirring it while, still boiling for the subsequent 15 min. After cooling, 7. 5 g cadmium iodide is added to the mixture and dissolved by shaking. In an emergency potassium iodide may be used if cadmium iodide is not available. The solution should be stored in a well-corked dark brown bottle in a dark and cool place. The keeping quality of the solution is enhanced by the addition of 1 ml formalin to this solution.

### Test for Chlorination Control

A control must be kept on chlorination by a regular examination of the treated water to make sure that the requisite amount of free chlorine has persisted in the water for the requisite time. This can be done by means of starch-iodide, thiosulphate with starch-iodide, orthotoluidine, orthotoluidine arsenite or neutral red.

#### Colour Test

Fill a white cup with chlorinated water to be tested and stir into it 10 drops of fresh cadmium-iodide-starch indicator solution. If there is one or more parts of free chlorine in million parts of water a blue colour will appear. In this test the residual chlorine replaces iodine and combines with cadmium radicle; iodine so released combines with starch and turns it blue.

#### Thiosulphate Test

Make a solution of 300 mg of sodium thiosulphate (100 mg-3 tablets) in a white cup full of clarified but unchlorinated water. Add this solution drop by drop with a glass pipette to the cup in previous para and continually stir until the blue colour just disappears. The number of drops of thiosulphate solution required divided by 10 approximately gives the parts of free chlorine in a million parts of the chlorinated water.

#### Orthotoluidine (OT) Test

This test carried out with the 'Comparator type of apparatus' (Lovibond Comparator) indicates chlorine below 1 ppm. It is used in peace stations, cantonment and garrison water supplies. A fixed amount of orthotoluidine solution is added to a specific quantity of the water in a standard glass cell or tube. The yellow colour, which develops, is matched against tinted glass discs. The immediate (flash) reading shows the free chlorine and that taken after 5 min (delayed) gives the combined content of chloramines and free chlorine. In the absence of the Comparator, the appearance of yellow colour on the addition of orthotolidine to a white cupful of treated water shows the presence of free chlorine without any indication of the proportion thereof.

#### Orthotoluidine Arsenite Test (OTA)

It is a modification of OT test. Certain interfering substances such as nitrates, iron, managanese etc which when present in water also gives yellow colour with orthotoluidine. The OTA reagent overcomes this drawback and hence gives better determination of free and combined chlorine separately.

#### Neutral Red Test

This reagent can be used as a tablet or as a 0. 03 percent solution in 50 percent glacial acetic acid. This has a purple

red colour. This colour is bleached to a light yellow tinge by a chlorine concentration of two parts per million parts of water. The method therefore only indicates superchlorination. Superchlorination by the 'fixed dose' method without Horrock's test is resorted to when this reagent is employed. It does not indicate the extent of chlorine demand of a sample of water or available chlorine in WSP, as is done by the Horrock's test. The actual method is as follows :

(a) Add 4 scoops of WSP per 500 L of water, stir well and wait for 15 min.

(b) Fill the white cup with chlorinated water and crush one neutral red tablet or add one scoop of solution to it.

(c) If the water becomes colourless or yellowish after one minute it is safe for drinking. If it is still red, add 2 more scoops of WSP per 500 L and repeat the test after 15 min and repeat the process until the test shows bleaching of neutral red.

(d) Add 4 taste removing tablets for every 500 L of water before consuming.

#### Chlorine Content in WSP

The chlorine content of a WSP sample is determined by either the Penot's arsenite test or by the thiosulphate test. A mixture of 10 ml of 1 percent WSP solution and 10 drops of fresh cadmium-iodide-starch indicator solution is taken in a beaker. The neutralizing reagent is then slowly run into it from a burette. The neutralizing reagent in Penot's test is a 0. 5 percent sodium arsenite solution which is prepared by dissolving 0. 5 g of arsenious oxide ($As_20_3$) and 2. 5 g of sodium carbonate ($Na_2CO_3$) in 100 ml of distilled water. In the thiosulphate test it is a 2. 48 percent sodium thiosulphate solution. The ml of neutralizing reagent required to decolourise the blue WSP indicator solution mixture multiplied by 3. 55 indicates the percentage of chlorine in the WSP sample under test. These tests require well-equipped laboratories and therefore cannot be carried out in field service.

A rough and ready field test can be carried out by the use of the Horrock's Box. A WSP solution is made by mixing one level scoopful of the WSP powder to be tested in the black cupful of clarified water. One scoopful of this solution is mixed with a scoopful of cadmium-iodide indicator solution in a white cup and a tablet of acid sodium bisulphate is added to it. The 0. 05 percent neutralising reagent is prepared by dissolving a 100 mg tablet of sodium thiosulphate in a white cupful of water. Scoopfuls of this solution are added to the blue mixture of indicator-WSP solution and stirred. The number of scoopful of the thiosulphate solution added until the blue colour first disappears indicates the percentage of chlorine in the WSP under test.

### Water Supply in the Armed Forces

The water supply for the Armed Forces is organized at various levels of echelons according to facilities available, with various grades of refinements in clarification and chlorination depending on the situation and availability of resources. All efforts should be made to avoid deficiencies in supply, such as the following:

(a) Pollution of the source

(b) Inadequate treatment

(c) Cross connections with sources of contamination

(d) Inadequate capacity resulting in low pressure

(e) Inadequate operation of the facilities

(i) inadequate disinfection

(ii) failure to provide standby facilities in the event of power or other equipment failure.

After floods, when water supply distribution system remains intact, the pressure in the pipelines should be raised so as to prevent polluted water from entering the pipes. Superchlorination is also an additional measure. Pipelines are routed alongside roads or public ways to facilitate inspection (for detecting leakage, unoperative valves, damage etc.) and to provide ready access for maintenance and repair. The most common pipe materials are cast iron (CI), ductile iron, steel, asbestos cement (AC), polyvinyl chloride (PVC), and high-density polyethylene (PE). General guidelines on sanitary control on water supply, its supervision and water quality surveillance are being given in subsequent paragraphs. Medical Officers are also advised to refer to standard manuals for detailed references (6, 11, 12).

#### Cantonment Water Supply

In Military cantonment and permanent garrisons well established permanent water works function under the management of the State or Central PWD. In some permanent garrisons where Cantonment Boards do not exist, similar water plants are established under the jurisdiction of the MES. Usually the sources of water supply are streams or deep wells. Clarification of water is carried out by sedimentation, first without and later with flocculation, followed by filtration. Large reservoirs for holding raw water, masonry or concrete settling tanks, slow or rapid sand filters and high level reservoirs for holding finally treated and chlorinated water ready for delivery are created. Chlorination or Chloramination is carried out with gaseous or liquid chlorine by chloronomes. Delivery of treated water from the overhead or high level reservoirs is through pipes. Quality control is maintained by regular chemical and bacteriological examinations and automatic orthotouidine testing and recording. The delivery of water to Armed Forces units may occasionally be through the unit or centralized station transport.

#### Garrison Water Plants

In semipermanent camps at the Corps HQ or Com Zone bases in field areas, the MES establishes central water points. Generally sedimentation with flocculation is carried out in masonry tanks. Chlorination by gaseous or liquid chlorine is usually the method of choice but sometimes it is carried out by either bleaching doses or manual application of WSP depending on the nature and duration of stay of the garrison. The sources of water have to be much more carefully selected as filtration is not

usually possible. Quality control is ensured by initial chemical and bacteriological examination repeated whenever the quality of raw water is likely to change. The Horrock's test is regularly carried out to assess the WSP requirements. Orthotolidine testing of water and recording is carried out every time the fresh quantity of water is chlorinated. Delivery of water may be through pipes, but quite commonly it is through unit or station transport.

#### Central Field Water Points.

In forward areas the MES or Corps of Engineers establishes various grades of 'central water points' at the Divisional and Brigade levels. The sources are most meticulously selected from the hygienic point of view and for the initial clarity of water. Purity of water and protection is ensured by fencing, policing and imposing strict prohibitory orders against the entry of unauthorised persons. The sources are the streams, deep wells or natural springs. For clarification and chlorination, masonry tanks can be constructed at the Divisional levels but usually the canvas tanks are used. Filtration is normally not feasible and only the sedimentation with flocculation is relied upon. If for any reason e.g. in mobile warfare it becomes impossible to establish a static water point, only the filtration without sedimentation may be carried out centrally, provided that the water tank trucks fitted with large size stellar or metafilters are available. Chlorination is carried manually with WSP after determining the quantity required. The Horrock's test is mostly carried out daily. Quality control is maintained by a colour test but the cadmium iodide-starch solution or the orthotolidine test is carried out every time the delivery tank is filled and chlorinated, but not earlier than half an hour after chlorination. Water is collected by units in water tanks or lorries with metal or improvised canvas tanks hoisted on them. Chlorination may be carried out at the units instead of at the central water point. If the quality of raw water shows wide fluctuations, superchlorination is preferable with dechlorination carried out just before consumption but not earlier than 30 minutes after adding WSP.

#### Unit Water Points

When central (Divisional or Brigade) water points are not feasible or when units are located at a long distance from such water points, water is collected, clarified and chlorinated under unit arrangements. Normally springs, wells or streams are used as sources. The selection of a source and collecting point has to be on much more rigid standards. The MO is required to exercise utmost caution in accepting the particular source. Checks on alternative sources should also be carried out. If water tanks with a meta or stellar filter are available they are used to collect and filter water. Otherwise, water is clarified in canvas tanks or CGI drums by flocculation. Chlorination is carried out by WSP after daily assessment of the required WSP dose. Quality control requires strict supervision and is carried out by a colour test or orthotolidine test.

#### Sub-Unit Arrangements

When such unit water points are too remote e.g. detachment and piquets, water is collected from clear reliable sources such as springs or wells in small containers like pakhals, drums or canvas tanks and manually superchlorinated after the Horrock's test, or by 'fixed dose method' if a Horrocks' box is not available, and is tested by the colour test. Dechlorination may be carried out just before consumption. Training needs to be given to personnel in its adoption.

#### Individual Water Sterilization

When troops have to rely solely on individual resources on piquets, patrols, reconnaissance or trekking , water from as clean a source and spot as possible is taken in water bottles, chaggals or buckets and super chlorinated with WSP by the fixed dose method or by the use of an individual water sterilizing outfit.

#### Arrangements While on the March

On a long march when a long halt is contemplated, a staff officer accompanied by an engineer officer and water duty personnel, medical officer and sufficient regimental police personnel should be sent forward to select halting grounds near a good source of water. They should arrange for the purification and chlorination of the water supply and take measures for its protection until the main body arrives. Thereafter systematic distribution to units/sub-units should be arranged. In movements by rail, troops must not use water supply without authority from a Railway Transport Officer.

### The Field Water Point

On active service in the field, water points are organized under the administration of the Corps of Engineers. The medical services in the field collaborate with the field engineers in the selection of a proper water source and water collecting point. The responsibility of ensuring the initial quality of raw water, recommendation on processes to be adopted for clarification and the dose of chlorination required is that of the Medical Services while the achievement of the Medical recommendations and quantity to be provided rests with the engineers. Medical services are also responsible to check the quality of water and standard of chlorination from time to time and advise on measures to be adopted for achievements and maintenance of the quality of water. The field water points is organized as under: -

(a) The sources of supply are usually a stream or well. The banks of streams or lakes should be suitably earmarked for drawing water for various purposes and indicated by different flags e.g. white for drinking-water, blue for watering animals and red for bathing or washing of clothes and animals in that order from upstream downwards (Fig.5).

(b) If water is obtained from springs, they should be bricked in and trapped. If a well is used as a source of water it should be properly constructed and maintained.

(c) Methods of water treatment adopted at the field water point are the sedimentation followed by chlorination or super-chlorination. The processes are generally carried out in 6000 L canvas tanks.

(d) The tanks should be raised on a properly laid gravel, clinker or stone base, which is properly drained.

(e) The raw water is either pumped or led by gravity into one or more canvas cisterns for sedimentation.

(f) Entry and exit roads, adequate drainage, fencing to protect the tank area, and military police or guards should be provided. Protection and policing of the whole water supply area from the moment the campsite is selected is absolutely essential.

(g) The treated water is delivered into unit water tanks or receptacles by hand or mechanical pump.

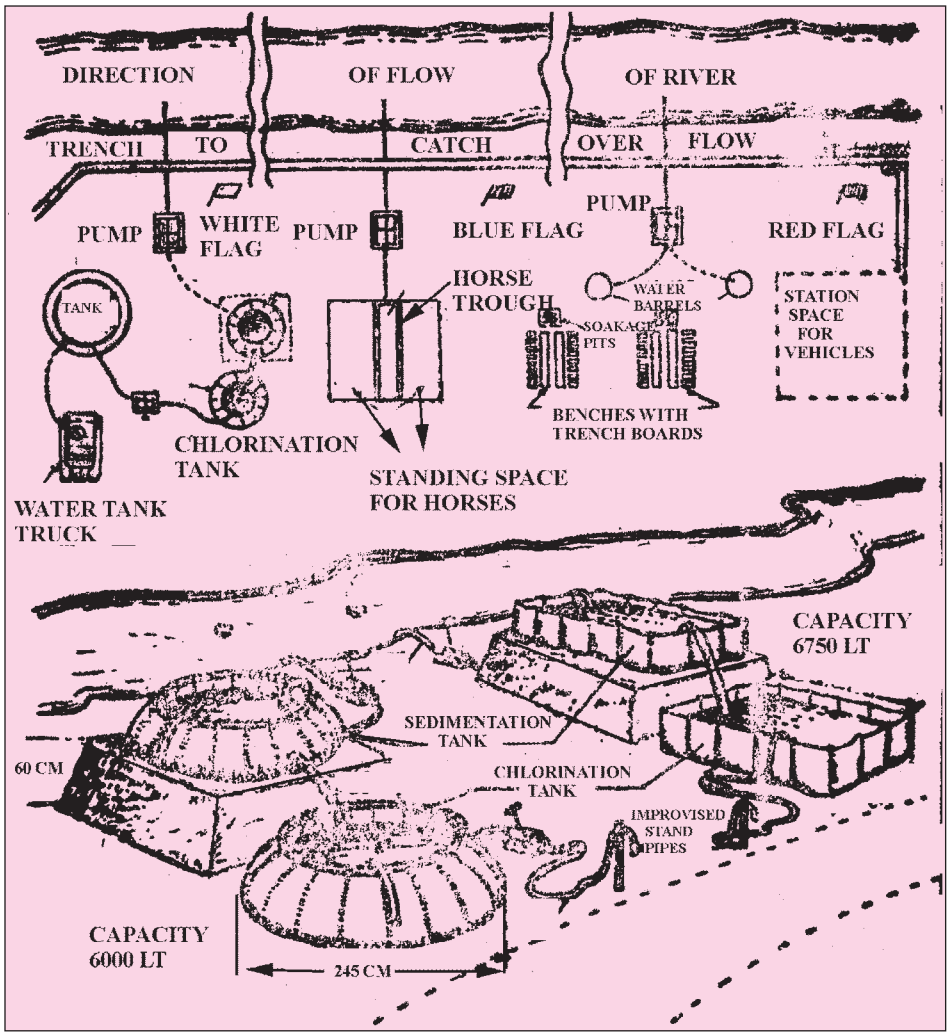
(h) The process of purification of water should be efficiently carried out under the constant supervision of a trained officer/JCO of the Corps of Engineers and checked by an Officer of the AMC. The Horrocks' test and colour test (orthtoluidine test) should be carried out by an AMC NCO trained and deputed specially for this purpose. Water duty personnel of the Field Coy Engineers or other unit organizing the water point must also be specially trained . The details of the process of water treatment is as under (Fig. 5)

Canvas cisterns should be arranged in as many sets as required to meet the water requirement, Each set should have 2 to 3 cisterns as decided to use for the water treatment. One cistern is used for sedimentation with flocculation and the second for chlorination and delivery. When available, the third may be used for storing water pending delivery. When water is more grossly turbid, the first tank may be used for sedimentation of coarse debris, flocculation is carried out in the second tank and chlorination in the third tank.

The first cistern of each set is filled with water to within 8 cm of the brim by a pump. For flocculation, 35g alum or alumino ferric per 1000 L of water is added as a coagulant. This is first dissolved in a bucket of water and the solution is distributed evenly throughout the water in the cistern. If the water is very turbid, upto 70 g per 1000 L of the coagulant may be necessary. Alternatively, a sandbag containing the requisite amount of crushed coagulant may be tied over the mouth of the delivery pipe so that water flows into the cistern through the bag.

The contents of the cisterns are then well stirred for a few minutes and allowed to stand for two to four hours or until the suspended particles have settled to the bottom leaving the supernatant water clear.

Fig - 5 : Layout of water points



If flocculation does not begin within a few minutes, the addition of lime (half the quantity as that of alumino ferric added) will produce flocculation and sedimentation.

The clarified water is then transferred to the next cistern either by pumping or by siphoning, care being taken not to disturb the sludge at the bottom of the setting cistern. A simple plan is to lash the hose pipe of the pump or siphon to a post near the cistern so that the intake end of the hose pipe is 15 cm above the floor of the cistern, or tie an empty sealed tin to it so as to serve as a float.

A sample of the clarified water should be taken and the Horrocks' test started just as the clarified water starts pouring into the tank.

The amount of WSP required is made into a thin paste with a litre or so of clarified water in a bucket and more water gradually added until the bucket is full of an even solution of WSP.

This is then evenly added to clarified water in the second cistern. If superchlorination is desired one more scoopful of WSP is added per 500 L of water.

The water is well stirred and allowed to stand for half an hour, or fifteen minutes if superchlorination has been carried out.

At the end of this time a sample of the chlorinated water is tested by the colour

test in a white cup. If a blue colour does not appear, the water is not safe to drink until sufficient additional WSP has been added to give a blue color after a further half an hour.

Dechlorination is carried out by adding two taste removing tablets per 500 L before consumption of water.

(j) Delivery of water to units should be made in their unit transport by pumping it in and not by manual lifting. The approach and exit to the water point should be free from dust and slush and made hard by coping or paving the paths. The water tank fitted in the lorry should be always cleaned and washed before receiving water in it and periodically sterilized by chlorine.

**The Water Tank Truck**

The water tank trucks, lorries or trailers equipped with mechanical filters are used in forward areas by forward formation and units whenever central water points cannot be established under the arrangement of the field engineers. By the judicious use of a water truck very often water from otherwise satisfactory local sources can be easily purified instead of obtaining it form the central water point situated several miles away. The essential functional parts and equipment on the truck or lorry are the water tank of varying capacity; the mechanically (or sometimes manually) operated pump; a pair of mechanical filters equipped with meta or stellar filter candles; water proof and leak-proof suction hoses on the farther end of which are carried the float and strainer. The filters are the most important equipment fitted one on each side of the front of the tank and connected to the pump. These filters have already been discussed.

**Chlorination in Small Containers in the Field**

When detachments are separated from the main bodies, the clarification of water to any great extent will not be possible. After short period of sedimentation by flocculation if possible, in small containers, it is chlorinated, or more commonly superchlorinated as under

In Pakhals, Buckets, Petrol Tins

The number of scoopfuls of WSP as indicated by the Horrocks' test should be mixed with clarified water in the black cup from the Horrocks' box. For supercholorination one extra scoopful of WSP should be added. The cup is filled with water upto the mark, stirred and allowed to stand until the chalk powder in suspension settles. One scoopful of this stock solution per 5 l of water will be required. The treated water is allowed to stand for 30 min before consumption. When superchlorination is carried out , dechlorination may be carried out before consumption but not earlier than 15 min contact. For this purpose the thiosulphate solution is prepared by dissolving two taste removing tablets( 1 g) in the black cup which is filled to the mark. One scoopful of this solution per 5 l of superchlorinated water is added. When Horrocks' box is not available a stock solution of 16 scoopful of WSP should be made in a water bottle. One scoopful of this stock solution to every five liters is required. For dechlorination dissolve 16 thiosulphate tablets in another water bottle full of water. One scoopful per 5 L of this is added after it has had 30 min contact with the chlorine or just before consumption.

In Water Bottles

**(i) By Individual Water Sterilising Outfit**

This aims at achieving superchlorination by a fixed dose. In the tin there are two bottles. Fifty sterilising white tablets, each containing 0.2 g of a mixture of 7.5 per cent halogen(para-sulphondichloramino-benzoic acid), 10.5 per cent anhydrous sodium carbonate and 82 per cent anhydrous sodium chloride, are continued in one bottle. Fifty taste removing blue tablets, each containing 0.1 g of a mixture of 85 % of sodium chloride and 15 % anhydrous sodium thiosulphate, are contained in another bottle. The bottles should be kept tightly corked when not in use and the tablets should only be taken out of the bottle when actually required for sterilizing water. One sterilizing tablet added to the full water bottle ensures 4 parts of chlorine per million parts of water. A minimum of 30 min contact is necessary to ensure sterilization. The longer the period of contact the better it is. The water bottle should be well shaken two or three times during this period. One taste removing tablets may be added to the bottle and the bottle well shaken before consumption of water but not earlier than 30 min after the addition of the white tablets.

(ii) Water sterilising powder

When the 'Individual Water Sterilizing Outfit' is not available, a stock solution of WSP should be made by adding to a water bottle full of water the number of scoopful of water sterilizing powder as indicated by the Horrock's test. For superchlorination add to the stock solution one scoopful more WSP than indicated by Horrock's test. If a Horrock's box is not available a fixed dose of four scoopful of WSP should be used to make a stock solution in the water bottle. One scoopful of this stock solution should be added to each water bottle. At least 30 min contact should be allowed before consumption. For dechlorination after superchlorination one scoopful of taste removing solution made by adding 4 TRT to a water bottle should be added to each water bottle before the actual consumption of water.

(iii) Aquatabs

Recently, Aquatabs (Bayer) have been included in the hygiene chemicals. The active ingredient is Sodium dichloroisocyanurate (Na DCC) (3.5 mg Tabs). One Tablet is added to the water bottle of capacity one litre and takes 30 minutes for the effect to build up. These tablets release limited amount of chlorine in the form of HOCl depeding upon the level of contamation and hence always maintain a baisc level of residual chlorine in water (13).

**Summary of Field Appliances**

(a) Water Bottle

Its capacity is 1.14 L

(b) Chagul

It is a bottle shaped receptacle of 4.5 or 9 L capacity. They should be well soaked before use. The contained water is cooled by evaporation from its surface.

(c) Pakhal

It is a zinc, or zinc coated, metal tank with a large brass screw on cover. It is oblong in shape and is covered with felt, which can be soaked for cooling the contents. Over the felt is a stout net and it is designed essentially for pack transport. Mule pakhal (cistern mule) has about 30 L capacity. Camel pakhal (cistern camel) has a capacity of about 60 L.

(d) Canvas Cisterns ( 225 and 450 L)

These are cubical with a lid and a tube delivery pipe. The cistern is usually supported in a collapsible wooden iron frame. They are most useful for small units and detachments.

(e) Iron Cistern (1820 L)

This is a normal size water cistern for small storage made of 5 sections of standard square steel plates. Larger sizes are made by adding more standard sections as required. Such tanks are usually painted red for preservation. For cooling they should be painted white or heavily white washed on the outside.

(f) Galvanized Cistern ( 225 and 450 L )

These are cubical cisterns, which may or may not be fitted with a lid and / or a draw-off cock.

(g) Canvas Cistern ( 6000 L)

These are used for water points in the field. In dusty areas, covers should be provided. The normal method is to use these tanks in pairs, one for sedimentation and the second for chlorination of the clarified water siphoned from the first. A third one may be used either for storing chlorinated water pending delivery or for initial gross sedimentation before flocculation is carried out in the second sedimentation tank.

(h) Circular Canvas Cisterns

These are 5500 L capacity with a kapok collar which rises as the cistern fills.

| Well (circular) |
|---|
| Depth of water X square of diameter X 785 = liters of water in the well. |
| Well (rectangular) |
| Depth of water X length X breadth X 1000 = liters of water in the well. |
| Unit of measurement : Meters |

(j) Water tank Truck

This consists of a 9900 L (working capacity 9000 L) tank mounted on a standard motor truck, provided with a mechanical force pump driven from the truck engine. Water is clarified by means of mechanical filter( meta or stellar filters) aided by alum or keiselguhr coagulant. Disinfection is carried out by chlorination or super chlorination.

| Yield per hour |
|---|
| Difference in two levels x square of diameter x 785 divided by the number of hours = yield of water in liters per hour. |

**Estimation of Yield**

Yield per hour

(a) Lower the water level rapidly by pumping out

(b) Measure water level from top of the well in meters

(c) After a few measured hours, measure the water level from the top again

Stream

Select 100 m length where the channel is uniform and where there are no eddies. Take the average breadth and depth in three or four places. Drop a chip of wood and find the time in seconds it takes to travel a measured distance which when divided by the time in seconds gives the surface velocity per second. 4/5 of this is the mean velocity of the stream. This multiplied by the sectional area in meters x 1000 gives the yield per second in liters.

## Surveillance of drinking water quality

Drinking-water supply surveillance is "the continuous and vigilant public health assessment and review of the safety and acceptability of drinking-water supplies" (WHO, 1976). This surveillance contributes to the protection of public health by promoting improvement of the quality, quantity, accessibility, coverage, affordability and continuity of water supplies (known as service indicators) and is complementary to the quality control function of the drinking-water supplier. Drinking-water supply surveillance does not remove or replace the responsibility of the drinking-water supplier to ensure that a drinking-water supply is of acceptable quality and meets predetermined health-based and other performance targets.

Surveillance is an important element in the development of strategies for incremental improvement of the quality of drinking-water supply services. It is important that strategies be developed for implementing surveillance, collating, analysing and summarizing data and reporting and disseminating the findings and are accompanied by recommendations for remedial action. Follow-up will be required to ensure that remedial action is taken.

It is appropriate for the drinking-water supply surveillance agency to carry out independent testing of water supplies and assess findings and report to and advise suppliers and communities.

**Surveillance of drinking water quality in a military station**

**1. Initial Baseline Survey**

Population characteristics

(a) List the units/Ests in the area of responsibility

(b) Divide the area into five sectors with the strength of troops and families.

(c) Prepare a layout map showing the five sectors with markings for units/ests and population density.

(d) Calculate the quantity of water required in each sector and the quantity supplied to find out the deficiency, if any.

Layout map of water supply system to include both the civil water works and the MES pumping stations.

(a) Mark the location of the civil water treatment plant, the major reservoirs/sumps, chlorination facilities available, Overhead reservoirs, the major pipe lines and the units/establishments being supplied.

(b) Similarly for the MES pumping stations mark their locations with chlorination facilities at each of these stations, if any. Identify the Major sumps with rechlorination facilities, the overhead reservoirs, the major pipelines and the units/establishments supplied pump house wise.

Initial sanitary survey of the following should be carried out

(a) Source stations

(b) Treatment facilities

(c) Layout of the major pipelines to identify

(i) Leakages

(ii) Sewage line cross connections

(iii) Deliberate break in lines

(iv) Water lines crossing the drains

(d) Any unauthorised source(s) being used by the units.

**2. Surveillance of supply system**

Civil Water Works

Liaison with PWD and CMO should be carried out and the civil water works should be visited at least once a quarter by the Officer Commanding Station Health Organisation (OC SHO).

Main sump/reservoir in which water supply from civil is received.

(a) Once a month by the health staff

(b) Once a quarter by the OC SHO.

MES Deep Tube wells

Each tube well along with storage and chlorination facility should be checked once a week in rotation as per plan ( 5 sectors) by the Health Inspector. Chlorination at pump and bleaching powder will also be checked besides chloronomes and dosers.

Water supply lines

Daily in rotation in the concerned sector so as to cover the enire area once in a week. Check for leakage /breakage /potential contamination by sewage. This should be done daily by the health staff, and once a week by the OC SHO. It should be planned in such a way that the entire area is covered by the health staff once a week and by the OC SHO once a month.

**3. Surveillance of water purification efficiency**

Free residual chlorine check

Consumer end points will be identified at least 2 fixed and 2 random end points in each sector (Total 20 points in entire area.) Identification of these points will be in a way that each source (6x MES pumps and 1 x civil source) is covered at these end points.

Free residual check at each sector by unit RMO should be carried out daily (results to be obtained by OC SHO on telephone).

Free residual check at railway stations at least once a week on the day when the concerned sector is being checked.

Once a week free residual check from the station swimming pool, the day on which sector coverage falls.

Bacteriology

Water samples from consumer end points- sector 1 Monday of First week/ sector 2 Monday of second week and so on till sector 5 on Monday of fifth week. Once a month last Friday from swimming pool. Minimum of 250 ml of water sample collected with aseptic precautions should be sent to the local MH lab and liaison should be done with the pathologist to ensure correct interpretation of the results.

Chemical analysis should be carried out on the following occasions

(a) on initiation of a new water source

(b) evidence of contamination on bacteriology/ Free chlorine check

(c) Any other situation decided by SHO

(d) Samples as per laid down procedure by AFMC

Water Poison detection

(a) Kit to be kept in readiness

(b) On as required basis in consultation with SEMO and Stn cdr

**4. Warning points and controls**

(a) If free residual chlorine is <0.2 ppm at any consumer end, inform MES and Station HQ on telephone to ensure chlorination and OC SHO should visit the source pump.

(b) If free residual chlorine is <0.5 ppm at any source pump, intimate GE and call for special joint inspection.

(c) If water bacteriology is 'suspicious', inform MES on telephone to bring chlorine level to 1 ppm, and repeat bacteriology.

(d) If 2nd sample also suspicious or any sample 'Unsatisfactory' ask for immediate joint inspection with GE and station HQ staff; and superchlorinate immediately.

(e) If any potential of cross contamination of water seen, immediately inform GE, CWE, Station HQ and SEMO, ask for immediate joint inspection and urgent repairs.

**5. Cleaning and Maintainence**

(a) Cleaning of OHT/Reservoirs should be done once in six months by MES; and certified by OC SHO

(b) All OHT/reservoirs to be kept covered, this should be checked by SHO and implemented by MES

(c) Any cross connection or leakage of water supply lines to be immediately repaired by MES in 24 hrs and certified by SHO as repaired. Instructions for repairs to be issued by Station Commander.

**6. Joint Inspection**

(a) Once a week a joint inspection of the water points should be carried out by SHO staff, Staff of GE and rep of Stn HQ

(b) Once a month a joint inspection of the water points should be carried out by OC SHO, GE and Adm Comdt.

(c) Emergency joint inspection if contamination suspected.

**7. Records**

(a) Spot map showing various sectors, Units, water sources, sumps, OHTs and major water pipe lines.

(b) Register of daily free chlorinechecks by SHO

(c) Register of daily free residual chlorine check by RMO

(d) Bacteriology register and file

(e) Chemical analysis register and file

(f) Water poison test register

(g) register of joint inspections

(h) Record of cleaning of OHTs

(j) Record of Station Quarterly Health Committee meeting and Antimalaria meetinh (points of water surveillance to be reflected)

(k) Station plan of sectorwise check of Free residual chlorine and Bacteriological tests.

(l) Water correspondence file.

## Swimming Pool

A swimming pool is an artificial structure where water volume per swimmer is relatively small. The water is thus exposed to contamination by ammoniacal and other organic substances as well as organism from skin, nasopharynx and other orifices of the swimmer. The health hazards associated with swimming in these pools are usually fungal, viral and bacterial infections of the skin, eye, ear, nose, throat and upper respiratory tract, intestinal tract and so on. Proper maintenance of pools is, therefore, of vital importance. General guidelines on sanitation of swimming pool are being given in subsequent paragraphs. Further details are available in standard texts (14).

A continuous inflow or a daily change of water, though ideal, is usually not feasible. The modern pools are equipped with continuous filtration and chlorination system. The "fill and empty" system is also encountered. Considerable attention is thus necessary to ensure that water is maintained continuously in a pure state in such pools. If the water is turbid provision for sedimentation in a separate settling tank may become inescapable. The water must be renewed at least once a week and 10-15 percent of the water should be replaced by a fresh daily inflow. When the pool is emptied, the floor and the sides should be thoroughly scrubbed and lime washed. Addition of copper sulphate 2g per 1000 l once a week will prevent algal growth and accumulation of slime.

Chlorination is carried out by injecting gaseous chlorine by the use of chloronome. Continuous maintenance of 1 ppm of free residual chlorine provides adequate protection against bacterial and viral agents. When chloronomes are not installed or not functioning, the required amount of WSP as calculated by Horrock's test is first made into a thin mixture and distributed evenly over the surface of water. The water is then stirred with paddles. Subsequently, each day until the next filling, half that amount of WSP should be added half an hour before the swimming time. Tests for free residual chlorine is to be carried out daily half an hour after adding WSP. It will be ideal to keep the pH of water between 7.4 to 7.8 as irritation of eyes due to chloramine formation will be minimum. In a swimming pool the process of chlorination preferred is 'breakpoint' chlorination. When chlorine is added to water it immediately forms chloramines with ammonia, which is always present. The process continues till all the ammonia present is used up and the concentration of chloramines reaches its peak. Chlormines are, however unstable and react with excess free chlorine present in water and get oxidized completely to nitrogen and thus water contains no longer any free chlorine. Break point is said to have been reached when water no longer gives 'flash' reaction of free chlorine. Any further addition of chlorine hereafter causes a proportionate rise in the residual free chlorine, which acts as efficient germicidal agent. The bacteriological quality of swimming pool water should reach as nearly as possible the standard of drinking water. The test should be carried out weekly.

## Purification of Water on a Small Scale

The growing use of household filters and bottled water, a sign that public has lost faith in the quality of the water supply, should stimulate corrective action by water surveyors and regulatory agencies. House hold purification of water could be carried out by the methods stated below :-

### Boiling

It is very effective and kills all bacteria, viruses, spores, cysts and ova when the water is boiled for 5 to 10 min. It also removes temporary hardness. The taste of water is, however, altered. Boiled water has also no residual protection against subsequent contamination and hence care to be taken to avoid contamination during storage.

### Chemical Disinfection

It may be carried out with either chlorine solution, bleaching powder, WSP, perchloron, chlorine tablets or iodine solution. The chlorine tablets manufactured by the National Environmental Engineering and Research Institute, Nagpur (NEERI) are about 15 times more potent than ordinary halogen tablets and are available in the market. A single tablet of 0.5 g is sufficient to disinfect 20

l of water. Potassium permanganate is no longer recommended, as it is not a satisfactory water disinfecting agent although it is a powerful oxidizing agent. It has other drawbacks such as alteration of color, smell and taste of water.

**Filtration**

It is done through ceramic filters such as Pasteur Chamberland, Berkefeld and Katadyn filters. The essential part of a filter is the candle, which is made of unglazed porcelain in Pasteur Chamberland type, and of Kieselgurh in Berkefeld type. The surface of the candle in Katadyn filter is coated with a sliver catalyst. The bacteria coming in contact with filter candle get killed by the oligodynamic action of silver ions. Filter candles are liable to be clogged. These are to be cleaned by scrubbing with a hard brush under running water. The candles should be boiled at least once a week. Relatively clean water should be used with ceramic filters. Filter candles, however, do not remove filter-passing viruses.

**Disinfection of Wells**

It is sometimes necessary on a large scale during epidemics of cholera and other gastro-intestinal infections. Chlorination with bleaching powder is the most effective and cheapest method for this purpose. The quantum of water in the well is first worked out and the amount of WSP required is then estimated by Horrock,s test. The required quantity of WSP is then made into a thin paste with little water in a bucket. The bucket is filled three-fourth with water stirring all the time. About 5 to 10 min time is allowed for the chalk to settle down. The supernatant clear solution is then transferred to another bucket and the chalk is discarded. The bucket containing the clear chlorine solution is lowered into the well and the well water agitated by lowering and drawing the bucket several times. After half an hour's contact, orthotolidine test is carried out. If fresh residual chlorine is less than 0.5 mg/ l, additional quantities of WSP will have to be added. During epidemics, wells should be disinfected every day.

## Examination of Water and its Sources of Supply

The appearance and taste of water afford no warning of contamination. Moderately contaminated water may sometimes be quite palatable and sparkling. The laboratory assessment of water quality comprises of physical, microbiological and chemical examinations; each having its own usefulness. On active service in the field, however, the quality of raw water is judged mainly by purity at its source and sanitation of the surroundings of the source and appearance of water. The source of water and its surroundings offer indications of the extent of pollution and purity of water at its source and the procedure to be adopted to maintain the purity and enhance safety until it is delivered for consumption. Frequent examination by the Horrocks' test and efficient chlorination are relied upon to further safeguard the water supply. Indeed, the bacteriological examination in the field assumes mainly the role of field test to judge the efficacy of the methods of purification rather than the purity of the raw supply. In any case the full laboratory examinations are not always feasible as a routine measure in the field. They are, however, essential when the establishment of permanent or semi-permanent water points are contemplated, while investigating the outbreaks of water related diseases and for a routine check on supplies in townships, garrisons and cantonments.

**Hygiene Inspection.**

The hygiene inspection of the source, surroundings and site of water supply is carried out by making a plan and following it systematically. The inspection should include the presence of any habitation on the banks of the stream or near the water source; the presence of any water-logging nearby, the sanitation of the surroundings; the presence of any waste disposal area, latrines or urinals; the presence of any cattle sheds or horse stables in the vicinity; any seepages or surface pollution especially of human and animal waste products and industrial effluents affecting the potability and purity of water; amount of vegetation in the vicinity, in the water course or reservoir; the use of the source by local inhabitants and their health status including the presence of enteric fevers, viral hepatitis type A and gastrointestinal flux; the amount of flow of water, and the factor of dilution of pollution in water. The presence of living and actively multiplying fish generally indicates low pollution, and absence of disease among the inhabitants consuming the water indicates its general wholesomeness. Quick filling power may indicate the presence of fresh springs in lakes and wells and a good yield in the case of a stream. However, the likelihood of seepages from surroundings may also cause increased yield and should be guarded against. The site for obtaining water for human consumption from the selected source should also be properly examined before final selection. A sanitary survey is an on-site inspection and evaluation by a qualified person of all the conditions, devices, and practices in the water supply system which pose a danger to the health and well being of the water consumer. No bacteriological or chemical examination can take the place of a sanitary survey as the pollution is often intermittent and may escape the laboratory testing. Surveys should be undertaken when

(a) a new source is contemplated;

(b) laboratory analysis indicates hazard to health;

(c) an outbreak of waterborne disease occurs in the area;

(d) to interpret bacteriological, chemical and physical analyses of samples;

(e) when any change takes place that can affect the water system, e.g., industries coming up in watershed and

(f) also on a regular basis depending on size and available staff and resources and population / area under coverage. Majority of samples should be from problem areas, i.e., those with poor results in the past, low pressure zones, areas with high leakage, densely populated areas with inadequate sewerage, dead ends on pipelines, areas far away from waterworks etc.

## Water Quality Standards

WHO guidelines on variaous parametres for drinking water quality are laid down in standard references (12, 15, 16, 17) and should be referred to as and when required. The methods of examination of water are also given in details in the publications of ICMR (18) and American Public Health Association (19). In brief the standards and procedures are as follows :

### Physical Parameters

Wholesomeness and acceptability of drinking water is determined by the following factors:-

Turbidity

On aesthetic grounds, drinking water with obvious turbidity, i.e., turbidity above 5 NTU, becomes unacceptable to the consumer. Turbidity indicates incomplete treatment of water and also interferes with disinfection of the water.

Colour

The acceptable limit for colour in drinking water is 15 true colour units (TCU). Colouration of water may be due to presence of organic matter such as peat, metals like iron and manganese or due to industrial wastes.

Taste and Odour

Even though no guideline limit values have been laid down, any water with significant degree of taste and odour is unacceptable to the user. Taste and odour may be due to mineral matter, presence of organic matter and occasionally due to excessive residual chlorine in treated waters.

Temperature

Cool water is generally more palatable and no guideline value is recommended for temperature since its control is usually impracticable.

### Inorganic Constituents

Total Dissolved Solids (TDS)

The amount of TDS in water has an important effect on its taste. Waters with very low concentrations of TDS, such as the rain water are not relished by the consumer because of the flat, insipid taste. The palatability of waters with TDS levels below 600 mg/litre is considered to be good and those above 1200 mg/litre become unpalatable and objectionable due to scale formation in pipes, heaters and household appliances. The guideline value is for TDS to be below 1000 mg/litre.

pH

The guideline value for pH of water is 6.5 to 8.5. Water with pH levels below this range may corrode pipelines, resulting in increased levels of certain chemical substances, such as lead, in water. At pH levels above this range, the efficiency of the disinfectant action of chlorine is reduced.

Hardness

Depending on the interaction of other factors, such as pH, water with a hardness above 200 mg/litre may cause scale deposition in the distribution system and may result in excessive soap consumption. On the other hand, water with a hardness of less than 100 mg/litre has a low buffer capacity and is corrosive for water pipes.

Dissolved Oxygen

Even though no health based guideline value has been laid down, depletion of dissolved oxygen content in water encourages microbial reduction of nitrates and sulphates to nitrites and sulphides respectively, with consequent odour problems.

Hydrogen Sulphide

The presence of hydrogen sulphide in poorly oxygenated, stagnant waters is easily noticed by the consumer by its characteristic 'rotten egg' odour. The guideline value for hydrogen sulphide is 0.05 mg/litre.

Ammonia

Ammonia in water is an indicator of possible bacterial, sewage and animal waste pollution. It may be present in a non-ionised or ionised form. Ammonia retards the efficiency of treatment processes including disinfection and may also give rise to taste and odour problems. The guideline value is 1.5 mg/litre.

Sodium

The taste threshold of sodium depends on the associated anion and the temperature of water. The guideline value is 200 mg/litre.

Chlorides

The guideline value for chloride is 250 mg/litre even though the maximum permissible level is kept at 600 mg/litre. Chloride content of water variers a lot from place to place and tends to be high in the neighbourhood of the sea. Any sudden increase in background levels of chlorides in water from a place should raise suspicion of contamination of water.

## Presumptive Coliform Test

This test is based on estimating the most probable number (MPN) of coliform organisms in 100 ml of water. The water samples are collected in 180 ml sterilised bottles with all necessary precautions. If possible the bottle should contain culture medium and be inoculated on the spot. If not, they should be packed in ice and sent expeditiously to the laboratory. Bottles containing a mixture of McConkey's broth, the sample of water and a small inverted tube are incubated for 24 to 48 h at 37$^{o}$C. The multiplication of the faecal organisms present in water under test produces acid and gas. From the number of samples turning acidic, as shown by the pink color of the mixture, and which have produced gas, as seen in the inverted tubes, the probable number of the coli-aerogens group of organisms per 1000 ml water is ascertained from the standard tables. The estimates are therefore 'presumptive' and not actually existing. Details of the proceedure are given by Cheesbrough (20). There are two methods usually employed in the laboratories: the 'ordinary method' and the 'field method'.

**Ordinary Method**

This method is used while examining water from urban water works. Two series of bottles are put up. Series 1 is used for the samples that are likely to be satisfactory and series 2 when water is obviously unsatisfactory. Samples showing upto 2 presumptive coli in 100 ml are considered 'good' while those showing above 10 are 'bad'; the intermediate grade samples from an otherwise good source may be acceptable in an emergency, provided that the efficient clarification and chlorination show no presumptive *E coli* in 100 ml. Table - 4.

Table - 4 : Composition of the ordinary & field methods

| Method | Series | No. of bottles | Quantity of water | Quantity single strength | Broth ml double strength |
|---|---|---|---|---|---|
| Ordinary | 1 | 1 | 50 | - | 50 |
| | | 5 | 10 | - | 10 |
| | | 5 | 1 | 10 | - |
| | 2 | 5 | 10 | - | 10 |
| | | 5 | 1 | 10 | - |
| | | 5 | 0.1 | 10 | - |
| Field | | 5 | 10 | - | 10 |

**Field Method**

This method gives rapid results enabling one to take quick decision in the field about the comparative merits of two or more water sources. Five bottles containing inverted tubes and 10ml double strength McConkeys broth are inoculated with 10 ml of the sample of water on the spot and incubated for 24 h after which none of the bottles should show gas or acid.

**Membrane Filtration Technique**

In some countries membrane filter technique is used as a standard procedure to test for the presence of coliform organisms. A measured value of the water sample is filtered through a membrane made of cellulose ester. Bacteria present in water are retained on the surface of the membrane. The membrane is then directly inoculated face upwards on suitable media at appropriate temperature. Within 20 h the colonies grow and can be counted (20).

| Water at the point of consumption | Plate count after 2 days at 37ºC | Plate count after 3 days at 22ºC |
|---|---|---|
| Disinfected | 0 | 10 |
| Not disinfected | 20 | 100 |

**Faecal Streptococci and Cl. perfringens Detection**

The significance of these two tests have been discussed earlier.

**Colony Count**

The colony count on nutrient agar at 37ºC and 22º C provide an estimate of the general bacterial content of water. A single count is of little value, but counts from the same source at frequent intervals are of considerable value. A sudden increase in the count serves as the earliest indicator of contamination and hence this test is gainfully used in the public water works. The recommended plate counts are:

Plate count on yeast extract agar at 22ºC for 7 days is even a better indicator due to the absence of chlorine residue when there is uninhibited bacterial growth.

**Colilert Method**

The World Health Organization (WHO) recommends the measurement of *E. coli* in drinking water samples as the best indicator of water quality. The WHO guideline for potable water is less than one *E. coli* per 100 ml of drinking water (World Health Organization 1998). Multiple tube fermentation, membrane filtration and Colilert (IDEXX Laboratories, Inc., Westbrook, Maine) are laboratory methods used to qualify or quantify the level of bacteria in drinking water samples. The multiple tube fermentation and membrane filtration tests measure total coliforms and *E. coli* and are standard methods for water quality assessments. Both tests assess the number of bacteria based on lactose fermentation with production of sheen colonies, gas, or acid and gas.

Results from the multiple tube fermentation method estimate the most probable number (MPN) of coliforms or *E. coli* per 100 ml after growth of coliforms in liquid medium. Results from the membrane filtration method approximate the number of coliforms or *E. coli* colonies per 100 ml after growth of bacteria on the surface of agar.

Colilert is a recently available method to determine the MPN of coliforms. Colilert uses defined substrate technology to detect and quantify total coliforms and *E. coli* from water samples (22). As coliforms grow, they use l3-galactosidase to metabolize the nutrient indicator o-nitrophenyl-l3-D-galactopyranoside and change it from colourless to yellow. E. coli use l3-glucuronidase to metabolize 4-methylumbelliferyl-l3-D-glucuronide, which creates a molecule that fluoresces under ultraviolet light. Colilert is simpler to use, allows greater throughput, and requires less time to standardize than standard methods.

Colilert is an acceptable method to measure the presence and quantity of coliforms in water samples in a developing country setting. (23)

## Chemical Examination

This test is assuming greater importance due to ever increasing chances of industrial and agricultural pollutants finding their way into the sources of raw water. In the Armed Forces, the test is carried out prior to establishment of a water works/permanent water point. The existing sources are also subjected to the test annually once or as frequently as desired. When a chemical examination is indicated commonly the presence, type and quantities of hardness and inorganic salts acquired from the geological strata, and estimation

of chlorides, nitrites, ammonia and 'oxygen absorbed' figures to determine the extent of pollution are required to be ascertained. Estimation of iodides, fluorides and calcium is required under special circumstances when subnormal or abnormal quantities of these in water are suspected. A complete chemical examination also includes analysis for toxic metals, pesticides, persistant organic chemicals and radioactivity. Potable water from a chemical stand point alone, however, is not adequate as the indicators cannot be relied upon to detect minute quantities of sewage contamination . For this, bacteriological examination is needed.

The organic matter increases the chlorine demand of water. Ammonia interferes in the process of chlorination due to the formation of chloramines. High salinity affects adversely the taste and consumption of water. On decomposition of nitrogenous organic matter, carbondioxide ($CO_2$) and ammonia ($NH_3$) are produced. Ammonia is oxidised to nitrites and then to nitrates. In recently polluted water, ammonia and nitrites are found in larger quantities than nitrates. Given below are the interpretations of some of the usual chemical contents of water :-

**Ammonia**

It may be free (F), saline(S), or Albuminoid (Alb). Free and saline ammonia most commonly result from the decomposition of urine. Rain water and deep well waters (containing reducing iron salts from green sand strata) may also have high F and S ammonia content but other constituents may be small. Sewage pollution of water also shows the same results, but other figures in that case will also be high. If both types of ammonia are low i.e. F and S are 0.05 ppm or less and Alb. 0.1 ppm or less, the water is probably good. If both types of ammonia are higher than the above figures the water is bad. Alb ammonia is typically a product of vegetable organic matter. Low F and S and high Alb. Ammonia indicate vegetable contamination, specially if the 'oxygen absorbed' figure is high.

**Oxygen**

It will be absorbed as long as there is oxidisable matter in the water. Some streams may be so heavily polluted with crude sewage that all dissolved oxygen is removed from the water and the aquatic animals might die. The 'oxygen absorbed' figure after 15 min when acidic potassium permanganate is used as an oxidising chemical agent, indicates the amount of reducing inorganic substances such as nitrites and ferrous salts, but at the same time it may indicate the presence of certain rapidly oxidisable substances in sewage. An examination of other figures in the analysis and the absence of iron will assist in forming an opinion. The $O_2$ absorbed figures after 4 hrs gives an indication of the total oxidisable matter present in the water including that described above and organic matter mainly vegetable (co-related with albuminoid) and also to some small extent sewage. If the difference between the two oxygen absorbed figures is high i.e. 0.8 or more probably vegetable pollution is present but this must be confirmed by noting if the albuminoid ammonia is also high and free and saline low, and whether the water is acidic and soft or peaty.

**Chlorides**

These are increased by pollution with sea water, sewage (urine) and water from certain deep strata. A figure of more than 30 ppm in surface waters may be due to contamination with sewage; comparison must be made with the average 'chloride figure' for the area or previous concentration of the same sample before attributing it to pollution in some deep wells, the figures may run from 10 to 200 ppm or more. Deep well waters in coastal regions may have chloride content as high as 1000 ppm .Other indications of pollution will also help in arriving at conclusions.

**Nitrites/Nitrates**

These are the first stage in oxidation of ammonia and indicate recent pollution. They can also be present in waters from a green sand strata due to reduction of nitrates. Nitrites should be zero in potable water unless it comes from a green sand stratum. Nitrates represent remote pollution and if found in amounts above 1 ppm in a surface water or above 5 ppm in a deep well, the water should be regarded with suspicion.

**Hardness**

For domestic use the amount of hardness of water should not be more than 300 ppm . For laundries and boilers the softer the water the better.

**Total Solids**

These have little importance if other figures are satisfactory. Potable water should not exceed a value of 500 ppm.

The above standards are not hard and fast dividing lines above which water is to be immediately condemned or below which it is safe to drink. The following table gives examples of some water analysis and their interpretation (Table-5). The interpretation of these samples (A to F) are as follows :

**Interpretation**

(A) Rain Water

F and S ammonia very high (from air) Alb ammonia absent and $O_2$ is absorbed very low. No nitrites or nitrates, very low chlorides, hardness and total solids. A pure rain water.

(B) Peat Surface Water.

Acidic brown colour, F and S ammonia very low, alb ammonia and $O_2$ absorbed very high. Nitrites and nitrates absent. Chlorides is about normal for surface water, Very low hardness and total solids and Iron is present. A soft water, presumably plumbosolvent not showing sings of animal pollution, either recent or remote.

(C) River Water Derived from Chalk Springs

F and S ammonia low; alb ammonia and $O_2$ absorbed very low. Nitrites absent, nitrates and chlorides higher than normal for clean surface water. Temporary hardness is high whereas permanent is low. A good river water, but showing some evidence of past animal pollution (nitrates and chlorides).

(D) Water From River (C) After Receiving Sewage

Table - 5 : Interpretation of Water Analysis Report

| | A | B | C | D | E | F |

| **Hardness** | | | | | | |
| Temporary | 2 | 8 | 228 | 196 | 20 | 150 |
| Permanent | Nil | 8 | 14 | 180 | 50 | 100 |
| **Total Solids** | 23 | 40 | 284 | 296 | 267 | 400 |
| **Metals** | Nil | Iron | Nil | Nil | Nil | Nil |
| | | | | | | |

Note turbidity and color changed from blue to brown. F and S ammonia very high, alb ammonia low, $O_2$ absorbed high. Nitrites present. Nitrates and chlorides rather high. Increase in permanent hardness probably due to sulphates in sewage. A very impure water showing evidence of recent animal pollution.

(E) Water From Pond Receiving Sewage

A turbid brown unpleasant smelling water. F and S and alb ammonia and $O_2$ absorbed all very high. Nitrites present, nitrates and chlorides very high. Permanent hardness probably due to sulphate from sewage. A very bad water showing marked evidence of recent animal and vegetable pollution

(F) Water from well with Bad /surface Protection

F and S ammonia high, alb ammonia and $O_2$ absorbed very high. Nitrites nil but nitrates rather high. Chlorides high (figure for this district 20.00) temporary and permanent hardness high. A poor well water almost certainly contaminated by surface washings.

## Water Quality Standards

Prevention of pollution of drinking water, though ideal, is beyond achievement even with the best of efforts. Hence to minimize all the known health hazards, governments or appropriate authorities have adopted specific drinking water standards. These standards are the exposure limits for bacterial, viral, chemical and physical agents. The WHO in 1996 has published guidelines for drinking water quality. The standards of water quality are, however, by no means static; these are constantly under review in the light of new knowledge.

### Microbiological Pollutants

These are the standards relating to the presence of bacteria and viruses in drinking water.

### Standards of Bacterial Quality

Treated Water

Ideally, all samples taken from the distribution system should be free from coliform organisms. In practice this standards is not always attainable and the following standard for water collected in the distribution system is therefore recommended throughout any year, 95 percent of samples should not contain coliform organisms in 100 ml; no sample should contain *E. coli* in 100 ml and a coliform organism should not be detected in 100 ml of any consecutive samples.

Individual or Small Community Supplies

The standards outlined above may not be attainable in the case of waters from wells and springs. In these waters, the coliform count should be less than 10 per 100 ml. Persistent failure to achieve this particularly if *E. coli* is repeatedly found calls for rejection of water supply.

### Standards of Viral Quality

As stated earlier, water free of faecal coliform need not necessarily be free of viruses. Enteroviruses, reoviruses and adeno-virus have all been detected in water. As per

Table - 6 : Toxic Chemical Sustances

| Substance | Upper limit of concentration (mg/1) |
|---|---|
| Arsenic | 0.05 |
| Cadmium | 0.005 |
| Cyanide | 0.05 |
| Lead | 0.05 |
| Mercury | 0.001 |
| Selenium | 0.01 |

WHO standards not more than one plaque forming unit (PFU) per liter of water is considered potable. There should also be complete absence of enteropathogenic viruses and faecal bacteriophages.

### Toxic Chemical Substances

The presence of the following substances in excess of the concentrations shown against each should constitute grounds for rejection of the water (Table 6).

Table - 7 : Desired Levels

| Substances | Highest desired level |
|---|---|
| Substances causing discoloration | 5 units |
| Substances causing odour | Unobjectionable |
| Substances causing tastes | Unobjectionable |
| PH range | 7.0 - 8.5 |
| Total solids | 500mg/1 |
| Total hardness | 2mEq/1 |
| Iron | 0.1 mg/1 |
| Manganese | 0.05 mg/1 |
| Copper | 0.05 mg/1 |
| Zinc | 5.0 mg/1 |
| Calcium | 75 mg/1 |
| Magnesium | 30 mg/1 |
| Sulphate | 200 mg/1 |
| Chloride | 200 mg/1 |
| Phenolic Substances | 0.001 mg/1 |

**Specific Chemical Substances.**

Fluorides

Optimum recommended concentration is 1 ppm (0.5 to 0.8 ppm in India).

Nitrates

The ingestion of water containing nitrates in excess of 45 mg/ L may give rise to methhaemoglobinaemia in infants.

Polynuclear Aromatic Hydrocarbons

Some of these are know to be carcinogenic. Their concentration, in general should not exceed 0.2 g / L.

**Substances Affecting the Acceptability of Water.**

Turbidity of water is caused by the presence of suspended matter which interferes with the passage of scattering and absorbing light rays, and thus giving the water a non-transparent, milky appearance. Turbidity may result from soil erosion, algal growth or animal debris carried by surface run off. Colour may be imparted by substances leached from decomposed organic matter, leaves or soil such as peat.

The following criteria have been suggested: -

Turbidity should be less than 5 NTU and before chlorination should be < 1 NTU

**Radioactive Substances**

There is an increasing hazard of pollution of water supplies by radioactive substances. The radioactivity of water is measured in picocuries per liter (pCi/l). The WHO has proposed the following limits of radioactivity as acceptable: -

Gross alpha activity 3 pCi/l.

Gross beta activity 30 pCi/l.

## Detection of Poison in Drinking Water

Water is the most vital source of all kinds of life on this planet. There is every possibility of sabotage of the drinking water source by the enemy/militants. It must be ensured that water is free from poisons before it is declared potable. Testing of poison in drinking water requires elaborate laboratory facilities, which are not possible in remote areas. A set of Kit has been developed by DRDE Gwalior and marketed by Hindustan Metal Industries, Nai Sarak, Gwalior-1(MP) keeping in view the above requirement and facilitated testing of most commonly present poisons, sulphur mustard, nerve agent and microbial contaminations.

**Description**

The kit is housed in aluminium container having shoulder strap to carry for field use. The kit is provided with the reagents/material, sufficient for testing poisons 50 times. Each of the consumable reagents/material are quite stable and are replenishable. The Field kit for the detection of poisoning in drinking water. (WPDK) test are specific and can be performed systematically within 30 minutes, excluding the test for microbial contamination which takes 18 hours alone.

**Warning**

The following points should be considered before performing the tests :-

(a) The sample of water should not be chlorinated. If chlorinated, water can be dechlorinated by adding sodium thiosulphate.

(b) Water sample should be made clear by filtering if turbidity is observed.

(c) pH of water sample should be close to 7.

(d) Deionised water may be used in lieu of distilled water. The deioniosed water can be prepared by shaking the water (50 ml) with four scoopful of resin from bottle No (3) for 5 minutes, supernatant of which can be used.

Table - 8 : Poisons in drinking water

| Poisons | Detection units mg/L |
|---|---|
| Nerve agents | 0.01 |
| Sulphur mustard | 2.0 |
| Cyanide | 0.05 |
| Mercury | 0.5 |
| Arsenic | 0.2 |
| Lead | 0.001 |
| Manganese | 0.2 |
| Copper | 1.5 |
| Microbial contamination | 1-3 coliforms per 100ml |

**Field Kit for the Detection of Poisons in Drinking Water (WPDK)**

Specification

(a) **Size :** L.317 mm. W. 270. mm. H. 100mm.

(b) **Capacity :** 50 tests for each poison and 5 test each for nerve agents and microbial contaminants

(c) **Poisons and their Detection Limit**

Procedure of detection

Nerve agents

(a) Take the sample of water more than half in the small glass bottle (24)

(b) Break the ampoule, big followed by small by means of clean glass plunger(25)

**Observation**

(a) The colour of the water sample will turn blue, wait for 5-8 minutes

(b) The blue colour will disappear. It shows that the sample under test is free from Nerve agents.

(c) If the blue colour of the water does not disappear even in 10 minutes. It shows the presence of Nerve agents.

Sulphur Mustard

(a) Open the cap of chemical heater assembly (19) and take out the metallic part.

(b) Add approximately 30 drops of distilled water/deionised water in the plastic container of the chemical heater assembly then add one crushed tablet (20) and put the metallic part in it.

(c) Place one mustard test paper (18) over the pre-heated metallic platform of the heater.

(d) Add 1-2 drops of catalyst solution (22)

(e) Add slowly 10 drops of water sample drop by drop and wait for 2 minutes.

(f) Add 1 drop of reagent No (21)

**Observation**

(a) Appearance of purple blue colour will indicate the presence of sulphur mustard.

(b) Intensity of colour will vary from light blue to purple blue depending upon the concentration of Sulphur mustard.

Cyanide

(a) Take 15 drops approximately of distilled water/deionised water in test tube.

(b) Add one tablet each of (11) and (4) together.

(c) Shake the test tube till it makes suspension, then add two drops of suspension on the filter paper (17).

(d) Now take 100 ml sample of water in a polythene bottle (14) add to it one tablet (12) and add one scoopful of (2).

(e) Quickly put the paper from step (iii) upside down directly on the mouth of the polythene bottle, prepared as step (iv)

(f) Wait for 5 minutes.

**Caution**

Cork of the plastic bottle may be put over the filter paper in order to minimise the escape of gas evolved through the sides of filter paper.

**Observation**

A distinct bluish green colour will appear on the filter paper indicating the presence of Cyanide.

Mercury

(a) Take a mercury test paper (16).

(b) Add slowly fifteen drops of water sample by means of droper on the centre of the paper allowing the drop to be soaked completely before adding the next drop.

(c) After adding all the drops, wait for 2 minutes.

**Observation**

(a) Appearance of brick red/orange colour will indicate the presence of Mercury.

(b) For better visibility see colour against white back ground.

(c) Any other colour has no significance.

**Arsenic**

(a) Take a filter paper (17) and add two drops of reagent (13).

(b) Now take 100 ml water sample in a polythene bottle (15) and add one tablet(5).

(c) Add one scoopful of (2).

(d) Quickly put the above fitter paper to which the reagent is already added, directly on the mouth of the polythene bottle, facing the water.

(e) Wait for 10 minutes.

**Observation**

Pink / voilet stain will appear on the filter paper facing the water indicating the presence of Arsenic. Yellow stain has no significance.

Lead

(a) Take 100ml of the sample of water in the polythene bottle (15). Add one scoopful of (No 1). After 5 minutes shake the bottle gently up and down for two minutes, then allow to settle the resin, reject the supernatant liquid. Add another 100 ml sample and repeat as above till one litre of sample extracted.

(b) Take the extracted resin on a filter paper to remove excess water. Transfer the resin thus dried in the test tube.

(c) Add 15 drops approximately distilled/deionised water in the test tube, crush and add one tablet each of (6) and (7) together in the test tube.

(d) Shake vigorously for 5-10 minutes. The solution will become turbid.

(e) Add five drops of turbid solution on a fresh filter paper (17)

(f) Take 5-6 crystals of (8) in another test tube and add 30 drops distilled/deionised water to make solution. Add 5 drops of this solution over the filter paper where turbid solution has already been added.

**Observation**

A distinct dark violet stain will develop to indicate the presence of Lead.

Manganese

(a) Put one tablet (9) on filter paper (17)

(b) Add 10 drops of water sample very slowly by means of dropper

(c) Wait for two minutes.

**Observation**

A distinct bluish green colour will appear on the filter paper indicates the presence of Manganese in water.

Copper

(a) Put one tablet (10) on a filter paper (17).

(b) Add slowly 10 drops sample of water on the tablet

(c) Wait for two minutes

**Observation**

A olive green colour will appear on the filter paper indicating the presence of Copper.

Microbiological Contaminations

(a) Take a bottle (23) unscrew it and immediately fill the sample of water up to the mark

(b) Shake the bottle for one minute.

(c) Keep the bottle at room temperature preferably at 30°C for 18 hours

**Observation**

After 18 hours see the colour of water, if it turns jet black it confirms the heavy biological contamination and if it is less means less contamination. Temperature will play an important role in the development of colour if sample of water is contaminated.

## The International Drinking Water Supply and Sanitation Decade 1981-1990(1, 2)

The 'Decade' was launched at a special meeting of the United Nations General Assembly on 10 November 1980 following the recommendation of the UN Water Conference at Mar del Plata in 1977. The priority given by the above conference to the provision of safe water supply and sanitation was influenced by the joint report of WHO and World Bank which showed that in I975 some I230 million people were still without safe water supplies and I350 million people had lack of adequate sanitation facilities. Among the rural populations of developing countries, only 22 percent had access to reasonable safe water and only 15 per cent had facilities for excreta disposal. The Mar del Plata action plan also urged the individual countries to establish goals for 1990, which match the global target of the Decade.

### Target of the Decade (1991-2000)

The targets were fixed by the Indian Government for the decade

100% urban and rural supply

50% urban sanitation

25% rural sanitation

The Guinea worm eradication programme was linked with this decade. In 1986 the National drinking water Mission (NDWM) popularly unknown as Technical Mission was launched in order to provide scientific and cost effective content to the centrally sponsored Accelerate Rural water supply programme. In 1987 the National Water Policy was announced that has given high priority to drinking water.

### Tenth Five Year Plan (2002-2007)

Broad Terms of Reference

Develop a perspective on demand and supply for the next two decades say, by 2021 taking into account the present status and the ground realities.

Evolve a long-term strategy for provision and Operation & Maintenance of drinking water supply and sanitation facilities, which should be contributory to the process of economic development in a sustainable framework.

To formulate objectives, policies, strategies and methodology for the Tenth Five Year Plan, suggest modifications, if any, in the existing schemes, formulate new programmes, designed to address the specific problems in the water supply and sanitation sector.

Recommend viable and efficient policy options with particular reference to financing, development of compatible institutions and planning systems in a decentralised set up.

Analyse the pattern of financial flow in the Central and State Government's Budgets in the recent Five Year Plans and suggest proposals for changes/enhancement in the allocation process of Central and State budgetary resources for this sector.

To review the current status of operation and maintenance of rural water supply and sanitation schemes and suggest policies, strategies ways and means for effective operation and maintenance of the assets created including transfer of responsibilities to PRIs during the Tenth Plan.

To make a critical review of the achievements, roles and involvement of the International and other External Support Agencies like the WHO, UNICEF, UNDI World Bank and bilateral donors and define their future roles keeping in view the national policies, objectives and priorities.

The chairman of the Steering Committee for drinking water supply and sanitation (Rural and urban) has been empowered by Govt of India to constitute Sub-Groups and co-opt other member(s) as deemed necessary.

### World Water Day 2005: "Water for Life". Start of the International Decade for Action 2005-2015

The United Nations General Assembly at its 58th session in 2003 proclaimed the years 2005 to 2015 as the International Decade for Action, and called upon the relevant United Nations bodies, specialized agencies, regional commissions and other organisations to deliver a

coordinated response to make “Water for Life” a “decade for action”.

The Water for Life decade sets the world's goals on “a greater focus on water-related issues, while striving to ensure the participation of women in water-related development efforts, and further cooperation at all levels to achieve water-related goals of the Millennium Declaration, Johannesburg Plan of Implementation of the World Summit for Sustainable Development and Agenda 21.”

# Management of Biomedical Waste

Col PS Chawla

## Introduction

Healthcare settings or hospitals are institutions intended to provide medical treatment and care for the ill or the injured. Contrarily, today most of them are increasingly turning out to be potential centres for spreading diseases due to improper biomedical waste management. Its magnitude can be gauged by the fact that in the metropolitan city of Mumbai alone, there are at least 15000 biomedical waste generators. Biomedical waste has been a growing concern because of the awareness in public regarding HIV AIDS and Hepatitis B as a result of exposure to discarded needles, syringes and other medical waste from municipal garbage bins and disposal sites. At the waste dump sites there are several rag pickers trying to salvage any discarded material to sell them and make a living. These rag pickers are exposed to the risk of injuries from contaminated needles and other sharp objects (1). Proper management of biomedical waste is a statutory requirement as per Biomedical waste (management and handling) rules 1998, under sec 6,8, and 25 of the environment protection act, 1986, of the Govt of India(2). The Gazette notification of the Ministry of environment and forests, Govt of India dated 20 Jul 98 lays down the rules in detail. It shall be the duty of the occupier of an institution (Person who has control over the institution and/or premises) generating biomedical waste (including a hospital, nursing home, clinic, dispensary, veterinary institution, animal house, pathology laboratory, blood bank.) to ensure that such waste is handled without any adverse effect to human health and environment.

General hospital hygiene is a pre-requisite for good medical waste management. It will be useless in terms of prevention of nosocomial infections to start improving hospital waste management if the hospital does not have a reliable supply of safe water and basic sanitation facilities accessible to hospital personnel, patients and visitors. Most hospitals in India lack these basic amenities. It is vital that the whole hospital be kept clean and in a satisfactory state of hygiene to prevent spread of infection from patient to patient, patient to health care providers and health care providers to patients. In terms of prevention of spread of infection outside the hospital, careful management of waste from the point of generation to safe disposal is of paramount importance (3, 4).

## Definition of Bio Medical Waste

As per Gazette Notification, 'Bio Medical Waste' means any waste, which is generated during the diagnosis, treatment or immunization of human being or animals or in research activities pertaining thereto or in the production or testing

Table - 1 : Biomedical waste (management & handling rules)

| Category | Type of Waste | Treatment & Disposal Option |
|---|---|---|
| **Category 1** | Human Anatomical Waste (Human tissues, Organs, body parts) | Incineration/deep burial |
| **Category 2** | Animal waste (Animal tissues, organs, body parts, carcasses, bleeding parts, fluid, blood and experimental animals used in research and waste generated by veterinary hospitals). | Incineration/deep burial |
| **Category 3** | Microbiology and Bio-technology waste (waste from laboratory cultures, stocks or specimens of micro-organisms, live or attenuated vaccines human and animal cell culture used in research and industrial laboratories, waste from biological production, toxins, dishes and devices used to transfer cultures) | Local Autoclaving / Microwaving / Incineration |
| **Category 4** | Waste Sharps (Needles, syringes, scalpels, blades, glass etc, that are capable of causing puncture and cuts. This includes both used and unused sharps) | Disinfection (Chemical)/Autoclaving/ Microwaving and mutilation/Shredding |
| **Category 5** | Discarded Medicines and Cytotoxic Drugs (Waste comprising of outdated, contaminated and discarded drugs and medicines) | Incineration/Destruction and disposal in land fills |
| **Category 6** | Soiled Waste (Items contaminated with blood and body fluids including cotton, dressings, soiled plaster, linens, bedding, other materials contaminated with blood) | Incineration/Autoclaving/ Microwaving |
| **Category 7** | Solid Waste (Waste generated from disposable items other than the waste sharps such as tubing, catheters, IV sets, etc.) | Disinfection by chemical treatment/Autoclaving/ Microwaving and Mutilation/Shredding |
| **Category 8** | Liquid waste (Waste generated from laboratory and washing, cleaning , house keeping and disinfecting activities. | Disinfection by chemical treatment and discharge into drains. |
| **Category 9** | Incineration ash (Ash from incineration of any Bio-medical waste) | Disposal in municipal land fills |
| **Category 10** | Chemical Waste (Chemicals used in biological production, | Chemical treatment & discharge into drains |

Source : (1)

of biologicals including categories mentioned in Table - 1.

### Bio Medical Waste Management Planning in the Armed Forces

All health care establishments have to formulate their Bio Medical Waste Management plan as per their needs based on the guidelines given below. Comprehensive instructions on the subject of handling and management of biomedical waste (BMW) have been issued by the office of the DGAFMS and all medical officers should familiarize themselves with the same (4). Simple handbook on the subject, developed by National AIDS Control Organisation (5) and Armed Forces AIDS Control Organisation (6, 7) are also available.

### Organisation Structure

At the highest level, an advisory committee for Biomedical Waste management in the Armed Forces, has been constituted under the DGAFMS. It has representatives from Ministry of Defence, DsGMS from the three services, E-in-C's branch and from other branches.

Similarly at the service HQ, Command HQ and lower fmn HQs, a nodal officer is designated to assist the senior medical staff officer in implementation of Biomedical Waste Management rules.

Commanding Officer of the Hospital and other health care establishments will be responsible for the implementation of the various provisions under the Rules in his establishment. His functions will be :

(a) To make an application for authorization in Form I to the prescribed authority.

(b) To submit Annual Report in Form II by 31 Jan each year.

(c) To report any accident in his establishment in Form III.

(d) To appoint a BMW Management Committee.

(e) Procure all consumables required for the system, including through LP under existing procedures, if the central supply does not materialize.

### BMW Management Committee of the Hospital

The Committee will be constituted as under wherever posted :

(a) Registrar/Senior Registrar - O/IC

(b) Specialist Pathology

(c) Principal Matron

(d) QM/Adm Officer

(e) OC SHO/ Specialist in PSM

(f) JCO I/C sanitation (Equivalent in Navy and Air Force),

(g) Senior most safaiwala / safaiwali

Functions of BMW Management Committee

The committee will formulate a SOP covering the following aspects :

(a) Segregation of the waste at source

(b) Collection storage, labeling, transportation of the waste to the site of treatment and final disposal.

(c) Make an inventory of waste; weight wise and category wise.

(d) Maintain a record of generation, collection, reception, storage, transport, treatment, disposal, handling by using appropriate forms and make the same available for inspection by the prescribed authority.

(e) Increasing the awareness of the rules amongst all pers and bring about an Attitudinal and Behavioral change among the HCE staff for observance of universal precautions and practices on BMW.

(f) Ensure use of protective clothing.

(g) Ensure education of the Health staff and the handlers by holding courses at least twice a year.

(h) To identify, procure, supply the quantity of consumables such as coloured containers, bags, trolleys, syringes and needle destroyers, face masks, caps, protective eye shields, aprons, gumboots, disinfectants etc. for proper management of the waste through central sources or locally, if the former system is disrupted, as per existing procedures.

## Principles of Infection control

The infections acquired in health care setting can be greatly minimised by observing some simple precautions. The broad principles of infection control include the following (6, 7) :

### (a) Infection Control Measures

(i) Each institution should establish an appropriate infection control policy (ICP) and programme. A mechanism should be set up for planning, implementing and monitoring the evaluations of ICP and programmes.

(ii) Hand washing is the most simple and cost effective measure and must be encouraged.

(iii) Disinfectants should be prepared and used according to the guidelines.

### (b) Patients Admission

A patient should not be admitted into a hospital unless it is absolutely necessary and he/she should be discharged as early as possible to reduce the risk of infection.

### (c) Hygienic Environment

Health care facilities should be kept clean and void of virulent organisms by proper house keeping. Cleaning of premises and room floors with water and detergent is recommended. Cleaning with a disinfectant is usually not necessary unless there is spillage with potential infectious material. Architectural design of a health care facility should permit good ventilation. Proper waste disposal, water treatment, disinfection and sterilization of equipment can reduce the risk of infection among patients, health care workers and community. To minimize the spread of infection, it is important that hospitals/health centres and the surroundings remain clean and no waste is spilled anywhere outside or inside

the hospital premises. A clean hospital has positive effects on its patients and its personnel too.

**(d) Monitoring of Infectious Agents**

Microorganisms responsible for infections in health care settings may originate from patients, the environment or health care workers. These sources of infection are to be identified and specific measures must be taken appropriately to prevent their spread.

**(e) Waste Reduction and Reuse**

There is a growing trend in health care settings to provide or use disposable materials in all aspects of work. Some are quite necessary for proper infection control and worker and patient safety. Hospitals should select a mixture of disposable and reusable material depending upon their situation, e.g. General Wards and OPD can use mostly reusable items but casualty departments may incorporate more of the disposable items. More waste means more expense on waste disposal. Reuse not only reduces disposal cost but also reduces procurement cost for medical items (2,3).

## Steps in Waste Management

In brief, the following steps should be followed for waste management. Medical Officers may refer to standard texts for more detailed information (3, 5-9) :

**(a) Waste Survey**

Waste survey is an important component of the waste management scheme. A survey helps in evaluating both the type and quantity of waste generated in the hospital. A survey aims to :

(i) Differentiate the types of waste.

(ii) Quantify the waste generated.

(iii) Determine the points of generation and the type of waste generated at each point.

(iv) Determine the level of generation and disinfection within the hospital.

(v) To find out the type of disposal carried out; and get familiar with the personnel at all levels.

**With this information, it will be easy to :**

(i) Provide specific receptacles for different wastes at different levels of output.

(ii) Determine the type of disinfection needed and the point at which it should be carried out in the waste stream.

(iii) Use the information in hospital specific training.

**(b) Waste Categories**

The Ministry of Environment and Forests has classified hospital waste, which is notified in the Bio-medical Waste (Management and Handling Rules). The categories of bio-medical waste and their treatment & disposal options are appended in Table - 1.

**(c) Segregation and Safe Storage**

(i) Segregation at source and safe storage is the key to whole hospital waste management process Segregation should be carried out at the point of generation, to keep general waste from becoming infectious. If the infectious waste, which forms a small part of hospital waste, is mixed with the other hospital waste, the entire waste will have to be treated as infectious waste which is an expensive option.

(ii) Thus, by segregation, a hospital can :

- Reduce total treatment cost.
- Reduce the impacts of this waste on the community.
- Reduce the chances of infecting health care workers.

(iii) It is essential that all sharps (whether infected or not), infected waste not containing sharps, chemicals and pharmaceuticals other than cytotoxic drugs, and other hazardous wastes are segregated by medical / paramedical personnel and kept separately in readily identifiable, preferably colour coded containers. Radioactive waste, cytotoxic drugs and high pressure containers require special handling and disposal channels.

**(d) Colour Coding and Containers for Disposal of Bio-medical Waste**

Ministry of Environment and Forests has notified the types of containers and their colour codes for storage of different categories of hospital waste as appended in Table - 2.

**(e) Choice of Bins or Receptacles**

(i) Hospital managers may prefer to use plastic or metal bins for waste.

(ii) If reusable containers are to be used, considerable thought should be given to methods of cleaning and disinfecting them. The containers should be smooth and well rounded from inside to allow effective and complete cleaning.

(iii) The size and number of receptacles should be appropriate to the amount of waste produced in the hospital sites.

**(f) Handling and Treatment**

The term treatment, refers to processes that modify the waste in some way before it is taken to its final resting place. Treatment is mainly required to disinfect or decontaminate by chemical disinfection of waste right at source, so that this is no longer the source of pathogenic organisms. After such treatment, the residue can be handled, transported, stored and disposed off safely. The following should be kept in mind while dealing with infectious waste :

(i) Infectious waste must be separated at the point of generation itself.

(ii) Bins with lids lined with polythene bags, or with inner chamber bucket should be used.

(iii) The bins and bags should also be labeled with the biohazard symbol.

Table - 2 : Colour coding for disposal of biomedical waste

| Colour | Type of Container | Waste Category | Treatment Option |
|---|---|---|---|
| Yellow | Plastic bags | Human & animal wastes, Microbial and Bio-technological wastes and soiled wastes (Category 1,2,3, and 6) | Incineration/deep burial. |
| Red | Disinfected container/ Plastic bag | Microbiological and Bio-technological wastes, soiled wastes, solid waste (Category-3,6 and 7) | Autoclaving/ Microwaving/ Chemical treatment. |
| Blue/ White transparent Destruction | Plastic bag/ Puncture proof container | Waste sharps and solid waste (Category 4& 7) | Autoclaving / Microwaving / Chemical treatment, and shredding. |
| Black | Plastic bag | Discarded medicines, Cytotoxic drugs, Incineration Ash and Chemical Wastes (Category 5,9 & 10 [solids]) | Disposal in secured landfills. |
| Green | Plastic Container | General waste such as office waste, food waste & garden waste etc. | Disposed in secured landfills. |

(iv) Personnel involved in infectious waste handling should be provided with suitable protective wear and should be properly trained.

(v) Polythene bags placed in the bins have to be changed with each shift or when they are 3/4th full. They should be sealed/tied at the top whenever the waste is being transported within or outside the hospital.

(vi) Infectious waste needs to be destroyed or disinfected by the recommended methods of disinfection / destruction of the biologically infectious waste such as autoclaving, microwaving and incineration.

**(g) Handling of Disposable Items**

(i) Disposable items like the gloves, syringes, IV bottles, catheters etc. have to be shredded, cut or mutilated. This ensures that they are not recycled/reused.

(ii) Extreme care has to be taken while handling the needles, syringes and blood bags.

(iii) Disposable items should be dipped in an effective chemical disinfectant for a sufficient time or autoclaved or microwaved so that they are disinfected properly.

**(h) Chemical Disinfection**

Chemical disinfection has wide application in small health care facilities. A good disinfectant is bleach. For chemically treating the waste, an optimum concentration of bleach has to be prepared. The concentration prescribed by WHO is 10 gm of bleach in 1 litre of water. However, it must be noticed that medical waste that has been chemically disinfected should continue to be treated as hazardous, unless careful bacteriological testing has shown disinfection to be complete. The bleach solution should be prepared at the beginning of the shift. At the end of the shift or after the bin is full and the waste has been treated with suitable chemical disinfectant, it has to be disposed off. The various chemical disinfectants commonly used are shown in Table - 3.

**(j) Sharps**

Major portion of the sharps are the needles, which can be cut by a needle cutter and contained in a bleaching powder solution or autoclaved and/or shredded or destroyed by a needle destroyer. Precautions in handling sharps are :

(i) All the health workers employed in/outside the hospital must be vaccinated against Hepatitis B.

(ii) All the health care workers should put on heavy duty gloves while dealing with infectious waste specially sharps.

(iii) Sharps should not be left casually on counter tops, food trays or beds as grievous injuries can result.

(iv) Recapping needles should be discouraged. In situations when recapping is unavoidable, the single hand method should be utilized.

**(k) Liquid Waste**

The liquid pathological waste should be treated with a chemical disinfectant. The solution should then be treated with a reagent to neutralize it. This can be flushed into the sewer system.

**(l) Radioactive Medical Waste**

Hospitals providing Nuclear Medicine for diagnosis or treatment of diseases have not only to check for radiation but also to ensure that instruments are properly maintained, proper protective wear is provided, not only to the physicians and other employees of the hospital, but also to the patients.

**(m) General Waste**

(i) The general office waste comprising of the waste papers can be clubbed with other recyclable materials.

(ii) According to the quantity of waste, kitchen waste

Table - 3 : Chemical disinfectants - Chlorine releasing compounds

| Available Chlorine Condition | "Clean" Condition | "Dirty" |
|---|---|---|
| Required Chlorine | 0.1 %, 1g/Litre | 0.5%, 5g/Litre |
| Sodium hypochlorite solution 5% available chlorine | 20 ml/litre | 100 ml/litre |
| Calcium hypochlorite 70% available chlorine | 1.4 gm/litre | 7.0 gm/litre |
| (NaOCl Powder) Sodium dischlorosocyanurate | 1.7 gm/litre | 8.5 gm/litre |
| (NaOCl Tablets) Sodium dischlorosocyanurate | 1 tablet/litre | 4 tablets/litre |

Non-chlorine releasing compounds (used for disinfection of Items which are adversely affected upon by chlorine).

| Name of Disinfectant | Required concentration | Contact period | Used for disinfection of |
|---|---|---|---|
| Ethanol | 70% | 3-5 min | Smooth metal surfaces, table tops, incubators, thermometers |
| Alkaline Glutaraldehyde etc. | 2% | 30 min | Ambu bags, suction tubes/bottles, laryngoscopes, endotracheal tubes, catheters |
| Formaldehyde/Formalin etc. | 3 - 4% | 30 min | Furniture, rooms, walls, blankets, beds, books |
| Savlon | 1% | 30 min | Cheatle forceps. |
| Dettol (chloroxylenol) | 5% | 15 min | Instruments & plastic equipment |

can be utilized in many different ways. In large hospitals, technologies like bio- digestion (vermicomposting) can be installed. In smaller establishments, kitchen waste can be composted.

(iii) Non-biodegradable waste can be disposed off in municipal bins

**(n) Disposal of Biodegradable Waste**

The biodegradable waste is comparatively easy to handle. It should be disposed off after its biodegradation which can be accomplished by Bio-digestion (using bacteria or earth worms or by Pit composting. After complete decomposition it can be used as a biofertlizer.

**(o) Chemical Hazardous Waste**

Hospital also generates a wide range of chemical hazardous waste, which may be segregated and properly managed. Chemical hazardous waste may include : solvents, chemotherapy waste, formaldehyde waste, radioactive waste, heavy metals like mercury used in instruments, other toxins and corrosives and waste anaesthetic gases. Minimization of the waste, careful segregation of these wastes and safe disposal of that waste, which cannot be recycled, is very necessary.

**(p) On-site Transportation**

Segregated waste has to be transported within the facility from the point of generation to the final waste disposal site. All bags should be fastened and small trolleys can be used in large facilities. Hazardous waste, even after decontamination, should never be transported with general municipal waste.

## Technologies for Waste Treatment (2, 4).

Some of the technologies, which are being promoted in India are :

**(a) Autoclave**

An autoclave is an instrument, which uses steam at high temperature to kill all microbes. There are two types of autoclaves :

**(i) Gravity Displacement Autoclaves**

In this system, the air within the autoclave is pushed out by entering steam. This process has a problem. There may be air pockets left within the waste, which is being autoclaved. This reduces the temperature of the waste and therefore reduces the efficiency of the system.

**(ii) Pre-vacuum Autoclaves**

Once the waste is put into the autoclave, a vacuum is created within the autoclave (all the air from the chamber is removed). Steam, which enters the chamber, is able to penetrate the entire waste. Absence of air pockets ensures that high temperature is achieved within the waste, rendering it harmless (Fig-1).

**(b) Microwave**

A microwave system uses high frequency waves. These waves cause the molecules within the waste material to vibrate. This generates heat from within the matter itself. The heat generated is high enough to ensure that all microbes are killed (Fig-2).

**(c) Chemical Disinfection**

(i) Chemical disinfection is cost effective and does not require large investments. In this form of disinfection, a chemical is used to destroy the pathogens.

(ii) Not all medical waste should be treated in this way. Only plastic, rubber and metals should be disinfected. It is not advisable to chemically disinfect cloth based medical waste because it is difficult to handle wet waste and it also adds to the weight and volume of the waste.

**(d) Incineration**

Incineration is the process of burning the solids at very high temperature in a furnace. The temperature in these furnaces is usually high enough to burn even the metals. The furnace is connected to a cline so that the smoke does not pollute the surrounding environment (Fig. - 3). The incineration area must be out of bounds for everyone except those working there.

**(e) Hydroclave**

Hydroclaving is a steam sterilization technology. Hydroclave is a double walled container, in which steam is injected into the outer jacket to heat the inner chamber containing the waste. Moisture contained in the waste evaporates as steam and builds up the requisite steam pressure which sterilizes the waste. The waste material gets dehydrated and reduced in volume

**(f) Plasma Torch Techniques**

The waste is pyrolysed (heated without air) at temperatures beyond 115°C, producing combustible gases and vitreous or glass like rock substance by deploying plasma technology. The residue is suitable for concrete and asphalt construction and the gases may serve as a source of energy.

**(g) Medical Waste Sterilization Unit**

Recommended for garrisons having large hospital bed strengths such as Pune & Delhi.

**(h) Secured landfill**

## Disposal of Disposable Material

| Technologies for treatment of Biomedical Waste | |
|---|---|
| 1. Autoclave | 2. Microwave |
| 3. Hydroclave | 4. Chemical disinfection |
| 5. Incineration | 6. Plasma torch technique |
| 7. Medical waste sterilization unit | |
| 8. Secured landfill | |

The following measures should be taken for disposal of the biomedical waste :-

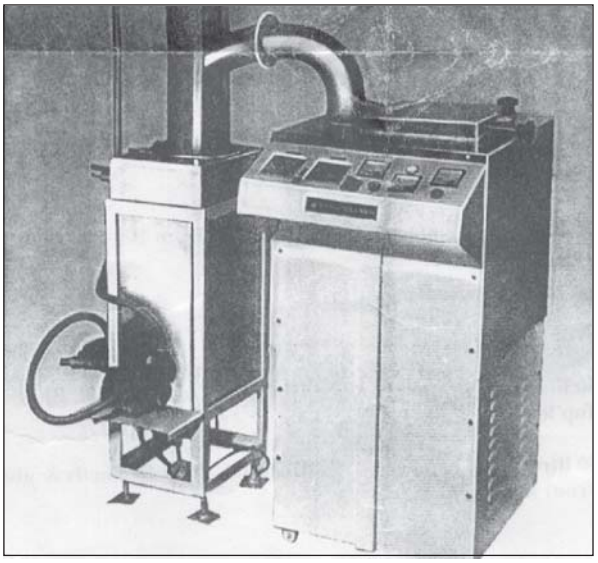
(a) Awareness of the danger of acquiring HIV infection while handling blood and blood contaminated material has resulted in sudden increase in the usage of pre-sterilized disposable material. In most of the hospitals, disposable needles are reused after boiling. This practice must be discontinued immediately.

(b) There is a definite problem of disposal of the disposable material used for injection and for other skin piercing invasive procedures in the hospitals. Further, there is a high possibility that unscrupulous persons may start re-cycling the

Fig - 1 : Autoclave

Fig - 2 : Microwave

Fig - 3 : Incinerator



disposable material resulting in their reuse without even proper sterilization.

(c) Thus, it is recommended that the disposable material should be given high priority by ensuring its destruction and eliminating reuse. Therefore, the following procedure is recommended:

(i) All the disposable material after use has to be accounted for like any other reusable material. This can be achieved by discarding the disposable material in a plastic/metal container and sealing this in the presence of a responsible person. The plastic container for piercing instruments like needles, etc. should be puncture resistant. Plastic breadboxes are suitable for this purpose. Other non-piercing material can be discarded in plastic bags.

(ii) The plastic material such as I.V bottles, I.V sets and syringes can be shredded with a shredder.

Fig - 4 : Biohazard symbol

**Biohazard Symbol**

The biohazard symbol to be used as labels on all containers and vehicles meant for storage / transportation of waste is shown in fig. 4.

**Conclusion**

Consequent to the Gazette Notification, it is now mandatory for all health care facilities to have sound Bio-medical waste management and handling facilities as per prescribed standards and schedules. It may not be possible to achieve all the standards in one go. The aim should be to make improvements and gradually move towards a sustainable system in order to achieve a healthier environment, mind and body.It is time that our service hospitals, who are eminently known for their high standards of hygiene, good maintenance and excellent administration, should take a lead in this vital area of health care. It is also of utmost importance that consideration be given to safe laboratory practices (10, 11). In the Armed Forces, a sound beginning has been made. Large scale research projects have been undertaken on this subject (12, 13) and detailed guidelines (7, 8), as well as administrative instructions (5) have been issued. It now devolves on all Medical, Dental and Nursing Officers and paramedical personnel to ensure the implementation of the guidelines. The Govt of India, through an amendment to the Gazette Notification of July 1998, issued on 17 sept 2003, appointed the DGAFMS as the prescribed authority for enforcing the provisions of the rules for all establishments under the Min of Defence. Medical Officers are therefore advised to go through, in detail, the Gazette Notification (2), as well as the amendment (14).

# Housing

Housing and shelter is a basic human need. However a 'house' means more than a roof over one's head: It means to have a home, a place which protects privacy, contributes to physical and psychological well-being, and supports the development and social integration of its inhabitants a central place for human life (1,2).

### The WHO approach to housing and healthy housing

'Housing' is a comprehensive concept taking into consideration a variety of factors contributing to the quality of housing and housing environment. The Habitat declaration, Istanbul (1996), defines the characteristics of an 'adequate shelter' as "Adequate shelter means more than a roof over one's head. It also means adequate privacy, adequate space, physical accessibility, adequate security, security of tenure, structural stability and durability, adequate lighting, heating and ventilation; adequate basic infrastructure, such as water supply, sanitation and waste-management facilities; suitable environmental quality and health related factors; and adequate and accessible location with regard to work and basic facilities….."(2).

Housing is a complex construct that cannot be represented merely by the physical structure of the home. The WHO understanding of 'housing' is, therefore, based on a four-layer model of housing, taking into consideration the physical structure of the dwelling as well as the meaning of home (for a family and each individual), and the external dimension of the immediate housing environment, and the community with all neighbours (3).

There is considerable evidence that housing conditions do affect health status. Nevertheless, we are still left with the question, "what is healthy housing?"

Housing is the conjunction of the dwelling, the home, the immediate environment and the community. The role of public health is to provide the circumstances under which people can be healthy (4).

## Housing as a determinant of health

An increasing body of evidence has associated housing quality with morbidity from infectious diseases, chronic ailments, injuries, poor nutrition and mental disorders. Some of the health effects of housing are summarized below:

### Infectious diseases

Poor housing standards and lack of basic hygiene facilities like lack of safe drinking water, lack of water for maintaining personal hygiene, inefficient or absent waste disposal systems, easy entry of diseases vectors and rodents, have long been associated with spread of infectious diseases. Overcrowding and poor ventilation are associated with the spread of respiratory diseases and tuberculosis.

### Chronic diseases

While inadequate housing conditions and infectious diseases have long been associated, epidemiological studies in more recent years have shown the relationship between improper/ substandard housing conditions and risk of chronic ailments. For example damp, cold and mould infested houses are associated with asthma, allergies and other chronic respiratory diseases. Houses with entry for mites, roaches, respiratory viruses, moulds have been linked to respiratory diseases.

Living in cold houses has been associated with a generalized lower health status and increased utilization of health services. Recent studies have shown that deviation of indoor ambient temperature beyond a relatively narrow range may be associated with increased risk of cardiovascular diseases. Exposure to toxic substances found in homes can result in chronic health problems. Exposure to ETS (environmental tobacco smoke) and its myriad ill effects are well documented. Volatile organic compounds (VOC) emitted by numerous household cleaning and disinfectant agents, floor coverings etc may be associated with several adverse health effects including asthma and Sick Building Syndrome. Some of the VOCs are known carcinogens. The relationship between lead exposure and neurodevelopment abnormalities is well established, now additional evidence suggests an association with hypertension (5).

### Injuries

Unintentional home injuries are a serious health problem. Dwelling design and maintenance is an important factor related to such injuries. Houses contain physical dangers like gas, electrical fittings, steps, stairs, balconies, breakable glass window panes, unprotected upper storey windows, low railings etc, which pose imminent risks for domestic accidents.

### Mental health

Data gathered from the WHO LARES (Large Analysis and Review of European housing and health Status) shows that people are significantly more depressed and more

Table - 1 : Sources and health hazards of indoor pollutants

| Pollutant | Sources/types | Health Hazard |
|---|---|---|
| Respirable particles | Tobacco smoke, smoke, stoves, biomass fuel etc | Respiratory tract disorders |
| Carbon monoxide, Nitrogen dioxide, Sulfur dioxide, Carbon dioxide | Combustion | Respiratory tract disorders |
| Volatile organic compounds | Cleaning materials, solvents Types: Formaldehyde, benzene, toluene | Asthma, allergies, mucosal irritation, carcinogens |
| Radon and daughters | Building material | Carcinogens |
| Asbestos | Insulation, fireproofing | Asbestosis, Carcinogens |
| Biological hazards | Bacteria( Legionella, Mycobacterium), viruses and fungi (moulds),pests (cockroaches, mites ,bedbugs, rats) | Airborne infections, asthma, infections |

anxious when they live in a dwelling that is overcrowded, has inadequate ventilation, does not offer adequate protection from noise, dampness, moulds etc. (2). Studies have demonstrated a consistent association between mental disorders and urban living conditions. Though alcoholism, vandalism, adolescent delinquency, schizophrenia etc, may not be caused by bad housing alone, and are symptoms of more complex social pathology, it is also accepted that stressful housing conditions can aggravate pre-existing psychiatric pathologies. Finally, indoor exposure to toxic compounds (i.e. heavy metals, solvents) may lead to neuropsychiatry disorders.

### Neighborhood health effects

Besides the conditions of the housing unit, the immediate neighborhood is also documented to have health effects on the inhabitants. These include increased rates of intentional injuries, poor birth outcomes, cardiovascular diseases, STD, depression, physical inactivity and obesity. Several features of the neighborhood may contribute towards ill health. The air quality may be poor due to proximity to major highways or roads, improper waste disposal in the neighborhood, absence of green spaces and walking areas may promote physical inactivity and obesity. Several social dimensions of neighborhoods also affect the health of the inhabitants (6).

### Built environment and health

The built environment encompasses all buildings, spaces and products that are created or modified by people. It includes our homes, schools, workplaces, parks, industrial areas, farms and roads. The built environment not only impacts indoor and outdoor physical environments (e.g., climatic conditions, indoor and outdoor air quality), but it also affects social environment and subsequently our physical health and quality of life. Recent research has explored the effect of built environment on physical activity, asthma, obesity, cardiovascular diseases, lung cancer mortality and mental health. These complex diseases are attributable to an interaction of genetic and environmental influences and many of the later can be directly connected to the built environment.

### Housing in special situations

The criteria of healthy housing have been laid down by several agencies and are updated form time to time. Housing and health: 'APHA-CDC Recommended Minimum Housing standards' sets the specific standards as related to basic facilities and equipment. The 'WHO Health principles of Housing' throws light on the wide range of behavioral factors that can influence health in relation to housing conditions. In India certain standards have been laid down, and have been enunciated in the recent document on Indira Aawas Yojana for housing for the poor. However none of these standards are legally enforceable, and can only be used as guidelines (2,3, 7).

### Housing in urban slums

In the last few decades with increasing urbanization, there has been a great increase in the number of people staying in peri-urban or urban areas in slums or shanties. These dwelling are not only highly substandard but they often lack basic sanitation, access to clean water supplies, medical care and other basic services. The proportion of people residing in such situations ranges from 20 to 80 percent in most cities through out developing nations like in South, South-east and South-west Asia, Africa and Latin America.

### Housing for the displaced populations

Short-term shelter in existing buildings

In many situations, people may independently seek shelter in buildings such as schools, community centers, offices, sports facilities, and even railway carriages and wagons. Such buildings are often also used for organized short-term evacuation centres. The evacuation centre should be as close as possible to the neighborhood or rural community concerned, but far enough from the disaster site to avoid secondary hazards. Buildings should be thoroughly inspected for structural damage. They

should have running water and toilets. Military barracks or school buildings are usually better equipped for large numbers of people. It is important that these accommodations are only used for a short period, and that they are cleaned and maintained intensively, to avoid a rapid deterioration in environmental health conditions.

As per guidelines on temporary shelters (8) : People sleeping on beds or mats should have a minimum of 3.5 $m^2$ of floor area or 10$m^3$ of air space. Beds or mats should be separated by a minimum distance of 0.75 metres. Smoking and the use of cooking fires in the shelter should be strongly discouraged.

To avoid very high temperatures in hot climates, buildings can be modified to increase shade, ventilation and thermal capacity. Buildings should have emergency exits and fire escapes; the flues of stoves / *bukharis* used for space heating should extend outside the building. Clear instructions on fire hazards and safety practices should be made and group of volunteers from among the survivors should be taught about the possible fire hazards and trained in the use of fire-fighting equipment.

Access to sufficient water for drinking, cooking, and personal and domestic hygiene should be provided. One wash basin should be provided for every 10 people or 45 metres of wash-bench for every 100 people; there should be separate benches for men and women, and waste receptacles at each bench. One shower head is needed for every 50 people in temperate climates and one for every 30 people in hot climates. Floors must be disinfected daily.

Arrangements must be made for human waste disposal. Water-flushed toilets may be available in existing buildings if the water supply has not been interrupted. Outside latrines should be located within 50 metres of the building, but at least 20 metres away from the kitchen, dining hall and water supply.

One refuse bin of capacity 50-100 litres should be provided for every 12-15 people. The bins should have tightly fitting lids. Special arrangements for the collection of refuse may be needed if the normal collection service is interrupted.

If existing buildings are not available

One possibility is to use tents or makeshift shelters made of plastic sheets, tarpaulins, or local materials, such as palm thatch, in a secure location where water, sanitation and food can be provided. The site should be free of vector habitats for diseases like malaria (8).

The topography of the land should permit easy drainage and the site should be located above flood level. Rocky, impermeable soil should be avoided. Land covered with excessive vegetation can harbor insects, rodents, reptiles, etc., and should be avoided or cleared. Ideally, the site should have a slope of 24% for good drainage, but not more than 10% to avoid erosion and the need for expensive earth-moving for roads and building construction.

Areas adjacent to commercial and industrial zones, exposed to noise, odours and air pollution should be avoided. Areas sufficiently close to blocks or rows of shelters should be identified for sanitation and waste management. The residential area of the camp should face the prevailing wind to avoid odours from latrines. Temporary camps for refugees should hold no more than 10000-12000 people, or should be subdivided into independent units of no more than 1000 people.

Drainage ditches should be dug around the tents or other shelters and along the sides of roads, especially if there is a danger of flooding. Care should be taken to lead water away from shelters, latrines, health centres, and stores. Persistent areas of stagnant water that are difficult to drain can be backfilled, or covered with polystyrene balls or a thin layer of oil, to control insects. Water points should also have adequate drainage to avoid mud.

Shelters should be arranged in rows or in clusters of 10-12 on both sides of a road at least 10 metres wide to permit easy traffic flow and access by ambulances or firefighting vehicles. In tented areas, there should be at least 2 metres between the edge of the road and the tent pegs. Shelters should be spaced 8 metres apart so that people can pass freely between them without being obstructed by pegs and ropes. A separation greater than 8 metres may lead to open-air defecation and should be avoided.

Shelters may be tents or prefabricated units, or may be built out of plastic sheeting together with timber, stone and thatch. Where plastic sheeting is used, it is common to provide one piece, 4 metres by 6-7 metres, per household.

No one should have to walk more than 500 metres to a water point, and there should be at least one water point for every 250 people.

Latrines or other facilities for excreta disposal should be provided (at least one toilet per 20 people), and gradually improved as time and resources allow.

Separate accommodation is necessary for unaccompanied children, with provision for adults (welfare staff and/or community volunteers) to stay with them; there should be at least one adult per shelter or room. These children may be very disoriented and frightened, and may also have special nutritional needs. The shelters should be situated near the nutritional rehabilitation centre and field hospital, and as far from sources of secondary hazards, noise and contamination as possible.

In conflict and famine related disasters, many people may be suffering from malnutrition and debilitation when they arrive, so specialized services such as intensive or therapeutic feeding may be needed. Intensive feeding or nutrition rehabilitation units should be provided with up to 15-30 litres of potable water per bed per day. Also, special care needs to be given to latrines and other waste-disposal facilities used by parents, children and staff. Means for hand-washing by all staff and parents concerned with child feeding are also important.

## Housing in the Armed Forces

Housing in the Armed Forces has its special considerations for the reason that the forces tend to be frequently on the move and may require to leave one area to occupy another or may at times have to reside in inhospitable terrains for very prolonged periods.

Quartering of the service personnel should be analyzed with respect to permanent accommodation in family stations and accommodation in field areas. While guidelines and recommendations on standards of housing may be adhered to for the living accommodation in peace / family areas, the same may not be possible during operations/ exercise locations. During operations/ exercise/ move etc, priority is given to safety of troops. Improvisations for comfort only follow after ascertaining the safety from the operational point of view. Often, due to operational requirements troops have to stay in compromised living conditions.

**Temporary accommodation for troops**

Accommodations for troops when they move out of their military camps usually include the following: Bivouacs, trenches, dug outs, bunkers and tents. While most of them are meant as a temporary measure, however at times, troops may have to occupy these for months on end.

Bivouac

A bivouac is a temporary, overnight shelter used during emergency, when troops are on the move / in an operational area. These provide very scanty shelter, usually in the form of a ground sheet stretched overhead.

Trenches, Dugouts, Bunkers

These are defensive fortifications. Bunkers are mostly below the ground. In certain areas massive bunker complexes were built to house strategic infrastructure as well as troops and stores. There are several types of bunkers like the trench bunker, pillbox bunker, industrial bunker and personal shelter bunker. The basic plan of a bunker is to provide a structure that can withstand physical compression. A bunker should deflect blast waves from explosions to prevent internal injuries to people sheltering in the bunkers. In the present scenario of nuclear warfare, the bunkers must also provide radiation protection. Technical expertise is provided by the Corps of Engineers during construction of these bunkers. However, factors which influence the health of the troops, like ventilation, protection from heat, cold, wind, snow etc, must be given due consideration. Prolonged occupation and maintenance of sanitation in bunkers, trenches and dug outs present difficult problems and are tiring for the physical and mental health of the troops.

Fig - 1 : TEFS (Tent Extendable Frame Supported

Tented Camps

Tented camps are usually of a temporary nature, but due to tactical, administrative, logistic and economic reasons, they may be protracted over longer durations. Various improvisations may have to be introduced to decrease the discomfort and health hazards to the troops. Ventilation, overcrowding are problems commonly associated with tented accommodation. Presently, use of TEFS (tent extendable frame supported) is common in the Armed Forces. After first appearing during the Second World War, these tents have through the years evolved into Extendible Modular types that have become widely acknowledged the world over as the most practical alternative shelters in times of unrest. Furthermore, Extendible Frame Supported Tents can today adapt many special requirements such as vehicle maintenance, field kitchens and mobile hospitals to the original standard modular tents. As far as possible, only authorized strength of persons should use the tents, four persons in the four man tent and two men in the two man tent. Modular shelters, fibre glass huts and various other prefabricated shelters are now in use. However, in all such shelters, problems of overcrowding and improper ventilation continue to worry the medical authorities. Risk of carbon monoxide poisoning and fire hazard are relevant concerns in high altitude living arrangements.

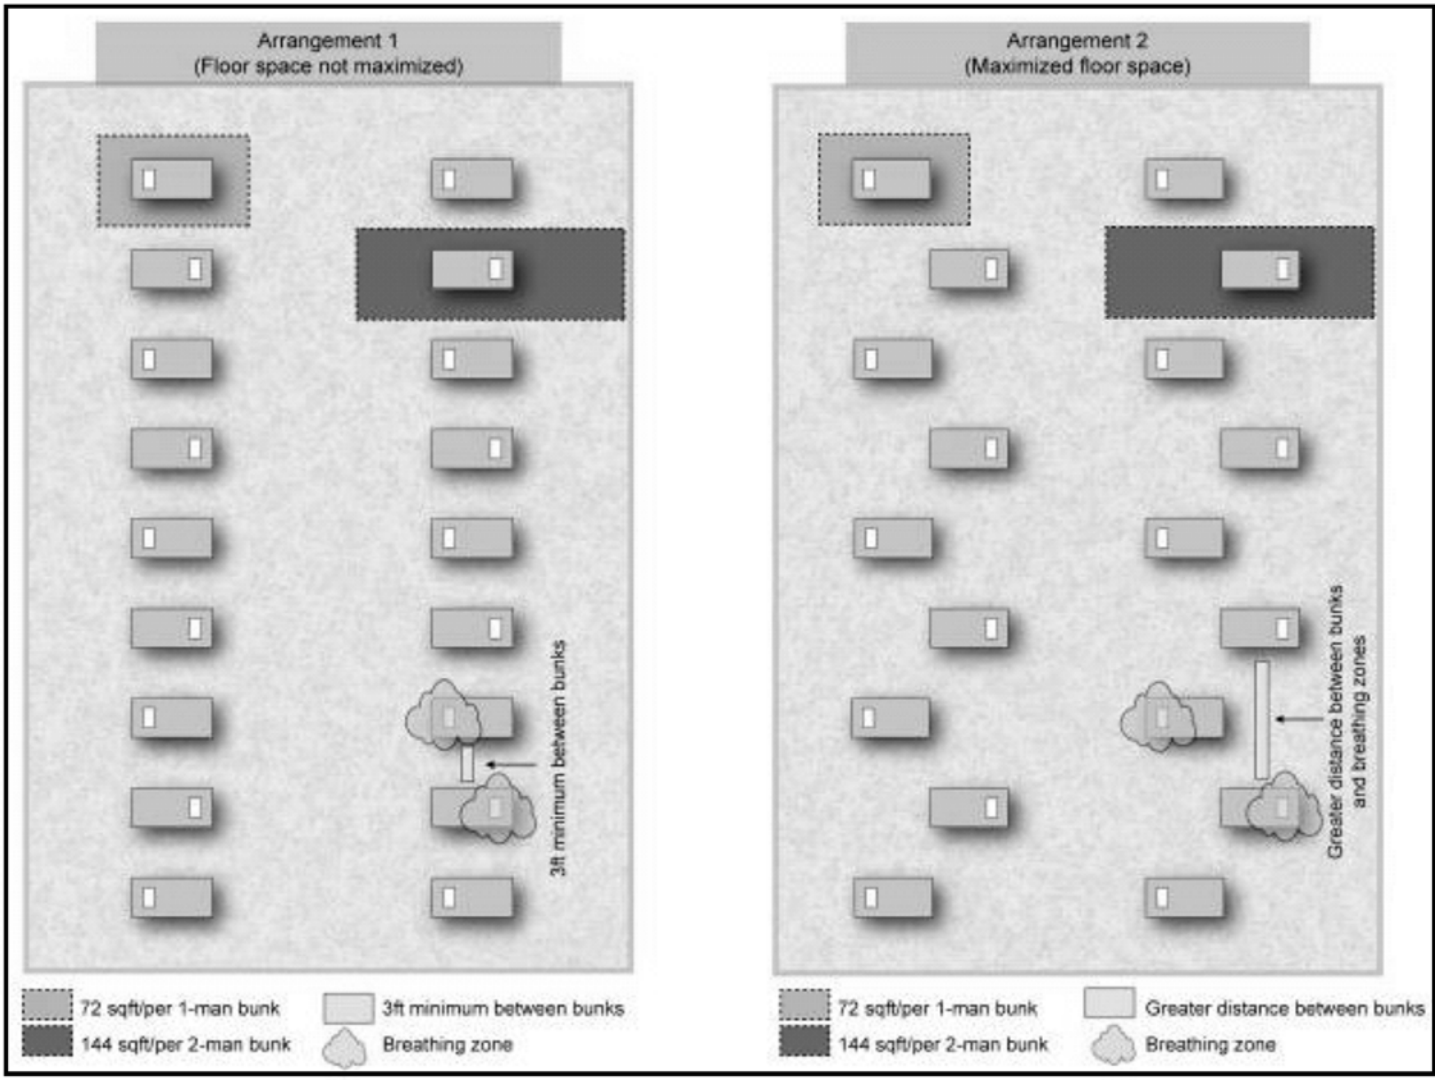
**Permanent Accommodation**

In cantonments, garrison stations and in peacetime, accommodation for single men is provided in permanent barracks. The primary consideration here is 'the health and comfort of troops' and this outweighs any other consideration. In general, married accommodation available for troops falls short of requirement. The commanding officer should ensure equitable allotment of such accommodation at his disposal so as to permit the personnel to bring their families by turn. Due to the shortage of married accommodation in most of the military stations, outliving or living under own arrangements (or CILQ) is usually resorted to, to enable the soldier to live with his family. The commanding officer of the unit is responsible for ascertaining that the hygiene, sanitation and other aspects of the accommodation proposed to be used by the service personnel is satisfactory, and periodic checks are also ensured by the unit rep to ascertain the living conditions from time to time. Scales of accommodation for the various ranks in the Armed Forces is given in Appendix (10).

Minimum prescribed standards

The housing for single men in the Armed Forces is unique in that a large number of people share the accommodation and are in close contact for a large period of time. Prevention of infections and diseases in such setting prompts the requirement for prescribing certain standards for 'healthy living space'. These standards may also prove to be useful in other circumstances where people may have to live in close contact like refugee camps, prisons, correctional centers, boarding schools,

Fig - 2 : Method for optimising floor space utilisation



tourists or pilgrim's camps etc. It may be in barrack, hut, bunker, basha or tent; principles applicable to one are applicable to all types of accommodation.

### Per person space requirement

The space allowed per individual in a barrack is a minimum 2 metres of linear wall space, 5 metre² of floor area and 18 metre$^3$ of air space with the exclusion of any height above 3.6 metre. The distance between centers of two adjacent beds / bunks should not be less than 1.8 metres, but during exigencies of service, these scales may have to be reduced after a medical review. The US Army in its technical bulletin on non-vaccine recommendations for prevention of acute infectious respiratory diseases among army personnel staying in close quarters has recommended 72 feet$^2$ of floor space per person with at least 3 feet between adjacent beds to minimize disease agent transmission. In all forms of accommodation, whether permanent, temporary or even in tents, this minimum space should be ensured. At times, overcrowding in the barracks becomes inevitable, as is usually seen in some regimental centers. Given below in an illustration of a method of optimizing floor space utilization, while allowing maximum space between the beds (Fig. 2).

### Ventilation standards

Various standards of ventilation have been prescribed by different workers. Ventilation is usually measured in cubic space, air change or floor space. The accepted standards are 1000 to 1200 feet$^3$ cubic space per person and 50 to 100 feet$^2$ floor space per person. However more subjectively, it is usually said that at 0300hrs in the morning, if no musty or unpleasant odors are perceived inside the barrack/ room, the ventilation is satisfactory. For ensuring adequate ventilation, the total window space should not be less than 1/10th of the total floor space and cross ventilation should be maintained.

### Temperature and Humidity

Though temperature and humidity are both perceived to be matters of personal comfort, both these factors are associated with health symptoms. High humidity can support the growth of fungus, moulds, mites etc. The

Occupational Safety and Health Administration (OSHA) recommend maintenance of indoor temperatures in the range of 68-76°F and humidity levels of 20-60%. However, these are only recommendations and not guidelines.

### Housing and public health

The notion of housing as a public health issue is not new. Attention has been directed towards housing and related facilities in response to outbreak of infectious diseases from time to time (e.g. Cholera in New York City in 1830s). In the early 1800s the relation between housing conditions and health was recognized among public health practitioners in the United States and Europe and several corrective reforms towards healthier housing facilities were also initiated. The eight essential components of primary health care as outlined by the Alma Ata Declaration included basic sanitation and thus encompass the housing conditions of the people. Current public health efforts to improve housing conditions include a focus on the basic and established aspects of health and housing as well as new strategies based on emerging issue and newer research. The WHO has a health and housing program and carried out periodic surveys aimed at comprehensive understanding of health and housing. In India the National Family Health Survey collects data on the housing condition of people. The data from NFHS-3 (2005-06) shows that only about 26% of rural India live in pucca houses, with only 28% having access to piped drinking water and 26% have access to toilet facilities (11).

### Housing and the government policy

Housing is a State subject but the Union Govt. is responsible for the formulation of policy with regard to programmes and approaches for effective implementation of the social housing schemes, particularly those pertaining to weaker sections of the society. The National Housing Policy is enunciated in the Five Year Plan and the State Govts implement the schemes in accordance with the plan priorities and local requirements.

In tune with the policy of the Government, a National Policy on Housing, taking into account the development on national and international scene on Shelter Sector has

# Environmental Sanitation

## Introduction

Environment, according to the present day concept, is no longer restricted to the traditional field of physical and biotic realms comprising visible, tangible and the inanimate aspects of man's surroundings but also encompasses the sociocultural setting fashioned by him. The physical environment comprises on one hand the natural factors like the topography, atmosphere, water, soil, climate, light, radiation and on the other hand the artificial human innovations, such as housing, clothing and air-conditioning created for his adaptation to the natural environment. The biological environment means the universe of living things, which surround him. The living things are the plants, animals, rodents, insects, microbes, helminths, viruses and so on. Social environment is represented by people, their activities, interrelations, culture, traditions, customs, habits, beliefs and standard of living.

Man, in his endeavour to support his biological, cultural and technical needs, is constantly altering the environment and also creating new environments, which are often inconsistent for healthful living. The environmental problems faced by man today are due to the widening gap between the technical developments and the abilities of his institutions to adapt to them. Development and population growth are much more rapid now than they were a century ago; and in many of the countries now undergoing development, the tropical, climatological and ecological characteristics add further difficulties. In addition to the creation of artificial human innovations and efficient management of air and water pollution, the control of physical environment includes safe disposal of human, animal, plastic and electronic wastes.

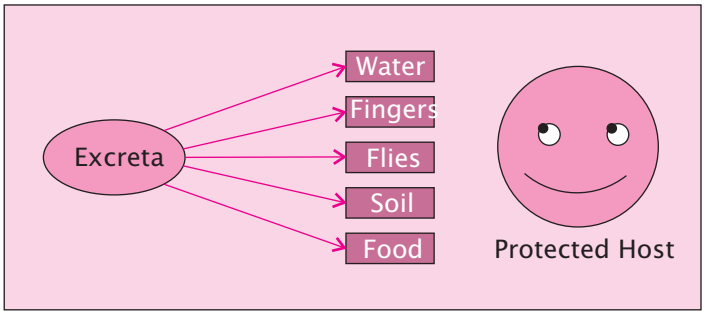
"Sanitation" refers to all conditions that affect health, especially with regard to dirt and infection and specifically to the drainage and disposal of sewage and refuse from houses (The Concise Oxford Dictionary). At its first meeting in 1950, the WHO Expert Committee on Environmental Sanitation defined environmental sanitation as including the control of community water supplies, excreta and wastewater disposal, refuse disposal, vectors of disease, housing conditions, food supplies and handling, atmospheric conditions, and the safety of the working environment. Environmental problems have since grown in complexity, especially with the advent of radiation and chemical hazards. Meanwhile, the world's needs for basic sanitation services (i.e., drinking-water supply, excreta and wastewater disposal) have greatly increased as a result of rapid population growth and higher expectations. This led to the designation by the United Nations of the International Drinking Water Supply and Sanitation Decade (1981-1990).

> Environmental sanitation deals with control of Physical environment (safe water supply, waste disposal, and housing) for prevention of diseases.

### Sanitation Barrier

The sanitation control which aims at interruption of transmission cycle of the disease agent from the reservoir to the new host can be achieved at several levels such as segregation of excreta and wastes, protection of water supply, protection of food and drinks, control of flies and the practice of personal hygienic measures. The most effective measure out of all these would be segregation of excreta and arrangement for its proper disposal so that the disease agents do not get a chance to reach the new host. The sanitation barrier (Fig. 1) in the simplest way can be provided by a sanitary latrine and a disposal pit.

Fig - 1 : Sanitation Barrier



### Waste

Waste is an unwanted or discarded material which may not be of any use to an individual who is throwing it but it may be of use to someone who may reuse it or recycle it. **Built of industrial waste and thrown-away items, the Rock Garden in the city of Chandigarh is perhaps the world's most poignant and salient statement of the possibility of finding beauty in the unexpected and accidental.** In India a number of people eg rag pickers and Kabadiwalas are earning their livelihood by retrieving articles from waste and they should be effectively utilized in waste management.

### Significance of Waste Disposal

Poor sanitation is known to increase the risk of morbidity and mortality from diarrhea among children. Several studies have found a high correlation between childhood morbidity and availability of sanitation services. It has been estimated that 1.7 million deaths each year, or 3.1% of all deaths are attributable to inadequate access to water, sanitation and hygiene[1]. Waste collection and disposal assume significance primarily on two fronts-public health and socio-economic. The Governments across the globe have understood the need for providing improved sanitation and have committed themselves at the "Millennium Declaration" to undertake measures to provide sanitation services particularly to the urban poor population [Millennium Development Goal-7; Target-11;

Indicator-31][2]. The significance of waste disposal is further discussed below :

(a) Public Health Aspects

Human excreta are the principal source of pathogenic organisms, which are transmitted through the various channels stated already. Diseases of special significance such as the enteric group of infections including cholera, typhoid, dysentery, diarrhoeal diseases and viral infections are the leading causes of death in developing countries, which comprise more than two-third of the world's population. Food crop contamination through insanitary irrigation practices and soil contamination by helminths including ascaris, enterobius and hook worm result in many morbid conditions. Breeding of *Culex fatigans* in standing pools of wastewater causing widespread filariasis is a serious hazard.

(b) Socio-economic Aspects

The socio-economic benefits of waste disposal are difficult to measure in quantitative terms. A lack of adequate sanitation measures means perpetual discomfort, fight against diseases, a sense of being unwell and consequently loss of productivity and mounting cost of health care for the community.

Improper disposal of biodegradable waste can spread diseases and pollute the environment, while waste management in environment friendly manner will not only prevent diseases but will give bio-fertilizer and methane gas for

**Waste Disposal versus Management**

Disposal means to get rid off. Since waste is not considered useful it is tried to be disposed by easiest mean or without wasting any money or time. People require to be educated regarding the usefulness of waste as well as the hazards associated with improper disposal of waste. Term waste disposal should be replaced by the term waste management so that the waste can be managed in a manner that money spent on handling / treatment is recovered (for example disposal of human excreta / animal excreta / biodegradable kitchen waste by biogas plant gives biogas for cooking purpose as well as manure for agricultural purposes).

**Classification of wastes**

For convenience of disposal, wastes may be grouped as under:

(a) Human excreta - faeces and urine.
(b) Animal excreta -cattle and horse dung.
(c) Dry refuse and garbage-household, municipal, and agricultural.
(d) Liquid wastes-household sullage.
(e) Dead animals, carcasses and offal of slaughtered animals.
(f) Electronic waste
(g) Biomedical waste

**Principles of Waste Management**

Following points needs to be considered :

Local bodies should adopt all the three approaches (Service, education and legislative) for efficient

(a)People to be educated to generate minimum waste.
(b)People to be educated to recycle or reuse packing material.
(c) Waste to be disposed in environment friendly manner.
(d) Waste to be disposed in a manner to retrieve biogas and manure.

**Integrated Approach for Waste Management**

Waste to be managed by a integrated approach by providing services to the people in terms of toilets, urinals or public bins etc., by educating the people regarding hazards of improper disposal of waste and enforcing legislation if people do not comply with rules and regulation.

**General Principles of Waste Management in the Armed Forces**

The methods of waste management in armed forces to be employed depend on the length of stay in any particular place. For convenience, Armed Forces camps are grouped as permanent, semi permanent and temporary camps. Permanent camps are occupied for a year or longer; they include cantonments, garrisons, base camps, large camps on the Comn Z, and so on; semi permanent camps are occupied for less than a year and more than six days. Temporary camps are occupied for six days or less. This grouping serves as a guide only and no hard and fast rules can be laid to distinguish the various kinds of camps. Moreover it should always be kept in mind that a particular camp can be required to be occupied for a more prolonged period than initially expected. Thus a temporary camp can become a permanent camp, and a semi permanent camp can become a permanent camp, garrison or even a cantonment. Generally in permanent camps, cantonments and in garrison stations where water carriage system of faeces disposal or other efficient systems of conservancy, sullage and refuse disposal exist, latrines and other sanitary conveniences are usually located from the point of view of users' convenience. In semipermanent and temporary camps, latrines and refuse disposal should be concentrated in a well defined circumscribed sanitary disposal area so as to facilitate efficient supervision of the working, even at the expense of the convenience of the users to some extent. However, the latrines should be as close as possible to men's living quarters, commensurate with the need for efficient supervision and working. The sanitary area should be clean and tidy; on the leeward side of the camp; away from the water supply points and cook houses; protected from rains and allotted according to the existing scale to units and subunits.

Responsibilities

The local Commander is responsible for the health and comfort of his men. Maintenance of the latrines and all other sanitary installations and appliances, detection and rectification of sanitary defects, and obedience of orders regarding sanitation are, therefore important responsibilities of the unit administration. The unit sanitary squad should carry out all these duties under the

supervision of the unit hygiene and sanitation officer. The officer should make a routine inspection at least once a day. Advising the local Commander on matters of health of the troops, prevention of ill health, and healthy living and working conditions is the responsibility of the medical officer. These duties should, therefore, oblige him to visit from time to time the latrine areas and unit lines and observe the state of unit sanitation and hygiene and make recommendations to improve them. He is also responsible to train and guide the unit hygiene and sanitation officer and the sanitary squad. For this purpose he can get assistance from the sanitary staff of the medical organization and the technical staff officer at the formation HQ

## Disposal of Human Excreta

A detailed description of all these methods of excreta disposal, which is in practice in different parts of the world, is beyond the scope of this manual. Only those ones, which are popular in the Armed Forces establishments in India, will hereafter be briefly discussed. Standard textbooks should be consulted for details (3, 4). Reference No 4 is generally accepted as a standard referral by MES authorities also. Disposal of excreta Can be divided in four groups

(a) **Temporary camp:** Shallow trench latrine, sanitary latrine based on improvised and removable Indian type sanitary water closet, incinerator latrine

(b) **Semi-permanent camp :** Deep trench latrine, Improvised deep trench latrine, dug well latrine, ventilation improved pit latrine ,Pour flush water seal latrine

(c) **Permanent camp :** Sewerage system, Combination of septic tank and soakage pit/subsoil irrigation, oxidation pond, biolatrine, Aqua farming

(d ) **High altitude:** Temperature controlled bio-digester

### Temporary camps

(a) Shallow Trench Latrines

STL has a problem of smell and fly breeding which can be overcome by educating the users to cover the excreta after defaecation

These are used strictly as a temporary measure only when the deep trench latrines cannot be constructed. Each trench is 90 cm long, 30 cm wide and 60 cm deep. Trenches are dug in parallel with an interval of at least 60 cm in between two trenches (Fig. - 2). The earth removed should be neatly piled at its head end. The trench is used by squatting astride it, with a foot on either side and not both feet on the same side. After defaecation the excreta must be covered by earth with a scoop. Fly breeding occurs if this is neglected. The latrine area must be policed by a member of the unit sanitary squad to ensure that each user carries out these instructions. After 24 hours, faeces should be covered with a 3 cm layer of slaked lime and trenches should be filled with earth. A new row of trenches is immediately dug in front of the previous day's row. While leaving the camp, the earth should be well rammed down, the whole area and the ground up to 1 m all round sprayed with the insecticides and the area suitably marked 'L' so as to indicate the ground as unusable by any unit camping thereafter.

(b) Sanitary latrine based on improvised and removable Indian type sanitary water closet

Although STL are easy to construct as well as are not costly but are hardly used by the troops due to smell and fly nuisance. By fitting a plastic or stainless steel Indian type of water closet on metallic sheet enforced wooden platform which can be placed on a trench and subsequently removed, a sanitary latrine can be constructed which will be aesthetic also and not have the problem of smell, fly breeding and non- utilization .

(c) Incinerator Latrine

It may be used in sandy desert, loamy or arid lands by small detachments for short periods. A shallow trench with dimension as given in Fig. - 3 is dug. Ghee tin 'A' has its bottom perforated top removed and corners cut and the sides bent outwards so as to receive the bottom of tin 'B'. The tin 'B' with its top and bottom removed is then placed in position projecting 15 cm above the ground level. The remainder of the trench is filled up to the level of the base of tin 'B' with stones Tin 'C' with its bottom perforated and the top 15 cm of its side adjacent to tin 'B' cut way is then placed in position. The top 15 cm of the side of tin 'B' adjacent to tin 'C' is cut and bent over to grasp the cut side of tin 'C. A fly proofed wooden seat battened with strips of wood on its under surface is then placed in position so as to fit tightly over the tins BC. Faeces fall into tin AB and urine into 'C' to soak into the small soakpit beneath. The seat must be kept clean. The faeces are burnt twice a day by pouring a small quantity of mixture of petrol, kerosene and sump oil and igniting after removing the seat. This latrine lasts for a fortnight for ten men. When the contents are 15 cm from the top, the seat is removed and the final burning is carried out. A sandbag soaked in oil is placed on top, the flap of tin 'B' is bent backwards and the remainder of tin 'B' is then filled with sand/earth and well packed. No flies can either enter

Fig - 2 Shallow Trench Latrine

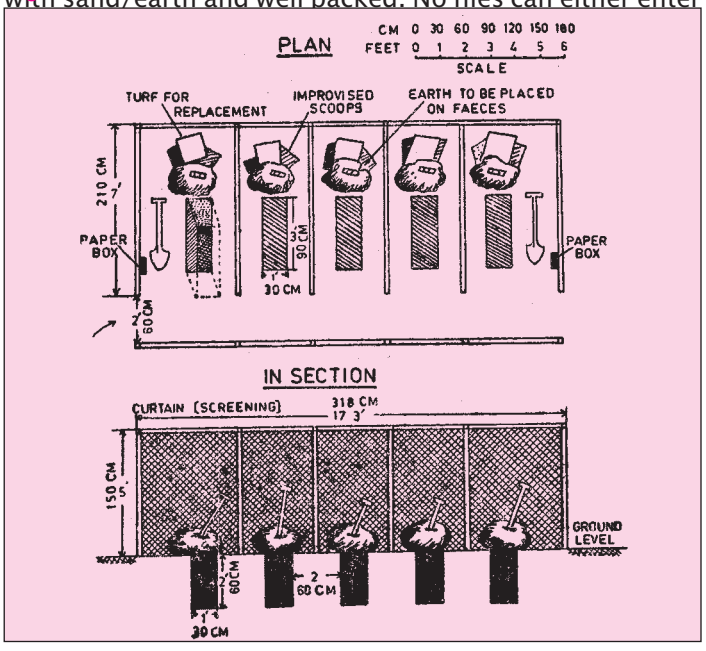


Fig - 3 : Incinerator Latrine

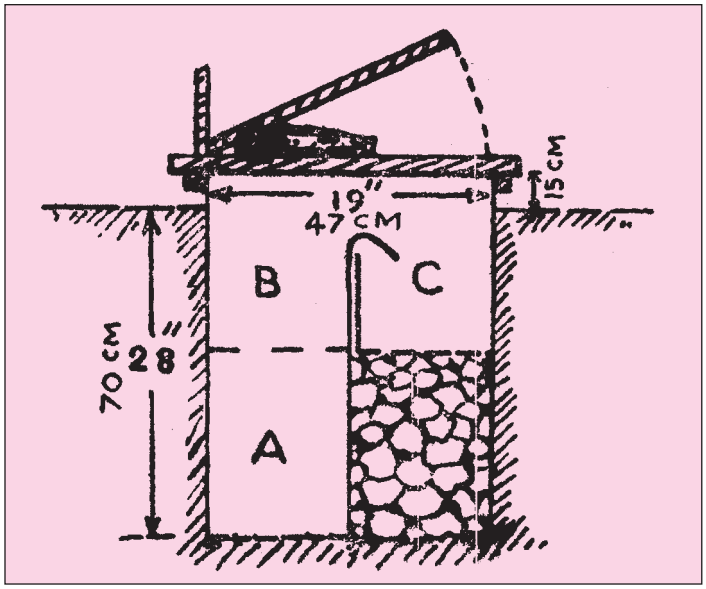


**Semipermanent camps**

In semi permanent camp human excreta can be disposed by deep trench latrine, improvised deep trench latrine, sanplat latrine, ventilation improved pit latrine, pour flush water seal latrine. Normally 5 seats per latrine are constructed at the scale of 10 percent of the strength of unit/subunit.

**Construction details of Deep Trench Latrine**

Broad details of the construction of DTL and its maintenance are given hereunder step by step. Unit sanitary personnel should be trained in proper construction and maintenance of the DTL with understanding of the rationale (Fig. - 4).

(a) The standard trench is 1 m wide, at least 2½ m deep and 3 m in length, or of the length of the superstructure available. If any danger of sides collapsing is envisaged, they should be riveted with bamboos, sandbags or wire netting. If sandbags are used the width should be 1.3 m. It should not reach the subsoil water level for chances of contamination of subsoil water level. If the subsoil water level is high, an increased depth may be obtained by building a mud bank upto one meter high all around the trench. This bank is riveted on both its internal and external faces with interlaced bamboo.

(b) The ground upto one metre around the trench is then dug to a depth of 10 cm and the loosened earth is removed. Strips of oil-soaked sacking, each 1½ m wide, are then spread over this dugout area with the inner edges hanging down to 15 cm over the sides of the trench and secured in position with small wooden pegs. The outer edges are sunk into the ground along the outer edge of the dugout area.

(c) Required numbers of joists (4 or 5) are placed over the trench, overlapping its edges by 60 cm to support the superstructure.

(d) The fly proof wooden superstructure made as described below is then placed over the joists so as to overlap the edges of the trench by 10 cm.

(e) The squatting type of superstructure should be flat as a table top, made of tongued and grooved timber, and its under surface completely covered by a double thickness of oiled sacking snugly tucked to the wood, except at the lidded squatting apertures.

(f) Each aperture should be 36X25 cm, with a distance of 30 cm from the next one and fitted with a hinged lid.

(g) The lid should overlap the aperture by 5 cm all round. It should be covered on the under surface with a double layer of oiled sacking. A device for opening without touching it with hands should be provided.

(h) The loose soil removed from around the trench is then mixed with heavy oil, replaced in the dug-out area around the trench on the top of the sacking and joists, and rammed down to form a hard impervious layer. Flies likely to hatch out inside the trench are trapped beneath the sacking while trying to reach the surface after emergence from their pupal cases.

(j) A flytrap may be constructed at one end of the trench.

(k) A shallow drain with a soakpit at its end to stop storm water from entering the trench is made all round the latrine.

(l) An overhead shelter must be provided as protection against rain and the sun. Partitions should be interposed between seats.

(m) Maintenance should be carried out as under :

(i) The superstructure must be maintained fly proof by replacing all wrapped lids, by caulking all cracks with oiled sacking and by replacing all torn sacking.

(ii) The lids must always be kept closed when the latrine is not in use.

(iii) It is unnecessary and even harmful to throw any disinfectant into the trench.

(iv) Oiling of superstructure or seats is unnecessary; they should be scrubbed daily and washed and always kept dry.

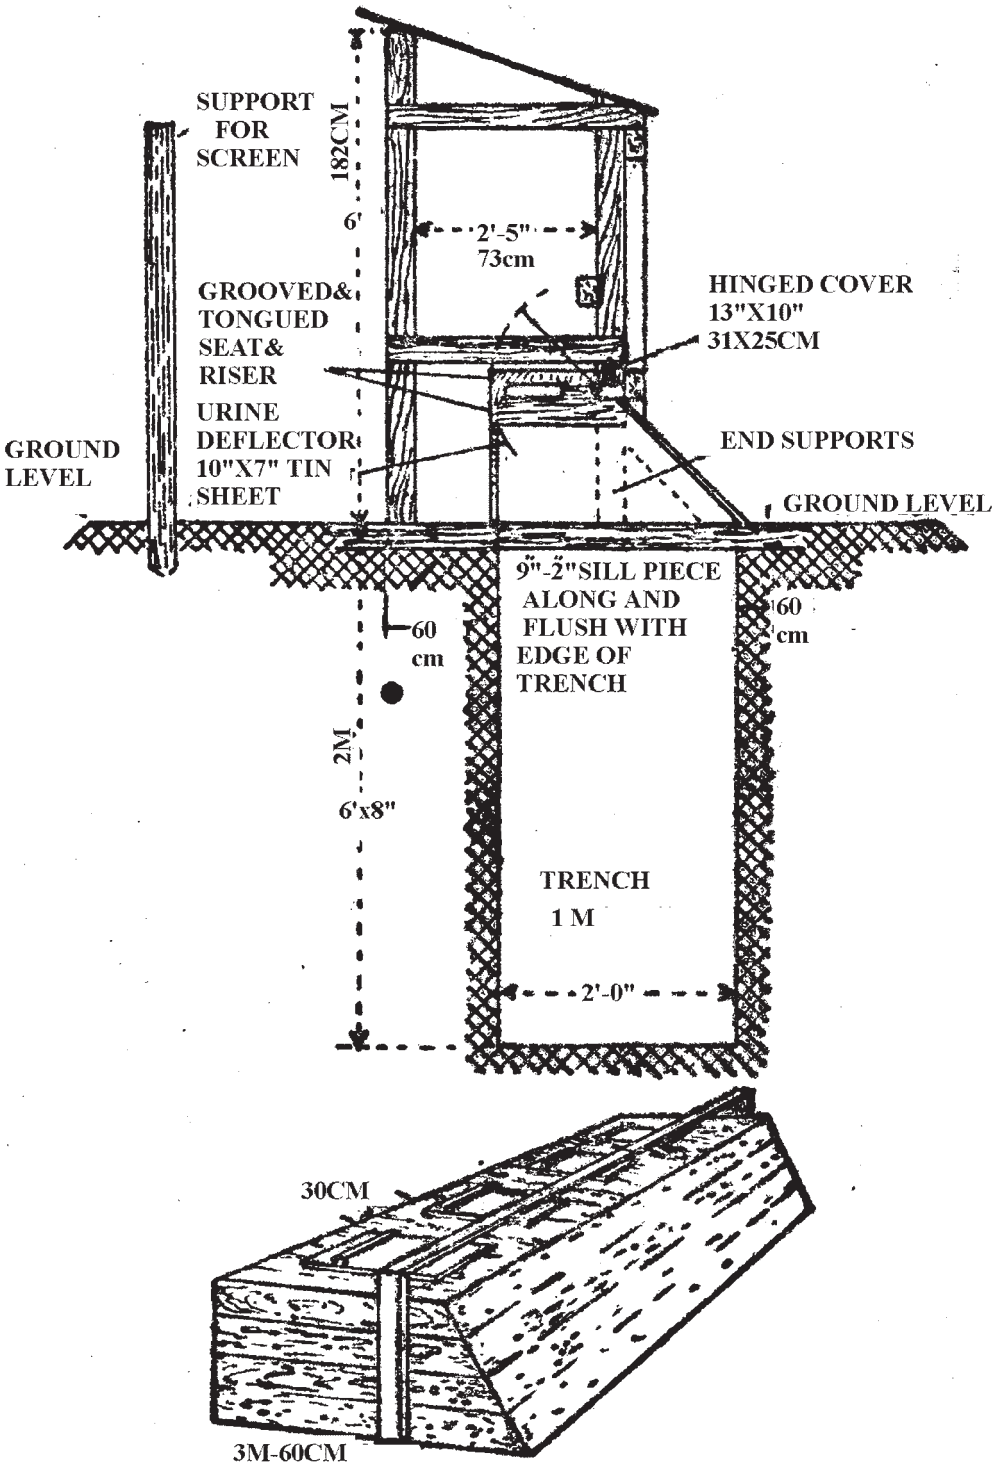
(v) Tins, bottles or other extraneous matter must not be thrown in.

(vi) Insecticide spray should be carried out on a fixed day once a week on the superstructures and 2 m all around the latrine.

**Improvised Deep Trench Latrine (IDTL)**

An improvisation of DTL may be carried out by placing the seats fitted with modified water closets, a meter and half in front of the long edge of the trench. The excreta are flushed through sewage pipes into the trench with small quantity of water. This type of latrine, therefore, is more hygienic and acceptable. It is similar in principle to the hand flushed water seal latrine evolved by the Planning, Research and Action Institute (PRAI) of the Ministry of Health, Government of India. The water seal performs two important functions. It prevents access to flies by sealing off the night soil and escape of foul gases. This type of latrine, therefore, is more hygienic and acceptable. For a

Fig - 4 : Deep trench latrine



**By Modifying DTL by incorporating water closet and water seal, problem of fly breeding and smell of DTL can be overcome.**

detailed description and functioning of the PRAI and RCA types of latrines, which have been found highly suitable for the rural masses in this country, standard textbooks may be consulted (4-9) Construction details for improvised DTL are as follows (10) :

(a) Trench

It is 1 meter wide, at least 2.5 meters deep and 3 meters long. The dimensions may vary depending on the type of soil / terrain and the level of subsoil water. The trench has to be covered with a superstructure that should overlap the trench all around up to 10 cm.

(b) Superstructure

Instead of the recommended wooden superstructure, the superstructure is made of a metallic sheet (iron / tin) of appropriate thickness which will be more hardy and long lasting. It has no apertures / lids so that there is no scope of lids getting broken / missing to cause fly breeding. A pipe of sufficient height for vent of gases is fitted at one corner of the trench.

(c) Water closets

Along the length of the IDTL on both sides, 3 to 5 Indian type water closet seats of plastic / fiber glass / chinaware are fitted. The seats should be put about 1.5 meters away from the edge on both the sides of the trench. This will lead to doubling of the number of seats available for each IDTL.

(d) Water seal

The WCs are fitted with a water seal (bend pipe) which is connected to a pipe leading into the trench.

(e) Water for flushing

Small quantity of water (2.5 to 3 liters) is sufficient to flush the WCs after each use. Water can be stored near the IDTL in a plastic tank.

(f) Shelter

A shelter with interposed partitions between the WCs using canvas / tarpaulin to provide privacy and protection from rain and sun.

(g) Storm water drain

A storm water drain dug all around the IDTL with a soakage pit at one end prevents rainwater from entering the IDTL.

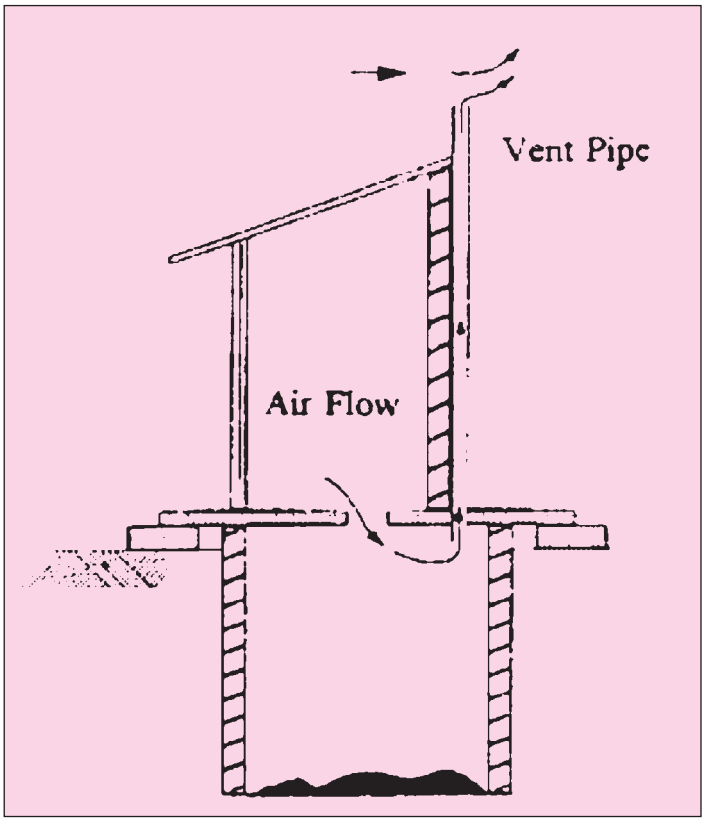
**Sanplat**

The sanplat (11, 12) is the cheapest and most basic pit latrine. It is a small concrete platform (usually 60cm or smaller), laid on top of logs or other supporting material traditionally used to cover the pit. The purpose of the sanplat is to provide a sanitary (san) platform (plat) which can be easily cleaned to limit the presence of helminths such as hookworm. Once the pit is full, the sanplat can easily be moved. However, the sanplat design does not overcome problems with odours or flies and may not be acceptable to some community members. The sanplat is best used when there is very little money for improving sanitation and where odours and flies will be tolerated.

**The VIP latrine**

The VIP (ventilated improved pit) latrine is designed (13, 14) to overcome some of the problems with traditional latrine designs, but it is more expensive than a sanplat. It has a vent pipe from the pit to above the roof of the building. When air flows across the top of the vent pipe, air is drawn up the pipe from the pit and fresh air is drawn into the pit from the building. Offensive odours from the pit thus pass through the vent pipe and do not enter the building. The location of VIP latrines is important: unless a clear flow of air is maintained across the top of the vent, the ventilation system may not be effective. VIP latrines should therefore be located away from trees or high buildings that may limit air flow. A dark vent pipe also helps the air to rise. The top of the pipe is usually covered with mosquito meshing. If the inside of the building is kept partially dark, the flies will be attracted to light at the top of the pipe, where they will get trapped and die.

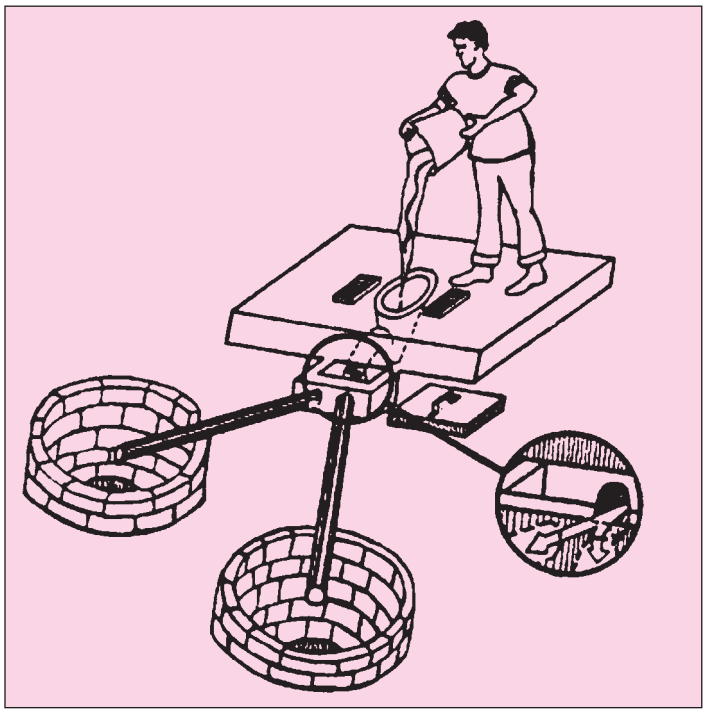
Fig - 5 : VIP Latrine



**Pourflush Latrine**

A pourflush latrine is a type of pit latrine where small volumes of water (commonly 13 litres) are used to flush faeces into the pit. They are most appropriate where people use water to clean themselves after defecating and where people have access to reliable water supplies close to the home. Solid waste should not be disposed of into pourflush latrines, as this could block the pipe and even cause it to break. A pourflush latrine has a small collection pan set in a slab. Wastes are disposed of through a section of pipe bent into a U shape (a U-bend) to maintain a water seal for reducing odour problems. A vent pipe may also be added to the pit to help with fly and odour problems. The

Fig - 6 : Double Pit Pourflush Latrine



pit of a pourflush latrine may be located directly beneath the slab or set to one side, but offset pits may require more water to prevent blockages. The pit is usually connected to a soak-pit to allow liquids to infiltrate the soil, leaving solid waste to decompose.

**Permanent Camp**

The method of excreta disposal in a permanent camp depends on the existence of sewerage system. The final treatment and disposal can be accomplished in sewage treatment plant, combination of septic tanks and subsoil irrigation/soakage pit, oxidation ponds and biolatrine. Broad principles of all these systems are given in subsequent paragraphs.

**Water Carriage System**

In this system human excreta and waste water from residential, commercial and areas are carried away by a network of underground pipes called sewers to the place of ultimate disposal. This is the method of choice for urban areas having piped water supply (15). There are two types of sewerage system, the combined and the separate systems. The combined system carries both sewage and storm water. In the separate system surface water is not admitted into the sewers. The latter is the system of choice. Although, first time the sewers in this country were laid in 1867, at Calcutta, till recently not more than 20 percent of the urban areas are estimated to have such facilities. The main problems are lack of funds, piped water supply, skilled manpower and low priority accorded to its construction. Importance of sewerage system was realized during floods at Mumbai in 2005 when heavy rain in Mumbai caused floods due to choked sewerage system leading to heavy economic losses and outbreak of Leptospirosis subsequently (16).

Components of Water Carriage System

It consists of house hold sanitary fittings, house sewers, street sewers and sewer appurtenances: -

**(a) Household Sanitary Fittings**

These include water closets, urinals, washbasins, bathtubs along with their plumbing systems.

**(b) Soil Pipes**

These are pipelines, which carry excreta from the water closets to the house drain. They are fitted with outlet ventilators for the escape of foul gases and hence are placed outside along rear walls of the houses and are carried above the roof tops.

**(c) House Drain**

It is an underground iron or stoneware pipe usually of 10 cm diameter and is laid in the courtyard 15 cm below the ground level on a bed of cement concrete mix with sufficient gradient towards the public sewer. It carries away the discharges from the household sanitary fittings to the street sewers.

**(d) Public Sewer**

It is a network of underground pipelines varying in diameter from 22 cm to 3 m for carriage of sewage from domestic, industrial and commercial areas to the place of final disposal. While laying the pipelines sufficient gradient is to be ensured for self- cleansing velocity of sewage. This velocity varies from 60 cm to 90 cm per second.

**(e) Sewer Appurtenances**

These are manholes and traps installed in the sewerage system: -

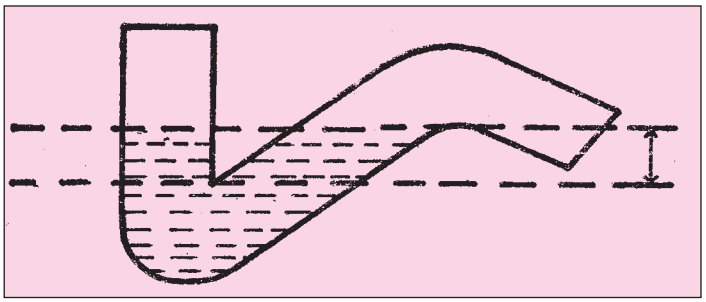
(i) Manholes

These are opening built in the sewers for the purposes of repairs and cleaning. They are placed wherever there is change in the direction of sewers, at the junction of two or more sewers and at a distance of 100 meters in the long, straight run of the sewers. Workers entering manholes are liable to gas poisoning and asphyxiation unless due precautions are taken.

(ii) Traps

These are devices designed to prevent the entry of foul gases inside the house and to remove sand, grit, grease etc. from sewage. Traps are placed at three points under the water closet, at the junction of the house drain and the street sewer and where the surface water enters the sewers. There are several designs of traps. The simplest one is a bentpipe containing water as a seal (Fig. - 7). The water seal in a trap is the distance between the highest

Fig - 7 : Water seal



level of water in the trap and the lowest point of the trap's concave upper surface.

## Composition of Sewage

It contains 99.9 percent water and 0.1 percent solids, which are partly organic and partly inorganic. Sewage is teeming with living organisms, some of which may be pathogenic. The strength of the sewage may be expressed in terms of biochemical oxygen demand, chemical oxygen demand and suspended solids.

### (a) BOD( Biochemical Oxygen Demand)

It is defined as the amount of oxygen absorbed by a sample of sewage during a specified period, generally 5 days at a specified temperature, usually 20°C for aerobic digestion. This is the most important test carried out on sewage. A sewage with a BOD value of 300 mg/l (300 ppm) or above is termed strong while that of 100 mg/l (100 ppm) or below is termed weak.

### (b) Chemical Oxygen Demand (COD)

The COD is the amount of oxygen required to oxidize the organic matter by use of dichromate in an acid solution and to convert it to carbon dioxide and water. The value of COD is always higher than that of BOD because many organic substances can be oxidized chemically but cannot be oxidized biologically. Commonly, BOD is used to test the strength of untreated and treated municipal and biodegradable industrial wastewaters. COD is used to test the strength of wastewater that is either not biodegradable or contains compounds that inhibit activities of microorganisms.

### (c) Suspended Solids

If the amount of suspended solids is 100 mg/L or more, it is termed strong.

## Sewage Purification

The aim of sewage treatment is to convert an offensive and potentially dangerous mixture into an inoffensive effluent and sludge which can be disposed off safely and without causing nuisance into rivers, into the sea, or on land and should even be capable of being reused to replenish non-potable water supplies and to provide water useful for agriculture in suitable circumstances and with due safeguard. The conversion of the complex organic matter in the sewage to simpler substances takes place by two processes, viz .aerobic and anaerobic. The aerobic method requires a continuous supply of free dissolved oxygen for the aerobic microorganisms to breakdown the organic matter into simpler substances such as carbon dioxide, ammonia, water, nitrite, nitrate, sulphate etc. The anaerobic process is highly effective where the sewage is highly concentrated and contains plenty of solids. Hence, this method is usually gainfully used for digestion of sludge in sewage works. The end products of anerobic decomposition are methane, ammonia, carbon dioxide, hydrogen etc.

### Sewage Treatment Plant

The main processes comprise of physical treatment to remove solids from the liquid and biological treatment brought about by aerobic and anaerobic bacteria. While the physical treatment is often referred as primary treatment, the biological treatment process is called secondary treatment. Treatment rendered in addition to the conventional secondary treatment for improving further the quality of effluent is termed 'tertiary treatment' or advanced waste treatment process. The sludge is also given treatment for stabilization and dewatering. Chemical treatment by the addition of coagulants may be used to assist sedimentation and sludge treatment. Flow diagram of a modern sewage treatment plant is show in (Fig. - 8).

Primary Treatment

Fig - 8 : Flow diagram of a modern sewage treatment plant

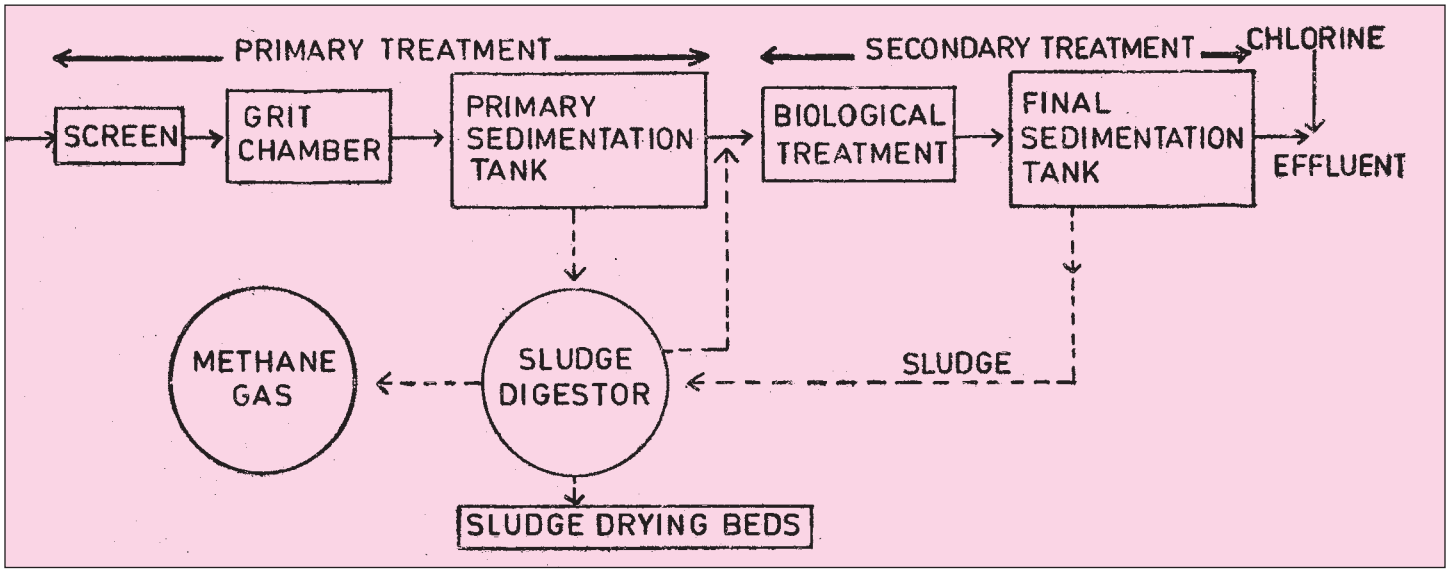


Fig - 9 : Diagrammatic section of a percolating filter for biological treatment of sewage

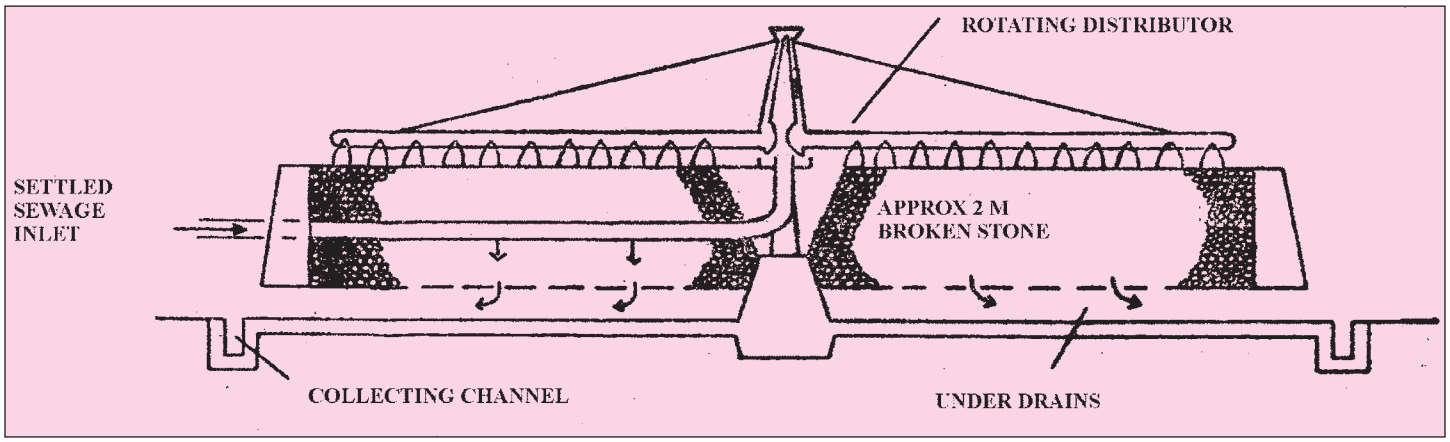


**(a) Screening**

It is the first step in the sewage treatment for removing the larger solids. The raw sewage is passed through bar-screens with openings of 8 to 10 cm between the bars placed across the inflow channels. The screenings can be manually raked from the screens and buried.

**(b) Grit Removal**

Combined sewerage systems carry grit from roads or other debris from general sullage and fine granular inorganic material. This material which otherwise causes heavy wear in pumps and tends to settle out and cause difficulty in later treatment processes must be removed in grit chambers and channels. The sewage is allowed to flow in a channel at a controlled velocity of about 30 cm/s, which is slow enough for the heavy non-organic solids to settle down but fast enough to carry the lighter organic solids forward. The grit is removed periodically, washed free of organic matter and dumped on waste land for reclamation or to fill excavations and quarries without causing nuisance.

**(c) Sedimentation**

It is the third step to remove as much of the organic solids as possible from the liquid sewage. The same principles as these for the treatment of water are employed. Sedimentation tanks may be rectangular with a horizontal flow, hopper-shaped with vertical flow, or circular with radial centrifugal flow. Slow moving paddles to encourage flocculation of solids and increased settling velocities may be incorporated. The sewage is retained in sedimentation tanks for 4 to 12 hours. The process removes 50-60 percent of the suspended solids and about 40 percent of the BOD of the sewage. The settled sludge is removed by mechanical scrapers to hoppers from which it is drawn off either continuously or at frequent intervals to prevent it from becoming septic. The sewage is then treated biologically.

Secondary Treatment

The secondary or biological treatment of sewage essentially involves the oxidation of suspended and dissolved organic matter by aerobic bacteria. Carbonaceous matter is converted to carbon dioxide and water, and nitrogenous material to ammonia, nitrites, and nitrates. Fungi, algae, ciliate protozoa, insects and worms supplement the bacterial digestion. The main processes employed for biological treatment are as under:-

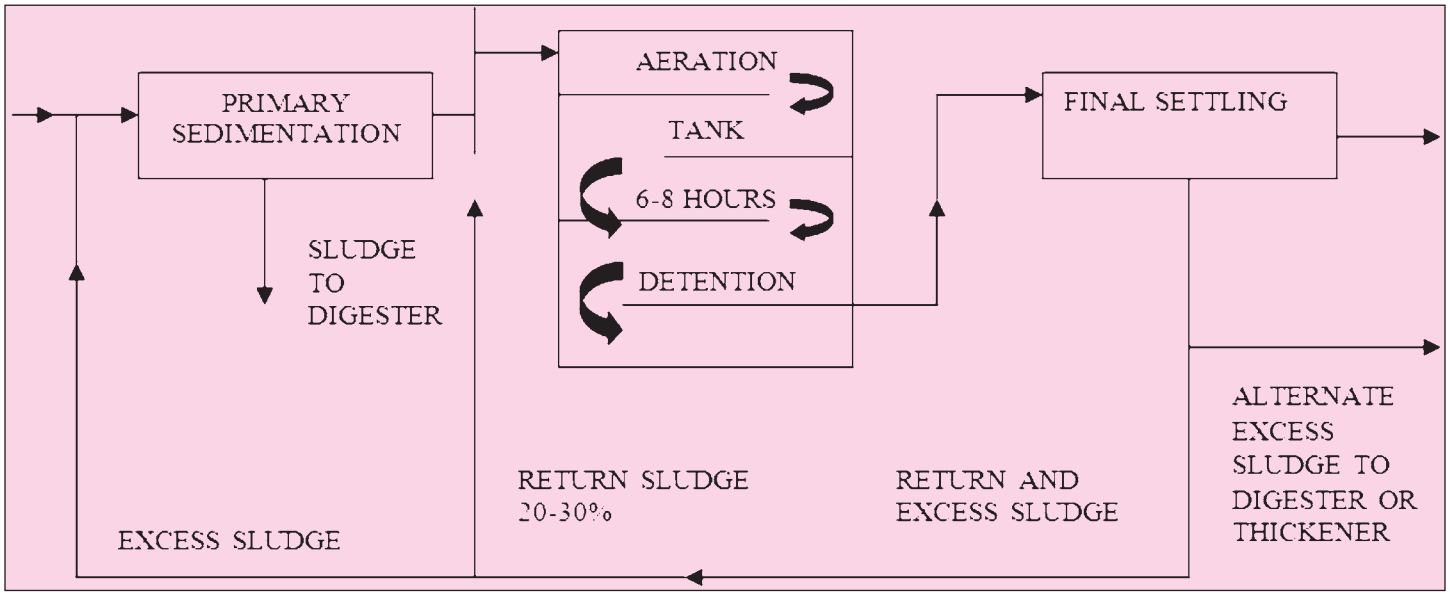
**(a) Percolating or Trickling Filters (Fig. 9)**

These consist of beds 1½ to 2 m in depth, made of stone, cinders, slag, or brick pieces, other impervious material generally from 3 to 8 cm in size over which effluent from primary sedimentation tanks brought in through a central pipe is intermittently percolated. The beds are usually circular with rotating distributors, or rectangular with horizontally gliding distributors and sometimes irregular in shape with fixed spraying nozzles. A slimy 'zoogleal' film of aerobic bacteria and other organisms develops on the surface of the stones. In trickling downward through the bed, the sewage donates its organic content to the vital zoogeal film for its nutrition and in return receives soluble organic salts produced by oxidation. Access of air through the filter is essential for the zoogleal fauna to oxidize the organic matter. Percolation is followed by final settling in humus tanks to remove the particles of the zoogleal matter and innocuous debris. The humus is separately disposed off or can be returned to the primary sedimentation tanks from which it is removed for treatment with primary sludge as described below. A competent percolating filter plant reduces the BOD of the raw sewage by 85 to 95 percent. A higher rate of treatment can be achieved by returning some of the filtered effluent to mix with the influent and reapplying it on to the filter, or by 'alternating double filtration', in which the sewage passes through two filters in series, their orders being reversed daily. Deep enclosed filters aerated by forced draught can also treat sewage at two or three times the normal rate while maintaining a high quality effluent

**(b) Activated Sludge Process**

In this process of biological treatment of sewage, the high BOD of the raw sewage from the primary sedimentation tank is satisfied by aerating it after intimately mixing with some of the sludge collected from the final sedimentation tank. The sludge from the final tank is called 'activated sludge' as it contains the active aerobic bacteria. The mixture is called 'mixed liquor'. In the presence of ample oxygen the aerobic bacteria utilize the unstable oxygen

Fig - 10 : Conventional activated sludge process



demanding solids in the raw sewage such as food materials and convert them into stabilized, odourless compounds having nil or very little oxygen demand. The process requires air supply and thorough mixing which brings about an intimate contact of the organic solids with oxygen and aerobic bacteria. First the effluent from the primary sedimentation tank is mixed for an hour or two with the activated sludge returned from the final sedimentation tank to form the 'mixed liquor', then the oxygenation of the mixed liquor is carried out by 4 to 6 hours aeration by one or more of the methods described below. The plant consists of a long channel or of a series of chambers through which the sewage passes while aeration proceeds. The aeration is followed by settling in tanks. The sludge is removed and the clear purified final effluent flows out for safe discharge. Most of the sludge is returned to be mixed with the sewage from the primary settling tanks as described above. Thus there is a continuous circulation of activated sludge carrying aerobic bacteria and protozoa, which are kept active by the constant replenishment of organic food and oxygen (Fig. 10). The common methods of aeration employed in the activated sludge process are :-

(i) Diffused Air System

Compressed air is blown through porous plates, domes or pipes fixed at the bottom of aeration channels.

(ii) Simplex Surface Aeration

Motor driven propellers are used to mix and break up the sewage into fine spray, bring it in contact with air and induce circulation in hopper-bottomed chambers.

Sludge Treatment

The sludge from primary or final sedimentation tanks contains 90 to 95 percent water. This high water content needs to be reduced for converting the sludge to a solid condition in which it may be used or disposed of harmlessly. Possible methods of dealing with sludge of which one or more or even all may be utilized in any given situation are shown in Fig. 10. The most profitable sludge treatment is anaerobic digestion. The sludge is pumped daily into enclosed digestion tanks in which anaerobic fermentation proceeds with the production of gas comprising about 70 percent methane and 30 percent carbon dioxide. This sludge gas is a valuable fuel to supply all power needs for pumping, air compression, electricity generation, and heating on the activated sludge plants. The gas may also be compressed and used as vehicle fuel. For most effective digestion and gas production, the digestors are heated to about 32° C. Digestion converts much of the organic solids to gas and soluble matter, and so reduces the quantity of solids to be handled eventually. Digested sludge is a black liquid with a tarry odour and is more amenable to subsequent de-watering than undigested sludge. Apart from digestion, the main object of sludge treatment is to de-water it so that it can be handled as relatively compact, moist solid rather than as a much greater volume of liquid with a low solid content. The following processes are used for de-watering the sludge and may be applied to either raw or digested sludge.

**(a) Air Drying**

Liquid sludge, after digestion, is placed on sand beds for air drying. Percolation into the sand and evaporation are the chief processes involved in the dewatering process. Air drying requires dry, relatively warm weather for greatest efficiency, and some plants have a greenhouse-like structure to shelter the sand beds. The semisolid sludge, which is left, is lifted manually or mechanically. Dried sludge in most cases is used as a soil conditioner; sometimes it is used as a fertilizer because of its 2 percent nitrogen and 1 percent phosphorus content.

**(b) Lagooning**

Sludge is stored in open basin, a few metres deep to allow settlement of solids. Clarified liquid may be drawn off,

and.the solids are eventually dug out.

**(c) Filter pressing**

In this, moisture is squeezed out through a filter cloth by mechanical pressure.

**(d) Vacuum Filtration**

Water is extracted by applying a vacuum to the inside of a filter drum, rotating partially submerged in a trough of the sludge.

Sewage sludge contains useful nitrogen and phosphorus, and although rather deficient in potassium, it forms a moderately good fertilizer. Undigested primary sludge and undigested activated sludge are easier to apply to land, and their humus content improves the soil. In suitable circumstances sewage sludge may be composted with municipal refuse. Where sludge cannot be used either as a fertilizer or for composting, or, in a few cases, for recovery of byproducts, it is usually tipped for land reclamation, dumped at sea, or incinerated.

Disposal of Effluent

The effluent after treatment is usually discharged on land or into bodies of water :

**(a) Disposal on Land**

If suitable land is available the effluent can be used gainfully for irrigation purposes. Over the past 20 years, there has been a considerable revival of interest in the use of wastewater for crop irrigation in arid and semiarid regions as a result of the scarcity of alternative water supplies and the need to increase food production. Reuse of treated effluent for the irrigation of crops and urban 'green spaces' (such as parks and golf courses) has expanded significantly in many countries. The viability of organisms in the soil or on crops irrigated by wastewater depends on the type of organism and its resistance to environmental factors such as climatic conditions, soil moisture, and the amount of protection provided by crops. Enteric viruses appear to be particularly persistent under natural conditions. Sewage farming or spread of treated effluent on farms is still used in many countries, particularly those having low rainfall and high temperatures. In wetter, cooler climates, the area of land required may become prohibitive. Enteric viruses have been found in raw sewage in concentrations of 1-10 per ml in various countries. Limited studies have shown that ingestion of 1 TCID of poliovirus can cause infection in man, but it is not known as to what percentage of persons would become infected with such a low dose or what size of infective dose would be needed for other enteric viruses. Only if water has been treated to such a degree that essentially all ammonia and nearly all residual organic matter has been removed, is it possible to achieve the free chlorine concentration of 0.5 mg/L for one hour recommended by WHO for effective inactivation of enteric viruses. It has been reported from India that hookworm and other enteric infections are much commoner among workers on sewage farms than among the farming population in general. The local custom of walking barefoot is a major contributing factor in the spread of some of these diseases.

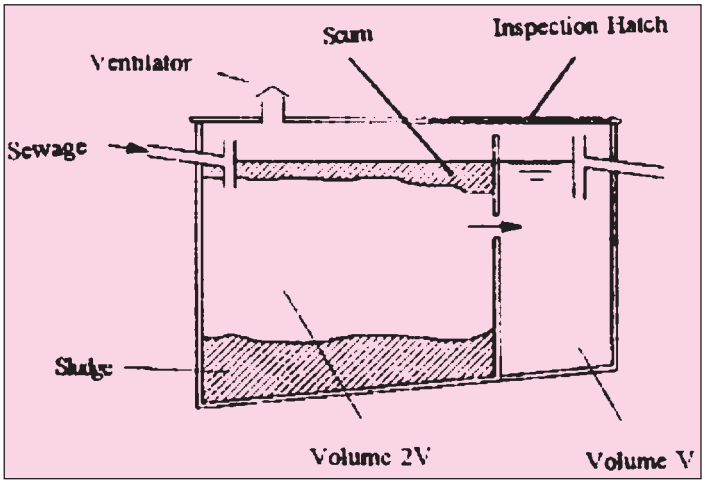
**(b) Disposal by Dilution**

Discharging the effluent into bodies of water such as rivers, streams, lakes and sea for the purpose of dilution as well as oxidation of the impurities by the dissolved oxygen in water is termed "disposal by dilution". The BOD content of the effluent and diluting capacity of the bodies of water are the important considerations. The BOD standards of effluent laid down by different countries, in particular, is towards lower values as newer chemicals which are increasingly discharged into the sewerage system may not be removed adequately by biological treatment. Consequently, the effluent may contain toxic substances, which may be harmful to man either directly or indirectly through the aquatic flora and fauna. In UK, the effluent standards have been raised to 10 mg/L each of BOD and 30 mg/L of suspended solids, laid down in 1908, by the Royal Commission. Even the present standards are not considered very satisfactory. In times of drought, the water supply source for Agra, consists almost entirely of partially treated sewage from New Delhi, 190 km away. The inadequacy of traditional methods of water treatment may perhaps be indicated by the outbreaks of infectious hepatitis in New Delhi, in 1955-56, when there were 30,000 cases, and in 1958. At the time of the outbreak, drought conditions prevailed, and the water abstracted from the river was estimated to contain about 50% of sullage water. When rivers contain a high proportion of effluents, the production of water from them should be regarded as analogous to the direct recovery of water from a sewage or industrial effluent, and safeguards appropriate to this situation should be imposed. Some rivers carry such a high proportion of treated and untreated wastewater that their use as a water source can be considered as essentially wastewater reuse.

## Septic Tank System

The efficiency of a septic tank system is certainly inferior to the sewage works but the former is fairly satisfactory for disposal of excreta and liquid wastes from individual houses, groups of houses and institutions having adequate piped water supply but lacking the facilities of a public sewerage system. It is much cheaper, quicker and easier to provide and maintain than sewage works. Hence it is often favoured in the Armed Forces permanent camps.

Fig - 11 : Septic Tank



Septic tanks are commonly used for individual households in low density residential areas.

**(a) Construction**

It consists of an underground concrete tank usually double chambered. A tank with more than two chambers is expensive and has no additional advantage. Even a single chambered tank has been found satisfactory for a small installation. The latrines should preferably be grouped together with one or more tanks placed close to a group. The sewers leading from the latrines to the tanks should have manholes at every 100 m and at every change of direction. Two or more medium sized tanks arranged in parallel instead of one large tank are preferable as these facilitate removal of sludge without disturbing the functioning of the system. The capacity of the tank should be at the scale of 13 /12 users with a minimum size of 3mx3m. The length of the tank should be a minimum air space of 30 cm above the liquid level. The septic tank is covered by a concrete slab with a manhole in it. The aeration chamber should be ventilated by one or more shafts, the opening of which should be screened with wire gauze. The inlet and exit pipes to the tank should be trapped. Agricultural drains are laid from the exit pipe at a suitable fall in a herring-bone pattern, 30 to 60 cm below the surface of the soil. The length of the agricultural drains per user should be 60 cm. Alternatively the effluent may be disposed into a soakwell. Septic tanks are commonly used for individual households in low density residential areas. The guiding principles in designing a septic tank are :-

(i) Provide sufficient retention time for the sewage in the tank to allow separation of solids and stabilization of liquid;

(ii) To provide stable, quiescent, hydraulic conditions for efficient settlement and floatation of solids.

(iii) To ensure that the tank is large enough to store accumulated sludge and scum

(iv) To ensure that no blockages are likely to occur and that there is adequate ventilation of gases.

**(b) Functioning**

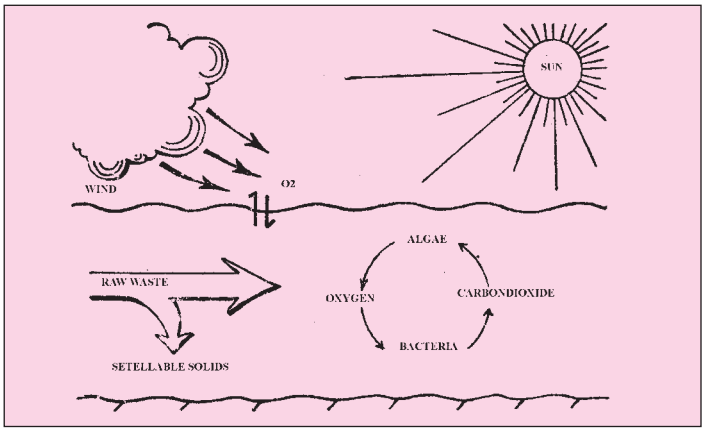
The action in a septic tank is by the biological process of anaerobic and aerobic digestion. The crude sewage on entry to the anaerobic chamber is allowed to stand for 2 to 3 days and is acted upon by the anaerobic micro-organisms. A colloidal solution is formed which is only partially digested and hence has an offensive smell. The complete oxidation and mineralization of the colloidal matter is carried out by the aerobic micro-organisms in the aerobic chamber and or in the agricultural drains. Though most of the pathogens, after having undergone aerobic treatment, die but the cysts and ova of the intestinal parasites survive. The effluent, however, loses most of its offensive smell. The minerals are absorbed from the soil by the plants. Many of the problems of septic tanks arise because inadequate consideration is given to the disposal of the tank effluent. A principal aim of septic tank design is to achieve hydraulically, quiescent conditions within the tank to assist the settlement by gravity of heavy solid particles. Large surges of flow entering the tank may cause a temporarily high concentration of suspended solids in the effluent owing to disturbance of the solids, which have already settled out. Grease, oil and other light materials float up, forming a layer of scum, which can become quite hard. The liquid moves through the tank sandwiched between the scum and sludge. The use of ordinary household soap in normal amounts is unlikely to affect the digestion process of a septic tank. The wastewater to septic tanks may be waste from toilets only, or may also include sullage. After desludging, the effective liquid retention time is greater because liquid then occupies the regions previously full of sludge and scum. The shape and size of septic tank should be such that there is achievement of even distribution of flow so that there are no dead areas and no "short-circuiting", i.e., the incoming flow shooting through the tank in less than the designed retention time. Surges and turbulence reduce the efficiency of settlement and can cause large amounts of solid matter to be carried out in the tank effluent.

**(c) Maintenance**

The operation and maintenance of a septic tank is simple. To commission a septic tank it has to be first filled with water and then seeded with a bucketful of sludge from another tank or a DTL. Not less than 25 L of water per day per user must enter the tank. Use of soap water and chemicals should be avoided. Sludge from the tank is to be bailed out once in a year or two. The tank cover or roof, which usually consists of one or more concrete slabs, must be strong enough to withstand any load that will be imposed. Removable cover slabs should be provided over the inlet and outlet. Circular covers, rather than rectangular ones, have the advantage that they cannot fall into the tank when removed. Routine inspection is necessary to check whether desludging is needed, and to ensure that there are no blockages at the inlet or outlet. A simple rule is to desludge when solids occupy between one-half and two-thirds of the total depth between the water level and bottom of the water tank. The most satisfactory method of sludge removal is by vacuum cleaner.

## Oxidation Pond

Fig - 12 : Oxidation Pond



Also known as the "Redox Pond, Sewage Lagoon and Waste Stablisation Pond", Oxidation pond is the cheapest method. It is an open shallow pool upto 5 feet deep with an inlet and outlet. The presence algae, bacteria decomposing organic matter and sunlight are mandatory for the functioning of oxidation pond. Bacteria oxidises sewage to carbon dioxide, ammonia and water. The algae, with the help of sunlight utilises carbon dioxide, water and other organic substances for their growth. Algae releases oxygen during photosynthesis, which is used by bacteria. So the pond works as a aerobic system during the sunlight hours, in night hours, the pond works anaerobically too, especially the lower layers. The effluent can be used for farming or can be discharged into rivers after suitable treatment. If the pond runs well, it is an accepted method for sewage disposal in small communities.

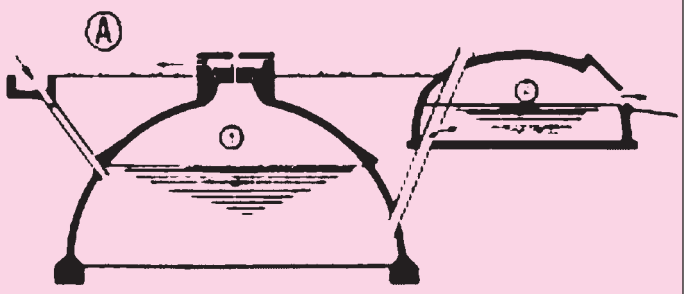
### Oxidation Ditch/Aerated Lagoon (17)

This process makes use of mechanical rotors for extended aeration and thus minimizes the requirement of land area. The land requirement in this method is barely one tenth of oxidation pond (Fig. 12).In primary sedimentation, a reduction of 30-40% in the number of coliforms is obtained, while in most full biological treatment processes the reduction is between 90% and 95%. Stabilization ponds with a 30-day retention period have shown reductions from 99% to 99.9%. Most vegetative bacterial pathogens appear to be removed in the same proportion as coliforms. Certain helminthic eggs may be effectively removed by primary sedimentation and even more effectively by stabilization pond treatment of 5-7 days duration; viruses are less effectively removed. Coagulation and filtration remove 98 to 99.9% of viruses. High standards (< 100 coliforms / 100 ml in 80% of samples) can often be obtained after complete biological stabilization, followed by heavy and carefully controlled chlorination (15-20 mg/l of chlorine with contact periods of 1-2 hours). The treatment was also effective in inactivating amoebic cysts. When treating a sewage of normal characteristics, the overall reduction of BOD and suspended solids to be expected from a conventional combination of primary and secondary treatment will be 85-95%. In a properly designed and operated pond, well over 90% of the polluting matter (in terms of its BOD) can be removed and the number of microorganisms much reduced. Ponds have the advantage of providing a fairly high degree of treatment at a relatively low cost, with little call for equipment or skilled operators.

### Biolatrine (Biogas plant)

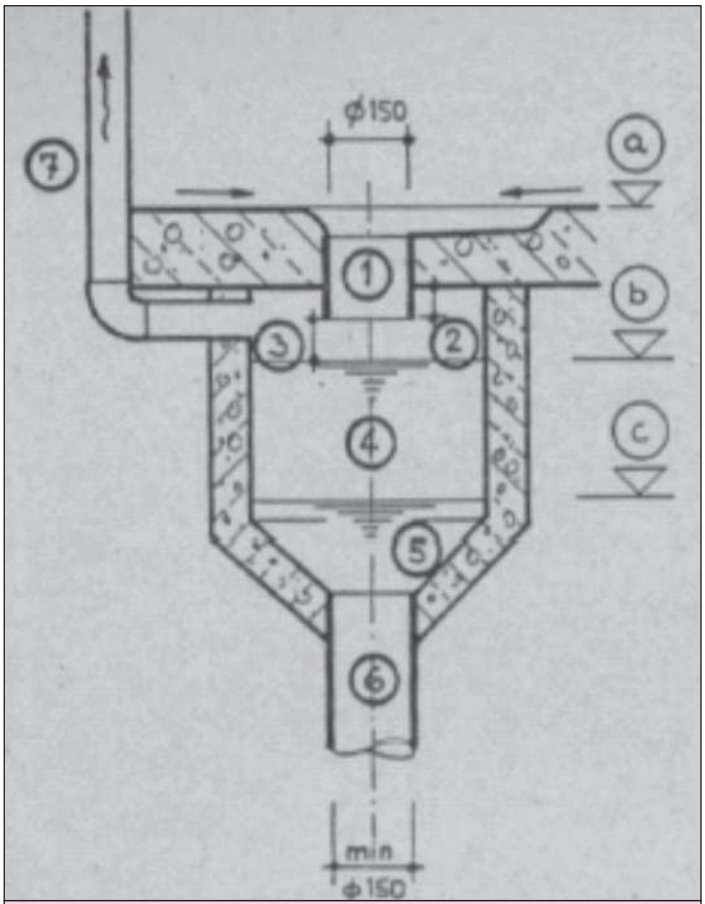
The biolatrine is in principle the centre part of a sanitary biogas unit for safe human faeces disposal, degrading the excreta anaerobically, thus producing biogas and digested substrate that may be utilized as fertilizer (18 - 20). The main focus is however mostly on sanitary aspects, i.e. clean toilets with low maintenance demand, rather than a high gas productivity. The soil conditions should however allow effluent and slurry absorption so as to prevent a disposal problem. Biolatrines are designed as integrated fixed-dome biogas plants (see Fig. 13), where up to 6 latrines can be installed around a dome. The main advantage of biolatrines is that they are generally run without water (except for the start-up phase), i.e. also not in connection with flush toilets, thus substantially

Fig - 13 : Fixed dome biogas plant



1) Digester 2) Expansion chamber

Fig - 14 : Construction details of toilets for a biolatrine



a) toilet floor b) highest and (c) lowest slurry level; (1) inlet pipe; (2) bottom of rim of inlet pipe; (3) inlet piece always above highest slurry level; (4) feeding chamber; (6) down pipe; (7)vent pipe.

reducing water demand and related costs. The urine will provide sufficient liquid for the substrate to be able to flow. The toilet chamber is connected to a vent pipe corresponding to those of the VIP latrine. For the main design criteria of the toilet, see Fig.14. Due to a required minimum flow rate, a biolatrine may only be an appropriate solution if at least 25 people are connected to its use. The excreta of 25 people will produce an average of about 1 $m^3$ of biogas per day (40 l per person and day), representing the approximate cooking energy demand of one household. Speaking of institutions with 500 or more attendants (depending on the type of institution and the mean time people spend at the location), the produced biogas may supply sufficient energy for a canteen. Application may occur for institutions like schools, prisons, religious centres, or for public facilities like markets. In Ralegaon Siddhi (Ahemednagar) Maharashtra community latrines has been connected to biogas plant. Biogas produced is being distributed to houses for cooking purposes .

## Aquaculture

Acting on the principle that sewage is not just waste water but also a source of nutrients, an experimental plant in operation since 1994 treats sewage with aquatic weeds and fish. One million litres of primary treated sewage a day, sits first in ponds containing duckweed, then in ponds stocked with carp and prawns. After five days, water quality has improved to the point where it may be used for agriculture, although not for drinking.Although faecal coliforms were found to be present in the system and in the guts and gills of fish fed on sewage, none were found in fish muscle. The sale of fish fattened in the sewage ponds for 8 to 12 months almost offsets the operating cost of the plant, leaving a net cost of 15 000 rupees a year, about US$385. The plant, which covers half a hectare, is run by two men.

The Aquaculture Sewage Treatment Plant (ASTP) cost 1.5 million rupees (US$38 000) to build, compared with 5 million to 6 million rupees (US$128 000 to US$154 000) for a standard Indian sewage treatment plant and 10 million rupees (US$256 000) for a comparable Western plant. The plant, located in Cuttack, Orissa, eastern India, is the brainchild of the Central Institute of Freshwater Aquaculture (CIFA), founded in 1986 with FAO's assistance. Cuttack, a city of 700 000, would need a plant with 60 times the capacity of the experimental station to treat its daily sewage output, currently untreated. A National Workshop on Sewage Treatment through Aquaculture, held in 1997 at CIFA, endorsed the plant design and recommended that more state governments adopt it (21).

## Management of Human Excreta at High Altitude areas

The problem of waste disposal, especially the faecal matter in high altitude and snow bound areas is rather complicated due to extreme cold temperatures causing difficulty in maintaining suitable thermal environment at which microorganisms effecting degradation can survive, multiply and remain active. A number of trials are in progress to find a suitable solution to this problem. In non-glacier regions the waste is collected and used as fertiliser in the field. Incineration and chemical treatment of human waste has also been attempted to overcome the problem. However, all these methods are either unhygienic or not practically viable alternatives.

Biological treatment is an attractive approach for solving the problem, but decreased metabolic activities of the micro-organisms, freezing of the substrate, non-availability of conventional energy sources and hilly terrains are some of the hurdles which need to be solved to make the process practically possible. DRDO has developed an innovative technology for disposal of human waste in eco-friendly manner at high altitude locations where temperature drops to -40°C or lower. The process culminates into treated effluent, which is free from pathogens and is also environmental friendly. During waste treatment, inflammable biogas (methane) is generated as a byproduct, which can be used for various energy intensive activities like cooking, water and room heating (22).

Fig - 15 : Temperature controlled Biodigester

The technology has two major components, low temperature active inoculum and temperature-controlled biodigester.A consortium of anaerobic bacteria has been formulated and adopted to work at temperature as low as 5°C. This acts as inoculum (seed) and converts the organic wastes into methane and carbon dioxide. The anaerobic process inactivates the pathogens responsible for water-borne diseases. Biodigester serves as reaction vessel for biomethanation and provides the anaerobic conditions and required temperature for the bacteria. The optimum temperature is maintained by microbial heat.

**Summary of Disposal of Human Excreta**

(a) **Temporary camp:** Shallow trench latrine, sanitary latrine based on improvised and removable Indian type sanitary water closet, incinerator latrine

(b) **Semi permanent camp:** Deep trench latrine, Improvised deep trench latrine, dug well latrine, ventilation improved pit latrine, Pour flush water seal latrine

(c) **Permanent camp:** Sewerage system, Combination of septic tank and soakage pit/subsoil irrigation, oxidation pond, biolatrine, treating sewage by aquaculture

**Salient Features**

Suitable for subzero temperature of Himalayan region as well as glaciers

(a) No dependence on the limited and costly conventional

energy sources

(b) Easy to transport and install in hilly terrains

(c) Maintenance free, continuous biological process

(d) Eliminates the pathogens

(e) Generates odourless and inflammable biogas which can be used for cooking

## Disposal of urine

### Permanent Camp

In a permanent camp having water carriage system, porcelain, cement or masonry urinals connected to the sewers should be insisted upon. If water carriage system does not exist, the urinals should be drained to a covered soakage pit.

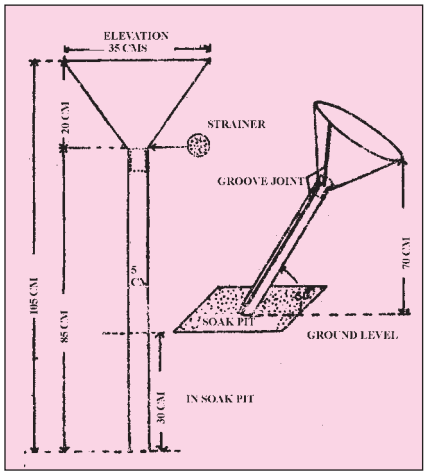
### Semi-permanent Camp

In a semi-permanent camp the standard type of funnel urinal or porcelain urinal connected to a covered soakage pit should always be used for disposal of urine.

### Temporary Camp

In a temporary camp improvised tin urinal placed over soakage pit may be used. A ghee tin with perforated bottom and half buried in a soakpit is the simplest of these types. A trench half a meter broad, 4 to 5 m long, dug down to 15 cm to 18 cm filled with brickbats or stones may be used in camps on the line of march. At the time of closing of the camps, the trenches should be filled with earth and layer of slaked lime spread over these.

Fig - 16 : Funnel Urinal



Funnel Urinal

The standard one can be made out of three ghee tins. The entire length of the urinal is 105 cm, of which the shaft is 85 cm and the funnel top in its central axis is 20 cm. The diameter of the funnel top is 35 cm, which tapers gradually to 5 cm where it joins the shaft. The outer surface of the entire urinal and the inner surface of the shaft should be treated with coaltar. The inner surface of the funnel may be painted white for easy visibility at night. A strainer of 5 cm diameter and made of a perforated tinplate is soldered inside at the junction of the funnel with the shaft. The urinal should be installed over the soakage pit so that 30 cm of the shaft is buried. That will leave 55 cm of the shaft and the funnel top above the ground. The urinal should be fixed inclined in such a way that the user can stand just outside the soakage pit. This is ensured by placing the shaft at an angle of 25° to 30° with the vertical axis. The edge of the funnel should not be less than 60 cm nor more than 75 cm above the ground. Naphthalene balls should be left in the funnel to minimize bad odour. A hessian cloth enclosure will ensure privacy.

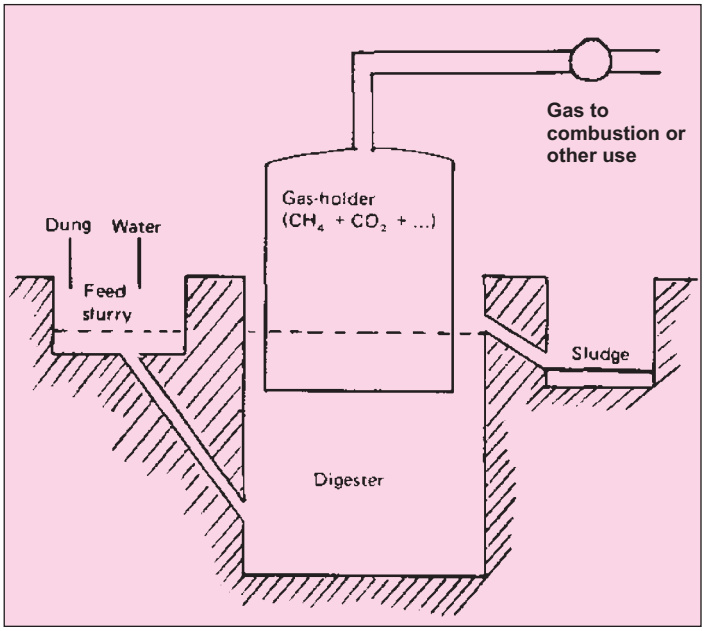
## Management of Animal Excreta

Animal excreta carry enormous potential of fly breeding and it should be managed by disposing in biogas plants (popularly known as gobar gas plants), sanitary land fill or composting (Disposal along with biodegradable solid waste).

### (a) Disposal in Biogas Plant (Gobar Gas Plant)

In view of the increasing energy crisis, this method is gaining rapid popularity, particularly in countries having large cattle population. In this method the dung gets converted into good quality manure under hygienic conditions and there is also generous liberation of biogas energy. This can be used as fuel in the kitchen, for running engines, lighting and other purposes. A biogas plant is cheap, simple in construction, easy to handle and can be made locally from indigenous materials. The digester is partly an underground masonry tank with an incomplete partition in the middle. It has an inlet and an outlet pipe. Dung mixed with water in equal proportion is put inside through the inlet. In the plant, excreta are often mixed with straw or other vegetable waste, and equal quantities of water added to make a slurry which is fed to the inlet side of the chamber. Effluent slurry is removed after a retention time of 30-50 days. Biogas production is greater at higher temperatures. At 300°C the rate of generation of gas is about twice that at 250°C and little gas is produced if the temperature is below 150°C. A few hookworm eggs survive and there is high survival of roundworm eggs. Many pathogens including schistosoma eggs are killed (Fig. 17).

Fig - 17 : Bio-gas plant



### (b) Composting

There are carried out in the same manner as for and often in conjunction with solid waste and night soil.

## Solid waste management

### Composition

Solid waste includes all unwanted or discarded material of domestic, street, commercial, industrial and agricultural origin. It consists of garbage and swill from cook houses and dining halls; house and street rubbish like waste papers, rags, glass pieces, ferrous and nonferrous metals, plastics, dried leaves, pieces of wood, ferrous and nonferrous metals, plastics, ashes, cinders, brick bats and commercial and industrial wastes of all types. Generally, wastes of animal and vegetable origin are very attractive to flies, cockroaches, rodents and other pests and therefore must be disposed off hygienically, as early as possible. Solid waste should be managed according to **Municipal Solid Wastes (Management and Handling) Rules 2000 (23) described in subsequent paragraph.**

### Collection

Suitable receptacles are to be provided at convenient places for collection of all rubbish awaiting disposal. Metal, fly proof receptacles, big enough to hold 24 hours collection, must be provided for storage of garbage and swill in the cook houses and dining halls. General camp refuse and house refuse other than garbage which is not so attractive to flies may be collected separately. In a permanent camp sanitary bins made of G I sheet are usually provided. In other types of camps receptacles having well fitted lids may be improvised from empty cresol drums, oil drums and ghee tins.

### Management of Solid waste

The recognized methods of disposal of solid wastes are dumping, burial, sanitary land-fill, incineration, composting, biogas plant, EM technology and salvaging. The choice of a particular method is governed by factors such as type of camp, cost, availability of land and labour.

Dumping

In this method waste is simply dumped in low lying areas. As the waste is kept lying loose it creates nuisance, pollutes the surrounding water and soil and encourages breeding of flies, rodents and other pests. Dumping, as a method of waste disposal, should be avoided. Dumping can be used to disposed demolition material in low lying areas.

Controlled Tipping (Sanitary Land-fill)

This is a satisfactory method if suitable land is available. This method is popular with local bodies and cantonments. It differs from dumping in that the material is placed in trenches or other prepared areas adequately compacted and covered with earth. Hence it minimizes the problem of offensive odour, unsightly appearance, pollution of the surrounding soil and water, and pest and vermin infestation. The site selected should be away from the habitation. A hollow low lying ground or an abandoned quarry or a swampy area is generally selected; otherwise broad trenches are dug on flat low lying ground. Long trenches are usually dug out, each having a depth of 2 to 3 m and breadth of 3 to 10 m. Filling of waste is to take place from the farthest end. At the end of the day's work it is covered with earth and compacted well. The method of controlled tipping has been revolutionized by mechanization. The bulldozer achieves the tasks of spreading, compacting and leveling the top. After this operation the top is covered with clinkers or sweet earth and fast growing shrubs may be planted. Pollution of surface and groundwater is minimized by lining and contouring the fill, compacting and planting the cover, selecting proper soil, diverting upland drainage, and placing wastes in sites not subject to flooding or high groundwater levels. Gases are generated in landfills through anaerobic decomposition of organic solid waste. If a significant amount of methane is present, it may be explosive; proper venting eliminates this problem.

Composting

It is usually employed for the combined disposal of solid wastes, stable litter, night soil and sludge. It entails proper preliminary construction, higher initial expenditure, running cost, efficient organization and supervision. The organic matter in this method breaks down under microbial action into relatively stable humus like substance called compost, which has considerable manurial value. The principal by-products are carbon dioxide, water and heat. The heat produced during composting rises to 60ºC or higher which is retained over a period of several weeks. The following methods of composting are now a days used- Bangalore method, mechanical method and vermicomposting. The first is an anaerobic method while the second is an aerobic one.

**(a) Bangalore Method (Hot Fermentation Process)**

This method of anaerobic composting was evolved under the auspices of The Indian Council of Agricultural Research at the Indian Institute of Science, Bangalore and hence termed Bangalore method. Long trenches are dug each having a depth of 1 m and breadth of 1.5 to 2.5 m. Depths greater than 1 m are not recommended because of slow decomposition. First a layer of refuse 15 cm thick is spread at the bottom. Over it, a layer of night soil of 5 cm thickness is added. The alternate layers of refuse and nightsoil are added in the proportion 15 cm and 5 cm respectively till the heap rises 30 cm above the ground level. The top layer of refuse should be at least 25 cm thickness. The heap is then covered with excavated earth. If properly laid; a man's leg will not sink when walking over it. Within 7 days considerable heat is generated in the mass. The heat persists for 2 to 3 weeks. At the end of 4 to 6.months the mass is ready to be taken out as manure. During decomposition of faeces and urine, the following processes take place :-

(i) Complex organic compounds such as proteins and urea are broken down into simpler and stable forms.

(ii) Gases such as ammonia, methane, carbon dioxide and nitrogen are produced and released into the atmosphere.

(iii) Soluble material is produced which may leach into the underlying or surrounding soil or be washed away by flushing water or ground water.

(iv) Pathogens are destroyed because they are unable

to survive in the environment of the decomposing soil.

**(b) Mechanical Composting**

In this method compost is manufactured on a large scale out of the raw materials within a very short time. The refuse first undergoes a process of mechanical sorting for items like rags, bones, metal pieces and glass which otherwise are likely to interfere with grinding operation. The entire mass is then pulverized in mechanically operated pulverizing equipment. The pulverized refuse is then mixed with night soil, sewage or sludge in a rotating machine and incubated under controlled temperature, pH, carbon-nitrogen ratio and aeration. The final product compost is ready in 4 to 6 weeks time. This method of composting is in vogue in developed countries. A few of the Indian cities with population more than 3 lakhs are presently in the process of installing such plants. The wastes are degraded biologically to a humus with a total nitrogen, phosphorus, and potassium content of 1 to 3 percent, depending on the material being composted. Afterwards, the product is ready for curing, blending with additives, bagging, and marketing.

**(c) Vermicomposting**

It is an eco-friendly method of disposal of bio-degradable wastes from kitchen, dining places, etc. which mostly contain organic food wastes, peels , and serves the dual purpose of disposing off garbage and at the same time mustering the environment.

(i) Principles of process

- Proper aeration of organic material
- Inoculation of required bacteriae
- Spraying of fresh cow dung.
- Keeping pH around 7
- Maintaining moisture at 50%

(ii) Method

A rectangular bed of earth of suitable size bound by a brick wall 2-3 ft high will serve the purpose. A few hundred earthworms are introduced on which waste can be dumped and water sprinkled daily. Agriculturally useful compost is formed in 2-3 months which can be periodically removed.

(iii) Advantage

- End product is value added bio-fertiliser (Manure) and can be used in agriculture and organic farming.
- Process converts the project site into a green patch.
- Organic agriculture produce is a recurring output making the project sustainable and viable.
- The process does not generate methane gas nor contaminates ground water by leaching.
- The process enriches the organic matter in the soil with bacteria and deep burrowing earthworms.

## EM (Effective Microorganisms) Technology

First developed by Dr Teruo Higa in Japan, EM technology (24) is now in use in 30 countries. It essentially consists of the use of friendly micro organisms like phototropic bacteria, Actinomyces, Lactic acid bacteria and yeast contained in a stock solution (EM1 solution), which is diluted in rice wash water that has sugar added to it (EM 3 solution). This is added to kitchen waste in specially designed drums which converts the waste into compost, a process which helps plants grow better. Effective microorganisms (EM) solution is a living entity containing active microbes. It has no chemicals and no genetically engineered organisms. These microorganisms are extremely beneficial, eco friendly and totally harmless .EM is very economical and easy to use. EM solution can be classified into 2 categories:

(a) Original EM (EM 1) - shelf life of 6 months

(b) Extended EM (EM 2) - 30 days

**Advantages**

(a) EM helps suppress E coli bacteria from water along with other coliforms

(b) EM eats up sewage. After dying, they dissolve in the water so your drains are clean, odourless and drainpipes will never get clogged

(c) Contamination of drinking water through leaking pipes reduced

(c) Greatly improves earthworms in vermiculture

(d) Drain pipes last longer and better

(e) If EM is added everyday to the drainage system through sinks and toilets, then within a month or two you will see visible differences in septic tanks

## Portable Biogas Plant Introduction

Portable biogas plant developed by Appropriate Rural Technology Institute, Pune, Maharashtra, India (25) can also be used to manage biodegradable kitchen waste and left over food.

Fig - 18 : Portable Biogas Plant

**Construction**

The biogas plant consists of two cylindrical vessels telescoping into one another. The larger vessel, called the fermenter, has a total internal volume of about 500 lit. A drum having diameter of 85 cm and height of 85 cm would have the desired volume. The smaller vessel, which telescopes into the larger one, serves as the gas-holder. The diameter of the gas holder is about 2 cm smaller than that of the fermenter. The fermenter vessel is provided with appropriate inlet and outlet pipes for introducing the feedstock into it and for removal of spent slurry from it. The gas holder is provided with a gas tap, through which the gas is led to the burner. The size of the gas holder may vary between 500 litres and 1000 litres depending upon the requirements of the family. In a family eating mainly rice or noodles, a capacity of 500 litres is adequate, but in the case of families eating chapattees or rotis, which have to be made one after the other, the gas has to last longer, and therefore a larger capacity of gas holder and fermenter are required

**Advantage**

This system is much easier to operate than the dung based biogas plant, because of the relatively small quantities of feedstock and effluent slurry to be handled. The effluent slurry generated daily by the plant is just a couple of litres. It can be used as manure for plants growing around the house. The 500 litre biogas plant, mass produced from moulded plastic drums, would cost about Rs. 8000.

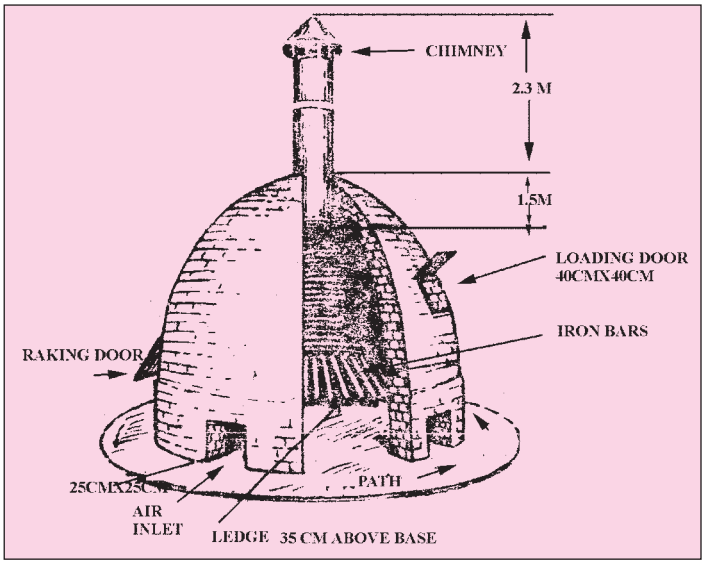
## Incineration

This is a hygienic method of waste disposal. Many developed countries use incinerators, which are complete with air pollution controls and heat recovery process. However, incineration is not considered very suitable in this country because the waste contains a high proportion of fine ash, which makes burning of refuse difficult. Besides it involves heavy initial cost on installation and recurring expenditure on fuel and maintenance. It also requires strict supervision and manpower management. With the present day energy crisis, incineration of community waste may be considered as loss to the country. However, incineration is still the best method for disposal of hospital waste. Incineration at times is resorted to in some of the Armed Forces permanent installations. The common types of incinerators used in the services are described follows: -

**(a) Beehive Incinerator**

The beehive incinerator is constructed preferably with fire bricks, over a concrete platform. The diameter of the incinerator up to the height of 1½ m is uniformly two metres. After this the construction tapers cone-fashion to half a metre in diameter at the apex. The total height of the incinerator is 2½ m up to the apex into which a chimney is fixed. This project out for 2 to 3 m and protrudes inside the incinerator for about ½ m. A circular ledge protruding inside is built in the wall about 35 cm above the base to support a grid-iron grill on which incineration takes place. Underneath the ledge there are four 25 cm square ventilating windows placed at equal intervals to provide cross ventilation. Above the ledge and the grid-iron grill, are 35 cm square taking windows. At the base of the tapering part of the incinerator a 40 cm square feeding window is provided with a chute protruding inside towards the centre of the incinerator. The feeding and the taking windows should have trap doors. Incinerators must

Fig - 19 : Closed beehive incinerator



be sited near the latrines and protected from the weather. A cement platform for drying and mixing faeces, camp refuse, animal manure and fuel and a water tight shed to store dry fuel are also necessary (Fig 19).

Working of the incinerator

The personnel must be skilled, properly trained and permanently employed. Adequate supply of readily combustible material such as dry camp refuse, dry leaves, paper, cinders or dried horse manure must be ensured. At least 15 kg of wood or coal each day will be needed in addition to the camp refuse. Coal or wood at the scale of 75 kg per 1000 men per day or an equivalent quantity of oil, may be necessary if camp refuse is not adequately available; a fire is first started with paper and other inflammable camp refuse. The faeces, manure and camp refuse are mixed to form sizeable lumps on the platform. When the fire has turned up brightly, the mixed mass is slowly tipped into the incinerator taking care not to overload the fire. Between the charges, camp refuse is added in small quantities to keep up the fire. The incinerator must be stoked carefully, otherwise the material will fall as a cake to the bottom of the fire. When the incinerator is working properly, all the smoke is consumed in the vault below the chimney. To keep the fire alive overnight, the air inlets should be blocked.

**(b) Modern Incinerators**

In incinerators of conventional design, refuse is burned on moving grates in refractory-lined chambers; combustible gases and the solids they carry are burned in secondary chambers. Combustion is 85 to 90 percent complete for the combustible materials. In addition to heat, the products of incineration include the normal primary products of combustion-carbon dioxide and water-as well

as oxides of sulphur and nitrogen and other gaseous pollutants; nongaseous products are fly ash and unburnt solid residue. Emissions of fly ash and other particles are often controlled by wet scrubbers, electrostatic precipitators, and bag filters.

### Resource Recovery

Numerous thermal processes, now in various stages of development, recover energy in one form or another from solid waste. These systems fall into two groups: combustion processes and pyrolysis processes. A number of companies burn in-plant wastes in conventional incinerators to produce steam. A few municipalities produce steam in incinerators in which the walls of the combustion chamber are lined with boiler tubes; the water circulated through the tubes absorbs heat generated in the combustion chamber and produces steam. Pyrolysis, also called destructive distillation, is the process of chemically decomposing solid wastes by heat in an oxygen-reduced atmosphere. This results in a gas stream containing primarily hydrogen, methane, carbon monoxide, carbon dioxide, and various other gases and inert ash, depending on the organic characteristics of the material being pyrolyzed.

### Burial

This is allowed in only temporary camps where incineration cannot be undertaken. Fly proof pits constructed exactly like an Otway's pit may be used for the purpose.

### Salvaging

This method of refuse disposal can be profitably used in metropolitan areas. Waste paper, polythene bags, wood pieces, glass pieces, tinkers, cigarette packets, tinfoils, rag and even the garbage and swill can be salvaged for economic gain before the unsuitable remnants are sent for disposal. The garbage and swill can be processed for use as chicken and hog feed. Rags and papers can be recycled. Metals both ferrous and non-ferrous, could be salvaged for gainful use. Today, recyclable materials are recovered from municipal refuse by a number of methods, including shredding, magnetic separation of metals, air classification that separates light and heavy fractions, screening, and washing. Another method of recovery is the wet pulping process: incoming refuse is mixed with water and ground into a slurry in the wet pulper, which resembles a large kitchen disposal unit. Large pieces of metal and other nonpulpable materials are pulled out by a magnetic device before the slurry from the pulper is loaded into a centrifuge called a liquid cyclone. Here the heavier noncombustibles, such as glass, metals, and ceramics, are separated out and sent on to a glass and metal-recovery system; other, lighter materials go to a paper-fiber-recovery system. The final residue is either incinerated or is used as landfill. In the developed nations, municipalities and private refuse-collection organizations require to keep bottles, cans, newspapers, cardboard, and other recyclable items separate from other waste. Special trucks pick up this waste and cart it to transfer stations or directly to recycling facilities, thus lessening the load at incinerators and landfills.

## Disposal of Liquid Waste

### Composition

(a) This includes waste water from bath rooms, ablution places, washing places, sullage from cook house and dining halls and industrial effluents. The main aims of liquid waste disposal are aesthetic considerations; prevention of water and soil pollution; prevention of water logging of grounds; prevention of mosquito, fly, and cockroach breeding; and protection of aquatic flora and fauna (26-28).

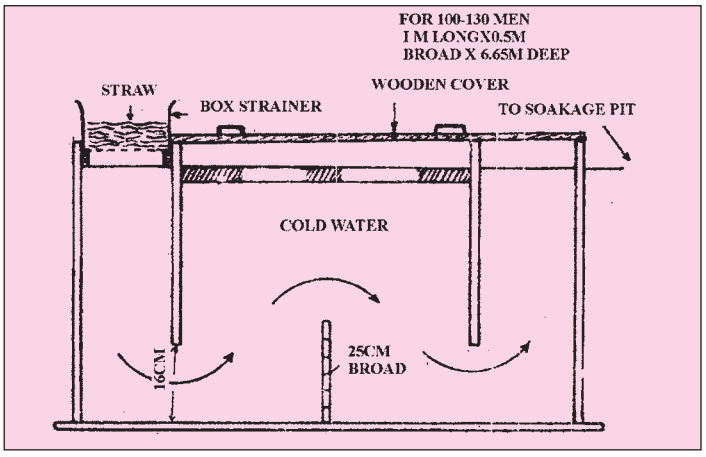
### Disposal

If water carriage system is existing, all liquid wastes can be conveniently discharged into the sewerage system. If this is not available, the most common method of disposal of these liquid wastes is into soakage pits or streams. The sullage from the cook houses and dining halls however, needs pretreatment before disposal due to its high fat content. Even with the most porous soil, fat, grease and soap form an impervious coating on the surface, which prevents percolation. When discharged into a stream untreated it can harm the aquatic flora and fauna by hampering oxidation. The simplest method of removal of grease from the sullage is by passing it through grease trap.

Cold Water Grease Trap

When warm waste water passes .into a sufficient quantity of cold water, the contained fat solidifies and rises to the surface and the clear water runs into soakage pits or into a stream. A cold water runs into soakage pits or into a

Fig - 20 : Cold water grease trap



stream. A cold water grease trap is used in semipermanent and permanent camps (Fig. 20 ). It is only useful for cookhouse sullage, but not for bathroom water because the soap does not float form scum. The construction and maintenance is as under:-

### (a) Construction

Grease traps for permanent camp should be made of cement concrete or masonry. while that for a semi-permanent camp may be made of wood. The quantity of water in a trap should be at least five times the peak-hour quantity of waste water entering it; otherwise the waste water will not be adequately cooled for the grease to

Fig - 21 : Strainer grease trap

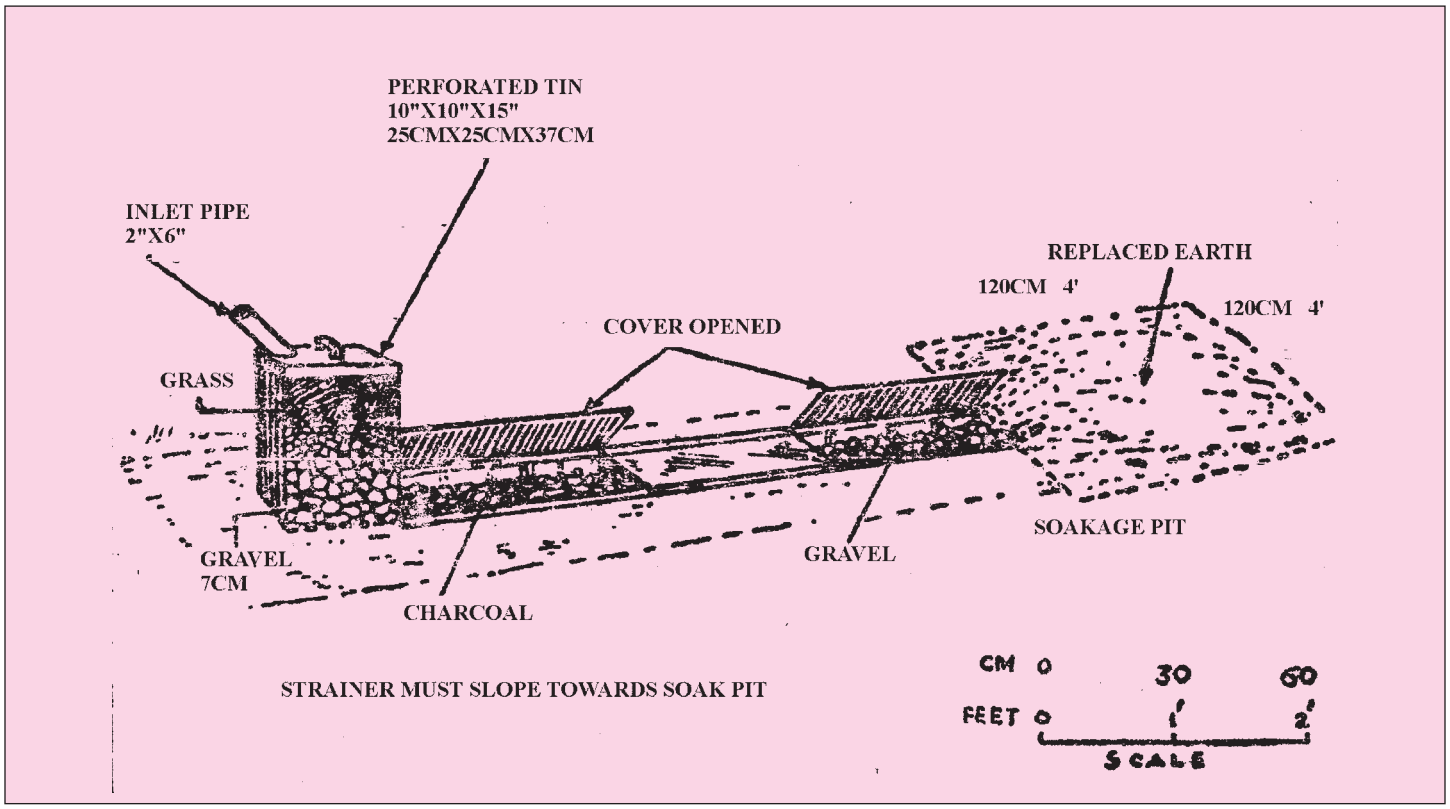


Fig - 22 : Soakage pit for kitchen sullage

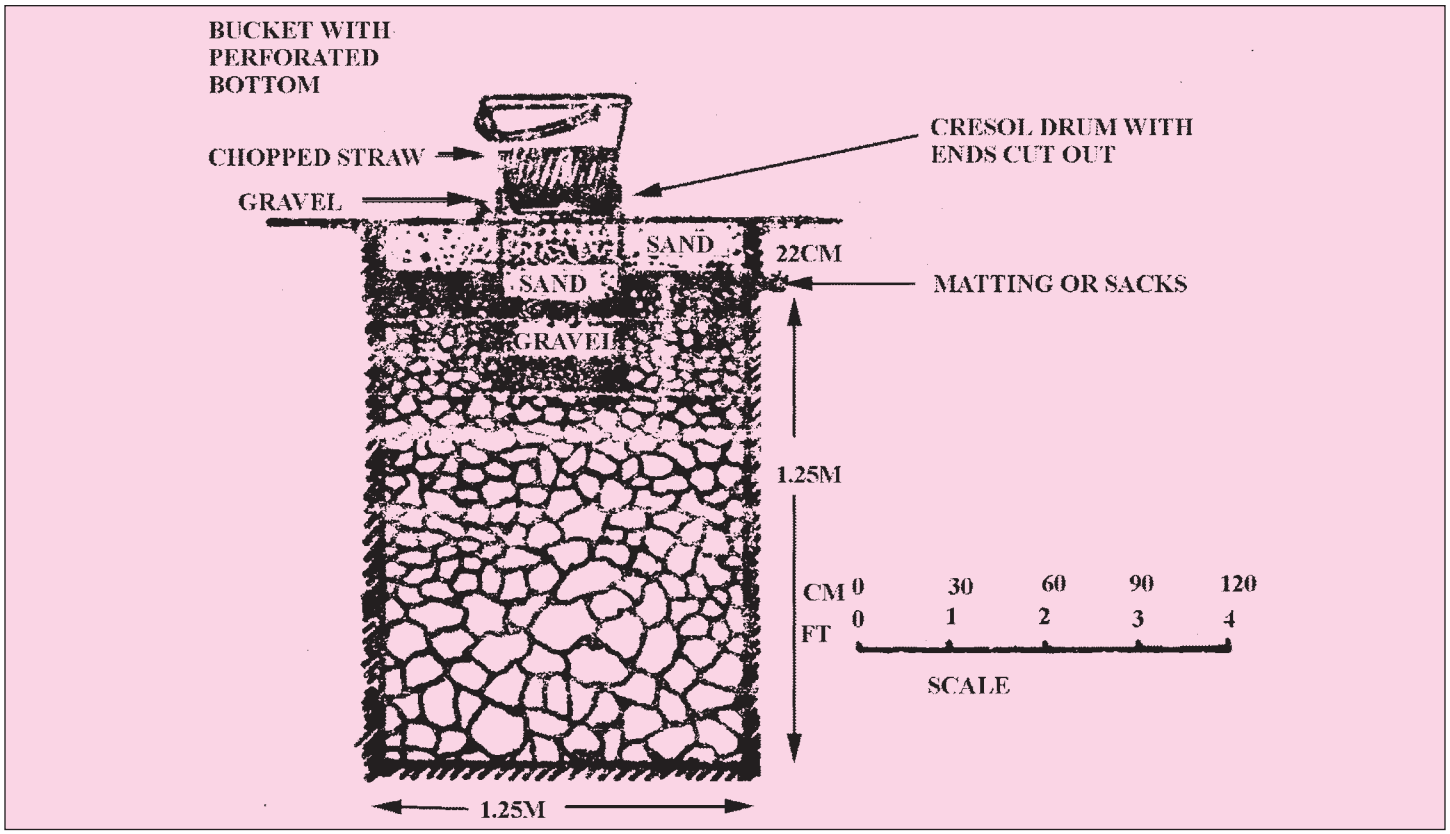

solidify. The normal cookhouse waste water yield is about 3 L per head at the peak hour. Therefore, a trap for a coy cookhouse serving 100 to 130 men should be 1m long, 0.5 m broad and 0.65 m deep. This will hold about 300 L of cold water. The trap is divided into three compartments with two baffle plates placed at about 25 cm distance each from the entrance and exist. They are deficient for about 16 cm at the bottom, hanging in the trap without touching its floor. The middle compartment holds the scum of grease floating. A third baffle plate about 20 cm broad is fixed in the centre of this grease compartment resting vertically on the bottom of the trap to stop the sludge. A strainer made of galvanized iron or tin may be interposed between the inflow and the first compartment to hold back any gross pieces of garbage. The water entering the trap gravitates down due to force of flush and finding its way under the first baffle enters the second compartment wherein the cold water freezes the grease in it. The sludge accumulates at the middle baffle.

**(b) Maintenance**

Surface grease should be removed daily with a ladle and burnt in an incinerator. The grease trap should be emptied once a week, all sludge removed from the bottom and buried; and the sides, bottom and baffles scraped and scrubbed before refilling with cold water.

Strainer Grease Trap

These are used in temporary camps (Fig. 21). The standard type of strainer grease trap is made from ghee tin or cresol drum with perforated bottom. The tin is then filled from below upwards with 7 cm layer each of gravel, coarse sand and fine sand. Over this is placed a 15 cm thick layer of hay or straw. A shallow tin strainer is placed over this grease trap and the sullage water is led into this tin strainer. Percolating downwards the sullage water deposits grease on the straw and top layer of fine sand. A soakage pit is prepared, the strainer grease trap is fixed directly over its centre and waste water is led to it through drain from the outfall of water from the kitchen. The straw should be burnt daily. Sand and gravel need replacement twice or thrice a week and the greasy material is burnt or buried.

The effluent may be run into the existing drainage system, a septic tank or into a stream at point where It does not pollute any source of domestic water supply or into a soakage pit or soak well. The usual method of disposal in the Armed Forces units is to a soakage pit.

Soakage Pit

It is made by digging a 1.25 $m^3$ pit (Fig. 22). The pit is then filled with stones and brickbats in a graded fashion. The final top layer is made of coarse gravel or sand. The pit is then covered with bamboo matting except at the centre for fixing the strainer grease trap over the pit or over an area of required dimension to receive the channel from the cold water grease trap. Heavily oiled hessian cloth is put over the bamboo matting extending upto 0.5 m all around. The soakage pit functions by physical as well as biological process. The physical process involves soakage and evaporation. The biological process is due to action of the 'Zooglea' that grows on the surface of the stones and brickbats. The stones not only provide a surface for growth of the 'Zooglea' but also help in evaporation by providing a large surface area. Soakage pits are, however, liable to clogging even with the use of efficient mechanical traps as some grease and soap from sullage will be left in the effluent and form an impermeable coating on the walls and floor of the pit. Spare pits are thus to be kept in readiness. The water-logged pit is dug out scraped and left open for drying and subsequently rearranged. Weekly insecticidal spraying is to be carried out around the pits.

**Lagoon Pans**

These are suitable in a very dry climate where the soil is porous. The effluent is allowed to flow over the surface for percolation and evaporation. The ground is usually divided into seven areas called the 'lagoon pans'. Each pan receives one day's effluent in turn; the largest area is reserved for Sunday. A central channel with three parallel channels running across the central channel is cut. The effluent is diverted into these by rotation for filling up the required pan. The channel could also be modified in the pattern of 'herring bone' system for better functioning. Periodic scrapping of the pans and the channels is to be undertaken. Flowering or vegetable plants may be grown advantageously in the pan areas.

## Disposal of Dead Animals

Incineration is the best method of disposal of a carcass of animal died of an infection. It requires 40 kg of wood and 10 L of kerosene to ensure complete combustion of a mule in an efficient destructor. For an ordinary non-infectious carcass burial is suitable. A mule or horse carcass needs a 4 x 2 x 2 m pit. Before the carcass is placed in the pit its belly and intestines should be opened to permit the gases of decomposition to escape. Otherwise the belly swells enormously and often forces open the grave. Burial places should always be remote from any campsite or source of water supply. Charring can precede the burial. A pit is dug beside the disemboweled carcass. The viscera are buried. The carcass is then dragged over the buried viscera and blood saturated soil. 20 kg of dried grass or litter soaked with 2 L of kerosene oil is spread over the carcass and ignited. The aim is to sterilize the surface by charring and not to incinerate. The charring should be done early after the death of the animal so that the saprophytic organisms have no time to penetrate tissues. The exposed surface affords attraction to flies. A disinfectant fluid consisting of 1 part of coal tar-creosote-oil with 14 to 18 percent tar acids, and 5 parts kerosene prevents smell and fly breeding. This can be sprayed over the carcass or injected into its carotid artery. Ten liters per horse are necessary. A spray of five percent cresol is also used. Slaked lime should be sprinkled over the carcass, in the grave and over the area. Animals slaughtered for rations and found unfit for consumption should be disposed of on similar lines.

If it is not possible to incinerate the carcass of animal dead of anthrax or suspected anthrax, the carcass may be buried. It, however, must not be cut open. If it is necessary to take a sample of blood for bacteriological diagnosis, an ear is cut off and sent to the laboratory wrapped in gauze well soaked in 5 percent cresol solution and covered by

sacking. The blood or discharges of the animals should not contaminate the ground. All orifices should be plugged with gauze tow soaked in 5% percent cresol and the body wrapped in sacking similarly soaked. The carcass placed in the pit should be surrounded on all sides with quick lime. The byres should be disinfected with 5 percent cresol, using long handled brushes, and then treated with the freshly chlorinated lime wash. Overalls and gloves should be worn throughout the operation.

## E WASTE

'E-Waste' is a collective name for discarded electronics devices that enter the waste stream from various sources. E-Waste comprises of waste electronic goods, which are not fit for then originally intended use. These range from household electronic appliances such as televisions, VCDs, DVDs, radio/ stereo systems, refrigerators, personal computers, printers, washing machines, air conditioners, telephones, cell phones to medical equipments, ATM machines etc.

E-Waste contains several different substances and chemicals, many of which are toxic and are likely to create adverse impact on environment and health, if not handled properly. However, classification of E-Waste as hazardous or otherwise depends on the extent or presence of hazardous constituents in it. Of the entire E-Waste generated, computer waste poses significant environmental and health hazards. Rapid advances in information technology, with new and varied innovation in computers, have led to increasing product obsolescence.

### Generation of E-Waste:

**(a) Industrial sector**

Electronic control panels, electronic gadgets, old wireless handset, EPBX system, UPS, medical equipments, testing instruments etc. The E-Waste generated from automotive and aerospace industry includes control systems, communication system, instrumentation, navigation system, safety system, diagnostic system.

**(b) Commercial sector**

ATM machines, electronic banners, computers, public addressing system, inverter, printers, copiers, fax, scanner etc.

**(c) Residential sector**

Computer, TV, VCD, DVD, Stereo, Radio, Washing machines, refrigerator, microwave etc. The major quantity of electronic waste worldwide is PC (Personal Computer)

### Environmental and Occupational Impact of E-waste

Although it is hardly well known, E-Waste contains many toxic substances such as lead and cadmium in circuit boards; lead oxide and cadmium in monitor cathode ray tubes (CRTs) mercury in switches and flat screen monitors; cadmium in computer batteries; polychlorinated biphenyls (PCBs) in older capacitors and transformers; and brominated flame retardants on printed circuit boards, plastic casings, cables and polyvinyl chloride (PVC) cable insulation that release highly toxic dioxins and furans when burned to retrieve copper from the wires. Due to the hazards involved, disposing and recycling E-Waste has serious legal and environmental implications. The recycling of E-Waste has serious occupational and environmental implications, particularly when the recycling industry is often marginally profitable at best and often cannot afford to take the necessary precautions to protect the environment and worker health.

### International Scenario (Findings Stated in Report by BAN)

(a) 50 to 80% E-Waste collected are exported for recycling by US Export is legal in US

(b) Export is due to cheaper larbour and taxed standard in poor countries

(c) E-waste recycling and disposal in China, India and Pakistan are highly polluting

(d) China has banned import of E-Waste

(e) Lack of responsibility on the part of Federal Government and Electronic Industry, Consumers, recyclers and local governments towards viable and sustainable options for disposal of E-Waste

### Need for Assessment Study on E-Waste

(a) Assessment of current scenario : quantification characteristics, existing disposal practices, environment impacts etc.

(b) Projections for next 10 years regarding consumption and waste generation of electronic goods particularly PC & its accessories, fax, photocopiers etc.

(c) Regulatory mechanisms in other countries (OECD and Non-OECD) and comparison with Indian conditions particularly with regard to regulation of import

(d) Possibility of collection system and requirement of legal instruments.

A study carried out regarding E-Waste in Mumbai, revealed that the electronic scrap is managed through low end management alternatives such as product re-use, backyard recycling etc. The accured electronic wastes are dismantled and manually sorted to different fractions such as plastics, copper/ iron/ aluminum components, wires/ cables, cathode ray tubes, printed circuit boards etc. These components are then subjected to recycling. Since a major portion of the components of e-waste is recycled, the residual generated is insignificant. The process of dismantling and sorting is done by bare hands and only with the help of screwdrivers and hammers posing a serious threat to the health of the workers.

From the survey, the quantity of obsolete electronic products generated by the households in Mumbai for the coming years was estimated based on an assumption mentioned in the study. It was concluded that with the affordability and availability of the products the problem of E-Waste in terms of its quantity will likely increase in the near future.

The way this E-Waste recycling industry is proliferating in the backyards and shanties of scrap dealers in Mumbai,

# Health Problems in Desert

### Introduction

The deserts are characterized by hot air temperatures, low humidity, hotter ground temperatures, high evaporation rates, lack of surface water, sparse vegetation and wide temperature ranges from day to night. Gigantic thunderheads, often moving at great speeds, may in a matter of minutes drop a half inch of rain on a locality, causing flash floods and instant erosion of the desert landscape.

Peculiar set of environmental conditions like these, increase stress on human physiology. Adaptation to such conditions by human body takes long. Inappropriate acclimatization and prolonged stay in desert causes deleterious effects on health & efficiency of individuals.

In India, the arid (desert) zone occupies nearly 12 percent of the total area sustaining a human population of over 19 million and live stock of over 23 million. The total area occupied includes 0.32 million sq. km. of hot desert mainly in Rajasthan, Gujarat and Haryana. Western Rajasthan, a part of the Thar desert, is covered by wind-blown sand and sand dunes. The five districts of Rajasthan, namely Ganganagar, Bikaner, Jaisalmer, Barmer and Jodhpur fall in this arid zone. The area suffers from extreme climate oscillations.

According to recent estimate 4.35 percent of Western Rajasthan has been affected by the process of desertification and another 76 percent is highly vulnerable to it. The human population in Rajasthan desert has increased from 3.42 million in 1901 to 10.84 million in 2001. The Indian desert is one of the most thickly populated deserts in the world. The population can be roughly divided into two major categories, namely, a diffuse and scattered population living in the hinterlands and a concentrated population living in the cities/towns. Working in desert area is beset with medical problems due to adverse environmental conditions and terrain (1).

### Desert Ecology and Human Physiology

The Indian arid zone is characterized by conditions of high aridity with low average annual rainfall ranging from 180 mm in Jaisalmer to 360 mm in Jodhpur. The rainfall is confined to the period from July to Sept.

The zone is also characterized by high temperature variation from less than Zero degree centigrade during nights in winter to more than 50°C in day time in summer. Relative humidity varies around 30% and sand storms are common during Apr-Jun. Vegetation is sparse with few trees in between. Full grown trees are still less though the ecology is changing fast. Drinking water scarcity compounds the problem.

### Zone of Thermoneutrality

The external temperature with which the homeostatic mechanism of thermo-regulation are not stressed and within which the resting heat production rate is at its minimum is called the zone of thermoneutrality. In a resting person this is 2°C on either side of 29°C depending on whether the person is clad or not. Deviation from this zone sets the homeostatic thermoregulatory mechanism in action. On the hotter side, the heat loss is increased while on the cooler side the heat conservation is stimulated. Body loses and gains heat by conduction, convection and radiation. By evaporation body only loses heat.

As the temperature rises beyond the thermoneutral zone, the immediate response is to cause vasodilatation in periphery to divert heat from core to periphery. As the temperature rises beyond 32.8°C vasodilatation alone cannot cause efficient cooling, hence body initiates sweating which is initially invisible but later on becomes visible and profuse. Approximately 6-8 ltr of sweat is produced after a spell of hard work in hot weather. One gram of sweat extracts out 537 calories of heat. Ultimately the loss of heat from body will depend on following factors: -

(a) Efficiency of body to produce adequate sweat.
(b) Efficiency of evaporation.

### Acclimatization in Desert

Over a longer period of stay in desert body achieves a more efficient mechanism of heat loss by setting in few physiological changes like :-

(a) Increased
  (i) Circulatory volume
  (ii) Cardiac output
  (iii) Aldosterone production
  (iv) Renal retention of sodium
  (v) Responsiveness of sweating
  (vi) Fluid requirement
(b) Decreased
  (i) Heart rate
  (ii) Volume of sweating

These changes constitute what is called acclimatization to heat and remain in place till the individual stays in desert area.

## Problems in Desert Area

### Water Supply

Only 3 percent of the ground water in Western Rajasthan conforms to normal standards of drinking water, i.e., containing less than 500 mg/L of total dissolved solids (TDS). As much as 42 percent of the water has a salinity, expressed in form of total chlorides, more than 600 mg/L. One percent of the ground water has a nitrate concentration of more than 50 mg/L, the maximum permissible limit laid down by the WHO. In some areas, the fluoride content of ground water is also high. However no

toxic elements are detected in the water of Western Rajasthan. It can thus be seen that this water deficit area has an acute problem of saline ground water, which is not potable and also hinders bathing, washing, and other community utility. Such a situation gives rise to a high incidence of gastrointestinal disease including viral hepatitis and skin diseases.

**Adverse Environmental Conditions**

During winter, there is a great drop of temperature after sunset which gives rise to the respiratory group of illnesses. During the day, especially during summer, high temperature accounts for a higher incidence of effects of heat like heat exhaustion, heat stroke and prickly heat. The sand and dusty environs lead to an increased incidence of foreign bodies in the eyes, conjunctivitis and trachoma. Desert sores are common and may develop from minor abrasions, and these heal slowly (2 – 4).

**Endemic Diseases**

Malaria, excremental diseases including viral hepatitis and skin diseases have a higher prevalence in desert areas.

**Local Fauna**

Desert areas are infested with poisonous snakes and scorpions. Cases of snake bites in summer and scorpion bites in winter are a common occurrence.

**Housing and Sanitation**

Sources of water in the desert areas are scarce and hence, people gather around such areas leading to overcrowding, unhealthy housing and fall in the standards of sanitation. There is a problem of waste water and sewage disposal in desert areas which may cause outbreaks of fly-borne and excremental diseases.

**Disposal of waste**

Disposal of dry and liquid waste is a problem in desert area due to caving in of the trenches/DTLs.

**Classification of Medical Problems in Desert**

There is no universally acceptable classification of medical problems in desert. These medical illnesses are also present in other parts of country but get exaggerated under desert conditions. Hence, a tentative classification is as under: -

(a) Illnesses due to high ambient temperature
  (i) Heat exhaustion
  (ii) Heat cramps
  (iii) Heat syncope
  (iv) Heat stroke

(b) Illnesses due to Solar Radiations exposure
  (i) Skin tanning
  (ii) Solar dermatitis
  (iii) Solar erythema (sun burn)
  (iv) Aging of skin
  (v) Rodent ulcer
  (vi) Cataract
  (vii) Retinal degenerative changes
  (viii) Pterygium
  (ix) Skin Cancers

(c) Illnesses due to dust
  (i) Chronic eye infections because of blocked / semiblocked eye punctum.
  (ii) Irritation of eyes
  (iii) Trachoma

(d) Miscellaneous
  (i) Prickly heat.
  (ii) Fluorosis
  (iii) Gastro- Intestinal illnesses
  (iv) Predisposition to urinary calculi.
  (v) Nitrates in water causing methaemoglobinaemia.
  (vi) Snake bite & scorpion bite.
  (vii) Eye injuries due to Acacia indica.
  (viii) Camel bites

## Preventive Measures

It is imperative that adequate preventive measures must be adopted to keep the wastage of adequate manpower due to sickness to a minimum. Guidelines to minimise the health hazards are given in the succeeding paragraphs.

**Water discipline**

Deserts are defined by their lack of water. Learn to ration sweat, not water. Rationing water at high temperatures is actually inviting disaster because small amounts will not prevent dehydration. Troops should be encouraged to keep the clothing on, including shirt and hat. Clothing helps by slowing the evaporation rate and prolonging the cooling effect. It also keeps out the hot desert air and reflects the heat of the sun. Arrangement should be made to stay in the shade during the day. As far as possible, one should sit on something 12 or more inches off the ground. Sitting on the ground could be uncomfortable as it can be 30 degrees hotter than a foot above the ground. When planning to travel in the desert, extra thought needs to be given to water supply. Enough water to meet personal requirements, must be carried. If travel is necessary, it is recommended to travel slowly and steadily. Mouth should be kept shut and breathing should be done through nose to reduce water loss and drying of mucous membranes. Conversation should be avoided for the same reasons. Alcohol in any form is to be avoided as it will accelerate dehydration. Food intake should be kept to a minimum if sufficient water is not available. In situations where there is a limited water supply, it is often recommended to throw food away.

**Effects of Heat**

(a) Acclimatization of troops is important for the prevention of effects of heat. To achieve acclimatization, the troops should be involved in progressive daily exercises for 10-14 days. After acclimatization the troops can work and stay well in hot conditions provided an adequate intake of water and salt is maintained (5).

(b) Provision of ample supplies of cool water should be ensured and the fluid intake should be enough to compensate for water loss due to sweating.

(c) Exertion should be judicious and rest and sleep must be adequate, to compensate for the activity. Reveille generally should not be before 0530h.

(d) Bathing must be ensured every day.

(e) Clothing should be light and loose and permeable to water vapour and air (4).

(f) Living quarters should be spacious, well ventilated and cool.

(g) Adequate calories must be consumed by troops as contained in their rations. Dining halls should be cool and comfortable.

(h) Medical examination must be thorough and regular to detect early symptoms of the effects of heat.

(j) Education of troops, including officers and JCOs in preventive measures against ill effect of heat is important.

(k) Cool rooms/Heat stroke Centres should be established at the various MI Rooms/Medical Units as per advice of SEMOs/SMOs.

(l) Special precautions should be observed during operation / recce missions to prevent dehydration and adverse effect of heat, by proper planning for provision of adequate supplies of potable water.

## Heat wave safety rules

**(a) Avoid stressful activities during the hot season**

**(b) Limit activities to cooler times of the day**

Strenuous activities like BPET and parade should be reduced, eliminated, or rescheduled to the coolest time of the day.

**(c) Keep pace slow and carry light loads**

While walking or horseback riding in the desert, maintain an even, comfortable pace. Rest often and never force yourself. Never carry more weight than you can use. Keep in mind, the more weight, the greater the stress and heat production.

**(d) Wear suitable clothing**

While shorts and sleeveless shirts may appear comfortable, they are not suitable for desert wear. Lightweight, light colored clothing is recommended because it reflects heat and sunlight better than darker material. The following items are recommended:

(i) WIDE BRIM HAT, protecting the eyes in front and the neck in back.

(ii) NECK PROTECTION : If the hat does not provide protection to the back of the neck, attach a piece of cloth onto the back of it.

(iii) LONG SLEEVED SHIRT, provide protection from the sun and also help to protect from scratches and insect bites. Cotton is probably the most suitable type of fabric.

Desert survival

- Always inform someone of where you are going, your route, and when you expect to return. Stick to your plan.
- Carry at least one gallon of water per person per day, a first aid kit, and personal survival kit.
- Be sure your vehicle has a sound battery, good hoses, a spare tyre, necessary tools, and sufficient Fuel and oil.
- Keep an eye on the sky. Flash floods may occur any time "thunderheads" are in sight, even though it may not be raining where you are.
- Be alert to three conditions which can pose an immediate threat to your life - HYPERTHERMIA, DEHYDRATION and HYPOTHERMIA.
- Stay near your vehicle if it breaks down. Raise the hood and trunk lid to denote "help needed." Leave a disabled vehicle only if you are positive of the route to get help. Leave a note for rescuers with the time you left and the direction taken.
- When not moving, use available shade or erect some shade from tarps, blankets, or seat covers to reduce the direct rays of the sun.
- Do not sit or lie directly on the ground. In sunlight, the ground usually is 30 degrees hotter than the air.
- Rest at least ten minutes each hour if walking. A normally inactive person should rest 30 minutes each hour. Find shade, sit down, prop up feet.
- If you have water, drink it. DO NOT RATION IT.
- If water is limited, avoid stressful activities. DO NOT talk, eat, smoke, take salt or drink alcohol.
- Keep clothing on, as it keeps your body temperature down and reduces the dehydration rate. Cover your head. Improvise a head covering if a hat is not handy.
- A roadway is a sign of civilization. IF YOU FIND A ROAD, STAY ON IT.
- To avoid poisonous creatures, put your hands and feet only where your eyes can see.

Source : (6)

(iv) LONG-LEGGED PANTS, help the body maintain normal temperatures.

(v) BOOTS, should be durable, fit well, provide support, provide insulation from the hot desert ground and provide traction.

(vi) DO NOT SMOKE : Smoking will hasten dehydration and reduce endurance.

**(e) Drink plenty of water or other non-alcoholic fluids. Do not ration!!**

Drink at regular intervals rather than when you feel thirst. When your body becomes dehydrated, your brain's ability to recognize trouble may be impaired. If there is a limited

amount of water, DO NOT RATION IT; attempt to conserve the liquids in your body instead.

**(f) Never start a desert trip on impulse**

Always be well organized and plan the entire trip.

**(f) Do not take salt tablets**

**(g) Do not drink alcoholic beverages**

Alcohol hastens dehydration.

**(h) Do not get too much sun**

## Endemic Diseases

### Malaria

Apart from occurrence of malaria in endemic form, outbreak of malaria and increased occurrence of falciparum malaria have become annual features. These outbreak should be contained by effective integrated vector control measures.

(a) All ranks should observe strict anti-malaria discipline. Personal protective measures such as use of mosquito nets, repellents, keeping sleeves rolled down and wearing long trousers with boots and anklets after dusk should be ensured. Patrol parties and other personnel engaged in night duties should apply DMP on the exposed parts of the body (7).

(b) Troops can be placed on suppressive treatment when operating in uncontrolled, highly malarious areas on recommendations of DDMS Command (8).

(c) Anti-malaria equipment to be maintained in good state of repair and adequate amount of hygiene chemicals should be provisioned.

(d) Authorised number of trained personnel and anti-malaria squads for spraying of insecticides/hygiene chemicals will be provided in each unit.

(e) Special malaria team should be organised to deal with the problem effectively.

### Skin Diseases

Due attention should be paid to personal hygiene especially keeping the skin clean by regular bath. Adequate laundering facilities should be available in the unit. Minor cuts and wound should be properly treated so that they do not get infected (9,10).

### Excremental diseases

A high standard of living in the camp area is not only conducive to a sense of well being but is of prime importance in the prevention of excremental diseases. Adequate disposal of excreta, refuse, garbage and other refuse matter needs to be strictly followed. Special attention should be paid to the sanitation of cook houses, dining halls and unit wet canteens. Strict anti-fly measures should be enforced. Water for cooking and drinking should be obtained only from authorised sources.

### Respiratory group of diseases

Temperature variations after sunset in desert areas are high. There is a sudden drop of temperature. Hence troops should be adequately clad in the evening and at night to avoid exposure to cold.

### Disposal of waste

Kitchen waste should be disposed off by deep burial. Modified soakage pits to be used for liquid waste. Revetting of DTLs should be done to prevent collapse. Incinerator latrine may be used in sandy desert by small detachments for short periods.

### Snakes and scorpion bites

All personnel should take personal protective measures by wearing ammunition boots and anklets. They should avoid probing into cracks and crevices. Anti snake-bite kits to be provided upto sub-unit level. RMO's/ authorised medical attendants should deliver talks on first aid measures and prevention of snakebite.

Before inducting troops, the unit Cdrs and RMOs must educate them about the prevalent diseases and their prevention and principles of survival in the desert (as given in the box). Maintenance of personal hygiene and cleanliness should be emphasized (11).

# General Concepts in Management

**Introduction**

Historically, management of men, material, money, time and other scarce resources became an inherent requirement for achieving goals ever since people started forming groups to accomplish those objectives which they could not achieve as individuals. In the last century, management emerged as a specialized field and many definitions were formulated by as many authors, none of which alone includes all essential elements of management. The most widely accepted definition of management is that "Management is the art of getting things done through and with people in formally organized groups. It is the art of creating the environment in which people can perform and individuals can co-operate towards attaining of group goals. It is the art of removing blocks to such performance, a way of optimizing efficiency in reaching the organisational goals" (Harold Koontz). A 'process-oriented' definition of management, as described by George R Terry is that "Management is a distinct process consisting of planning, organising, actuating and controlling performed to determine and accomplish the stated objectives by use of human and other resources".

Some other definitions of Management evolved by authors are as under :

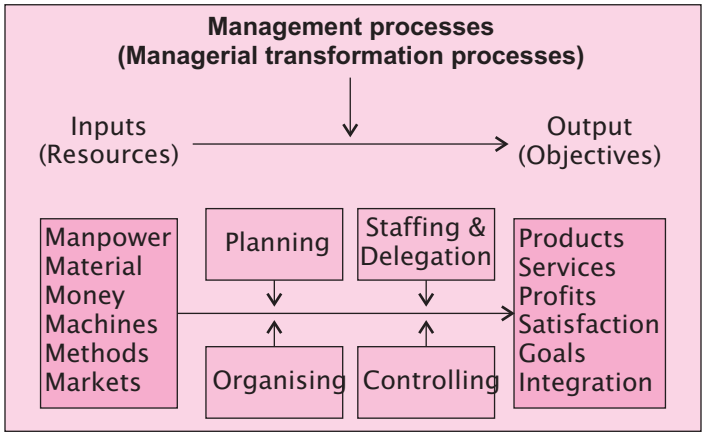
(a) Management is accomplishing a predetermined objective through the efforts of other people. (George R Terry)

(b) Management is the process of organising and employing resources to accomplish predetermined objectives. (Billy J Hodge)

(c) Management is effective utilization of human and other resources to achieve the enterprise's objectives. (William F Glueck)

Inspite of many definitions, the most simple and comprehensive definition remains "Management is getting things done through people. "

Following is the graphical representation of management



:

**Management vs Administration**

Many people think management and administration to be distinct functions while many others consider them to be different aspects of management itself. Newman has defined administration as "The guidance, leadership & control of the effort of a group of individuals towards some common goal", while Sheldon has defined administration as "That function in the industry which is concerned with determination of policy, finance, production, distribution and ultimately control the activities for accomplishing objectives. Thus, policy making, planning and decision making are the basic aspects of administration while supervision, implementation and operation are considered main elements of management. Administrative Management can thus be said to be the major function of top management, concerned with decision making and problem solving while operative management is function of lower management, concerned with operative aspects such as supervision & control (Keith Davis). The following

Level-wise Skills in Management

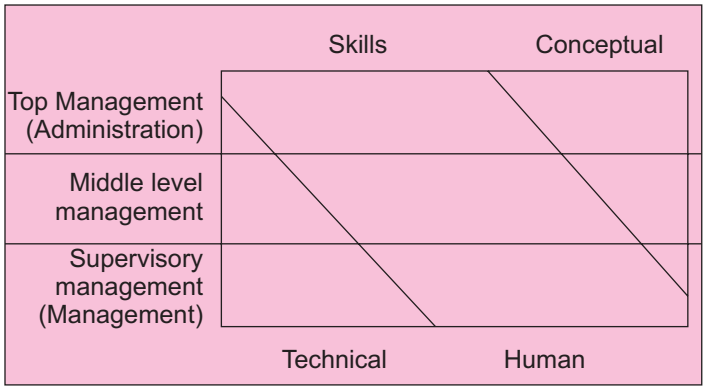


diagram clearly brings out the distinction between Administration and Management :

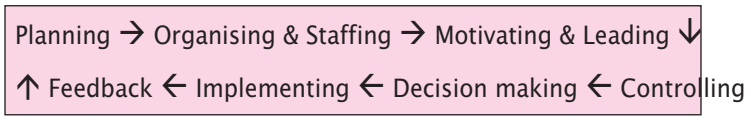
**Management Processes**



The essential processes in any managerial activity can be summarized as under :

**Planning**

Planning, being the basic process involved in management, is the process by which a manager decides in advance the objectives of organisation in short and long run, and the means to attain those objectives. It is the conscious determination of the course of action and the objectives to be reached, by channelising energies of an

organisation in a systematic manner towards achieving the objectives. Planning is needed to allocate the organisation's scarce resources towards achieving the predetermined objectives in the best possible manner and to anticipate and prepare for future opportunities and problems. For example, going out of the house on a cloudy day with an umbrella is one's way of planning to cover the risk (of getting wet) against an anticipated but uncertain thundershower. The process of planning bridges the gap between where we are presently and where we want to go, by making it possible for things to happen which would otherwise not have happened.

**Thus planning as a managerial process implies :**

(a) Making choices - Choosing the alternative (out of large number of potential actions) which offers maximum potential for profit and cost effectiveness.

(b) Committing resources - Scarce resources (manpower, material, money, time etc) have to be allocated for achievement of organisational goals during the planning stage itself. It must be borne in mind by managers that these resources may not be available for other activities of the organisation.

(c) A time horizon - Planning process must be completed within a stipulated time frame, for it to benefit the organisation.

**Elements of Planning**

(a) What will be done - objectives of the organisation to be reached

(b) What resources to be used - estimation of available and potential resources

(c) How will it be done - determining strategies & policies

(d) Who will do it - assigning responsibilities & delegation of authority

(e) When will it be done - timing & sequence

**Objectives of planning are as under :**

(a) To offset uncertainty and change by anticipating future challenges and opportunities, thereby minimizing losses caused by unfavourable situations.

(b) To focus attention on objectives by making them tangible and concrete.

(c) To make operations more economical by selecting the most cost effective course of action out of the many alternatives available.

(d) To facilitate control through policies, procedures, methods, standards and budgets, which are all part of planning process.

(e) To increase organisational effectiveness by providing basis for allocating optimum resources at minimum cost.

(f) To provide criteria for decision-making through strategies & policies, thereby specifying the limits within which each department of individual has freedom in making decisions.

**However, planning comes at a cost and certain limitations, which are :**

(a) Uncertainty about future : The forecasts and premises in planning stage are subject to change since future can never be predicted with perfect accuracy.

(b) Expensive & time consuming : Planning involves commitment of human, financial and physical resources and time, which may delay action in some cases.

(c) Internal inflexibility : Internal rigidity of an organisation may compel managers to make rigid plans, which can not be subsequently changed in case of changed circumstances.

(d) External factors : Plans may be affected by external factors beyond the control of managers, like government policies, wars, natural calamities etc.

**Any effective plan, in order to achieve it's objectives must have the following components :**

(a) Planning process must start from the top and percolate down throughout the organisation.

(b) Planning must be flexible to anticipate and prepare for uncertainties of the future. Planning process should also cater to alternative and contingency plans.

(c) Manager should be provided clear objectives in terms of short-term plans which should integrate to form long-term plans.

(d) The people responsible for implementation of plans should invariably be involved in planning process from the very beginning to ensure proper implementation of the plans.

The Planning Cycle

**Perception of opportunities :** preliminary assessment of possible future opportunities and their evaluation in light of its strengths and weaknesses.➔**Establishing Objectives :** imply the expected results and indicate end points of what is to be done, where the primary emphasis should be and what is to be accomplished by network of strategies, policies, procedures, rules, budgets & programs. ➔ **Establishing planning premises** in form of various factors that affect planning, like political control, govt policies, demand & supply etc. ➔ **Determining alternative courses of action ➔ Evaluating alternative courses of action** in light of the predetermined objectives ➔ **Selecting the best possible alternative after evaluating all alternatives ➔ Formulating supporting plans for various departments inorder to achieve the overall objective ➔ Numberizing the plans by converting them into budgets**

Any planning process would broadly involve the following steps.

Types of Plans

Various types of plans formulated to achieve the overall objectives are :

**(a) Strategies**

Are any decision or behaviour which takes into account the probable or actual actions, policies and strategies of competitors, suppliers, government, trade unions etc and aims to achieve organisation's objectives by taking into account strategies of rivals and other external factors. Strategies focus on actions and imply development of resources for their implementation.

**(b) Policies**

Are guide to decision-making for the manager and establish the broad framework with which managers operate at various levels. Policies do not tell a manager what he should do in specific situations but tell him what he can do, thereby laying down the limits to his decision.

**(c) Rules**

Are guide to action (in contrast to policies which are guide to decision-making) for the manager. Rules prescribe the acceptable behaviour and define what should and should not be done. Rules are often accompanied by penal clauses for non-compliance. For example, a rule on attendance states that late arrival for three days in a month will result in loss of one day's casual leave of the worker. Rules thus, regulate the behaviour but at the same time restrict the initiative of the manager.

**(d) Procedures**

Lay down the sequence of activities that several individuals should follow to accomplish a specific objective. Procedures are thus, plans that establish a required method and sequence of handling future activities to attain the goal.

**(e) Programs**

Relate to those activities which have distinctive mission and time schedule. Programs can be described as means of achieving some desired results within a scheduled time frame. For example, implementation of various aspects of Vision 2020 by the year 2020 is described under a program.

**(f) Budgets**

Are statements of expected results in numerical terms and are often called 'numerical plans'. Budgets are most widely used planning instruments used for control. Financial budgets are well known in form of profit budgets or capital budgets, however, non-financial budgets also exist in form of manpower budget, performance budget, material budget, sales budget etc.

**Planning can broadly be classified as Strategic Planning and Operational Planning, depending on the time-frame.**

(a) Strategic Planning is long-term planning, covering a period which may extend from a few years to few decades. It also takes into account all activities of an organisation and thus refers to planning process for the entire organisation over a long time.

(b) Operational Planning, also called Tactical or Short term planning usually extends upto a period of one year and is more detailed in nature.

**Organising & staffing**

As one of the major functions of management, organising consists of identifying and grouping of activities, assigning authority to managers and providing for co-ordination. Staffing essentially consists of matching the right people with the right jobs.

Essential steps in process of Organising

**Step 1 :** Detailed enumeration of all activities that will have to be carried out to achieve the organisational goals.

**Step 2 :** Group the various activities into departments in some meaningful manner, for example, all activities related to a particular field of medicine may be grouped into one department (Department of Laboratory Sciences, including Pathology, Microbiology, Blood Transfusion).

**Step 3 :** Assign each department to a manager with sufficient authority necessary to supervise the functioning of that department. This is called 'delegation of authority'. The top manager may delegate part of his authority to his subordinates and make them accountable too. Thus authority, responsibility & accountability are important parts of organising process.

**Step 4 :** Horizontal and vertical co-ordination of various groups to achieve organisational goals in the best possible manner. Since individuals, groups and departments perform their respective tasks mostly in isolation, the overall goals of an organisation can get relegated due to conflicts. For example, Head of Medicine Dept of a medical college may insist on purchase of costly equipment for his dept, even though the overall goal of providing better medical education may be served by establishing a new lecture hall.

Principles of Organising

(a) Unity of direction implying one head and one plan for a group of activities having the same objectives.

(b) Unity of Command implying that one subordinate reports only to one boss, to avoid conflict, which is inevitable if a subordinate receives conflicting orders from more than one boss.

(c) Authority commensurate with responsibility.

(d) Optimum span of control, which is the number of persons which a manager can effectively supervise.

(e) Flexible organisational structure to accommodate changes inside & outside the organisation.

(f) Management by exception wherein all routine decisions should be taken by subordinates and top manager should get involved only in exceptional matters, leaving him free to concentrate on planning and policy matters.

Line functions are those activities that have direct responsibility for accomplishing objectives of the

organisation, while staff functions are those that help the line managers to work most effectively in achieving the objectives. In staff capacity, the primary job is to advise and not command, whereas in line capacity, one must take decisions and issue orders.

### Line Organisation

In an organisation having only line relationship, authority flows in a straight line and no subordinate is under more than one superior.

**Advantages :** A line organisation

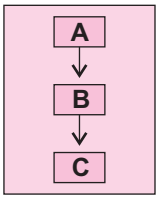
(a) Is simple to implement & understand in an organisation.

(b) Is economical and effective, esp in small organisations

(c) Maintains the unity of command

(d) Directly fixes responsibility for performance

(e) Is conducive to effective control



**Disadvantages :** Such a line organisation

(a) Is not workable in a large organisation

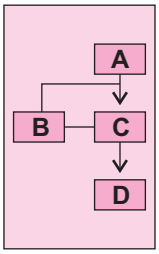
(b) Lack specialization

(c) Does not allow for benefits of expert advice

### Line & Staff Organisation

In an organisation having both line and staff relationships, experts are attached to line managers to advise them, in addition to the line structure.

For example in the organisation shown, A, C & D are in line relationship and B is in staff capacity as advisor and is not in direct line capacity.



**Advantages** : A mixed organisation, besides advantages of line org

(a) Benefits from expert knowledge of staff specialists at various levels

(b) Staff specialists take over specialist functions like accounts & thus take load off from line managers

(c) Help line managers in taking better decisions

(d) Add flexibility to the organisation

**Disadvantages** : Mixed organisations often face some disadvantages as under :

(a) Conflict between line and staff managers regarding authority and advice

(b) Staff personnel are not directly responsible for results, hence may not be fully committed to achieving organisational objectives

(c) Limited promotions for staff appointments result in competition among staff experts to gain favour with senior line managers.

### Functional Organisation

In modern organisations, which are huge and complex organisations, it is not possible to always maintain unity of command and one worker has to take orders from more than one superior on different matters. Therefore different superiors, performing different functions, command the same worker in their respective functions. This is called functional organisation, as depicted in the flow chart at the bottom.

This kind of functional organisation has the following advantages :

(a) Benefits of specialization are available to organisation since one man devotes his entire time to doing only one thing.

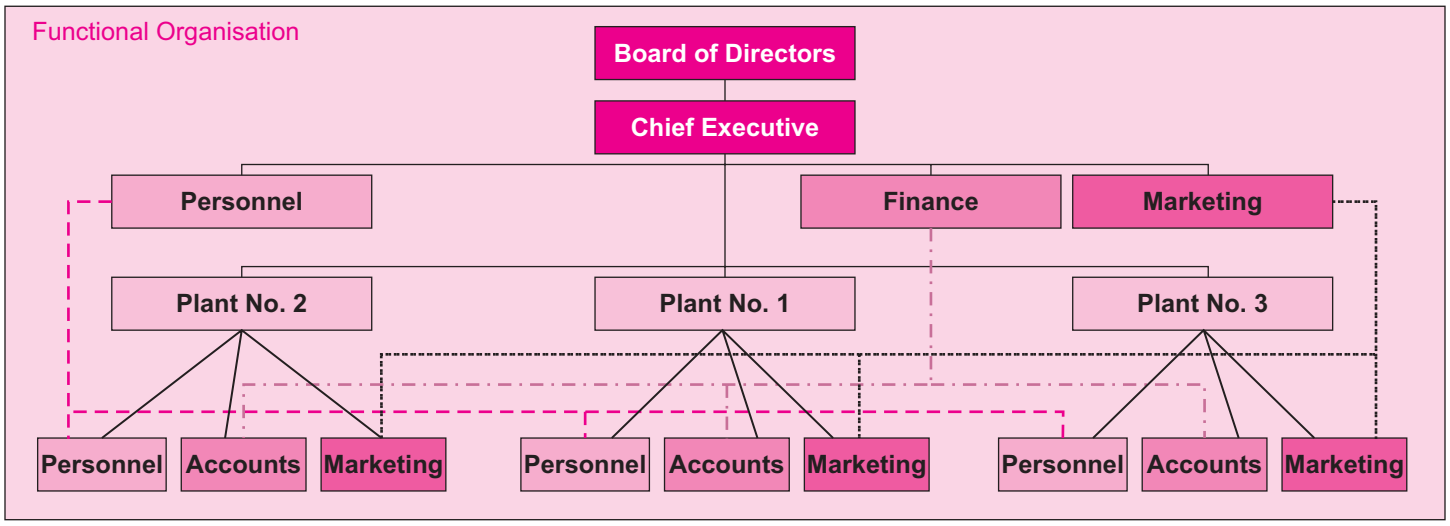
(b) Makes supervision easy because each manager is expert in a narrow range of skills.

Some of the disadvantages of functional organisation are :

(a) System is confusing from procedures / control viewpoint since exact nature of functional activity is not defined.

(b) The clear cut lines of authority and responsibility are completely lost.

(c) Complicates the control process by making



workers work under more than one superior.

(d) Fixing of responsibility for unsatisfactory results is not easy

Having organized related activities and people into formal groups in a specific manner, given them authority with adequate span of control and having found and matched the right people with the right jobs, it becomes essential to retain them. This is where motivation and leadership finds a place.

**Motivating & leadership**

After establishing objectives, plans to achieve these objectives and organisational structure with authority, a manager has to now get his people to work in order to achieve the objectives. This is done through motivation and leadership. Every individual has needs, desires and drives, which prompts him to act in a particular manner, which are collectively called motives and which channelise all his energy towards achieving some objective which the individual perceives to be beneficial to him. A manager's essential role is to channelise all energies of his workers towards attaining the organisational objective through various motivators, which can be described as below :

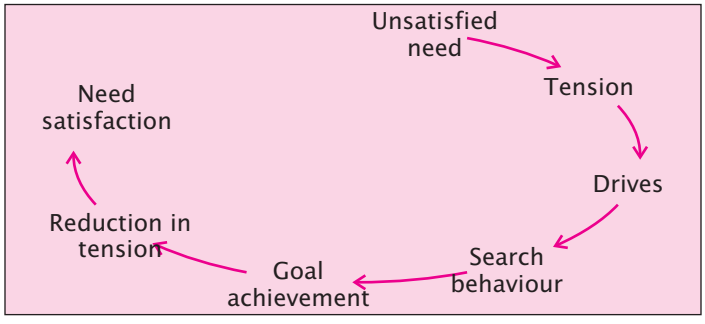
(a) Work Rewards, including monetary benefits (salary) and non-monetary benefits such as free medical cover, company car & driver, furnished house, etc.

(b) Work environment as a motivator, refers to the status of the organisation and the status enjoyed by the worker within the organisation. For example, it is well known that WHO hires only the best health professionals, thus working for WHO itself would be a powerful motivator for any health professional, even if he earns less than private practice.

(c) Work relationships developed with superior, colleagues and subordinates are important motivators. Strained relationship with boss at work place often is reason enough to leave an otherwise attractive job. On the other hand, a congenial & friendly work atmosphere has great motivating value.

(d) Work Content is the design and content of actual work to be done, which is a great motivating factor, if there is an element of freedom to take decisions and experiment with new ideas.

Thus, motivation can be described as the willingness to do something and is conditioned by this action's ability to satisfy some need of the individual. A need is an internal state that makes certain outcomes appear attractive and beneficial to the individual. The basic motivational process can be described graphically as under :



Motivation is described by various authors through Theories on Motivation, as under. The details being out of scope of this book, the reader is recommended to read books on management for detailed description :

(a) Maslow's Hierarchy of Needs (Abraham Maslow)

(b) McGregor's Theory X and Theory Y (Doughlas McGregor)

(c) Herzberg's Motivation - Hygiene Theory (Frederick Herzberg)

(d) McClelland's Achievement, Affiliation and Power Motives (David McClelland)

(e) Expectancy Approach

(f) Psychological Approach

**Leadership**

Leadership is the ability to persuade others to seek defined objectives enthusiastically, by influencing the activities of individuals or groups for achieving the organisational goal in a given situation (Keith Davis). Following are the important elements in leadership process :

(a) Leader tries to influence an individual in a particular way.

(b) Leadership, being rooted in feelings, contemplates interpersonal influence.

(c) It is a dynamic and ever-evolving process. A leader must lead continuously.

(d) Leadership is exercised in a particular situation. A non-leader may also become a leader under a particular situation.

Leadership Styles

The issue of adopting the most appropriate leadership style is essentially concerned with deciding the extent to which a manager should be dictatorial and the extent to which he should be participatory. Broadly, the leadership styles are as under :

**(a) Autocratic leadership**

In this style, the leader gives orders and insists that they should be obeyed, often by instilling the fear of punishment for non-compliance of orders. The leader formulates policies without consulting subordinates and simply tells the group what steps are to be taken immediately, without giving out any future plans. Praise or criticism is awarded to subordinates on initiative of leader alone and the leader remains aloof from the group for greater part of the time.

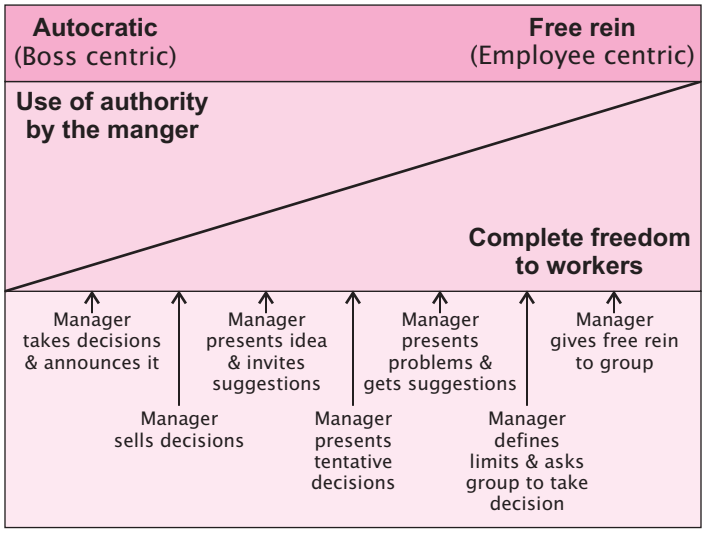
**(b) Democratic leadership**

A democratic leader gives orders only after consulting the group members, policies are discussed and decided by group discussion, subordinates are always asked to do

things after explaining to them the long-term plans on which they are working. The leader participates in the group as an active member.

**(c) Laissez faire leadership**

Such a leader does not lead and leaves the group entirely



to itself. The leader here is incapable of assuming control over his subordinates and does not participate with the group.

**Leadership as a continuum (Tennenbaum and Schmidt)**

The reader may consult books on management for description of leadership styles as under :

(a) Hawthorne Studies (Mayo & Roethlisberger)
(b) Theory X & Y (McGregor)
(c) Iowa Leadership Studies (Lippitt & White)
(d) Michigan Studies on Leadership Styles (Likert)
(e) Ohio State Studies on Leadership Styles (Stogdill)
(f) Scientific Manager's Style (Taylor)

Managerial Grid Theory

Blake & Mouton (1978) proposed that leaders may be task-oriented or person-oriented. Accordingly, leaders are

| | | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| 1,9 | | | | | | | | 9,9 |
| | | | | | | | | |
| | | | | | | | | |
| | | | | | | | | |
| | | | | 5,5 | | | | |
| | | | | | | | | |
| | | | | | | | | |
| | | | | | | | | |
| 1,1 | | | | | | | | 9,1 |

most effective when they achieve a high and balanced concern for both the task and people. According to the Managerial Grid, all leaders can be rated as under :

**Task orientation**

Although there are 81 possible combinations of person and task orientation, it is important to understand the basic 5 types or leadership shown in the diagram :

(a) The (9, 1) leader is primarily concerned with task at hand and has little concern for welfare or issues pertaining to his subordinates. Known as the Task-Management Leader, he is concerned with his responsibility to complete the work at any cost.

(b) The (1, 9) leader is mainly concerned with welfare of his subordinates and has least concern for the task at hand. Known as the Country Club Management Leader, his main concern is establishing a harmonious, safe & pleasant work atmosphere among subordinates.

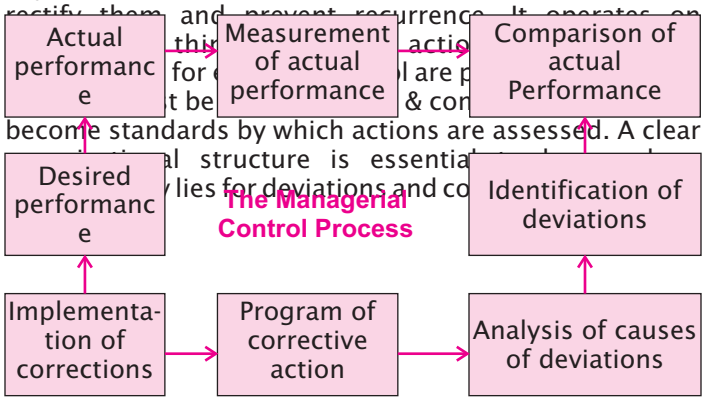
(c) The (1, 1) leader is concerned with neither the task nor the people and avoids the conflict between achievement of goals and establishment of good work atmosphere. Known as Impoverished Management Leader, he remains aloof from his organisation.

(d) The (5, 5) leader, called the Middle of the Road Management Leader, seeks to attain a compromise between attainment of organisational goals and welfare of his subordinates.

(e) The (9, 9) leader, known as Team Management Leader, is extremely concerned about both attainment of objectives and welfare of his subordinates. An ideal situation, this state is difficult to attain.

**Controlling**

The managerial process of controlling consists of measuring and correcting activities of subordinates to ensure that events conform to plans. Thus, controlling is the process of measuring performance against predetermined goals and plans, indicates where deviations from plans exist and helps in achieving organisational goals through remedial actions to correct the deviations. According to Henry Fayol, "In any organisation, control consists of verifying whether everything occurs in conformity with the plans adopted, the instructions issued and principles established. Its object is to point out weaknesses and errors in order to



The Managerial Control Process

become standards by which actions are assessed. A clear structure is essential lies for deviations and co

Thus, it is seen that control process has three essential steps, as under :

(a) Establishing standards, which are criteria for performance and include verifiable goals set in quantitative or qualitative terms. Standards can be based on past performances, managerial judgment or scientific analysis. Standards are used to measure performance and indicate success or failure.

(b) Measurement of performance, which is comparison between "what is" and "what should be" the performance. This has the aim of detecting deviations from the expected well in time and initiate corrective actions, thus it should be undertaken as a prospective action rather than as a post-mortem.

(c) Reinforcing success in case performance is as per expected standards and correcting deviations when they are apprehended or noted.

Important techniques of managerial control

**(a) Budgetary Control**

A budget is a plan showing how resources will be acquired and utilized over a specified period of time. Budgetary control ensures most optimum utilization of resources with the aim to obtain maximum returns. It directs every action towards attainment of organisational goals, provides basis for co-ordination & integration of various activities, measures performance by comparing it with budgeted figures and makes employees conscious about cost & performance. Budgets are democratic way of controlling since subordinates at all levels are involved in preparing budgets and there no undue centralisation.

**(b) Non-Budgetary Control**

**(i) Statistical Data**

Analysis of data in terms of averages, percentages, ratios, correlation etc indicates deviation of actual performance from actual performance.

**(ii) Special Reports & Analysis**

Where routine analysis fails to indicate a specific problem, detailed report by a group is useful in indicating the problem area.

**(iii) Internal Audit**

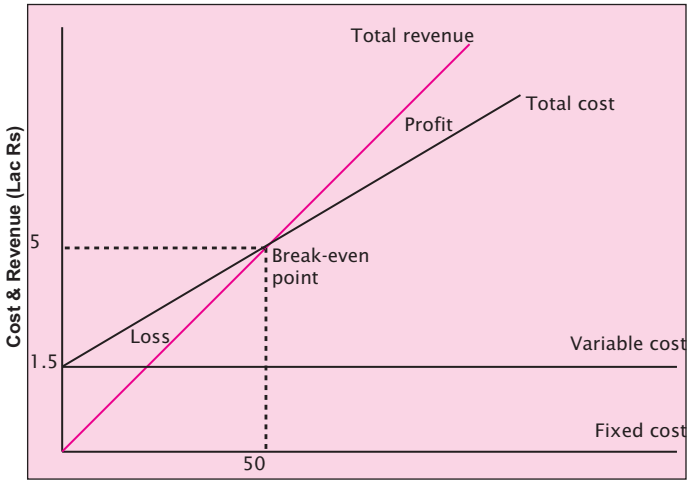
In contrast to external audit which is unconcerned with operational aspects of the organisation, internal audit (also called operational audit) is carried out by manager himself and encompasses entire range of organisational activities including appraisal of policies, procedures, use of authority, quality of management, effectiveness of methods, special problems and issues related to operations.

**(iv) Personal Observation**

As a means to managerial control, personal observation through discussions with subordinates and visits to actual sites of operations provide a manager with valuable information that can only be conveyed through face to face contact personal observation and conversation. For example, with a new man on the job, the supervisor would like to watch his work more closely than work of an experienced worker.

**(v) Break-even Analysis**

Is mainly concerned with the effect that changes in fixed costs, changes in sales volume & changes in sales price will have on the profits. Break-even analysis thus establishes a relationship between cost of production, volume of production, sales & profit. This analysis helps in determining the volume of sales which fully covers total cost price and beyond which profits start accruing and below which there will be loss. The volume of sales at which sales revenue exactly equals total cost of production (no-loss, no-profit point) is known as Break-even point (shown below) :



In the above figure, suppose fixed cost is Rs. 1. 5 lac and variable costs & sale price are Rs 7 and Rs 10 per unit respectively. Here the Break-even point is 50, 000 units of sales because at this point, the total cost is equal to the total revenue. At this point, the total cost is Rs 5 lac (fixed cost Rs 1. 5 lac + variable cost Rs 3. 5 lac) and the total revenue is also Rs 5 lac. The area to the right of this point represents the profit potential and spread to left shows the loss potential.

**(c) Modern Management Control Techniques (Network Techniques)**

Network analysis is a means of planning and controlling process. In this, a project is broken up into small operations which are arranged into logical sequence. Thereafter, the order in which these actions are to be

performed is decided and a network diagram shows the relationship between the various operations involved. Thus, any network analysis indicates the relationship between various operations involved and also points out which activities are to be completed before the others are begun. For example, the simple processes of making tea and snacks may be interlinked with each other by common resource (gas stove). Also the activity of serving tea can not be completed till the time the activity of preparing tea has been completed. This is a highly simplified example of network analysis, which indicates interdependence between two or more activities and the time-schedule between such activities in a large project. Time management of a project, an important managerial control technique, can be done through Critical Path Method (CPM) and Project Evaluation & Review Technique (PERT).

Critical Path Method (CPM)

Here, it is assumed that durations of individual activities in a project are known with certainty. The method thus helps to determine the earliest possible start time & latest possible start time for each activity. CPM also identifies the critical activities, which are critical because if any of these activities are delayed by even short period, the entire project will be delayed. CPM requires greater planning but this is justified by concentrating on critical path only and avoiding expense on strict supervision & control on non-critical activities or on whole project. Besides ascertaining the time schedule of a project, CPM is also the standard method of communicating project plans, progress and costs.

Project Evaluation & Review Technique (PERT)

PERT involves planning, monitoring and controlling of projects where time taken for each activity in the project is not known. It uses probability to estimate the timings of various activities in the project and linear programming for maximizing the achievement of objectives. PERT is classically used in long-term projects like construction of ships, roadways and buildings, in planning & launching of new products, in publication of books etc where exact time for each phase is not known with certainty. PERT uses probilistic and linear programming methods to assist a manager in planning schedules & costs, determining time& cost status, forecasting skill requirements, predicting schedule slippages & cost overruns,

$$\text{Expected Time for an activity} = \frac{\text{Optimistic Time} + (4 \times \text{Most Likely Time}) + \text{Pessimistic Time}}{6}$$

developing alternate time cost plans & committing resources to various tasks. Under PERT, three time estimates are made, as under :

(a) **Most Likely Time** : Time taken most frequently in completing a particular activity.

(b) **Optimistic Time** : Time in which an activity can be completed, if all goes well.

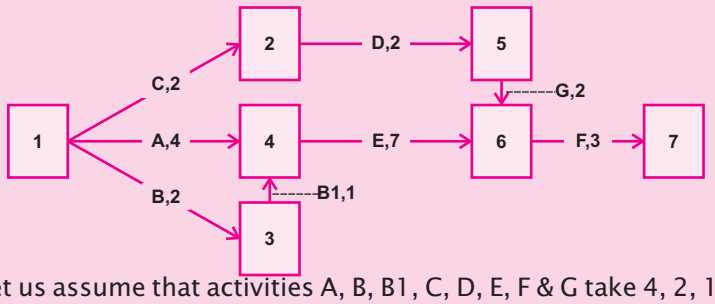
(c) **Pessimistic Time** : Time taken to complete an activity under most adverse conditions.

From the above estimates, expected time for completion of an activity is computed as under :

Unlike in CPM, when time taken for various activities are uncertain, time of completion of the project is uncertain.

Critical Path Method : An illustration

**Let us depict a project by breaking it up into individual activities (A to G) as under :-**



Let us assume that activities A, B, B1, C, D, E, F & G take 4, 2, 1, 2, 2, 7, 3 & 2 weeks respectively in the entire project of Step No 1 to 7. Here we see that A, B & C can be started simultaneously since they do not have any preceding activity. Activities A, E & F for steps 1, 4, 6 & 7 take a total of 14 weeks (4+7+3). This is the critical path since any delay in this sequence will result in delay for entire project. For the sequence 1-2-5-6 (6 weeks), we have a lead time of 8 weeks since sequence 1-4-6 will take minimum of 14 weeks. Similarly sequence 1-3-4 (3 weeks) has a lead time of 1 week over activity A which will take minimum of 4 weeks.

This way, CPM not only helps in planning & sequencing of activities, it also indicates the critical activities (which when delayed, will lead to delay in entire project), thereby concentrating on strict control & supervision of such critical activities.

CPM is an effective managerial control technique where time taken for various activities are known with certainty. However, very often, for long projects, esp in Research & Development, time duration for various activities can not be predicted. Here, we use the Project Evaluation & Review Technique (PERT)

Hence the expected time of completion & variance of project completion time are estimated. The expected completion time can be estimated as in case of length of critical path in CPM method, by replacing activity times by the expected time of various activities. Further, a crude estimate of variance of project completion time can be obtained by adding variances of all the activities on the critical path. Thus, project completion time (when time taken for each activity is not known) is equal to sum of variances of various activities on the critical path. Probability estimates of the completion time of project can be made using the fact that the project completion time has normal probability distribution with mean as expected completion time and variance as variance of the critical path.

### Management By Objectives (MBO)

The purpose of taking any decision in any organisation is to increase either the efficiency, effectiveness or both. Efficiency is the best way of performing a task and is defined as the ratio of output to input (the more output that can be derived from a given input, the more efficient is the utilization of inputs). On the other hand, effectiveness is described as "doing the right task". A manager may be very efficient in his actions, but if he is doing the wrong things (not being effective), his efficiency certainly does not help the organisation. MBO is a managerial tool by which a manager can improve their performance and their overall effectiveness.

The concept of MBO can be considered a mere extension of normal management functions of planning, control & motivation. The term MBO was first used by Peter Drucker more than 25 years ago in a very broad sense as an approach to or philosophy of management. John Humble of United Kingdom described MBO as "a system which integrates an organisation's need to achieve its objectives with the managers' need to contribute and develop himself". Thus, MBO can be defined as a managerial approach which uses objectives as a focal point to improve managerial performance & effectiveness at individual and organisational levels. The important feature of MBO which distinguishes it from other planning and control processes is the emphasis on results (objectives) rather than on activities & processes. In MBO, the emphasis is on outputs and not on inputs. MBO, being based on behavioural approach to management, is based on concepts as under :

(a) Emphasis on results rather than activities.

(b) Defining objectives (expected results) for specific positions.

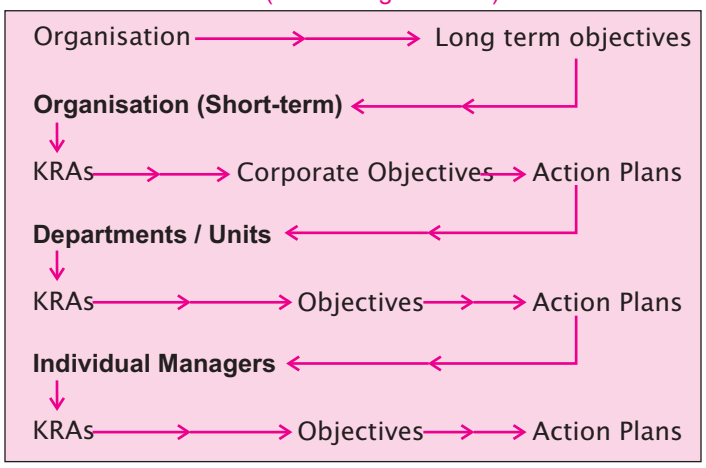
(c) Participatory or Joint objective setting.

(d) Identification of Key Result Areas (KRAs)

(e) Establishing a Periodic Review System.

MBO also emphasizes the concept of "means-ends" sequence. Results at one echelon in an organisation are the means to results at the next higher level and results for a given span of time are the means to results for a longer time-span. MBO leaves detailed methods & actions to the concerned managers by focusing on attaining objectives, and therefore. Results in better delegation, decision-making & job satisfaction at all levels.

Means - Ends Process (Cascading Process)



The MBO Process

There are broadly four steps involved in MBO process, as under

**(a) Identifying the Key Result Areas (KRAs)**

KRAs delineate the broad areas on which the organisation must focus its attention. They are based on the concept that a smaller part of manager's activities yield larger proportion of his results. Here, it is worthwhile to mention the 20 : 80 concept, which implies that 20% of a manager's activities (which are thus critical & important) account for 80% of his results and as much as 80% of his activities (which are thus not important) lead to only 20% of results. KRAs help to identify those 20% activities which will yield 80% of the results, thereby focusing on them and improving effectiveness. Once KRAs have been correctly identified, it is easy to concentrate on important aspects and give low priority to less important activities. A KRA is an area where results are important, where success would lead to significant gains and where failure would be disastrous. Although the emphasis is on objectives in MBO, it is even more important to identify KRAs. There are several ways to identify KRAs, including data analysis and brain storming, wherein all possible KRAs are listed and a short list is thereafter selected. The process of identifying KRAs by the top management consists of the following broad steps :

(i) SWOT Analysis : Analysis of Strengths, Weaknesses, Opportunities and Threats.

(ii) Brainstorming exercise to identify all possible KRAs.

(iii) Discussion, analysis & classification to arrive at an agreed list of KRAs.

(iv) Establishment of specific objectives in each KRA.

(v) Preparation of Action Plans, including assignment of responsibilities for results to be achieved.

**(b) Setting up Objectives**

Having identified KRAs, the next step is to set up

objectives within these KRAs, which will be measurable and quantifiable. The broad organisational objectives define the purpose & mission of the organisation and generally answer the question "what is our business ?" Long-term and short-term objectives emanate from organisational objectives. Strategic objectives are related to choice of product, technology or market. Choice of objectives (statement of expected result) is the starting point for management process in MBO. Hence under MBO, all inputs and processes are modified to meet the requirements of objectives. No doubt that activities are essential to obtain results, but it is well known that all activities do not contribute to achievement of objectives. In addition, objectives should be stated in terms of expected results and not merely in terms of planning activities or activities. It is well established that specific, quantifiable, measurable and concrete objectives result in higher levels of performance as compared to when managers are merely told to do their best. An objective is a statement of expected results, which provides guidelines for decisions and actions at lower level & provides standards against which performance is assessed.

Any objective thus, should have the following four elements, which are also determinants of improved performance :

(i) Quantity
(ii) Quality
(iii) Cost
(iv) Time

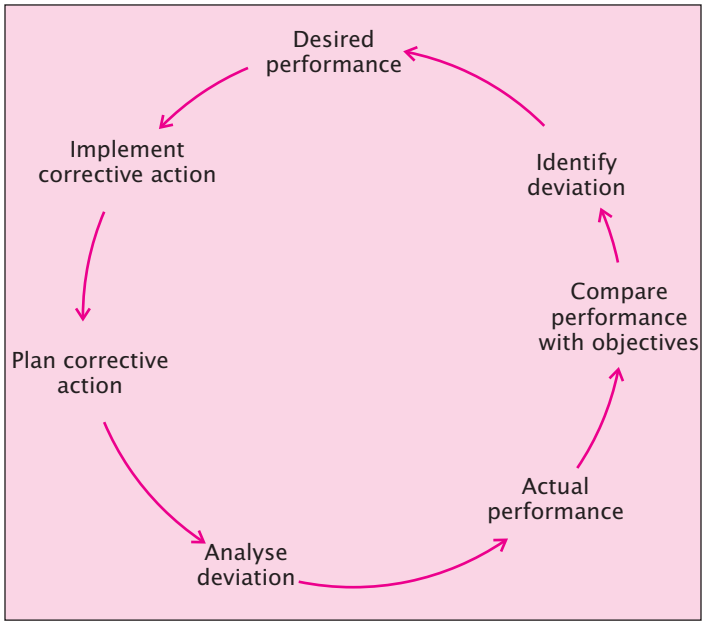
Objectives are successful as guidelines only if they are quantifiable & measurable. If you can not count, can not describe, can not measure what you want, you probably do not know what you want, and hence can not use it as an objective in your plan of action.

**(c) Action Planning**

Action plans are the means to convert objectives into reality. Objectives describe what is to be achieved, whereas action plans describe how these objectives are to be achieved. Every objective has to be achieved only through converting them into specific action plans, which specify what activities will be performed and the specific time when each activity will be performed. The 4 broad steps essential in all action plans are :

(i) Choice of strategies which are essential for achieving objectives.
(ii) Fixing the responsibility for achieving each objective.
(iii) Resource allocation for achieving the objectives.
(iv) Scheduling specific activities in specific sequence for maximum utilization of resources.

Activities (series of acts) have to be done in a particular sequence for attaining the objectives. Thus, all activities have to be arranged sequentially in most logical manner & each activity has to be completed within a stipulated time frame. This is called scheduling, which converts plans into action plans. An example of Action Plan is given below. Let



**Advantages of MBO**

- Greater role clarity, job satisfaction and better measurement of performance.
- No wastage of scarce resources.
- Single-minded dedication to achievement of objectives.
- Motivating factor & weeds out non-performers
- Increases productivity through role clarity & increasing job satisfaction.
- Strengthens superior-subordinate relationship.
- Provides objective appraisal method.

| | | | Action Plan | | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| S No. | KRAs | Objectives | Jan | Feb | Mar | Apr | May | Jun | Jul | Aug | Sep | Oct | Nov |
| 1. | Upgradation of infrastructure | 1. Tiling of rooms | | | | | | | | | | | |
| | | 2. Est of LAN | | | | | | | | | | | |
| | | 3. Est of Comptr | | | | | | | | | | | |
| 2. | Printing of new magazine | 1. Release of funds | | | | | | | | | | | |
| | | 2. Printing | | | | | | | | | | | |

Where ▬ is the planning phase a[illegible] ▬ is the execution of activities

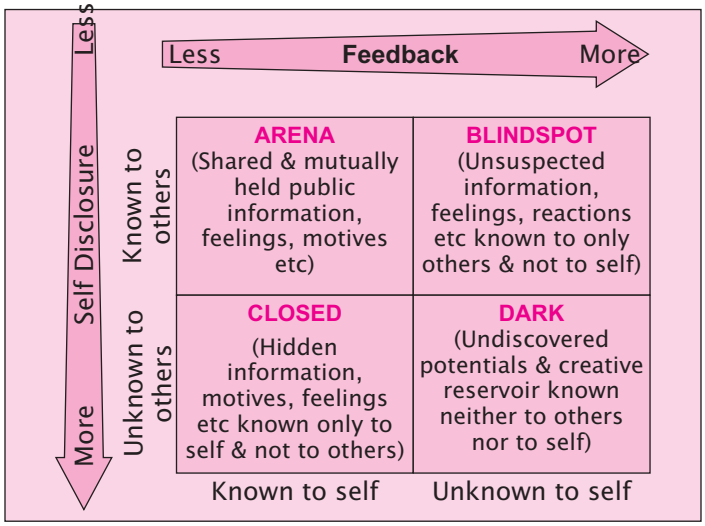
**Disadvantages of MBO**

- Problem of joint setting of objectives among unequals in the organisation.
- MBO may not always percolate to the lowest level in the organisation
- Difficult to implement in situation of change.

**Some additional important managerial concepts**

(a) Developing Interpersonal Styles

The JoHari Window :- Interpersonal relationships between groups is determined by how the groups relate to each other. In order to develop a fruitful relationship, the groups must get to know each other. The JoHari Window is a conceptual model for understanding interpersonal relationships. It is a schematic model that shows how people expose themselves to others and receive feedback from others. The name "Johari" is derived from Joseph Luft and Harry Ingham, who developed the model.



The implication of the JoHari Window is that when Arena is enlarged through self disclosure & feedback, meaningful interpersonal interaction can take place. As the Arena expands, the Closed area shrinks and it no longer becomes necessary to hide or deny things one knows or feels. The Blindspot takes longer to reduce since the person is not even aware of the information, feelings etc. The ultimate goal of this exercise is to move elements from the Dark quarter (of undiscovered potentials) into the Arena (where information, potentials are realized by others as well as self).

(b) Inventory Management

'Inventory' can be defined as 'presently idle but useable resource'. Inventory management deals with determination of correct policies and procedures for procurement of commodities. Broadly speaking, inventory management is concerned with maintaining an adequate supply of some resource to meet an expected demand for that resource. Thus, inventory management is considered a 'necessary evil'. Inventory related costs are

(i) Cost of carrying inventory (holding or opportunity cost of blocking material in non-productive form, expressed as Rupees / item held in stock / unit time)

(ii) Cost of incurring shortages (opportunity cost of not having an item in stock when one is demanded, due to lost sales or backlogging)

(iii) Cost of replenishing inventory (amount of money / efforts expended in procurement of resources, generally called Ordering cost).

Inventory aims at minimizing the uncertainties of demand & supply by 'decoupling' the demand & supply sub-systems. Inventories in form of buffer stock of resources are essential because of uncertainties of demand & lead time, time lags in delivery of resources, backlogging of production process etc.

Types of Inventory Systems

**(a) Lot Size Reorder Point Policy**

Under this policy, the inventory is constantly monitored and as soon as the inventory level falls to a prescribed level (called 'Reorder Point') a fresh replenishment order of a fixed amount of inventory (called Economic Order Quantity, EOQ) is ordered. Thus, the order size is always constant and economically determined.

**(b) Fixed Order Interval Scheduling Policy**

Under this policy, the time interval between two consecutive replenishment orders is always constant, whereas the quantity of stock ordered is determined by the stock already held. This ensures that when high amounts of resources are held, smaller replenishments are ordered.

**(c) Optional Replenishment Policy**

Popularly known as (s, S) policy, here the inventory is periodically reviewed and maximum stock levels (S) and minimum stock levels (s) are pre-determined. If at review of inventory, the stock level is less than or equal to s, an order is placed so that the stock held in hand and order placed equals the maximum stock level of S. If during review, stock held is more than s, no order is placed during that review.

**(d) Other types of Inventory Systems**

Under special circumstances, other types of inventory systems may be adopted. These may be a One-for-one order policy where a replenishment of one unit is demanded whenever there is a requirement of one unit, generally for slow moving goods. Under Multiple reorder policy, more than one reorder points are established. Static Inventory System involves single purchase decision which is adequate for entire project duration and such decisions are not repetitive.

Selective Inventory Management

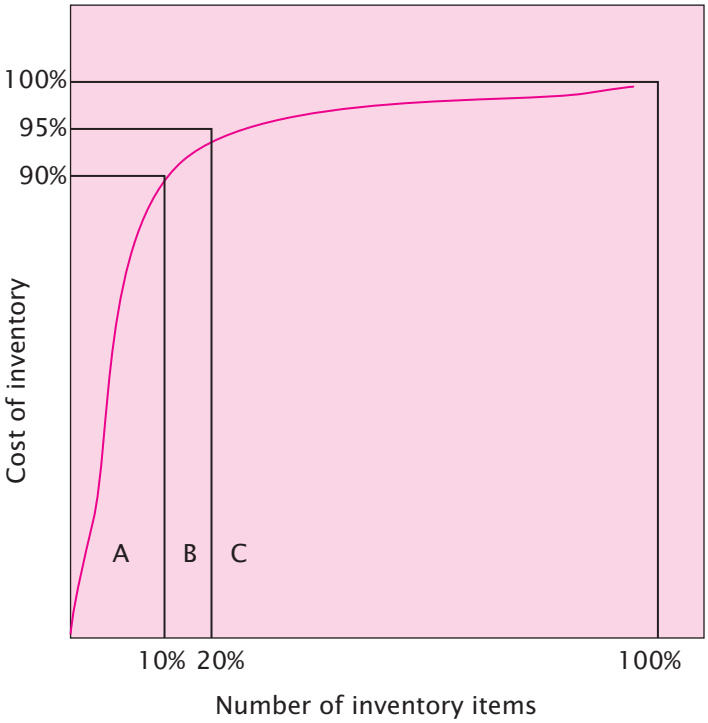
Due to the large variety and numbers of the stocked items in an average organisation, it is prohibitive to apply strict inventory control measures to all items. Appropriate type of inventory policy has to be adopted for selective items depending on the value, criticality and usage frequency of the items. Under selective inventory control, items are

grouped in few categories depending on their value (ABC analysis), criticality (VED analysis) and usage frequency (FSN analysis).

**ABC analysis**

is based on the universal Pareto's Law, which states that in any large quantity, there are 'significant few' and 'insignificant many'. Thus, in any large inventory, there may be only 10% of the items which cost 90% of the entire inventory cost, making them the significant few which require strict inventory control. This is depicted graphically as under :

ABC Analysis



In the example shown, 10% of the items categorized as A account for as much as 90% of the cost of total inventory, 10% of goods classified as B account for 5% of total inventory cost and 80% of total inventory goods classified as C cost only 5% of the total inventory cost. It is thus natural that item A should be subjected to strict control since it costs as much as 90% of the total inventory cost.

**VED Analysis**

Here, the inventory items are classified into three categories (Vital, Essential & Desirable), depending on the seriousness of consequences of stockout of the item. vital items are most critical and shortage of such items may be disastrous for the organisation, Essential items are quite critical for functioning of an organisation and should be by and large available whereas Desirable items do not have serious consequences when in short supply.

**FSN Analysis**

This is based on frequency of demand of various items and items are grouped as 'Fast-moving', 'Slow-moving' and 'Non-moving' items. Obviously, fast moving items must be replenished on priority as any shortage of such items is bound to adversely affect the functioning. Slow

# Health Care System in India

### Historical Perspective

History of health care and public health in India dates back to antiquity. The "Indus Valley Civilization" excavations revealed existence of well planned cities with drainage and sanitary practices as far back as 3000 B. C. Anecdotes of traditional practices of medicine and battlefield medical care and environmental sanitation are mentioned in the epics of Mahabharata and Ramayana. The systems of medicine that are considered to have originated in India are Ayurveda and Siddha. Both these systems are quite similar in concept and practice. Ayurveda means "Knowledge of Life". This comprehensive system of medicine has its roots in Vedic period. The famous practitioners of this system in India were Atreya, Susruta, Charaka and Vaghbhatt. The famous treatise on Indian health and medicine include Manu Samhita, Charaka Samhita and Susruta Samhita. The practice of setting fractures, amputations, cataract surgery is recorded in history. Ayurveda is based on "Tridosha" theory wherein body in health has equilibrium of three humors namely "Vata (wind), Pitta (gall) and Kapha (mucus)". Disease results whenever this equilibrium is disturbed. Ayurveda flourished during Buddhist times. Indian medicine spread to China, Indonesia, and Central Asia and as far as Japan and played a similar role as Greek medicine played in Europe. (1)

Other systems of Indian medicine are Unani (Greek-origin) Siddha and Homeopathy which are not indigenous but widely practiced. Unani-Tibb system of medicine was brought to India by Muslim rulers in 10th century. Besides the above system many types of traditional healing practices continue to be in vogue despite rise of scientific medicine.

## Evolution of Health System in Modern India

Epidemiologically, India is passing through a transition phase in health like any other developing country. It continues to face the scourge of emerging and re-emerging infectious diseases on account of population explosion, haphazard development, in-sanitary conditions, poorly staffed and under equipped public health infrastructure and lack of basic amenities like safe water and sanitation to the poor and underprivileged. Newer, fast growing epidemics of non-communicable diseases are posing a health challenge on the other front due to rapidly growing economy and increasing life expectancy. India has already been dubbed as the Diabetic Capital of the world.

In the pre-independence period, the British had started a number of Public Health initiatives. Quarantine act was passed in 1825. Commission of Public Health in 1859 had pointed out the need of safe water and environmental sanitation to prevent occurrence of epidemics. Sanitary commissioners were appointed in all three provinces of Bombay, Madras and Bengal. Local self government act was passed in 1885. Decentralization of health administration had begun in 1919 with Montague-Chelmsford constitutional reforms. Bhore committee constituted in 1943 laid the framework on which the health care was eventually built in the independent India. The health care in India has since moved from bureaucratic government based top down approach to decentralized community based bottom- up system after the Panchayati Raj came into being. This model was long ago propagated by the Father of the nation "Mahatma Gandhi".

### Bhore Committee

In 1943, Government of India appointed the "Health Survey and Development Committee" under chairmanship of Sir Joseph Bhore. The committee submitted its report in 1946. (2) The recommendations on integration of curative health care with preventive services and development of primary health centre in rural areas were made by this committee. It envisioned development of Primary Health Centre in both short and long term perspective. A PHC would serve a population of 40, 000 as a short term measure, with a staffing of 2 medical officers, 4 Public Health Nurses, 1 Nurse, 4 Midwives, 4 trained Dais, 2 Sanitary inspectors, 2 Health assistants, one pharmacist and fifteen other class IV employees. In the long term (3 million plan), the PHC would have a 75 bedded hospital for a population of 10-20, 000. It also reviewed the system of medical education and research. This document laid the utmost emphasis on primary health care which became the key strategy to achieve Health for All (HFA) by 2000 during Alma-Ata conference. The Bhore committee model was based on the allopathic system of medicine. The traditional health practices and indigenous system of medicine prevalent in rural India, which had greatest influence and were part of their socio-cultural milieu were not included in the model proposed by Bhore committee. The approach was not entirely decentralized but had a top down approach. However it provided a ready-made model at the time of independence and thus was adopted as a blueprint for both health policy and development of the country.

### Mudaliar committee

To review the progress made since submission of Bhore committee report and to make recommendations for development of Health services based on the needs, Government appointed "Health Survey and Planning Committee" under Dr A L Mudaliar in 1959. It found that services provided by PHCs were inadequate. It recommended strengthening of PHCs and development of referral centres. It also suggested constitution of an All India Health Service. (3)

### Jungalwalla Committee

In 1967, Central Council of Health appointed "Committee on integration of Health Services" headed by Dr N. Jungalwalla. It recommended a unified cadre, common seniority, no private practice and good service conditions.

**Kartar Singh Committee**

The Committee headed by then additional secretary, MOH and Family planning was constituted to study and make recommendations on the structure for integrated health services at peripheral and supervisory levels. It was to study the feasibility of bipurpose and multipurpose workers in the field. It recommended "Female Health Worker" in place of ANM and "Male Health Worker" in place of malaria surveillance worker, vaccinators, health education assistants and family planning health assistants. The committee proposed a PHC per 50, 000 population with 16 subcentres, each covering a population of 3000-3500. (4)

**Shrivastav Committee**

This was a "Group on Medical Education and Support Manpower" constituted in 1974 by the Government. (5) The concept of community participation in the health sector originated wherein it was felt that "health of the people is placed in the hands of people". This group recommended that primary health care be provided within the community itself through specially trained workers. Based on these recommendations "Rural Health Scheme" was launched by the government in 1977-78.

**Alma-Ata Declaration**

The concept of health care passing through the stages of "Comprehensive health care" and "Basic health services" had finally moved on to the concept of "Primary Health Care". This new strategy was adopted by all member countries during Alma-Ata conference held in 1978 in then USSR, as the key to attainment of "Health for All by 2000". Primary Health Care has been defined as "essential health care made universally accessible to individuals and acceptable to them, through their full participation and at a cost the community and country can afford". (6) This concept of Primary health care is based on the principles of equitable distribution, community participation, intersectoral coordination and use of appropriate technology. The basic principle in this remains the involvement of the community in health care.

**Health for All (HFA) by 2000**

During 30th world Health Assembly "Health for All by 2000" was set as the social goal for all the member countries. All countries were to develop their norms and indicators and formulate their own strategy to achieve this with "Primary Health Care" as the key strategy. The HFA was defined as "attainment of a level of health that will enable every individual to lead a socially and economically productive life". The important elements of primary health care as included in Alma-Ata declaration are education on prevalent health problems and methods to prevent and control them, adequate food supply and proper nutrition, provisioning adequate and safe water and access to basic sanitation, MCH care including family planning, immunization services, prevention and control of locally endemic diseases and appropriate treatment of common diseases and injuries and provisioning of essential drugs. WHO proposed 12 global indicators for assessment of a country's progress towards HFA that included a minimum life expectancy of 60 years and maximum IMR of 50 per 1000 live births. (7) Report of the study group on "Health for All- an alternative strategy" sponsored by ICSSR and ICMR under the chairmanship of Professor V Ramalingaswami and report of the working group on HFA by 2000 of Ministry of Health and Family Welfare formed the framework for formulation of National Health Policy-1983. Goals that were set to be achieved by year 2000 are given in Table 1. Subsequently the National Health Policy was revised in 2002 and fresh targets were laid down (

Table - 1 : National Health Policy- HFA by 2000 Goals

| Sr. No | Parameter | Present (1983) | Goal to be achieved by 2000 |
|---|---|---|---|
| 1 | Reduce IMR | 125 | < 60 |
| 2 | Raise Life Expectancy | 52 | 64 |
| 3 | Reduce CDR | 14 | 9 |
| 4 | Reduce CBR | 33 | 21 |
| 5 | Achieve NRR | NRR = 1 by 2000 | |
| 6 | To provide potable water to the entire rural population by 2000 | | |

refer to chapter on National Health Policy for details)

**Millennium Development Goals**

During millennium summit in September 2000 at New York, 189 member countries adopted United Nations Millennium Declaration. The goals to be achieved related to health, poverty, gender inequality, environmental sanitation etc are referred to as Millennium Development Goals (MDGs) (8). Three of the 8 goals, 8 of the 18 targets and 18 of the 48 indicators are health related. Governments have set out 2015 by which they plan to achieve these goals. Tackling poverty and hunger is the top priority.

The list of health related goals (MDGs) is given as under -

Goal 1- Eradicate extreme poverty and hunger

Goal 4 – Reduce Child mortality

Goal 5 – Improve Maternal health

Goal 6 – Combat HIV/ AIDS, malaria and other diseases

Goal 7 – Ensure Environmental sustainability

Goal 8 – Develop global partnership for development

To achieve these goals, a number of targets and indicators have been decided by each country and suitably modified.

**Panchayati Raj**

In 1952 community development programme was started for all round development of the rural areas. This was a multipurpose programme including the facets of agriculture, communication, education, health and sanitation. A block consists of 100 villages & a population of 80,000 to 1,20,000.

The village panchayats have existed in India since ancient times. Gandhiji defined his vision of village Panchayats in the following terms "Village swaraj is a complete republic independent of its neighbours for its own vital wants and yet interdependent for many others in which dependence

is a necessity". Panchayati Raj represents the struggle of the people to regain the power vested in them at independence. It means resources and power and to control them administratively. The Panchayati Raj is a form of local self government in India. It is structured at village, block and at district level. People's model of health is based on the strengths of our own culture and utilizes all modes and systems of appropriate health and medical care in an integrated and holistic manner. At the village level there is a panchayat, Panchayat Samiti at Block and Zila Parishad/ Zila Panchayat at the district level. The aim of these institutions is to make people participate in the development process.

### Health Resources

The resources required to look after the health needs of the community depend upon the size of the population, communication facilities and the educational status. The resources available depend upon the economic status, political will, priority of health in national development planning process and level of awakening and empowerment of the community. Three elements of health resources are Health manpower, money and material and time. Health manpower planning is an important step in Community Health care planning (10). Suggested norms for health personnel is given in Table - 2.

Table - 2 : Suggested Norms for Health Personnel

| SNo | Category | Suggested Norm / population |
|---|---|---|
| 1 | Doctors | 1/ 3500 |
| 2 | Nurses | 1/5000 |
| 3 | Health worker Male/Female | 1/5000-Plains 1/3000- Hills/Tribal areas |

### Five Year Plans

Planning commission formulates five year plans. Health sector for purpose of planning has been divided into many sub-sectors like water supply and sanitation, control of communicable diseases, medical education, training and research, medical care including hospitals and PHCs, family planning and indigenous system of medicine. Tenth five year plan (2002-2007) has focused on the optimizing coverage and quality of care by improving access and quality of primary health care in both urban and rural areas. The percentage of fund allocation for health has been grossly inadequate The spending on health has never touched 5% of the national plan outlay which has been suggested by WHO as goal to achieve HFA. India spends 3% of GNP on health. The health infrastructure saw some growth in the first two plans but later plans focused on urban-based curative services. The PHCs were relegated to mere instruments of achieving national targets. Some key facts are shown in Table - 3, 4 & 5.

### National Rural Health Mission

It was launched on 5th April 2005 for a period of seven years (12). The details are discussed in a separate chapter.

## Organization of Health System in India

Health is the responsibility of the state as enshrined in constitution of India. Health is a basic right of every individual. Based on these principles, various health programs were formulated and implemented. However the involvement of community and its importance was realized only after these "Vertical" programs failed to achieve the desired results and the "Health Gap" between the urban and rural areas continued to widen. The "Primary Health Care" promises to fill this gap. There has been some progress on the health front since independence, albeit a bit slow. The economic progress promises to hasten this progress coupled with emphasis on strengthening of rural health infrastructure under

Table - 3 : Plan wise Expenditure on Health and Family Welfare

| Plan Period | Total plan outlay (in Rs. Crores) | Health | Family Welfare | Sub Total |
|---|---|---|---|---|
| 1951-56 | 1960 | 65.2 (3.3 %) | 0.1 | 65.3 ( 3.3%) |
| 1956-61 | 4672 | 140.8 (3%) | 5 (0.1%) | 145.8 (3.1 %) |
| 1961-66 | 8576.5 | 225.9 (2.6%) | 24.9(0.3%) | 250.8 (2.9%) |
| 1966-69 | 6625.4 | 140.2 (2.1%) | 70.4 (1.1%) | 210.6 (3.2%) |
| 1969-74 | 15778.8 | 335.5 (2.1%) | 278.0 (1.8%) | 613.5(3.9%) |
| 1974-79 | 39426.2 | 760.8 (1.9%) | 491.8 (1.2%) | 1252.6(3.2%) |
| 1980-85 | 109291.7 | 2025.2 (1.8%) | 1387 (1.3%) | 3412.2(3.1%) |
| 1985-90 | 218729.6 | 3688.6 (1.7%) | 3120.8 (1.4%) | 6809.4 (3.1%) |
| 1990-91-92 | 137033.5 | 2253.8(1.64%) | 1805.5(1.32%) | 4059.3(2.9%) |
| 1992-97 | 798,000.0 | 7582.2 (1.75%) | 6500 (1.5%) | 14082.2 (3.25%) |
| 1997-2002 | 859,200.0 | 10818.4 (1.26%) | 15120(1.75 %) | 25938(3.01%) |
| 2002-07(X Plan) | 1484131.3 | 31020.3 (2.09%) | 27125 (1.82%) | 58145(3.91%) |

Table - 4 : Targets for Xth Plan (2002-07)

| S. No. | Target | Remarks |
|---|---|---|
| 1 | Reduction of Poverty | 5% points by 2007<br>15 % points by 2012 |
| 2 | Primary Education | All children to attend school-2003<br>All children to complete 5 year of schooling by 2007 |
| 3 | Reduce Gender gap | Literacy and Wage rate by 50% by 2007 |
| 4 | Literacy | 75% within plan period |
| 5 | Reduction of IMR | To 45 per 1000 live births by 2007<br>To 28 per 1000 live births by 2012 |
| 6 | Reduction of MMR | 2 per 1000 live births by 2007<br>1 per 1000 live births by 2012 |
| 7 | Access to Potable | All villages |

Table - 5 : The progress of various key parameters since independence

| Sr. No. | Item of information | 1951 | 1991 | Current |
|---|---|---|---|---|
| 1 | Population (in million) | 361 | 846 | 1131(mid 2007) |
| 2 | Crude Birth rate | 39.9 | 29.5 | 24 |
| 3 | Crude Death rate | 27.4 | 9.8 | 8 |
| 4 | Infant Mortality Rate | 134 | 80 | 57 (SRS 2006) |
| 5 | Annual Growth Rate (%) | 2.19 | 2.07 | 1.96 |
| 6 | PHCs | 4793 | 20139 | 22669 |
| 7 | Sub Centres | 17521(1967) | 130984 | 144988 (2005) |
| 8 | CHCs | - | 2070 | 3910 (2005) |
| 9 | Beds per lakh population | 32 | 83 (1982) | 89 (2003) |
| 10 | Doctor per lakh population | 17 | 47 | 70 |
| 11 | Health expenditure (%of GDP) | | 0.22 | 0.960.91 |

NRHM based on the pillars of primary health care.

### At Centre

Before 1947, the medical and health services at the centre were administered by two separate departments, one under the Director General of Indian Medical Service and the other under the commissioner of Public Health.

Presently, the Union Ministry of Health and Family Welfare is headed by a cabinet minister. The ministry has three main departments- Health, Family welfare (created in 1966) and Indian system of Medicine and Homeopathy. Department of Health deals with medical and public health matters, including drug control and prevention of food adulteration. The secretary to the Government of India in Ministry of health and family welfare is in overall charge of Family Welfare. The functions of the Union Ministry of Health are given in 7th schedule of Article 246 of constitution of India under concurrent and union list. Technical advice on all medical and public health matters is rendered by the Director General Health Services (DGHS). The directorate comprises of Medical care and hospitals, Public Health and general administration. The main functions are listed in table-6

### Central Council of Health

This was created to ensure coordination and cooperation on health related function of states and centre under concurrent list. This council is headed by Union Minster of Health and Family Welfare and State Health Ministers are the members.

### State Level Organization

Each state has a state ministry of health and state health directorate. The state health minister heads the ministry assisted by a deputy

Table - 6 : Functions of DGHS

| SNo | Function | Remarks |
|---|---|---|
| 1 | International Health Relations & Quarantine | All international Sea and Air ports |
| 2 | Control of Drug standards | Drug controller |
| 3 | Medical Store Depots | Mumbai, Chennai, Kolkata, Karnal, Guwahati , Hyderabad |
| 4 | Post graduate Training | AIIHPH Kolkata, NIMHANS Bangalore, NTI Bangalore, NICD Delhi, CRI Kasauli, NIHFW Delhi |
| 5 | Medical Education | LHMC Delhi, MAMC Delhi, Medical Colleges at Goa and Pondicherry |
| 6 | Medical Research | ICMR, Research centres e.g. NIN, NIV |
| 7 | Central Government Health Service | |
| 8 | National Health Programs | RNTCP, NLEP, NMCP, NACP |
| 9 | Central Health Education Bureau | Preparationof health education material |
| 10 | Health Intelligence | CBHI |

minister. Health Secretariat is the official organ of this ministry and is headed by a Secretary. Director of Health Services is the chief technical adviser to the state government on all issues of medical care and Public health. In some states this designation is also known as Director of Health and Family welfare. The director is assisted by a number of Deputy and Assistant directors. They may be regional or functional in their nature of duties. Director Medical Education has also been added as new appointment due to increased number of medical colleges. Public Health Engineering is an organization which functions under the umbrella of Public Works Department.

### District Level

The district is the principal functional unit of administration in the country and this also holds true for health care delivery and management. The district is sub-divided into sub-divisions, tehsil / taluka, community development blocks, villages and panchayats. The Blocks comprise of about 100 villages and a population of 80, 000 to 1, 20, 000. The Block is basic unit of rural development and planning. The urban areas of district are organized into the forms of local self government based on the size of population covered e. g. town area committees (population 5000-10, 000), Municipal Boards (Population 10, 000-200, 0000), Municipal corporations (Population > 2 lakh).

The medical and health organization varies from state to state. Under the MPW scheme, it has been suggested to have a Chief Medical Officer assisted by three Deputy CMOs. The District Hospitals have been re-christened as District Health Centres thus integrating preventive, promotive and curative services.

## Levels of Health Care

Traditionally health care has been described as Primary, Secondary and Tertiary involving varying degrees of technical expertise and complexity. Primary or "First contact" care is provided by Primary Health Centres and their Sub-Centres. Secondary care is provided through Community Health Centres (CHCs) and District Health Centres. The CHCs are also referred to as FRUs (First Referral Units). Tertiary health care is very sophisticated, technically advanced form of medical care with super specialist facilities available only at select institutions at state and central level.

### Primary Health Care

As adopted during Alma-Ata Conference, Primary Health care is the key strategy to attain "Health for All". The underlying principles of Primary Health Care are equitable distribution of health services, community participation, and intersectoral coordination and by using appropriate technology. By equitable distribution it is implied that health services are made available to all irrespective of socio-economic status and place of residence. Most of the health facilities are concentrated in the Urban areas with the majority of rural and under privileged still do not have access to basic health care. Community participation it is meant that community must be actively involved in planning, implementation and maintenance of health services. The Village Health Guides and ASHA are steps in this direction. All related sectors and aspects of community development like agriculture, animal husbandry, food, industry, education, communication and housing must work hand in hand with health care system. Appropriate technology means a technology that is scientifically sound, adapted to local needs and acceptable to the community and based on the principles of self reliance and affordable.

### Health Care Services

The basic aim of health services is to improve the health status of the population to achieve the goal of Health For All as defined during Alma-ata conference. The health services should be comprehensive, accessible, and acceptable to community with their participation and at a cost the country or community can afford.

In India, the health services are provided by Public Health sector, Private sector, traditional / indigenous systems of medicine, voluntary health agencies and various national health programs related to various diseases and disorders. Besides the above there are comprehensive health care services of Defence and Railways.

### Village Level

At the village level, Village Health Guide scheme was introduced in 1977. These health volunteers came from the same community they were supposed to serve. All the VHGs are now females. They are trained at PHC for 3 months (300 hours). They are volunteers who do this health care task for 2-3 hours and continue to pursue their vocation.

At present there are 3. 23 lakh VHGs. The target is to provide one VHG in each village or per population of 1000. Under Rural Health Scheme (1977-78), a program was initiated to train local dais (Traditional Birth attendants). This training is for 30 days at PHC and she is required to conduct at least 2 deliveries under supervision and guidance of Health Worker (F), ANM or Health Assistant (F). She is issued delivery kits and receives honorarium of Rs 10 per delivery and Rs 3 per child registered.

ICDS (Integrated Child Development Services) program based on supplementary nutrition was launched in 1975 in pursuance of National Policy for Children. Under ICDS there is a provision for an Anganwadi for a population of 1000. The beneficiaries are pre-school children below 6 years of age, adolescent girls in age group of 11-18 years and pregnant and lactating mothers. There are 100 Anganwadi workers in each ICDS project. As of date 5671 ICDS blocks are functional across the country.

### Sub-Centre

The Sub-Centre is the most peripheral health delivery unit in Primary Health Care. A Sub-centre is provided for a population of 5000 in plains and 3000 in hilly and tribal areas. The Sub-Centre is staffed with a Multipurpose Health Worker (MPW) male and MPW female. They function as link between the population and PHC. They provide the basic MCH services. It has been planned to upgrade their training and job description under NRHM. The work of these Health workers is supervised by Health Assistant at

PHC.

Health Worker Female registers all antenatal cases, eligible couples and newborn children. She provides care for antenatal cases including distribution of Iron and folic acid tablets, immunization against tetanus, vitamin A solution to children. She carries out deliveries and supervises the deliveries by TBAs and refers difficult cases to PHC/ District Health Centre. She makes at least 3 visits after the delivery to educate mothers on breast feeding, postnatal care and motivate them for family planning. She also distributes contraceptives. She carries out universal immunization and growth monitoring of children. She helps MO and Health Assistant in all MCH and Family planning activities during the clinic at sub-centre.

Health Worker Male is responsible for record keeping on demographic data on Family records and village registers. He undertakes activities related to Malaria, Communicable diseases like diarrhea, fever, STDs etc. He also refers cases of blindness and cataract. He also carries out task related to management and treatment of Tuberculosis and Leprosy. He also ensures water safety and environmental sanitation. He helps and compliments the Health Worker Female in Family planning and immunization activities.

**Primary Health Centre**

The genesis of Primary Health Centre can be traced back to the concept of "Rural Health Centre" envisioned by Health Organization of League of Nations during European conference on Rural Hygiene of Geneva in1931. (13) The Bhore Committee Report recommended development of PHCs as the institutions to deliver integrated health care in rural area. The recommendations of Bhore committee on staffing of a PHC still remain to be realized even after 60 years. These PHCs were developed for a population of a block (80, 000 – 100, 000). They failed to deliver due to poor staffing and a large population base to serve. The national health policy in 1983 laid down the requirement of one PHC for a population of 30, 000 in plains and for every 20, 000 in hilly and tribal areas. As of 2005, a total of 23236 PHCs have been established. The functions of the PHC include medical care, MCH and Family Planning, prevention and control of locally endemic diseases, basic lab support, national health programs, training, referral and collection and reporting of health data. The staff (total 15) at PHC includes a medical officer, pharmacist, ANM, HW (M&F), Health assistant (M&F), UDC & LDC, Lab Technician, driver and 4 class IV employees. The job description of Health male and female is same as for them at a sub-centre. The Health Assistants supervise and monitor the work of 6 Health Workers under them.

**Community Health Centres**

Each CHC is required to provide cover to a population of 80, 000 to 1. 2 lakh. These have been established by upgrading the PHCs. There are 30 beds and facilities are provided in the specialties of surgery, medicine, gynecology and pediatrics along with facilities for X-ray and laboratory services. A second medical officer is provided in some states in place of community health officer who is a non-medical person. Under IPHS criteria each CHC is required to provide "assured services". These are also referred to as Rural Hospitals in some states. They are also referred as the First Referral Units in Primary Health Care setting.

Indian Public Health Standards for Community Health Centre (CHC)

These standards have been designed to ensure and achieve an acceptable standard of quality of care at CHCs.

The assured services include -

(a) Care of routine and emergency cases in surgery and medicine including hernia, hydrocoele, appendicitis, fistula, intestinal obstruction, dengue/DHF, cerebral malaria etc.

(b) 24 hour delivery services including normal and assisted deliveries

(c) essential and emergency obstetric care including caesarean

(d) safe abortion services

(e) newborn care

(f) Routine and emergency care of sick children

(g) Procedures like tracheostomy, nasal packing and foreign body removal

(h) Delivery of all national health programmes

(j) Diagnostic and surveillance facilities

(k) Blood storage facility

(l) Transport for referral

(m) Essential laboratory services

To achieve the above, additional posts of an anesthetist, eye surgeon (for every 5lac population under "Vision 2020") and a public health programme manager (Block Surveillance Officer) making a total staff of 21-22+2* (*1ANM and 1 PHN for family welfare under ASHA scheme) personnel has been recommended.

Besides the above, all national health programs are delivered through CHCs. Providing DOTS, AIDS control program activities, NLEP, Vector borne diseases like malaria, filarial, dengue, JE etc their diagnosis and management are also the functions of the CHC.

**ASHA (Accredited Social Health Activist)**

ASHA is selected for a population of 1000, from the local population as any lady who is in age group of 25-45 years, educated minimum up to 8th standard who functions as health activist. She is a community health activist who shall create awareness amongst the population on health issues, counsel women on MCH care, motivate people to access health care services, provide elementary medical care for minor ailments and provide DOTS. She will be provided with a drug kit including drugs of indigenous system of medicine. She will be guided and trained under the Anganwadi worker and ANM. ASHA will identify, escort and guide pregnant women and those children requiring treatment and admission at nearest health facility. She will function as depot holder for essential drugs like ORS, Iron and Folic acid, chloroquine, OC pills, disposable delivery

# National Health Programmes

## Introduction

India was one of the first countries in the World to conceptualize a comprehensive health care system, based on primary health care. In 1946, the Health Survey and Development Committee, headed by Sir Joseph Bhore recommended establishing a well-structured and comprehensive primary health care infrastructure. This report, besides being a historical landmark in development of Indian public health system, also laid down the blueprint for subsequent health planning and development in independent India. The report also recommended addressing the major health problems, through special programs under the overall umbrella of general health care services to be made available to all. Subsequent health committees constituted from time to time have also endorsed this view-point of having vertical or horizontal health programs, under the overall umbrella of primary health care (1).

## Relevance of National Health Programs for Indian Armed Forces

Armed Forces Medical Services (AFMS) provide comprehensive health services (promotive, preventive, and curative) to its clientele. By and large these services are self sufficient and insulated from the civilian health services. National Health Programs are planned to deal with specific health problems among most affected population subgroups, allocating large sums of money. These health problems are also relevant to defence service persons and their families. All efforts should be made to take full advantage of the resources available through these programs, by maintaining good liaison with civil health authorities at all levels. The following examples of collaboration between the civilian health authorities and military medical services bring out the importance of the national health programs in service settings. Implementation of national health programs within their respective areas of responsibility is an important task of specialists in Preventive and Social Medicine in Indian Armed Forces (2, 3).

### (a) Liaison with Civil Health Authorities

Communicable diseases do not respect any boundaries, natural or man-made. Most cantonments/military stations exist in close proximity with civilian settlements. Any public health menace in the civil population will spill over among the troops and families. Health intelligence on prevailing disease patterns among local population has to be obtained by liaison with civil health agencies. At times, combined efforts by the military and civilian health authorities may be indicated.

### (b) Supply of Vaccines

Under Universal Immunization Program, all vaccines for childhood immunization in Armed Forces are obtained from local civilian health authorities, to maintain cold chain. Reports and returns on vaccine utilization and surveillance on vaccine preventable diseases have to be periodically submitted to local civilian health agencies.

### (c) Family Welfare Program

There is close collaboration in family welfare program between the civilian and military health services. Service hospitals are actively participating in the National Family Welfare Program, by providing ante-natal care, immunization services and family planning services including tubectomies and vasectomies.

### (d) Treatment of Families and Dependants of Service Personnel for Certain Diseases

Families and dependants may not be entitled for indoor treatment of certain chronic diseases like Hansen's, malignancies, tuberculosis, etc. in a particular station or else the family may be staying in a place (e.g., native village) where no service medical facility is available. Awareness of the benefits available to the common citizen under the various health programs enables the service medical officers to appropriately counsel the clientele about sources from where appropriate treatment and care is available through civil health sources.

### (e) Adoption of Disease Control Strategies in Service Setting

At times, disease control strategies being followed under some national health program can be adopted in service setting with advantage. On the other hand, we may also learn lessons from failures in our National Health Program (e.g., NMEP) so that similar mistakes can be avoided in our public health practice.

### (f) Reports and Returns

Reports and returns for various diseases and health problems sent periodically from all Armed Forces establishments, compiled at the highest level should contribute to the statistics of our programs at the national level.

A brief account of important National Health Programs, currently in operation, is given in succeeding paragraphs.

## National Anti-Malaria Program

National Malaria Control Program (NMCP) was launched in India in April 1953, with broad objectives of reducing malaria transmission to a level where it would cease to be a public health problem and to hold down malaria transmission at such low level indefinitely. It was based on indoor residual spraying (IRS) with DDT (1 g per sq m of surface area) twice a year in endemic areas where spleen rates were over 10 per cent. The NMCP was in operation for 5 years (1953-58). The program was initially highly successful in that the incidence of malaria declined sharply from 75 million cases in 1953 to 2 million cases in 1958, an estimated 80% reduction of the malaria problem. It also paid rich dividends in different fields like agriculture, land projects and industry. Encouraged by these spectacular results and based on recommendations of 8th World Health Assembly (1955), Government of India (Ministry of Health) changed the strategy from malaria control to eradication, and launched an ambitious

National Malaria Eradication Program (NMEP) in 1958, with the objective to eradicate malaria in the next 7-9 years. According to International standards, the program was divided into preparatory, attack, consolidation and maintenance phases.

Initially, NMEP was apparently highly successful and no death from malaria was reported in 1965. But very soon setbacks appeared in form of focal outbreaks. These focal outbreaks soon assumed epidemic proportions and annual incidence of malaria cases in India escalated from 50,000 in 1961 to a peak of 6.4 million cases in 1976 (4).

### Revised Strategy - Modified Plan of Operation (MPO) (4)

Based on recommendations of several Expert Committees appointed by the Govt, attempts at malaria eradication were soon abandoned and a Modified Plan of Operations (MPO) to control malaria was evolved, put into operation from April 1977 with objectives

(a) To prevent deaths due to malaria

(b) To reduce malaria morbidity

(c) To maintain agricultural and industrial production by undertaking intensive antimalarial measures in such areas

(d) To consolidate the gains so far achieved.

Flexibility in policies & implementation according to the epidemiological situation and local conditions was the essential feature of this program.

Reclassification of Endemic Areas

Under MPO, areas with Annual Parasite Incidence (API) of 2 and above were taken up for spray operations, to stabilize malaria transmission in the country. This led to abolition of earlier classification into attack, consolidation and maintenance phase areas, and reclassification of areas according to API.

**Areas with API of 2 or more**

The following activities were carried out :

(**a) Residual Indoor Spray :** 2 annual rounds of DDT indoor spray. In case vector was found to be resistant to DDT, 3 annual rounds of indoor spray with malathion were recommended. Areas refractory both to DDT and malathion were to be treated with 2 rounds of synthetic pyrethroids spray at intervals of 6 weeks. DDT, malathion, and pyrethroids dosage applied were 1.0, 2.0 and 0.25 g per sq. meter surface respectively. BHC has been discontinued since April 1997 because of its adverse environmental effects.

(**b) Entomological assessment :** Carried out by entomological teams by conducting susceptibility tests and suggesting appropriate insecticides to be used in particular areas.

(**c) Surveillance** : Collection and examination of blood slides was a key element under MPO. Active and Passive surveillance activities were to be carried out fortnightly in all areas with API 2 and above.

(**d) Treatment of cases** : Emphasis on presumptive and radical treatment of cases.

**Areas with API less than 2**

The following activities were undertaken : -

(a) **Spraying** : Focal spraying was to be done only in areas where *P. falciparum* cases were detected during surveillance. Routine indoor residual spray was not done.

(b) **Surveillance** : As these areas were not under regular spraying, active and passive surveillance operations were to be undertaken vigorously every fortnight.

(c) **Treatment** : All detected cases were to receive radical treatment as prescribed

(d) **Follow-up** : Follow-up blood smears were collected from all positive cases on completion of radical treatment and thereafter at monthly intervals for 12 months.

(e) **Epidemiological Investigation** : All malaria positive cases were investigated, including mass surveys.

Drug Distribution Centres (DDC) and Fever Treatment Depots (FTD)

With increasing number of malaria cases, demand for antimalarials also increased tremendously. It became clear that drug supply only through surveillance workers and medical institutions was not enough. This led to establishment of a wide network of Drug Distribution Centres and Fever Treatment Depots. Drug Distribution Centres are only to dispense the antimalaria drugs as per NMEP schedules. Fever Treatment Depots collect blood slides in addition to the distribution of antimalarials. These centres are manned by voluntary health workers from the community.

*P. falciparum* Containment

Within MPO, an additional component known as "P. falciparum containment program" was introduced from October 1977, with assistance from Swedish International Development Agency (SIDA). The specific purpose of this component was to prevent or contain spread of falciparum malaria.

Currently the program is operating in North East India, and some areas in the states of Orissa, Bihar, West Bengal, Andhra Pradesh, Madhya Pradesh, Gujarat, Maharashtra and Rajasthan. Four zones have been established to tackle the problem in these districts. Under this program, special inputs have been provided to strengthen the supervision of field operations.

### Malaria Action Plan (MAP)

Modified Plan of Operation (MPO) was able to contain malaria deaths for some time after its implementation. From 1994 to 1996, malaria outbreaks were reported from several states like Rajasthan, Manipur, Nagaland, Assam, Maharashtra and West Bengal. An expert committee formed to review the situation recommended criteria to identify "high risk areas" in rural areas and identified 20 worst affected cities which contributed as much as 80% of urban malaria. Based on the recommendations, guidelines for malaria control, known as Malaria Action Plan (MAP) were formulated. Under this, malaria control activities were 100% centrally sponsored for seven North-Eastern states, Andhra Pradesh, Bihar,

Gujarat, Maharashtra, Orissa and Rajasthan. The expert committee identified epidemiological parameters for high risk areas and strategies for anti-malaria activities, as under :

(a) Hardcore Areas (Tribal Areas)

Where malaria control operations for the last 40 years had failed to contain the disease. These included areas with :

(i) Predominantly tribal population

(ii) High prevalence of *P. falciparum*

(iii) Stable malaria with transmission period of more than 9 months

(iv) High incidence of deaths due to malaria, difficult terrain and remote areas

The control strategy under MAP in these areas consist of early case detection through Multipurpose Workers (MPW), presumptive treatment of fever through DDC / FTD / ACD / PCD, slide collection and examination and radical treatment within 48 hours with priority for Pf cases. Alternative drug therapy has been introduced in chloroquine resistant areas.

(b) Epidemic prone areas

Where periodic malaria outbreaks have caused large number of deaths due to malaria, including areas of North-Western plains, semi-arid regions with upto 100 mm of annual rainfall and Indo-Gangetic plains. The control strategy in such areas is similar to that in hardcore areas.

(c) Project Areas

These are areas where development of large scale projects attracts migrant labour from infected areas or non-immune labour into endemic areas. There is large scale increase in vector breeding places and increased man-mosquito contact. The strategies recommended for malaria control in such project areas include mass screening of migrant labour, mass presumptive treatment along with single dose of 45 mg primaquine and alternative drug therapy in chloroquine resistant areas.

(d) Urban areas

Under the Urban Malaria Scheme, it was found that 15 cities accounted for as much as 80% of Pf cases in the country. The control strategies adopted were active weekly surveillance for malaria in slums, intensified passive surveillance in hospitals by establishing a malaria post, presumptive treatment to all fever cases and radical treatment with priority to Pf cases. Under this, it was proposed to provide one worker for 20,000 slum population and establish one malaria clinic for every 50,000 population, preferably adjoining slum areas.

Research

Various monitoring teams are working in different parts of the country to identify P. falciparum sensitivity to chloroquine. Studies by ICMR have identified chloroquine-resistant foci in Orissa, Assam, Bihar, Maharashtra, North Eastern States, UP, Andhra Pradesh, Delhi, Madhya Pradesh, Andaman and Nicobar islands.

Reorganization

Before implementation of MPO, NMEP units were formed on the basis of poplulation, which in many places did not conform to administrative boundaries. This was now rectified and Anti-malaria Units have been reorganized in conformity with the geographic boundaries of the district making the District Health Officer (DHO) responsible for implementation of the program. The existing Unit Officers have been designated as District Malaria Officers (DMOs) and are posted at district headquarters. They have been entrusted with operational and evaluation aspects of the program. Asst. Malaria Officers usually assist the DMO. Under MPO, laboratory services were decentralised to minimise time lag between collection of blood smears and their examination. Laboratory technicians were posted at each PHC. Entomological teams were attached to all 72 zones in the country. The Chief Medical Officers and the Medical Officers of PHCs have to play a key role in execution of the program. The program, which was vertical before, is now horizontal and integrated with general health services from district level to the periphery and gradually surveillance workers are being replaced by Multi-purpose workers.

The 1994 resurgence of malaria compelled the Government of India to appoint an Expert Committee on Malaria to identify the problem areas and to suggest specific measures against the different paradigms of malaria. Thus Malaria Action Program (MAP) was evolved and guidelines were distributed to all the states for prediction, early detection and effective response to malaria outbreaks at district level (5, 6). It necessitated the need to strengthen the health promotion component of the program by observing "Anti-malaria month" before the onset of monsoon i.e. during the month of June to create awareness in the community regarding malaria and its prevention.

**Enhanced Malaria Control Project (EMCP)**

Enhanced malaria control project was launched in April 1997 with the assistance of the World Bank. This will directly benefit six crore tribal population of the eight peninsular states covering 100 districts and 19 urban areas. However, the population living in other malaria endemic areas will also benefit, as the strengthening of IEC, Training and Management Information System will cover the entire country.

The aim of the project is to cover most problematic areas where :

(a) API is more than 2 for the last 3 years

(b) Pf cases are more than 30% of the total malaria cases

(c) 25% of the population of the area is tribal

(d) The area has been reporting deaths due to malaria and also has the flexibility to direct resources to any needy areas in case of outbreak of malaria.

**Objectives**

(a) Effective control of malaria to bring reduction in malaria morbidity.

(b) Prevention of death due to malaria; and

(c) Consolidation of the gains achieved so far.

Strategies

(a) Early case detection and prompt treatment.

(b) Vector Control by indoor residual insecticidal spray in rural areas with API of 2/1000 and above in the preceding three years with appropriate insecticide.

(c) Health education and community participation.

Components of Enhanced Program

**(a) Early case detection and prompt treatment :** The equipment and staff provisions with their functions for early detection and prompt treatment are as follows:

(i) A link worker in high Pf areas for population of 2000 to be appointed by Panchayat and paid Rs 500 per month. He/she will collect blood smears, provide presumptive treatment and forward slides to PHC.

(ii) A microscope for every 30,000 population at PHC in rural areas and for 50,000 in urban areas.

(iii) Dipstick test in selected areas.

(iv) One fever treatment depot for every village.

(v) Existing MPWs and ANMs will continue to function as doing previously.

(vi) Adequate quantities of drugs should be made available.

(vii) Involvement of private sectors in case detection and treatment.

**b) Selective Vector Control**

**(i) Bio-environmental methods**

- Introduction of larvivorous fish
- Use of Biocides - Bacillus thuringiensis H-14(Bt) in selected urban areas
- Environmental Management Methods would be applied

**(ii) Selective Spray**

Village in which there is one case of falciparum malaria or more would qualify for spray in project area.

**(c) Legislative Measures** : Model bylaws for control of mosquitoes as in Bombay Municipal Corporation would be extended to cover the whole country which will bring changes in structural design of buildings to prevent mosquitoes.

**(d) Personal Protective Measures :** Bednet treatment program is more cost effective as compared to residual spray. Social marketing techniques involving local NGOs will be used for promotion of bednets. In areas where use of bednets is wide-spread and which also contribute most of the Pf cases in the country, a program has been launched for use of Insecticide Treated Bednets using synthetic pyrethroids mainly deltamethrin (2.5%) at a dosage of 25mg/sq m and cyfluthrin (5%) at 50 mg/sq m.

**(e) Epidemic Planning and Rapid response & Intersectoral Coordination:** Sectors like agriculture, environment, education and so on will be sensitized to the malaria problem and the steps to be taken for its prevention.

**(f) Institutional and Management Capabilities Strengthening :** Training in and strengthening of Management Information System (MIS) and Information Education and Communication (IEC) is required in the country.

**(g) Operational Research**

(i) Health seeking behaviour especially of malaria patients

(ii) Economic analysis of various interventions

(iii) Alternative drug regimens

(iv) Evaluation of impregnated bednets and curtains

(v) Trials with biolarvicidal agents

(vi) Entomological monitoring

(vii) Migratory patterns leading to malaria outbreaks (7, 8)

**(h) Community Participation :** Planning would be "bottom up" in which village Panchayat would be responsible for all matters related to health and development.

Progress of Enhanced Program

After its inception in 1997, 62.2 million population in 1045 PHCs in 100 districts (predominantly endemic and tribal districts) in peninsular states on Andhra Pradesh, Jharkhand, Gujarat, Madhya Pradesh, Chhatisgarh, Maharashtra, Orissa and Rajasthan have been covered. In addition, 19 cities with high incidence of malaria have also been covered under the project. Since 1997, Pf cases had declined from 0.72 million in 1997 to 0.41 million by 2004.

### National Vector Borne Diseases Control Program (NVBDCP) (9)

With the aim to conserve precious resources, including manpower and avoid duplication of effort, Govt of India, in 2003-04, approved National Vector Borne Diseases Control Program (NVBDCP), with the objective to control five major vector-borne diseases, namely, Malaria, Kala Azar, Filaria, Japanese Encephalitis and Dengue group of diseases. The program is presently 100% sponsored in North-Eastern states.

Strategies for prevention and control of malaria in rural areas under NVBDCP

(a) Early diagnosis and treatment

(b) Integrated vector control through optimal combination of various vector contol measures like indoor residual spray, anti larval measures, use of insecticide treated bed nets, larvivorous fish, environmental & engineering measures.

(c) Epidemic preparedness and rapid response for initiating epidemic control measures.

(d) Social mobilization and behaviour change, resulting in better awareness.

(e) Intersectoral collaboration by involving various govt / non-govt departments like Defence, Railways, corporate sector, local self govt etc.

(f) Capacity building by training medical and paramedical workers at primary, secondary and tertiary levels.

(g) Monitoring and evaluation of the program through periodic reviews, field visits etc.

Strategies for Urban areas (Urban Malaria Scheme) (9)

The urban malaria scheme was launched in 1971 to reduce and interrupt malaria transmission in towns and cities, after it was realized that urban malaria was a significant potential and unchecked mosquito breeding in urban areas could negate the advances made under NMEP. The strategy consists of early detection and prompt treatment (EDPT) through passive surveillance at hospitals, vector control by intensive antilarval measures, bio-environmental measures like desilting, deweeding, filling ditches, water disposal and sanitation, biological control using larvivorous fish, IEC campaigns and urban bylaws like those being implemented in Delhi, Mumbai and Goa. The scheme covers all towns with more than 50,000 population and showing API more than 2 in the preceding three years.

**Organisational setup**

UMS is a centrally sponsored scheme implemented by local administrative authorities under the supervision of state health authorities. The scheme is implemented and supervised by Director, NVBDCP at Central level, Additional / Joint / Deputy Director (Malaria & Filaria) at State level and Biologist at Town level.

At present, Urban Malaria Scheme as part of NVBDCP protects more than 967 lakh population in 131 cities in 19 states and UTs. Model civic bylaws have been prepared under NVBDCP which are implemented in Delhi, Mumbai, Kolkata, Chandigarh, Banglore, Chennai and several other cities.

**Malaria Surveillance**

Surveillance in malaria is of two types, namely, active and passive.

Active Surveillance

This is carried out by the multipurpose workers (MPWs). Each MPW is allotted a population of 10,000 or approximately 2,000 houses and for every 4 MPW, there is a surveillance inspector (Health Assistant). For difficult terrain areas, there is one surveillance worker (MPW) for a population of 8,000 and one surveillance inspector for 32,000 population. The surveillance worker (MPW) will visit each house in his area once a fortnight and enquire :

(a) Whether there is a case of fever in the house, including guests or visitors in the house

(b) Whether there was a fever case in the house between his previous visit and the present visit. If the answer to either of these two questions is "yes", the surveillance worker/MPW collects a blood film (thick and thin on the same slide) and administers a single dose (600 mg for adults and proportionate doses for children) of chloroquine according to the prescribed NMEP schedule. This is known as "presumptive treatment". The MPW makes necessary entries in the stencil or house card about his visit and dispatches the blood slides at least twice a week to the unit laboratory (primary health centre) for microscopic examination. He is also required to collect the blood slides from the subcentres and fever treatment depots and send these to the laboratory. If the blood film is reported positive for malaria parasite, the MPW returns to the patient and administers a course of radical treatment for malaria, as prescribed.

Passive Surveillance

The search for malaria cases by the local health agencies such as the primary health centres, sub-centres, hospitals, dispensaries and local medical practitioners amongst people reporting to the facilities is known as "passive surveillance". Their contribution to case detection is by no means small, because cases of fever which escape the net of active surveillance workers are screened by the passive surveillance agencies. The passive agencies collect blood smears from all fever cases and also from those with history of recent fever. After the collection of blood smear, a single dose treatment for malaria is administered as is done under the active surveillance program. The blood slides are collected by the MPW and sent to the unit laboratory for examination. The results of the blood examination are communicated to the local surveillance worker/MPW for institution of radical treatment.

**Parameters of Malaria Surveillance**

These include annual parasite incidence (API), annual blood examination rate (ABER) and slide positivity rate (SPR). The details are given in the chapters on Malaria in the section on Communicable diseases.

**National Drug Policy for Malaria in India**

The National Drug Policy for Malaria under NVBDCP issues the following guidelines for treatment of various forms of Malaria (10) :

Any fever case in an endemic area during malaria transmission season without any other obvious cause must be investigated / treated for malaria.

Though drug resistance foci are present in India, chloroquine still remains safest, effective, cheapest and simplest to administer antimalarial.

Diagnosis on the same day as collection of blood smear and prompt treatment remains the best approach to malaria control.

Broad Drug Policy for malaria is enumerated as under. However, minor changes have to be incorporated for infants and children, for which the reader may consult textbooks in Preventive Medicine.

Low Risk Areas

**Presumptive treatment** : Single dose of chloroquine @ 10 mg/kg b.w. to all fever suspected malaria cases.

**Radical treatment on confirmation**

| | |
|---|---|
| *P.vivax* | Chloroquine 10mg/kg b.w & Primaquine 0.25mg/kg b.w on day1 |

| | |
|---|---|
| | Primaquine 0.25mg/kg b.w/day for next 4 days(total 5 days) |
| *P. falciparum* | Chloroquine 10mg/kg b.w & Primaquine 0.75mg/kg b.w stat |

High Risk Areas

**Presumptive treatment**

Day 1 Chloroquine 10mg/kg b.w

Day 1 Primaquine 0.75mg/kg b.w

Day 2 Chloroquine 10mg/kg b.w

Day 3 Chloroquine 5mg/kg b.w

**Radical treatment on confirmation**

| | |
|---|---|
| *P.vivax* | Primaquine 0.25mg/kg b.w for 5 days |
| *P. falciparum* | No further treatment is given |

Chloroquine resistant

| | |
|---|---|
| Pf case | Sulfadoxine or Sulfalene 25 mg/kg b.w Pyrimethamine 1.25mg/kg b.w on Day1. Followed by Primaquine 0.75 mg/kg bw - the next day |

***Primaquine is contraindicated in pregnancy and infants

**Severe and complicated malaria** : Quinine 10 mg/kg b.w IV infusion in 5% dextrose solution 8 hourly. Total duration of treatment 7 days including both parental and oral doses. Semiconscious or comatose patients with severe Pf infection should be treated with injectable Quinine, which also is the drug of choice in pregnant women and infants. OR

Injectable Artimisine compounds are recommended for management of severe and complicated malaria.

Injectable Choloroquine is likely to produce low blood pressure in any age group and is associated with high mortality and is thus more hazardous than parenteral administration of injectable quinine.

### Global Malaria Control Strategy : Roll Back Malaria (11)

Roll Back Malaria (RBM) is a global partnership founded in 1998 by WHO, UNDP, Unicef and the World Bank with the objective to reduce world's malaria burden by half by the year 2010 (7, 8). In April 2000 in Abuja, Nigeria, political leaders from 44 African Nations endorsed the RBM goal for 2010 as the "Abuja Declaration".

RBM, which is a partnership involving national governments, civil society, NGOs, research institutions, professional associations, various United Nations development agencies, development banks and private sector, set interim targets to :

(a) Provide prompt access to correct, affordable and appropriate treatment to at least 60% of malaria cases within 24 hours of onset of symptoms.

(b) Provide suitable combination of personal and community protective measures to at least 60% of those at risk from malaria, particularly pregnant women and children.

(c) Provide chemoprophylaxis or presumptive intermittent treatment to at least 60% of pregnant women at risk of malaria.

Roll Back Malaria is based on four main technical strategies of providing prompt access to effective antimalarial treatment, promoting the use of insecticide treated bednets, prevention and treatment of malaria in pregnant women and improving the response capacity of local governments to malaria epidemics. The strategy also accords importance to research in malaria and measures to prevent re-emergence.

### National Filaria Control Program

National Filaria Control Program has been in operation since 1955. According to recent estimates about 450 million people are exposed to the risk of infection. It is estimated that 6 million people have attacks of acute filarial disease every year and 45 million persons suffer from one or more chronic filarial lesions (12 – 14).

In June 1978, the operational component of the program was merged with urban malaria scheme for better cost effectiveness. Initially all control activities were confined to urban areas, however, since 1994, the program has been extended to rural areas also. The training and research components are with the Director, National Institute of Communicable Diseases.

The following activities are carried out under the program :

a) Delimitation of the problem in hitherto unsurveyed areas.

b) Control in urban areas through :

(i) Recurrent antilarval measures

(ii) Anti-parasitic measures

So far, 238 of the 300 districts situated in endemic areas have been surveyed, and 175 have been found to be endemic for filariasis. Survey work is in progress in other districts.

National Filaria Control Program is being implemented through 206 filaria control units, 27 survey units, and 199 filaria clinics functioning in the endemic urban areas. The population protected so far is hardly 47 million out of 450 million at risk. Since the "vertical" approach to the control of filariasis has had a limited success, it is now recognized that the horizontal approach making use of the primary health care is essential. The village health guides are responsible for anti-filaria activities under supervision of Medical Officer of PHC. Training in filariology is being given at three Regional Filariasis Training and Research Centres situated at Calicut (Kerala), Rajahamundry (AP), and Varanasi (UP), under the National Institute of Communicable Diseases, New Delhi. Besides 12 Headquarters Bureau are functioning at the State level. Details of filarial control measures in the Armed forces are given in DGAFMS medical memorandum (15).

National Health Policy – Elimination of Lymphatic Filariasis by 2015

This strategy follows the WHO recommendation of Annual Single Dose – Mass Drug Therapy with DEC as a supplement to existing activities in highly endemic areas

to reduce transmission of filariasis to very low levels. It was proposed to implement this strategy as a pilot project in 13 endemic districts of Andhra Pradesh, Bihar, Kerala, Orissa, Tamil Nadu, Uttar Pradesh and West Bengal for five years covering 400 million population. The strategy was initially introduced in South Arcot, Vallalar district in 1996 by the State of Tamil Nadu and in 8 districts of Kerala, Orissa, Uttar Pradesh, and West Bengal since 1997 by observing Annual Filariasis Day. Approximately 49.7 to 94 percent coverage was observed in these districts. The drug was distributed from door to door in Tamil Nadu and by booth system in other States. The centre provides DEC tablets for the mass therapy campaign and cash assistance for IEC activities to these states. As a long term measure, the national health policy – 2002 envisages to achieve elimination of lymphatic filariasis by the year 2015, besides other targets in respect of other programs (16).

## National Leprosy "Eradication" Program

The National Leprosy Control Program was launched in 1954-55 as a centrally aided program to achieve control of leprosy through case detection and dapsone monotherapy on an ambulatory basis. The program gained momentum during the 4th Five Year Plan after it was made a centrally sponsored program. In 1980 the Government of India declared its resolve to "eradicate" leprosy by the year 2000 and constituted a working group to advise accordingly. In 1982-83 the control program was re-designated as National Leprosy "Eradication" Program (NLEP) with the objective to eliminate leprosy as a public health problem by the year 2000 (17). Multi Drug Treatment (MDT) was initially launched in Purulia (WB) and Wardha (Maharashtra) and by 1995-96, all districts in the country were brought under MDT in a phased manner. In 1991, WHO also proposed elimination of leprosy as a public health problem. Accordingly, the target for Ninth Plan was to reduce case load to 1 (or less) per 10,000 population.

### Strategy

The initial strategy was based on early detection of cases (by population surveys, school surveys, contact examination and voluntary referral), short term multi-drug therapy (MDT), health education, ulcer and deformity care, and rehabilitation of the cases. The regimen recommended by the WHO was adapted to local operational and administrative requirements .

The program provides free domiciliary treatment in endemic districts through specially trained staff, and in moderate to low endemic districts it provides services through mobile leprosy treatment units and primary health care personnel. Treatment of leprosy cases with MDT was taken up in a phased manner. As a result number of cases discharged as cured are increasing over the years.

### Infrastructure

NLEP was initially implemented through the establishment of Leprosy Control Units (LCU); Survey, Education, and Treatment (SET) Centres; and Urban Leprosy Centres. The Leprosy Control Units were established in endemic areas with one medical officer, 2 non-medical supervisors and 20 paramedical workers – each unit covering a population of 4.5 lacs. Each paramedical worker covered 15 to 20 thousand population and was expected to examine at least 8000 persons per year by house to house surveys in the population under his care. The staff appointed at SET centres comprised of 1 paramedical worker for 20 to 25 thousand population, and one non-medical supervisor for every 5 paramedical worker. The SET centres were attached to Primary Health Centres and placed under the administrative control of the medical officer in charge of the primary health centre. One urban leprosy centre was established for every 50,000 population.

Mobile leprosy treatment units provided services to leprosy patients in non-endemic districts. Each mobile unit consisted of one medical officer, one non-medical supervisor, two para-medical workers and a driver. 2 MLTU for each moderately endemic district and 1 MLTU for each low endemic district.

Under the NLEP, the State Leprosy Officer was the chief coordinator and technical advisor to concerned State Government. At Central level, leprosy division of Directorate General of Health Services, New Delhi, was responsible for planning, supervision and monitoring of the program. The division was under control of a Deputy Director General who advised the Government on all anti-leprosy activities.

World Bank assisted NLEP Phase I (1993 – Sep 2000)

Phase I of World Bank assisted NLEP from 1993 to Sep 2000 provided logistic support to the vertical program in endemic districts. Mobile Leprosy Treatment Units (MLTUs) were established for moderate and low endemic districts. District Leprosy Societies were also formed under the program. In Jan 1997, the program was re-designated as National Leprosy Elimination Program with the objective to reduce prevalence rate to 1 or below 1 per 10,000 population. In Feb 1998, 1st Modified Leprosy Elimination Campaign (MLEC) was launched which included 3 day technical training to general health care services staff, intensive IEC campaign and active search for leprosy patients by staff of general health services.

World Bank assisted NLEP Phase II (Oct 2000 – Dec 2005)

Phase II of World Bank assisted NLEP was launched in Oct 2000 with the objectives of achieving elimination of leprosy (defined as prevalence rate of 1 or less than 1 per 10,000 population) by end 2005 and to integrate leprosy control activities with general health care services in the country. The elimination strategy also included decentralization of NLEP to States & Districts, leprosy training to functionaries of general health care services, surveillance for early diagnosis and prompt MDT, promotion of self reporting, intensified IEC using local and mass media approaches, prevention of impairment & disability (POID), rehabilitation (medical, social and economic) and reconstructive surgery. In addition, NGOs have been actively involved in leprosy control activities in the country.

### Strategic Plan of Action (2004-05)

During 2004-05, the focus of NLEP shifted from states to districts & blocks with high and medium endemicity. A strategic plan of action was implemented which included intensified focused action with strong supervisory support in 72 high priority districts (with prevalence rate of more than 5/10,000) and 16 moderately endemic districts which had more than 2000 leprosy cases detected during 2003-04. Under this program, intensive IEC, training and integrated service delivery was undertaken in high endemic pockets in 86 medium priority districts. A two week long Block Leprosy Awareness Campaign (BLAC) was launched, through Leprosy Counseling Centers at subcenter level, in 836 blocks with prevalence rate of more than 5/10,000 population, with the aim to follow up existing cases and encourage self reporting of new cases.

Focused Leprosy Elimination Plan (FLEP-2005)

In Mar 2005, priority areas (42 districts and 552 blocks in 7 endemic states) with prevalence rate of more than 3/10,000 population were identified for undertaking focused action, which included intensive IEC, training and integrated service delivery.

Modified Leprosy Elimination Campaign (MLEC)

A mid-term appraisal of the program in April 1997 indicated that while the progress of the program is satisfactory at national level, it is uneven in some states. It was decided to launch a leprosy elimination campaign by giving short term orientation training in leprosy to all health staff including medical officers, health workers and volunteers and increase public awareness about leprosy. House to house search has been conducted to detect new leprosy cases throughout the country.

Research into the basic problem of leprosy is also part of the activities of the program. This is mainly carried out in the Government sector, viz. the Central JALMA Institute of Leprosy at Agra and the Central Leprosy Teaching and Training Institute at Chingelput, Chennai, supported by Regional Training and Referral Institutes at Aska (Orissa), Raipur (Chhattisgarh) and Gouripur (WB). In the field of leprosy eradication, there is considerable element of foreign assistance from international agencies, viz. SIDA, DANIDA, WHO, UNICEF, Damien Foundation, etc. It is understood that presently about 285 voluntary organisations are working towards leprosy prevention and control in our country. With the inclusion of leprosy eradication in the 20-point program a new impetus has been given both for expansion and monitoring activities

India achieved elimination of Leprosy in 2005

The World Health Assembly in May 1991 adopted a resolution for global elimination of leprosy by 2000. In 2001, after majority countries achieved leprosy elimination, a target was reset for the remaining 15 countries to achieve leprosy elimination on a national level by Dec 2005. The National Health Policy – 2002 also sought to eliminate leprosy from our country by the year 2005. The country achieved the goal of leprosy elimination as a public health problem (defined as less than 1 case per 10,000 population) in the month of Dec 2005. As on 31 Dec 2005, India recorded a prevalence rate of 0.95/10,000 population. 24 States / UTs (Nagaland, Haryana, Meghalaya, Himachal Pradesh, Mizoram, Tripura, Punjab, Sikkim, Jammu & Kashmir, Assam, Manipur, Rajasthan, Kerala, Arunachal Pradesh, Daman & Diu, A & N Islands, Pondicherry, Gujarat, Karnataka, Tamilnadu, Lakshadweep, Andhra Pradesh, Uttaranchal and Madhya Pradesh) had achieved leprosy elimination by Mar 2005. Maharashtra & Goa achieved elimination status in Sep 2005 and Nov 2005 respectively. As on 31 Dec 2005, there were 6 states of Bihar, Chhattisgarh, Jharkhand, Orissa, UP and West Bengal with prevalence rate between 1 and 3 per 10,000 population. These 6 states with 41% of country's population now contribute more than 60% of the country's case load of leprosy.

During the tenth Five-Year Plan (2002-2007), it was envisaged to eliminate leprosy from all parts of the country, for which the following strategies have been adopted :

(a) Horizontal integration of NLEP with the general health care system by 2007, wherein all personnel employed under NLEP will be transferred to States.

(b) Integration of leprosy workers under NLEP with primary health care system of the country by retraining and redeployment of more than 30,000 leprosy workers. It is proposed to fill the existing vacancies of male multipurpose workers and laboratory technicians in the primary health care system.

(c) Skill upgradation of existing personnel in primary health care system, to enable them for early detection, treatment and referral of leprosy cases.

(d) Provisions for reconstructive surgery within easy reach so to reduce functional disability of leprosy patients.

(e) Increased contribution and involvement of NGOs in detection and management of leprosy cases in community (17, 18, 19).

## National Tuberculosis Control Program

National TB control program (NTP) was launched in 1962 in the country with the objective of early detection and treatment of cases, as under (20) :

**(a) Long Term Objectives**

To reduce tuberculosis in the community to that level when it ceases to be a public health problem, i.e.,

(i) One case infects less than one new person annually

(ii) The prevalence of infection in age groups below 14 years is brought down to less than 1 percent against about 30 percent at present.

**(b) Operational or Short Term Objectives**

(i) To detect maximum number of TB cases among the outpatients attending any health institution with symptoms suggestive of tuberculosis and treat them effectively

(ii) To vaccinate newborns and infants with BCG.

(iii) To undertake the above objectives in an integrated manner through all the existing health institutions in the country.

**District TB Program (DTP)**

NTP operated through the District Tuberculosis Program (DTP) which was the backbone of NTP. Over 600 TB clinics were set up in the country, of which 390 were upgraded as District TB Centres (DTC) to undertake district-wise TB control in association with general health and medical institutions. This concept was evolved by the National Tuberculosis Institute, Bangalore and was accepted by the government for implementation in 1962. District Tuberculosis Centre (DTC) was the nucleus of DTP. The function of DTC was to plan, organize and implement DTP, in the entire district, in association with general health services. The health institutions available for inclusion in DTP were government general hospitals and community health centres, primary health centres, tuberculosis clinics, clinics other than DTC and OPDs of tuberculosis sanatoria and hospitals, hospitals including those managed by the government health schemes (e.g., CGHS, Railways, etc), Employees State Insurance Scheme, local bodies, religious missions, voluntary organizations, and private charitable societies. Only those PHIs (peripheral health institutions) were to be selected for implementation of the program, which were under charge of qualified Medical Officers. At present out of 460 districts in the country, District TB Centres have been established in 446 districts. Besides the DTC, 330 TB clinics are functioning in the country. A total of 47,600 beds are available for tuberculosis patients (21).

17 TB training and demonstration centres have been established in major States of the country. Two premier TB institutes, namely National Tuberculosis Institute Bangalore, and Tuberculosis Chemotherapy Centre, Chingleput, Chennai conduct training and research activities.

Activities of DTC : Under NTP, activities of DTC included (20) :

**(a)Case finding**

An average district has a population of 15 lakhs, and the number of sputum positive cases in each district was expected to be 3000. There would be at least 2 to 3 sputum positive cases and 8-12 radiologically active TB cases, in each of our villages with an average population of about 700 at any point of time. A review of case finding activities in various states revealed that case-finding efficiency was hardly 30 percent of its potential. In view of this, targets were fixed for the first time in 1982-1983, for the conduction of sputum examination at each primary health centre to detect new TB cases in rural populace. According to the new strategy, each PHC would have to examine 2 sputum per day (50 per month and 600 per year) from symptomatic patients so as to diagnose 5 new bacillary cases per month or 60 cases per year. To further improve case finding, male health workers were required to collect and fix sputum of the symptomatic on a slide during their routine visits to the villages and send these to the nearest health centres for microscopic examination. In this way, case finding was expected to reach the very doorsteps of all symptomatic patients, even at the periphery.

**(b) Treatment**

Treatment was free and was offered on domiciliary basis from all health centres. It was organized in such a way that patients were expected to collect drugs once a month on fixed dates from the nearest treatment centre. When the patient failed to collect drugs on "due date", a letter was sent and in the event of no response within 7 days a home visit was paid by the health staff. The compliance for one year was the most important part of the program. Short course chemotherapy was introduced in 18 selected districts as a pilot project. Later, more districts were covered in a phased manner, and at present 292 districts have been covered.

**(c) BCG Vaccination**

With the inclusion of BCG vaccination in the UIP, the BCG coverage had gone up to 97 per cent of the target by 1998.

**(d) Recording and Reporting**

The names and addresses of all the sputum positive cases are sent to the DTC every Saturday. The DTC registers all sputum-positive cases in the "District Tuberculosis Case Index" which is the nerve centre of DTP.

**(e) Supervision**

The DTC team visits the peripheral health institutions regularly and helps them in planning and rendering TB control services. These visits are called "supervision" visits. Supervision includes guidance, keeping the supplies moving and ensuring proper work standards.

Organization

District Tuberculosis Program consists of one District Tuberculosis Centre (DTC) and on an average 50 peripheral health institutions comprising of PHCs, general hospitals, rural dispensaries, etc.

To implement the program, a specially trained team of key program personnel is posted at each DTC. The team consists of:

(a) District Tuberculosis Officer
(b) Second Medical Officer
(c) Laboratory technicians
(d) Treatment organizer/health visitor
(e) X-ray technician
(f) Non medical team leader
(g) Statistical assistant
(h) Pharmacist

**Revised National Tuberculosis Control Program (22, 23)**

Need for revised strategy : In 1992, Govt of India conducted a nationwide survey with the help of WHO and SIDA, which highlighted the following reasons for failure of NTP :

(a) Treatment completion rate was only 30%.
(b) Inadequate budgetary outlay
(c) Irregular supply and shortage of antitubercular

medicines

(d) Undue emphasis on diagnosis through radiology

(e) Poor quality of sputum microscopy

(f) More emphasis on case detection rather than cure

(g) Poor organisational support

(h) Multiplicity of treatment regimes, especially among private practitioners

(j) Poor integration of the program with general health services

(k) Low level of awareness among patients about various aspects of the disease

(l) Non availability of trained staff

Based on these findings Govt of India, with the help of World Bank, revised the strategies and objectives in 1997, adopting DOTS (Directly Observed Treatment Short course), as advocated by WHO.

The objectives of Revised National Tuberculosis Control Program (RNTCP) were :

(a) Achieve at least 85% cure rate of infectious cases through supervised Short Course Chemotherapy involving peripheral health functionaries.

(b) Augmentation of case finding activities through quality sputum microscopy to detect at least 70% estimated cases.

(c) Involvement of NGOs, Information, Education and Communication and improved operational research.

The revised strategy was introduced in the country as a pilot project in 1993. The pilot Project showed that the new strategy was feasible and acceptable to project staff and patients. The average cure rate achieved was more than 80% and the proportion of sputum positive cases rose to more than 50% of all cases found (24). It is envisaged, under the National Health Policy – 2002, to reduce the mortality due to tuberculosis by 50%, by the year 2010 (16).

Progress of RNTCP

In 1992, National level review of existing NTP concluded that efforts so far had not made any significant impact, leading to launch of RNTCP in 1993, with DOTS as the main strategy. World Bank granted a loan of US $ 142 million to Govt of India to implement RNTCP in at least one third of the country. Till 1998, only 2 percent of the total population of India was covered by RNTCP. During the later half of 1998, large-scale expansion of the program was undertaken and by 1999 RNTCP had expanded 7 folds to become the second largest such program in the World. By Mar 2001, more than one third of the country (430 million population in 190 districts) was covered by the RNTCP. More than 200 tuberculosis control societies had been formed in states and more than 1.5 Lakh health workers including 10,000 doctors & 3000 laboratory technicians had been trained till Mar 2001 using high quality modular training materials. More than 1400 supervisors were deputed to ensure the quality of diagnosis & treatment. By 2005, 1065 million population in 607 districts of more than 22 states was fully covered under RNTCP. The program had finally achieved case detection rate of 72% as against the global target of 70% and treatment success rate of more than 85%.

Under RNTCP, patients presenting themselves with symptoms suspicious of tuberculosis are screened through 3 sputum smear examinations. Revised program began initially in health institutions having X-ray facilities and extended to other centres. Supervision and monitoring were strengthened under the new scheme. Supervisory teams per 5 lakh population in urban areas and per 3 lakh population in rural areas are positioned, each consisting of a MOTC (Medical Officer Tuberculosis Control), STLS (Senior Tuberculosis laboratory Supervisor) and STS ( Senior Treatment Supervisor).

Important definitions under RNTCP (23) :

(a) **New Case** : A tuberculosis patient who has never taken antitubercular drugs or has taken antitubercular drugs for less than one month.

(b) **Case (Pulmonary), Smear positive** : TB patient in whom at least 2 initial sputum smear examinations (direct smear microscopy) are positive for AFB.

Or

TB patient with one sputum examination positive for AFB and radiological abnormalities consistent with active TB, as determined by treating physician.

Or

TB patient with one sputum examination positive for AFB and culture positive for M. tuberculosis.

(c) **Case (Pulmonary), Smear negative** : TB patient with symptoms suggestive of TB with at least 03 sputum examinations negative for AFB and radiographic abnormalities consistent with active pulmonary TB, followed by decision to treat the patient with full course of ATT.

Or

Diagnosis based on positive culture for AFB but negative sputum examinations.

(d) **Chronic case** : A TB patient who remains smear positive for AFB even after completing a re-treatment regime.

(e) **Cured** : Initially smear positive patient who completed treatment and had at least two negative sputum examinations, one of which should have been on completion of treatment.

(f) **Defaulted** : A TB patient, who at any time after registration, has not taken ATT for 2 months or more consecutively.

(g) **Died** : TB patient who died during treatment, irrespective of the cause.

(h) **Extrapulmonary Tuberculosis** : TB of any other organ other than lungs. However, a patient diagnosed with both pulmonary and extra-pulmonary TB is classified as pulmonary case.

(j) **Failure** : Smear positive patient who is tested smear positive at 5 months or later after starting ATT. Failure also includes initially smear negative patients who turned smear positive anytime during treatment.

(k) **Relapse** : A TB patient declared cured under RNTCP, but who reports back to health services and is found to be bacteriologically positive.

(l) **Treatment after default** : A patient who received ATT from any source for one month or more and who re-starts treatment after defaulting, i.e. after a gap of two months or more consecutively.

(m) **Transferred in** : A TB patient who has reported to a Tuberculosis Unit / district after starting treatment in another unit where he / she has been recorded.

(n) **Transferred out** : A TB patient who has been transferred to another TU / district and his treatment results are not known.

(o) **Treatment completed** : Sputum positive case who has completed treatment , with negative smear results at the end of initiation phase but none at the end of treatment.

Or

Sputum negative patient who has received full course of ATT and has not become smear positive at the end of treatment.

Or

Patient with extra pulmonary TB who has received full course of ATT and has not become smear positive at the end of treatment.

(p) **Tuberculous infection** : Presence of viable, multiplying and virulent tubercular bacilli within cells or tissues of human being without any manifestation of clinical symptoms.

DOTS is a community based tuberculosis treatment and care strategy which combines the benefits of supervised treatment, and the benefits of community-based care and support.

It has two phases :

(a) Intensive phase during which all the doses of chemotherapy are given supervised

(b) Continuation phase during which patient collects drugs from the center on a weekly basis and must present the empty blister pack of the drugs consumed at the time of the next week's collection. The first dose of the continuation phase must be administered under direct observation.

DOTS ensures high cure rates through its three components

(a) Appropriate medical treatment

(b) Supervision and motivation by a health / non-health worker,

(c) Monitoring of disease status by the health services.

DOTS will be administered by peripheral health staff such as MPWs, or through voluntary workers such as teachers, anganwadi workers, dais, ex-patients, social workers, etc. They will be known as DOTS 'agent' and will be paid incentive/honorarium of Rs 150 per patient completing the treatment.

The five components of DOTS are as under :

(a) Case detection with help of microscopy with provision for multi-tier cross checking and quality assurance of sputum smear.

(b) Regular and uninterrupted supply of medicines in colour-coded, patient-wise boxes.

(c) Direct observation by an observer (health workers or community volunteers) while the patient is on chemotherapy.

(d) Systematic evaluation and monitoring to ensure cure.

(e) Political will, thereby ensuring financial support and sustainability of the program. (25)

## National AIDS Control Program (26, 27)

With the spread of AIDS from one country to another it became necessary to initiate a National AIDS Control Program (NACP) in India. The Government of India in 1985 constituted a task force to look into this matter. It began by pilot screening program of high-risk population. National AIDS Control Program was launched in 1987. From 1987 to 1992, surveillance activities were undertaken in 55 cities in 3 states, with program implementation being left to the states without much central guidance. In the year 1992, Ministry of Health and Family Welfare set up National AIDS Control Organization (NACO) as a separate wing to implement and monitor various components of the program. The government launched a five-year HIV/AIDS Control Project (Phase-I) from September 1992 to September 1997 as 100% centrally sponsored project for all states and union territories. The project was later extended to March 1998.

The national strategy has the following important components: establishing of surveillance centres to cover the whole country; identification of high risk groups and their screening; issuing specific guidelines for management of detected cases and their follow-up; formulating guidelines for blood banks, blood product manufacturers, blood donors, and dialysis units; information, education and communication activities by involving mass media; research; reduction of personal and social impact of the disease; control of sexually transmitted diseases and condom promotion.

### NACP Phase I (1992 – 1999)

The aim of first phase of NACP was to prevent further transmission of HIV, to decrease morbidity and mortality associated with the infection and to minimize the social and economic impact of the epidemic.

### NACP Phase – II (1999 – 2001)

The National AIDS Control Program Phase – II was launched on 15 Dec 1999. It was implemented by NACO

with support from World Bank, USAID and the Department for International Development (DFID). NACP Phase II had features that brought about a paradigm shift in the nation's response to prevention and control of HIV/AIDS at all levels. Based on the epidemiological data obtained from annual sentinel surveillance, the country was divided into three categories,

(a) Maharashtra with prevalence of 2-2.4 percent in the age group 15-49 years,

(b) Andhra Pradesh, Karnataka, Manipur, and Tamil Nadu with a prevalence of 1-2 percent in the 15-49 age group, and

(c) The rest of the country where the prevalence less than 1% in same age group. The goal was to achieve zero level of new infection of HIV by the year 2007.

The objective under the second phase was to restrict future spread of HIV infection to less than 5% in Maharashtra, less than 3% in Andhra Pradesh, Karnataka, Manipur, and Tamil Nadu and less than 1% in rest of the country.

The objective was to be realized by focusing on targeted intervention by

(a) Raising the level of awareness on STD/HIV in rural areas and other vulnerable groups of population;

(b) Encouraging health seeking behaviour in general population for reproductive tract infections RTI and STDs;

(c) Making people aware about the services available in the public health system for the management of RTI/STD;

(d) Provision of facilities for early detection and prompt treatment

(e) Implementing focused IEC strategy.

**NACP Phase II achieved certain important aims, as under**

(a) Shifted focus from raising awareness to changing behaviour through interventions, particularly for groups at high risk of contracting and spreading HIV.

(b) Supported decentralisation of service delivery to the states and municipalities and a new facilitating role for NACO. Program delivery was made flexible, evidence-based, participatory and relied on local program implementation plans;

(c) Protection of human rights by encouraging voluntary counseling and testing and discouraging mandatory testing;

(d) Support structured and evidence-based annual reviews and ongoing operational research; and

(e) Encouraged management reforms, such as better managed State level AIDS Control Societies and improved drugs and equipment procurement practices. These reforms were proposed with view to bring about a sense of ownership of the program among the States, Municipal Corporations, NGOs and other implementing agencies.

**National AIDS Prevention and Control Policy (NAPCP) 2002 (27)**

The NAPCP was announced in 2002 with the aim to achieve zero transmission level of HIV by 2007. It adopted the following strategies :

(a) Interrupting the transmission of HIV by generating awareness among high risk groups and providing them with necessary skills and tools for protecting them from getting infected, mainly as under :

(i) Control of Sexually Transmitted Diseases (STDs) among sexually active and economically productive population.

(ii) Promoting condom usage among especially high risk groups as a means to protect them from HIV infection.

(b) Generating a positive socio-economic environment to enable infected individuals to manage the problem.

(c) Improving the health delivery system for PLWA, in hospitals as well as in community, through domiciliary care.

**NACP Phase III (28)**

Expert opinion is that India's AIDS epidemic is still at relatively early stage, which provides an opportunity for preventing infection rates from rising. Accordingly, Phase III of NACP (2006 – 2011) has been formulated to achieve the following goals :

(a) Preventing new HIV infections in high risk groups and general population through targeted interventions among high risk groups and intensified interventions among general population.

(b) Ensuring care, support and treatment to higher proportions of people living with AIDS (PLWA).

(c) Strengthening the prevention program in terms of infrastructure, systems and trained manpower at district, state and national level.

(d) Strengthening the strategic information and management system at national level.

Program framework for NACP III

Program framework for NACP III consists of

(a) Creating an enabling environment by introducing reforms in legal procedures and policies and structural constraints that impede interventions aimed at marginalized populations such as commercial sex workers, IV drug users and MSM groups

(b) Implementation of strategic communication by developing the existing IEC strategy towards holistic and strategic approach for high level advocacy, creating an enabling environment, bringing about behaviour change and social mobilisation at all levels

(c) Greater involvement of PLWA as resources for appropriate and effective response. PLWA should be incorporated into NACP III for ensuring access to prevention, care, support and treatment services

(d) Tackling the gender and socioeconomic issues such as gender inequalities, socioeconomic status, occupation, education, ethnicity and age.

Objectives of NACP III

NACP III is being implemented with the following objectives :

**Objective 1**

**Prevention of New Infections**

Estimates of 2004 indicate that 0.9% of Indian adult population (between 15-49 years) is presently infected with HIV. Thus nearly 99% Indian population is presently uninfected and should be targeted with effective preventive strategy. This is proposed to be achieved by :

(a) **Intensive coverage of High Risk Groups through targeted interventions** : Surveys conducted under NACP II indicated presence of high risk groups in all parts of the country and a focused strategy was launched to raise their awareness, motivating them to adopt safe behaviour, improving their access to preventive services and tools such as condoms. NACP III will aim at increasing the coverage of such services especially for high risk groups, identified as sex workers and their clients, transgender population, men having sex with men (MSM) and IV drug users in urban and rural areas. The 'bridge population', identified as truck drivers, street children, prison inmates and migrant workers would also receive special attention under NACP III. The essential elements of target interventions proposed under NACP III are access to behaviour change communication, prevention services such as condoms, STI services, needles and syringes, treatment services in form of STI clinics, drug substitutions for IV drugs, antiretroviral therapy and creation of an enabling environment under all project sites.

(b) **Intensification of interventions among general population** : Although 99% of Indian population is not infected, a high level of vulnerability exists, especially among young people, women, migrant workers and marginalized populations. NACP III aims at reducing risk, vulnerability and stigma through increased awareness and targeted behaviour change. The program is considered to be effective when 99% of population can recall three modes of HIV transmission and two methods of prevention. This is to be achieved through increased awareness through communication, social mobilisation & advocacy and through integration and expansion of integrated HIV related services like HIV counseling, testing, STI treatment, PPTCT and post exposure prophylaxis at sub district hospital, community health centres and PHCs.

(c) **Sexually Transmitted Diseases (STD) Control Program (29)** : Evidence suggests that likelihood of contracting HIV infection is 8-10 times higher in presence of other STDs, particularly genital ulcers. In view of the established relationship between HIV and STIs, Min of Health & Family Welfare adopted a policy of integrating HIV/AIDS and STD control within the existing health care system. Under the program, emphasis is given to comprehensive treatment of STIs at primary health care level and integration of non-stigmatised services with greater accessibility and acceptability by patients and community, while maintaining confidentiality and privacy of the patients. NACO took over the STD control program (in operation since 1946) in 1992 and made it an integral component of AIDS control policy. After overcoming the shortcomings of the erstwhile STD contol program (like poor community acceptability, poor accessibility, stigma), NACP III continues to provide STI services based on syndromic approach, with the aim to improve etiological management of STIs. The broad objectives of STI control program under NACP III are to reduce STD infections, thereby controlling HIV transmission by minimizing a risk factor and to prevent short and long term morbidity & mortality due to STDs. This is to be achieved through the following strategies :

(i) Development of adequate & effective program management by strengthening existing STD clinics, appointing STD program officers in State AIDS Control Societies and identification of district nodal officers who would supervise working of STD clinics.

(ii) Promotion of IEC activities for prevention of transmission of STD & HIV infections in form of activities to educate people for responsible sexual behaviour, safer sex and greater condom usage.

(iii) Improving case management including diagnosis, treatment, counseling, partner notification and screening for other diseases, in form of two sets of guidelines for PHC level and for referral of STD specialists.

(iv) Increasing access to health care for STD by strengthening existing STD clinics, increasing health seeking behaviour through IEC & NGOs and establishing First Referral Units in collaboration with Dept of Family Welfare.

(v) Creating facilities for diagnosis & treatment of asymptomatic infections by providing trained lady medical officer and sensitizing community through Family Health Awareness Campaigns for early detection and referral to PHCs.

(d) **Voluntary Counseling and Testing (VCT)** : VCT specifically involves increasing availability and demand for voluntary testing including joint

testing of couples, training grassroot health workers in HIV counseling and providing counseling through blood banks and through STI clinics. Under NACP III, it is envisaged that at least one voluntary testing centre would be established in every district. Pretesting counseling (before HIV testing) essentially prepares an individual for undergoing HIV test, identifying high risk behaviour by the individual and changing his/her high risk behaviour. Post test counseling helps the client to understand the importance and meaning of negative or positive HIV test, benefits of changing the high risk behaviour and constructively handling the marital and sexual needs.

(e) **HIV testing** : Under the present HIV testing policy of Govt of India, there is no rationale for mandatory HIV testing of any individual. It is established that any form of mandatory testing usually drives 'underground' those who are at highest risk due to stigma & discrimination and is thus counter-productive in the long term. According to present HIV policy, HIV testing is carried out on voluntary basis with adequate pretest and post-test counseling. Govt of India has formulated a comprehensive HIV testing policy, in accordance to WHO guidelines, which states that :

(i) No individual shall be made to undergo any form of mandatory HIV testing.

(ii) HIV testing shall not be imposed as a precondition to employment or for providing health care facilities during employment.

(iii) Adequate facilities for voluntary testing with pre-test and post-test facilities will be made available throughout the country in a phased manner, so as have at least one HIV testing centre in every district.

(iv) Disclosure of HIV status to spouse of the person will depend entirely on willingness to part with such information. However, all efforts should be made so that the individual voluntarily shares such information with family, to ensure proper home based care.

(v) In case of marriage, when one partner insists on knowing the HIV status of other partner, HIV testing should be arranged by contracting partner to the satisfaction of person concerned.

(vi) Different testing strategies are to be adopted under different circumstances, as under :

- **Mandatory testing** : Screening in blood banks for blood safety. However, testing in all blood banks will be undertaken on collected blood samples in an unlinked & anonymous manner so as to only identify the status of blood sample and not of the donor.
- **Unlinked and anonymous testing**: To be undertaken for epidemiological surveys and HIV surveillance to monitor the trend of HIV infection in community.
- **Voluntary and confidential testing** : To be undertaken as confirmatory testing for subclinical infections / clinical management and as voluntary testing.
- **Need based testing**: To be undertaken with explicit consent, for research purposes, after ensuring all ethical considerations.

For screening of donated blood, a single test by either Rapid or ELISA method is enough to eliminate possibility of HIV infected blood. For epidemiological surveys, the same procedure is adopted with one or two of Rapid / ELISA / Simple which has high sensitivity. In such cases, testing is unlinked and anonymous and result is not given to the person. For clinical management and for confirmation of HIV status of individuals who voluntarily asks for it, testing is done by at least two ELISA and one Rapid/Simple test using different antigen preparation. The result of HIV testing in such cases has to be disclosed only after proper pre-test and post-test counseling of the concerned individual.

(f) **Prevention of Parent to Child Transmission (PPTCT)**: Various studies have indicated that chemoprophylaxis (in the form of Nevirapine) before delivery in case of HIV-infected pregnant woman significantly reduces mother-to-child transmission rate from 33% to 8.4% at birth or 10.1% at age of two months. The intervention cost has been worked out to Rs 175 per woman, which is a very cost effective method to prevent perinatal HIV infection. NACP III envisages that antenatal clinics will be used for imparting HIV education to pregnant women through trained counselors. Special emphasis would also be given to drug prophylaxis linked with infant feeding, nutritional support and contraception. Drug regimes used for chemoprophylaxis would be modified according to emerging evidence of efficacy of the drugs.

(g) **Occupational Health and HIV/AIDS** : NACP III has addressed the issue of expanding HIV/AIDS response at work place. Under NACP III, specific guidelines have been formulated in collaboration with employers, workers organisations, ministries and civil society, with the aim to strengthen response to HIV and mitigate the effect of the disease at work place. The key areas for intervention at work place are prevention of HIV/AIDS, management & mitigation of impact at work place, care & support for infected workers and reducing stigma and discrimination at work place.

(h) **Universal Protection & Post Exposure Prophylaxis (PEP)** : Under NACP III, health care workers will be provided specific protection against occupational exposure to HIV. NACP III recommends following measures after occupational exposure

(i) Rapid testing facility for HIV testing.

(ii) Exposure with HIV should be considered a medical emergency.

(iii) Chemoprophylaxis should be started within 4 hours after exposure.

(iv) Chemoprophylaxis should be reviewed on 1, 3 and 6 month interval.

(v) Under NACP III, only following drugs are approved for post exposure prophylaxis :

- Zidovudine – 300 mg twice daily for 4 weeks.
- Lamivudine – 150 mg twice daily for 4 weeks.
- Indinavir – 800 mg thrice daily (only as part of expanded regime)
- Saquinavir – 600 mg thrice daily.

(j) **Blood Safety Program** : In India, blood banking infrastructure is highly decentralized and there is acute shortage of trained manpower, equipment and financial resources necessary to provide the desired quality of blood. In addition, there is often shortage of blood which encourages private blood banks with inadequate infrastructure and quality control.

Blood safety has remained an integral part of NACP since its inception and NACP III has included the objectives of

(i) Ensuring organized blood banking services at State / District level

(ii) Educating & motivating community about importance of voluntary blood donation

(iii) Enforcing quality control for all units of blood to be infused.

**To achieve the above objectives, NACP III has formulated certain strategic plans as under :**

(a) Strengthening National Blood Transfusion Services.

(b) Ensuring adequate blood supply to all blood transfusion centres.

(c) Ensuring safety of blood and blood products.

(d) Developing facilities for production of blood components from whole blood.

(e) Developing facilities for plasma fractionation

(f) Strengthening quality control of blood and blood products.

(g) Undertaking research on blood transfusion services.

(h) Strengthening effective management, monitoring and evaluation of blood transfusion. NACP III emphasizes on establishing HIV testing facilities, provide for testing of other blood transmissible diseases and modernization of blood banks.

**The Hon' Supreme Court ruling on Blood Transfusion Services** : The Hon' Supreme Court of India in a landmark judgment, issued certain directives on 04 Jan 1996, as under :

a) To establish forthwith a National Council of Blood Transfusion at Central, State and UT level as a society registered under Societies Act 1860 with funds provided by central / state / UT govt.

b) To license all blood banks.

c) To stop professional blood donation.

d) To grant 100% Income Tax exemption to any individual who makes donation to national / state blood councils.

e) To consider feasibility of separate legislation for regulating collection, processing, storage, distribution and operation of blood banks in the country.

**National Blood Policy (30)** : The Hon' Supreme Court's ruling of 1996 helped in phasing out unlicensed blood banks by May 1997 and abolished professional blood donation in the country by December 1997. Mandatory testing for HIV, Syphilis, Malaria, Hepatitis B & C helped in checking transmission of blood borne infections. The National Blood Policy has been laid down to ensure easy accessibility and adequate supply of safe blood & blood components and to ensure blood transfusion under supervision of trained health care workers.

(k) **Condom Promotion Program** : In India, heterosexual transmission constitutes the major transmission route of HIV and condom usage remains the single most effective and practical method to prevent HIV transmission. Accordingly, Condom Promotion Program under NACP III proposes that there should be no moral, religious or ethical inhibition in promoting condom usage among sexually active individuals, especially those who practice high risk behaviour. Under NACP III, it is envisaged to convince people to use condoms not only for family planning but also as the best preventive measure against HIV, convince commercial sex workers and their clients to use condoms as a means to prevent sexually transmitted diseases including HIV and to make available low cost, good quality condoms to people all over the country easily at the time and place where they will need them. The objective of Condom Promotion Program is to ensure easy access to acceptable, good quality and affordable condoms with the view to promote safe sex. The following are used as indicators for success of Condom Promotion Program under NACP III :-

(i) Percentage of persons who report easy availability of condoms within 500 meters of the place where they need them.

(ii) Percentage of persons reporting consistent use of condom in sexual encounters with non-regular partners in last 30 days.

(iii) Percentage increase in number of non-traditional outlets for condoms, like post offices, shopping malls etc.

**University Talk AIDS Project (UTA)** : UTA Project began as

early as Oct 1991 with partnership between National Service Scheme (NSS), Dept of Youth Affairs & Sports and NACO. The project aims to generate awareness among students on HIV related issues through seminars, talks, workshops and written material. The program also deals with related issues pertinent to youth like drug abuse, relationships, courtships, marriage and thus aims to enhance life style skills among the youth.

Objective 2

Care, Support and Treatment

NACP III has incorporated comprehensive community and home based care, psychosocial support to HIV infected individuals and households and aims to ensure accessible, affordable and sustainable treatment to infected individuals. To achieve the above objectives, NACP III has adopted the following strategies :

(a) Treatment for opportunistic infections (OI) previously available at district level would be now available at CHC and PHC levels. Drugs would be given free at all govt hospitals and few NGOs with good track record in providing HIV care would also be incorporated for treating OI. NACP III also proposes close linkage between NACP and RNTCP since tuberculosis remains the most common and most lethal opportunistic infection among HIV infected individuals.

(b) Anti retroviral therapy to as many infected individuals has been attempted under NACP III. NACP III proposes to enhance the service through private-public partnerships and through community partnership and ownership. Serpositive women who have participated in PPTCT program, children below 15 years with HIV/AIDS, PLHA referred under targeted interventions (such as for commercial sex workers, truck drivers or migrant workers) and AIDS patients getting treatment from govt ART centres will be given priority for ART. It is proposed that by 2010, as many as 1,84,000 individuals would be on ART.

(c) NACP III also proposes to establish DNA PCR facility for diagnosis of HIV in children through selected national referral centres, to meet the requirement due to increasing number of infected children.

Objective 3

Capacity Building

Under NACP III, capacity building at national, state and district levels is envisaged through multiple strategies to meet the fast evolving challenges of HIV epidemic in the country. Possible centres for imparting training, identified by a multidisciplinary standing committee (including an epidemiologist, economist, microbiologist and public health, marketing, communication specialists among others) will identify training needs at various levels and also help States to plan their training. In addition, capacity building under NACP III will include issues of program management, finance and procurement of infrastructure, human resource and medicines at various levels. Recruitment of staff in NACO would be demand based and all staff would receive refresher training periodically. Specialised areas such as program management & implementation, finance and procurement etc will receive special attention under the program. The district planning under Rural Health Mission will attempt to integrate HIV related services into the general health services. Cross linkages with other relevant programs like RNTCP & RCH would be established for optimum outputs. NACP III also makes an attempt to co-ordinate various programs being implemented by different agencies, thereby ensuring joint analysis of results and sharing, monitoring and evaluation of progress.

Objective 4

Monitoring & Evaluation

**HIV Surveillance**

Effective and accurate HIV surveillance is essential to monitor progress of the control program. NACP III undertakes HIV surveillance with the objective to estimate incidence, prevalence, morbidity and mortality due to HIV and also to identify behavioural and biological markers on progress of preventive program.

**HIV Sentinel Surveillance**

HIV Sentinel Surveillance is undertaken every year jointly by NACO and Min of Health & Family Welfare since 1998 with the aim to update HIV estimates for the country. Under this program, HIV prevalence in the country is estimated based on HIV prevalence recorded at designated sentinel surveillance sites (such as STD clinics, de-addiction centres and intervention centres for female sex workers) for different risk groups. Women attending antenatal clinics are taken to be representative of the general population. Blood samples collected (between 01 Aug – 31 Oct) by unlinked anonymous method are tested at regular intervals annually and the data is used for epidemiological analysis and estimation of HIV prevalence in the country.

**High Risk Behaviour Surveillance Survey (BSS)**

BSS is undertaken to provide behavioural measurement for recording trends of high risk behaviour among selected population groups. A set of 9 indicators, as under, were used on three occasions to assess the trends.

(a) Knowledge indicators

  (i) Proportion of respondents who know 2 acceptable ways to prevent STDs.

  (ii) Proportion of respondents who know that condoms prevent STDs.

  (iii) Proportion of respondents who know 2 acceptable ways to prevent HIV.

  (iv) Proportion of respondents who know that condoms prevent HIV.

(b) Behaviour Indicators

  (v) Proportion of respondents who report heterosexual intercourse with non-regular

partner in the last year.

(vi) Proportion of respondents who report condom usage during last sexual intercourse with non-regular partner in the last year.

(c) Prevalence of Urethritis

(vii) Proportion of male respondents who report symptoms of urethritis during last one year.

(viii) Proportion of male respondents who sought treatment from qualified medical practitioners for urethritis in the last year.

(d) Appropriate perception of risk indicators

(ix) Proportion of respondents with high risk behaviour who perceive that they can get infected with HIV.

## National Program for Control of Blindness (31)

The national program for control of blindness was launched in the year 1976 as a 100% centrally sponsored program and incorporates the earlier trachoma control program started in the year 1963. The various activities of this program include establishment of Regional Institute of Ophthalmology, upgradation of ophthalmology departments of medical colleges and district hospitals, development of mobile eye units, recruitment of required ophthalmic manpower and provision of various ophthalmic services. NPCB initially laid down the goal of reducing prevalence of blindness to less than 0.3% by 2000 as compared to 1.49% in 1986-89. The program failed to achieve its targets due to various reasons and 10th Five Year Plan reformulated the targets as

(a) To reduce prevalence of blindness to 0.8% by 2007

(b) Increase cataract surgery rate to 450 per lac population

(c) Improve visual outcome of cataract surgery by performing IOL implantation in > 80% by 2007

(d) Develop 50 pediatric ophthalmology units in the country

(e) Provide facilities for early diagnosis & treatment of glaucoma and diabetic retinopathy

(f) Setting up 20,000 vision centres in the country

(g) Develop 25 fully functional eye bank

(h) Develop human resource and institutional capacity.

**Initial strategies under NPCB were:**

(a) Strengthening of service delivery

(b) Developing human resources for eye care

(c) Promoting out-reach activities and public awareness

(d) Developing institutional capacity.

Due to failure to achieve targets, strategies were revised to include:

(a) Strengthening services for other causes of blindness like corneal blindness (requiring transplantation), refractive errors in school children, improving follow -up services for cataract operated persons and treating other causes of blindness like glaucoma.

(b) Shift from eyecamp approach to fixed facility approach and from conventional surgery to IOL implantation.

(c) Strengthen participation of voluntary organisations in the program and to earmark geographical areas to NGOs and govt.

(d) Enhance coverage in tribal and underserved areas.

Under NPCB cataract operations using IOL implants are conducted, with minimum annual target for cataract surgeries set at 400 per lac population. NGOs are encouraged to organize eye camps in remote areas along with District Health Services. Augmentation of infrastructure in form of construction of eye wards, operation theatres and dark rooms have been undertaken in 7 states, assisted by World Bank. NPCB also envisages training to surgeons for IOL implantation. Other important issues addressed by NPCB are school eye screening program (where refractory errors among school children are confirmed by ophthalmic assistants and corrective spectacles are prescribed), collection & utilization of donated eyes (where more than 20,000 donated eyes are collected and utilized every year), control of Vitamin A deficiency (where 2 lakh IU of Vitamin A solution is given to every child every 6 months till the age of 6 years. This component, included under CSSM program ,is now an integral part of RCH program), control of trachoma (where chemotherapeutic intervention is undertaken to reduce severity, lower incidence and reduce prevalence of trachoma in community). Under NPCB, an ophthalmic assistant is placed at PHC/CHC level for implementation of program strategies.

The program aims to improve the physical, technical and managerial capabilities of non-profit institutions to provide high quality cataract treatment in situ or in camps. The program is implemented through a combination of service delivery models – Medical Colleges, district hospital, base hospitals, community health center, primary health centers, camps in fixed facilities, camps in improvised facilities and if necessary in private facilities in collaboration between the central government, state government and non-government organizations.

The program intends to strengthen medical colleges and Regional Institutes of Ophthalmology to train ophthalmologists and selected health professional on cataract diagnosis, screening, surgery and follow-up care and it will provide managerial training for central and state project coordinators and other project staff requiring managerial and administrative skills training.

**Infrastructure Development**

At the apex, a National Institute of Ophthalmology (Dr Rajendra Prasad Centre for Ophthalmic Sciences, AIIMS, New Delhi), has been established with 10 other Regional Institutes of Ophthalmology for manpower development, research and referral services. In addition 82 Medical Colleges have been upgraded, out of which 39 medical colleges have been designated as training centres for paramedical ophthalmic assistants. So far 166 eye banks

have been developed in the government and non-government sector, 445 district hospitals have been equipped for ophthalmic services. The concept of District Blindness Control Society was first developed in five pilot districts. Based on the success of these societies, as many as 512 District Blindness Control Societies have been formed under the chairmanship of District Collector. These societies have multidisciplinary structure with representatives from government, non-government and private sector.

**Vision 2020 – The Right to Sight**

Launched in early 1999 in Geneva by WHO – The Right to Sight has as its goal the elimination of avoidable blindness by the year 2020. While adopting the basic strategy of providing comprehensive eye care as an integral part of the primary health care system, 'Vision 2020' includes three major components: specific disease control, human resource development, and infrastructure and appropriate technology development. In the first five-year, disease control efforts will focus largely on cataract, trachoma, onchocerciasis, avoidable causes of childhood blindness, uncorrected refractive error, glaucoma and diabetic retinopathy. Human resource development under the program includes augmentation of middle level ophthalmic personnel. Proposed infrastructure development under NPCB includes establishing 20 centres of excellence, 200 training centres, 2000 service centres and 2000 vision centres. As VISION 2020's mission statement emphasizes, "Our mission is to eliminate the main causes of blindness in order to give all people in the world, particularly the millions of needlessly blind, the right to sight".

## National Iodine Deficiency Disorders Control Program (NIDDCP) (32, 33)

India commenced a 100% centrally sponsored National Goitre Control Program in 1962, based on iodized salt, after successful trials in Kangra Valley in Himachal Pradesh. At the end of four decades, the prevalence of the disease still remains high. In retrospect, it became clear that the failure was mostly due to operational and logistic difficulties. That is, the production of iodized salt did not keep pace with the requirement. Operational difficulties such as inadequate production of iodized salt and continued sale of un-iodized salt in endemic areas resulted in this program having little impact on the goitre problem in the country. Reassessment of the magnitude of the problem by ICMR showed that the problem was not restricted to the goitre-belt as was thought earlier, but is extremely prevalent in other parts of India as well (e.g., Gujarat, Punjab, Maharashtra, Madhya Pradesh, Andhra Pradesh and Kerala). Similarly, the iodine-deficiency manifestations were not limited to endemic goitre and cretinism but to a wider spectrum of disability including deaf-mutism, mental retardation, and various degrees of impairment of intellectual and motor functions. It is estimated that nearly 200 million persons are exposed to the risk of IDD, of which 61 million are having goitre, 2.2 million are cretins and 6.6 million have mild neurological disorders.

In 1992, the program was renamed National Iodine Deficiency Disorders Control Program (NIDDCP) and nation-wide, rather than area-specific use of iodized salt was promoted. It was decided as a national policy to fortify all edible salt in a phased manner by end of 8th plan. The essential components of NIDDCP are use of iodized salt in place of common salt, monitoring and surveillance, manpower training and mass communication.

**Goals of 10th Five Year Plan** (34) : Under the 10th Five Year Plan, specific goals were laid down to achieve universal access to iodized salt, generate district-wise data on consumption of iodized salt and reduce prevalence of iodine deficiency disorders in the country to less than 10% by 2010. In order to achieve these goals, a survey conducted estimated that nearly 200 million people in India are at risk of iodine deficiency disorders. NIDDCP envisages that only iodized salt would be available in the country. To achieve this, sale of non-iodized salt has been banned in 26 states and 7 UTs under PFA Act 1954. Recently central govt has issued complete ban on non-iodized salt throughout the country. Guidelines for quality control for iodated salt have been laid down. Min of Health & Family Welfare has issued notification banning sale of non-iodized slat for direct human consumption in the entire country, effective from May 2006.

## Universal Immunization Program (35, 36, 37, 38)

Experience with small pox eradication program proved that immunization was the most powerful and cost effective weapon against vaccine preventable diseases. In 1974, WHO launched the "Expanded Program on Immunization" (EPI) against 6 diseases which were common during childhood, viz. diphtheria, pertussis, tetanus, polio, tuberculosis, and measles. From the beginning of the program UNICEF has been providing significant support to EPI.

Government of India launched its EPI in 1978 with the objective of reducing mortality and morbidity resulting from vaccine-preventable diseases of childhood, and to achieve self-sufficiency in the production of vaccines. This program was revised (with focus on infants and pregnant mothers) and renamed as Universal Immunization Program (UIP) 1985. It had two vital components: immunization of pregnant women against tetanus and immunization of children in their first year of life against the six target diseases. Measles vaccine was also included under UIP in 1985. UIP was merged with Child Survival and Safe Motherhood (CSSM) program in 1992 and later became part of RCH program in 1997. The aim was to achieve 100 per cent coverage of pregnant women with 2 doses of tetanus toxoid (or a booster dose), and at least 85% coverage of infants with 3 doses each of DPT, OPV, one dose of BCG and one dose of measles vaccine.

The immunization services are being provided through the existing health care delivery system (i.e. MCH centres, Primary Health Centres, and subcentres, hospitals, dispensaries, and ICDS units). There is no separate cadre of staff for UIP since it is an integral part of RCH.

Although the target was 100% immunization, no country has ever achieved "universal" immunization in children.

"Universal" immunization is therefore best interpreted as implying the ideal that no child should be denied immunization against tuberculosis, diphtheria, whooping cough, tetanus, polio and measles. It is, however, generally accepted that when immunization coverage reaches a figure of 80% or more, then disease transmission patterns are so severely disrupted as to provide a degree of protection even for the remaining children who have not been immunized, because of "herd" immunity. It is also important that children are immunized during the first year of life and that levels of immunization are sustained so that each new generation is protected.

**UIP under RCH** : It is envisaged that that under RCH II the immunization program shall be further strengthened. Immunisation coverage will be enhanced for underserved communities, for which Dept of Family Planning has formulated a strategic plan for UIP for the period 2004-2009.

The success of UIP can be measured in terms of burden of vaccine preventable diseases (VPD) in community. UIP has contributed significantly to bringing down infant mortality rate (IMR) from 104 per 1000 live births in 1984 to 60 infant deaths per 1000 live births in 2003. There were certain constraints in UIP under RCH I such as irregular coverage, poor cold chain system, poor implementation, poor staffing & training, poor vaccine supply and poor maintenance of equipment. These have been addressed under RCH II by laying down six goals as under :

(a) Provisioning of safe and efficient immunsation to all infants and women at district level.

(b) Global polio eradication, reduction in mortality due to measles and elimination of neonatal tetanus.

(c) Provisioning of adequate and assured funding for the program.

(d) Reduce social and cultural barriers to immunization services and increase demand for immunsation in community by means of IEC activities.

(e) Introduction of new and underutilized vaccines against diseases which are prevalent in India, like Hepatitis B, Japanese Encephalitis (JE) etc.

(f) Accurately monitor use of immunization services, antigen coverage and drop rates among community

**Urban Measles Campaign** : Measles is highly contagious viral disease, generally occurring in overcrowded living places with poor ventilation, poor living conditions and poor vaccine coverage. By 2000, 63 cities were covered under the Measles vaccination drive initially launched by UNICEF. Presently under the program, the aim to vaccinate all children below the age of 3 years. Under the UIP, MMR can be administered upto the age of 5 years, although ideal age is 15 months.

**Elimination of Neonatal Tetanus** : Neonatal tetanus still contributes significantly to infant mortality in many areas in the country. Fortunately, NNT can be prevented by immunizing all women in reproductive age group by tetanus toxoid. The National Program of Elimination of Neonatal Tetanus under RCH has laid down the following objective of reduction of incidence of NNT to less than 1 per 1000 live births by 2000 (now extended to 2009) through immunizing all pregnant women by two doses of TT, promoting "The Five Cleans" (clean hands, clean surface, clean blade, clean stump and clean tie) during delivery, provisioning of disposable delivery kits and accurate community based surveillance of NNT.

Elimination of NNT is defined as incidence of less than 1 case per 1000 live births in any given geographical area. The state of Andhra Pradesh was the first to be certified in Nov 2003 by a team of National & International experts to have eliminated NNT. With the aim to eliminate NNT from the entire nation by 2009, intensive measures were initiated in all parts of the country.

**National Immunisation Schedule** : Vaccination against TB, polio, tetanus, diphtheria, pertusis and measles is recommended under the routine immunization schedule, as under :

| Age | Vaccines |
|---|---|
| At Birth | BCG, OPV (zero dose) |
| 6 weeks | DPT, OPV, Hep B (first dose) |
| 10 weeks | DPT, OPV, Hep B (second dose) |
| 14 weeks | DPT, OPV, Hep B (third dose) |
| 9 months | Measles |
| 15-18 months | MMR (only in Delhi / New Delhi) |
| 16-24 months | DPT (first booster), OPV |
| 24 months | Typhoid (only in Delhi/New Delhi) |
| 4-5 years | DT (booster), OPV (only in Delhi / New Delhi) |
| 10-16 years | TT |
| Pregnant women (un-immunised) | 2 doses of TT at interval of 1 month |
| Pregnant women (immunized) | 1 booster dose of TT |

Other vaccines recommended by Indian Academy of Pediatrics (IAP) but not included under the National Schedule are as under. These are optional for those who can afford the cost of the vaccines :

| Age | Vaccine |
|---|---|
| 6 weeks | HiB (first dose) |
| 10 weeks | HiB (second dose) |
| 14 weeks | HiB (third dose) |
| 12 months | Chicken Pox, Influenza |
| 18 months | HiB (booster) |
| 24 months | Hep A, Meningococcal meningitis |
| 30 months | Hep A |
| 5 years | Typhoid, Meningococcal meningitis |

## Polio Eradication Program (39)

World Health Assembly of WHO passed a resolution in May

1988 to eradicate Poliomyelitis from the World by the year 2000 and accordingly, all nations launched a concerted drive against Polio. The Americas were declared Polio-free in 1994, followed by Western Pacific in 2000 and Europe in 2002.

Pulse polio program was launched in India in 1995. Under this program, children less than five years of age are given additional oral polio drops every year on fixed National Immunisation Days (NIDs).

Pulse Polio Immunisation means administration of oral polio to all children 0-5 years of age in the country on a single day, regardless of any previous immunisations. Polio vaccine is usually given as two rounds about 4 to 6 weeks apart during low transmission season of polio; i.e. during winter months, with the aim to replace wild polio virus with vaccine virus in community. The doses of OPV during PPIs are extra doses which supplement and do not replace the doses received during routine immunisation services. The children including 0-1 year old infants should receive all their scheduled doses and PPI doses. There is no minimum interval between PPI and scheduled OPV doses.

For India to progress towards the goal of eradication of wild polio virus, it is important to identify poorly vaccinated areas, to determine primary reasons for poor coverage of immunisation and to use this information to ensure high coverage of subsequent supplementary door-to-door immunisation rounds. Now it is clear that PPI campaign using only booth- based approach is not sufficient to interrupt the wild poliovirus transmission in the areas where it is mostly persistent. A recent action research on PPI non-acceptors showed that 10-15 percent of eligible children were missed in earlier PPIs. An area in which wild poliovirus transmission has recently occurred is by defintion an area of low immunisation coverage and area of poor surveillance.

Presently, the basic strategies being followed to eradicate polio from the country are :-

(a) Routine immunization of all infants with at least 4 doses of trivalent OPV.

(b) Pulse Polio Immunisation (PPI) Program through National Immunisation Days (NIDs) wherein additional doses of OPV, 4-6 weeks apart, are administered to all children upto 5 years of age. Intensified Pulse Polio Immunisation (IPPI) is being undertaken in the form of house to house search and vaccination of unvaccinated children after the "booth days".

(c) Surveillance for Acute Flaccid Paralysis (AFP), defined as "any child upto 15 years of age who has sudden onset of flaccid paralysis or paralytic illness in any individual in absence of any obvious reason and where polio is suspected to be the underlying cause". The surveillance program incorporates the following components :

(i) Establishment of AFP Reporting Units, in the form of hospitals, pediatricians, doctors & health/medical care establishments in government and private sector. These reporting units send a weekly report to District Immunisation Officer (DIO).

(ii) Notification of AFP cases to DIOs, immediately on occurrence, following which investigation is undertaken.

(iii) Investigation of AFP cases is to be undertaken within 48 hrs of notification by DIO / SMO, wherein, after confirming the diagnosis of AFP, the child is clinically examined and detailed history is recorded on Case Investigation Form (CIF).

(iv) Collection and transportation of two stool specimens (at least 24 hrs apart) from AFP case is undertaken within 14 days of onset of paralysis. About 8 gms of stool is collected, labeled and transported (in clean, dry, screw-capped, non-sterile bottle without any preservative or transport media) under "reverse cold chain" to a designated national laboratory for identification and isolation of the polio virus.

(v) Outbreak Response Immunistaion (ORI) is organized in community after occurrence of any AFP case. All children below 5 years of age are administered one dose of OPV irrespective of their previous immunization status, through a door-to-door coverage round. The ORI round is to be organized at the earliest after occurrence of AFP case and if travel history of the case is suggestive, ORI should also be conducted at other places of stay of the AFP case.

(vi) Active case search in community is to be conducted by house-to-house search, conducted along with ORI. The case definition to be used in case search is "Flaccid paralysis in a child between 0-15 years of age with onset within last 60 days."

(vii) 60 day follow up examination by DIO is undertaken through re-visit and re-examination of every AFP case 60 days after onset, to confirm residual weakness. A child is said to have residual weakness if the child has any one sign out of weakness, asymmetric skin folds, difference in left/right mid arm/mid thigh circumference.

(d) Extensive house-to-house immunization in form of Mopping up campaigns, under which extra rounds of door-to-door immunization is undertaken with or without fixed booths. This is usually undertaken before onset of summer and rainy months, when residual polio virus in community is likely to appear again in community.

An important improvement in PPI since 1998 has been incorporation of vaccine vial monitor (VVM). Colour monitors or labels are put on vaccine bottles. Each label has a circle of deep blue colour. Inside it is a white square

which changes colour and gradually becomes blue like that of surrounding circle if the temperature is not maintained and then the vaccine should be considered ineffective. Thereby, the health worker can easily ascertain that the vaccine being given is effective or not. This mechanism has been made mandatory in all vaccine procurements since 1998.

**Actions to be taken on Occurrence of AFP Case**

(a) Admission to Hospital : The patient should be immediately admitted to hospital and isolated.

(b) Disinfection : Concurrent disinfection should be carried out.

(c) Notification should be carried out as per existing orders.

(d) Attendants should wear gowns and wash hands after handling patients.

(e) Contacts : Close contacts should be kept under surveillance for 14 days and should not be exposed to violent muscular effort, trauma and inoculations.

(f) Water and Food Sanitation : The clarified water should be superchlorinated before supply. Food sanitation should be kept at highest standard.

(g) Flies : They should be destroyed by use of insecticide sprays and breeding should be prevented by proper disposal of garbage.

(h) Oral Vaccine : Mass vaccination should be organised to achieve the most rapid and complete immunization of epidemiologically relevant groups, particularly younger children.

## National Guinea – Worm Eradication Program (14, 43)

India launched its National Guineaworm Eradication Program in 1984 with technical assistance from WHO. From the very beginning the program was integrated into the national health system at village level through primary health care. With well defined strategies, an efficient information and evaluation system, intersectoral coordination at all levels and close collaboration with WHO and UNICEF, India was able to significantly reduce the disease in affected areas. The last Guinea worm case in the country was reported in August 1996 from Jodhpur (Rajasthan). The country has reported zero cases since then. In February 2000, the International Commission for the Certification of Dracunculiasis Eradication recommended that India be certified free of dracunculiasis transmission and subsequently India was declared to "Guinea Worm Disease free" on 15 February 2001.

## Japanese Encephalitis Control Program (14, 44, 45)

Japanese encephalitis (JE) is a disease with high mortality rate and those who survive do so with various degrees of neurological complications. JE has been reported in the country since mid fifties. With increasing development of irrigation projects and changing pattern of water resource management there has been a progressive increase in number of States reporting JE in India. Twelve States/Union territories have reported outbreaks of JE in the last decade and 378 million population is exposed to the risk of JE. States of Andhra Pradesh, West Bengal, Assam, Tamil Nadu, Karnataka, Bihar and Uttar Pradesh are reporting maximum number of cases.

A task force has been constituted at National level for control of JE, which reviews the situation and control strategies from time to time. Technical support for prevention, control and investigation of outbreaks is provided under National Vector Borne Diseases Control program (NVBDCP), with separate budget allocation of funds for JE control, including training and IEC under NVBDCP.

**The Strategies for Control of Japanese Encephalitis:**

(a) Surveillance activities through sentinel sites.

(b) Early diagnosis & treatment at PHCs, CHCs and tertiary hospitals.

(c) Behaviour Change Communication (BCC) for early reporting & personal protection.

(d) Integrated vector control measures in the form of antilarval measures, space spraying in animal dwellings and fogging when outbreaks are imminent.

(e) Training of medical & nursing staff.

(f) Efforts to develop a safe and standard vaccine.

Under the program, vaccination with killed JE vaccine is not recommended for control of an outbreak. Primary immunization (not included under the program) in the form of 2 doses of 1 ml (0.5 ml for children upto 3 years) each is to be given subcutaneously at 7-14 days interval. Booster dose of 1 ml is to be given after one year, with re-vaccination after 3 years. Vaccination is considered as a very cost-effective method to permanently control JE at community level.

## Kala-Azar Control Program (14, 46)

Kala-azar (Visceral leishmaniasis) continues to be a serious public health problem in several states in the country. Available data indicates that Kala-azar is endemic in 32 districts in Bihar, 4 districts in Jharkhand, 11 districts in West Bengal and 2 districts in UP, with an estimated 129 million people at risk. Periodic outbreaks of Kala-azar with increase in morbidity and mortality continue to occur in these states. Over 90% of the reported cases and over 95% of the reported deaths are from Bihar. Over two thirds of the cases in Bihar are reported from 7 districts. National Health Policy 2002 has laid down the goal of elimination of Kala Azar by 2010.

The Government of India is implementing a Centrally Sponsored Scheme for control of Kala-azar in Bihar and West Bengal. Following reported increase in the number of cases and deaths due to Kala-azar in 1989-91, an intensive program for containment of Kala-azar was launched in 1992.

The strategy for control of infection includes interruption of transmission through residual indoor insecticide spraying, early diagnosis with RK 39 Rapid Detection Kits, prompt treatment with oral Miltefosine, intensive IEC activities for sustained behaviour change, capacity

building in form of infrastructure and training, close monitoring & evaluation and Operational Research.

After 1993-94, financial aid was provided to Bihar and West Bengal to control Kala Azar, along with chemicals for residual spray and drugs (Sodium stibogluconate and Pentamidine isothionate). The program was operational on cost sharing basis till 2000-2001, with centre providing the chemicals and drugs and states providing the expenses for spray operations and other strategies. However, since 2003-2004, the program is being implemented as a 100% centrally funded program.

## Dengue Fever Control (14, 47)

Dengue outbreaks have been reported from urban areas from all states. All four types of dengue viruses exist in India. The vector *Aedes aegypti* breeds in peri-domestic fresh water collections and is found both in urban and rural areas. Dengue outbreaks occur both in urban and rural areas. Dengue fever occurred in Kolkata from Jul 1963 to Mar 1964 and since then more than 60 outbreaks have been reported from all other states in the country, including the outbreak in North India in 2006.

All areas in the country have been found to be susceptible to Dengue outbreaks because extensive breeding exist in all urban areas (in form of desert coolers, water storage tanks, wells & fountains, tyre dumps, junk cans and uncleared garbage dumps) and absence of any *Aedes* Control Program in the country.

Since there is no specific treatment for Dengue or effective vaccine available, the control strategy is based primarily on surveillance through sentinel sites, early reporting and prompt case management, vector control through reduction, personal protection, community mobilisation and intersectoral co-operation. There is no separate funding for Dengue control at present in the country and resources under NVBDCP are utilized for various control & prevention activities.

## National Cancer Control Program (14, 48, 49)

In India, Cancer is among the top ten leading causes of death, with over 2.5 million cancer cases at point of time and 7 lakh new cases and 3 lakh deaths occurring every year. Tobacco- related cancers (cancer of oral cavity & lung) and cancer of cervix form more than 50% of overall cancer burden in the country. Current projects indicate that cancer burden in India will double by 2026 due to continued use of tobacco, increasing longevity and greater exposure to environmental carcinogens. Changing dietary patterns (high calorie, high fat intake) and lower parity is likely to result in increasing incidence of breast cancer among women.

The Cancer Control Program was initiated in 1975-76 as a 100% centrally funded Central Sector project. It was renamed as National Cancer Control Program in 1985 and revised in 2004. The objectives of the program are

(a) Primary prevention of cancers through health education

(b) Secondary prevention by early detection & diagnosis (especially of cervical, breast & oropharyngeal cancers)

(c) Strengthening of existing cancer treatment facilities

(d) Provide palliative care for terminal stage cancer patients

(e) Research and training.

At present there are 24 regional cancer research centres, whose main functions are detection & treatment of cancers, after care and rehabilitation, education & training, cancer registration, research and coordination with medical colleges and general health care system. In addition, National Cancer Control Program aims to establish Oncology wings in all medical colleges of the country. The District Cancer Control Program for preventive health education, early detection, palliative care, training and coordination was launched in 1990-91 in collaboration with Regional Cancer Centres.

**National Cancer Registry Program** : Cancer registration consists of scientifically and accurately collecting, compiling and recording data on malignant cancers, which may be either hospital based or population based. National Cancer Registration Program was launched by ICMR in 1982 to provide accurate and reliable data on cancer prevalence & incidence. At present, there are 5 urban population-based cancer registries (Delhi, Mumbai, Bhopal, Bangalore & Chennai) and 1 rural registry at Barshi in Maharashtra. 6 hospital-based cancer registries are maintained at Chandigarh, Dibrugarh, Thiruvananthapuram, Bangalore, Mumbai and Chennai. A total of 3.3% of Indian population are covered by these cancer registries, which has been expanded by six additional population-based registries in North Eastern States and one rural registry at Ahmedabad.

## National Mental Health Program (14, 50)

It is estimated that 10 to 15% of the population suffer from mental health problem. The National Mental Health Program (NMHP) was initiated by the Government of India in 1982 with the objective of improving mental health services at all levels of health care (primary, secondary and tertiary) for early recognition, adequate treatment and rehabilitation of patients with mental health problems within the community and in the hospitals. The strategies to achieve these objectives were integration of mental health care with primary health care, providing tertiary care centers for treatment of mental illnesses and minimizing stigma and discrimination against mentally ill individuals through regulatory mechanisms like State Mental Health Authority. The Mental Health Act, 1987, which came into force with effect from April 1993, requires that each State/UT set up its own State level Mental Health Authority as a Statutory obligation. Majority of the States/ UTs have complied with this and have formed a Mental Health Authority.

During the eighth plan, NIMHANS Bangalore developed a district mental health care model in Bellary district with the following aims:

(a) To provide sustainable basic mental health services to the community and to integrate these services with health services;

(b) Early detection and prompt treatment of patients;

(c) To provide domiciliary mental health care and to reduce patient load in mental hospital;

(d) Community education to reduce the stigma attached to mental illness

(e) To treat and rehabilitate patients with mental problems within their family setting.

During the ninth plan period the experience gained in implementing mental health care both in Central and State sector will be utilized to provide sustainable mental health services at primary and secondary care levels and to build up community support for domiciliary care. IEC on mental health especially prevention of stress-related disorders through promotion of healthy lifestyles and operational research studies for effective implementation of preventive, promotive and curative programs in mental health through existing health infrastructure will receive due attention.

The thrust areas for mental health during 10th Five Year Plan are :

(a) District Health Progamme in an enlarged and more effective form would be covering the entire country.

(b) Modernization of mental hospitals in order to modify their present custodial role.

(c) Upgrading department of Psychiatry in medical colleges and enhancing the psychiatry content of the medical curriculum at the under-graduate level.

(d) Strengthening the Central and State Mental Health Authorities with a permanent secretariat.

(e) Research and training in the field of community mental health, substance abuse and child/adolescent psychiatric clinics.

## National Diabetes Control Program

The National Diabetes Control Program was included as a pilot program in the Seventh Five-Year Plan during 1987 in two districts in Tamil Nadu and one district in Jammu & Kashmir. Several states initiated district diabetes control program as part of State Plan scheme during the Eighth Plan period. Experience gained in implementing the district diabetes control program during Seventh and Eighth Plans have shown that integrated treatment of diabetes mellitus, hypertension and heart disease within primary and secondary care level is possible, provided functional linkages between these and tertiary care centres are developed and utilised. During the Ninth Plan period these experiences were utilised to develop integrated program of non-communicable diseases prevention, detection and management program at primary and secondary care level in all districts.

Initially, the objectives of National Diabetes Control Program were :

(a) Identification of high risk subjects & early intervention in form of health education

(b) Early diagnosis and appropriate management of cases,

(c) Prevention, arrest or slowing of acute metabolic as well as chronic cardiovascular-renal complications of the disease

(d) Providing equal opportunities for education and employment for diabetic patients

(e) Rehabilitation of partially or totally handicapped diabetic patients.

Recently, ICMR has initiated and is managing the National Integrated Disease Surveillance Project, focusing on risk factors for non-communicable disease like cardiovascular diseases, diabetes mellitus, cancers, obesity etc.

## National Water Supply and Sanitation Program (51)

The National Water Supply and Sanitation Program was initiated in 1954 with the object of providing safe water supply and adequate drainage facilities for the entire urban and rural population of the country. In 1972 a special program known as the Accelerated Rural Water Supply Program was started as a supplement to the national water supply and sanitation program. In spite of increased financial outlay during successive five-year plans, only a small dent was made on the overall problem. During the fifth plan, rural water supply was included in the Minimum Needs Program of the State Plans. The Central Government is supporting the efforts of the States in identifying problem villages through the Accelerated Rural Water Supply Program. A "problem village" has been defined as one where no source of safe water is available within a distance of 1.6 km or where water is available at a depth of more than 15 metres or where water source has excess salinity, iron, fluorides, arsenic, etc or where water is exposed to the risk of cholera.

Despite financial constraints, the government is committed to provide safe drinking water to all the villages. The latest assessment indicates that safe water is available to about 85% of the total population and 16% population has access to adequate sanitation facilities (out of which 2% are in rural areas).

## Minimum Needs Program

The minimum needs program was introduced in the first year of the fifth plan (1974-78). The objective of the program is to provide certain basic minimum needs and thereby improve the living standards of the people. It is the expression of the commitment of the government for the "social and economic development of the community particularly the underprivileged and underserved population". The program includes the following components:

(a) Rural Health

(b) Rural Water Supply

(c) Rural Electrification

(d) Elementary Education

(e) Adult Education

(f) Nutrition

(g) Environmental improvement of urban slums

(h) Houses for landless labourers

## 20-Point Program

In addition to the five-year plans and programs, in 1975, the government initiated a special activity. This was the 20-point program – described as an agenda for national action to promote social justice and economic growth.

On August 20, 1986, the existing 20-point program was restructured. Its objectives are spelt out by the government as "eradication of poverty, raising productivity, reducing inequalities, removing social and economic disparities and improving the quality of life".

At least 8 of the 20 points are related, directly or indirectly, to health. These are:-

| | |
|---|---|
| Point – 1 | Attack on rural poverty |
| Point – 7 | Clean drinking water |
| Point – 8 | Health for all |
| Point – 9 | Two-child norm |
| Point – 10 | Expansion of education |
| Point – 14 | Housing |
| Point – 15 | Improvement of slums |
| Point – 17 | Protection of the environment |

## Integrated Child Development Services (ICDS) (52)

The ICDS scheme was initiated by the then Ministry of Social and Women's Welfare on 02 Oct 1975, in pursuance of the National Policy for children. The Ninth Five Year Plan aimed to universalise ICDS, i.e. cover the whole country. The beneficiaries of ICDS are :

(a) Children below 6 years
(b) Pregnant and lactating women
(c) Women in the age group of 15-44 years
(d) Adolescent girls in selected blocks

The ICDS seeks to lay a solid foundation for the development of the nation's human resource by providing an integrated package of early childhood services. These consist of:

(a) Supplementary nutrition
(b) Immunization
(c) Health check-up
(d) Medical referral services
(e) Nutrition and health education for women
(f) Non-formal education for children up to the age of 6 years
(g) Care of pregnant and nursing mothers

Under the 10th Five Year Plan, the objectives emphasized are (53) :

(a) Achieve optimum intra-familial distribution of food by strengthening the food and nutrition component.
(b) Reach the children in 6-36 month age group, pregnant and lactating women
(c) Weighing all vulnerable population & put on treatment within 3 months
(d) Universal screening every quarter to identify causes for growth hindrance
(e) Interventions, including take home food supplements
(f) Identifying and treating health problems associated with severe malnutrition
(g) Training and supervision

The administrative unit of an ICDS project is the "community development block" in rural areas, the "tribal development block" in tribal areas and a group of slums in urban areas. The rural/urban project has a population of 1 lac and a tribal project about 35,000. The number of villages in the rural project may be 100 while in tribal areas it may be only 50. The focal point for the delivery of integrated early childhood services under the ICDS scheme is the trained local woman known as the Anganwadi worker. Other functionaries are the Child Development Project Officer, who is in charge of 4 Supervisors and 100 Anganwadi workers.

**Nutritional Program for Adolescent Girls :** The 10th Five Year Plan and Nutritional Policy proposed a nutritional program for girls weighing less than 35 Kg and for pregnant women weighing less than 45 Kg and below poverty line, who would get ration of Rs 6/- per month in form of wheat or rice, through the Public Distribution System.

**Scheme for Adolescent Girls in ICDS : Kishori Shakti Yojana :** The adolescent girls need appropriate nutrition, education, health education, training for adulthood, training for acquiring skills as the base for earning an independent livelihood, training for motherhood, etc. Similarly on the other side their potential to be a good community leader has to be realized. A scheme for adolescent girls in ICDS was launched by the department of Women and Child Development, Ministry of Human Resource Development in 1991. All adolescent girls in the age group of 11-18 years (70%) receive the following common services:

Watch over menarche

(a) Immunization
(b) General health check up once in every six months
(c) Training for minor ailments
(d) Deworming
(e) Prophylactic measures against anaemia, goiter, vitamin deficiency, etc.
(f) Referral to PHC/District hospital in case of acute need

# National Health Policy, National Population Policy and National Rural Health Mission

## National health policy – 2002

National health policy (NHP) was first enunciated in 1983, and since then there have been marked changes in the determinant factors relating to the health sector. Some of the policy initiative outlined in the NHP-1983 yielded results, while in several other areas, the outcome was not as expected. Government initiatives in the public health sector have recorded some noteworthy successes over time. Smallpox and Guinea Worm disease have been eradicated from the country. Polio is on the verge of being eradicated. Leprosy, Kala Azar, and Filariasis can be expected to be eliminated in the foreseeable future. There has been a substantial drop in the total fertility rate and infant mortality rate. The success of the initiatives taken in the public health field are reflected in the progressive improvement of many demographic, epidemiological and infrastructural indicators over time. Accordingly, the NHP – 1983 was revised and a new, extensive NHP was enunciated by the Govt of India in 2002.

### Objectives

The main objective of this policy is to achieve an acceptable standard of good health amongst the general population of the country. The approach would be to :

(a) Increase access to the decentralized public health system by establishing new infrastructure in deficient areas, and by upgrading the infrastructure in the existing institutions.

(b) Overriding importance would be given to ensuring a more equitable access to health services across the social and geographical expanse of the country.

(c) Emphasis will be given to increasing the aggregate public health investment through a substantially increased contribution by the Central Government. It is expected that this initiative will strengthen the capacity of the public health administration at the state level to render effective service delivery.

(d) The contribution of the private sector in providing health services would be much enhanced, particularly for the population groups which can afford to pay for services.

(e) Primacy will be given to preventive and first-line curative initiative at the primary health level through increased share of allocation.

(f) Emphasis will laid on rational use of drugs within the allopathic system, and also increased access to tried and tested systems of traditional medicine will be ensured.

Within these broad objectives, NHP-2002 will endeavour to achieve the time-bound goals mentioned in Box-1. On a short term basis, within the context of the NHP, the Important health related targets for the tenth five year plan (2002 – 2007) are :

Box - 1 : NHP Goals to be achieved by 2000-2015.

| | |
|---|---|
| Eradicate Polio and Yaws | 2005 |
| Eliminate Leprosy | 2005 |
| Eliminate Kala Azar | 2010 |
| Eliminate Lymphatic Filariasis | 2015 |
| Achieve Zero level growth of HIV / AIDS | 2007 |
| Reduce Mortality by 50% on account of TB, Malaria and Other Vector and Water Borne diseases. | 2010 |
| Reduce Prevalence of Blindness to 0.5% | 2010 |
| Reduce IMR to 30/1000 and MMR to 100/Lakh. | 2010 |
| Increase organization or public health facilities from current level of <20 to >75%. | 2010 |
| Establish an integrated system of surveillance, National Health Accounts and Health Statistics. | 2005 |
| Increase health expenditure by Government as a % of GDP from the existing 0.9% to 2.0%. | 2010 |
| Increase share of Central grants to Constitute at least 25% of total health spending. | 2010 |
| Increase State Sector Health spending from 5.5% to 7% of the budget | 2005 |
| Further increase state health spending to 8% | 2010 |
| | |

(a) To achieve growth rate of GDP @ 8%.

(b) Reduction of Poverty ratio to 20% by 2007 and to 10% by 2012.

(c) Universal access to primary education by 2007.

(d) Reduction in decadal rate of population growth, between 2001 to 2011 to 1.62%.

(e) Increase in literacy rate to 72% within the plan period and to 80% by 2012.

(f) Reduction of IMR to 45 per 1000 by 2007 and to 28 by 2012.

(g) Reduction of MMR to 20 per 1000 by 2007 and to 10/1000 by 2012.

(h) All villages to have sustained access to portable drinking water by 2012.

(j) Cleaning of all major polluted rivers by 2007 and other notified striations by 2012.

### Major Strategies of NHP-2002

(a) Financial Resources

It is concerning that Public Health expenditure has declined from 1.5% of GDP in 1990 to 0.9% of GDP in 1999. Given the extremely difficult fiscal position of the State Governments, the Central Government will have to play a key role in augmenting public investments. It is planned, under the policy, to increase health sector expenditure to 6 percent of GDP, with 2 percent of GDP being contributed as public health investment, by the year 2010. The State Governments would also need to increase the commitment to the health sector. In the first phase, by 2005, they would be expected to increase the commitment of their resources to 7percent of their budget, and in the second phase, by 2010, to increase it to 8 percent. With the stepping up of the public health investment, the Central Government's contribution would be 25 percent from the existing 15 percent by 2010.

(b) Equity

To meet the objective of reducing various types of inequities and imbalances, i.e., interregional; across the rural – urban divide; and between economic classes – the most cost-effective method would be to increase the sectoral outlay in the primary health sector. Such outlets afford access to a number of individuals, and also facilitate preventive and early stage curative initiative, which are cost effective in recognition of the public health principle, NHP-2002 sets out an increased allocation of 55 percent of the public health investment for the primary health sector, the secondary and tertiary health sectors being targeted for 35 percent and 10 percent respectively, for strengthening existing facilities and opening additional public service outlets, consistent with in the norms for such facilities.

(c) Delivery Of National Public Health Programmes

The policy envisages a key role for the Central Government in designing national programmes with the active participation of the State Governments. Also, the policy ensures the provisioning of financial resources, in addition to technical support, monitoring and evaluation at the national level by the Centre. However, to optimize the utilization of the public health infrastructure at the primary level, NHP-2002 envisages the gradual convergence of all health programmes under a single field administration. Vertical programmes for control of major diseases like TB, Malaria, HIV/AIDS, as also the RCH and Universal Immunization Programmes, would need to be continued till moderate levels of prevalence are reached. The policy also envisages that programme implementation be effected through autonomous bodies at State and district levels.

The policy envisages that apart from the exclusive staff in a vertical structure for the disease control programmes, all rural staff should be available for the entire gamut of public health activities at the decentralized level, irrespective of whether these activities relate to national programmes or other public health initiatives. It would be for the Head of the District Health administration to allocate the time of the rural health staff between the various programmes, depending on the local need.

(d) The State Of Public Health Infrastructure

The policy envisages kick-starting the revival of the Primary Health System by providing some essential drugs under Central Government funding through the decentralized health system. It is expected that the provisioning of essential drugs at the public health service centre will create a demand for other professional services from the local population, which in turn, will boost the general revival of activities in these service centers.

This policy recognizes the need for more frequent in-service training of public health medical personnel, at the level of medical officers as well as paramedics. Such training would help to update the personnel on recent advancements in science, and would also equip them for their new assignment. When they are moved from one discipline of public health administration to another.

Global experience has shown that the quality of public services is closely linked to the quantum and quality of investment through public funding in the primary health sector. Therefore the policy, while committing additional aggregate financial resources, places great reliance on the strengthening of the primary health structure for the attaining of improved public health outcomes in an equitable basis. Further, it also recognizes the practical need for levying reasonable user-charges for certain secondary and tertiary public health care services for those who can afford to pay.

(e) Extending Public Health Services

State Governments may consider the need for expanding the pool of medical practitioners to include a cadre of licentiates of medical practice, as also practitioners of Indian Systems of Medicine and Homoeopathy. Simple services / procedures can be provided by such practitioners even outside their disciplines, as part of the basic primary health services in under-served areas. Also, NHP-2002 envisages that the scope of the use of paramedical manpower of allopathic disciplines in a prescribed functional area adjunct to their current functions, would also be examined for meeting simple public health requirements.

(f) Role Of Local Self-Government Institutions

NHP-2002 lays great emphasis upon the implementation of public health programmes through local self-government institutions.

(g) Norms For Health Care Personnel

Minimal statutory norms for the development of doctors and nurses in medical institutions need to be introduced urgently under the provisions of the Indian Medical Council Act and Indian Nursing Council Act, respectively. The policy also envisages the setting up of a Medical Grants Commission for funding new Government Medical and Dental Colleges in different parts of the country. To enable fresh graduates to contribute effectively to the providing of primary health services as the physician of first contact, this policy identifies a significant need to modify the existing curriculum. A need-based, skill-oriented syllabus, with a more significant component of practical training would make fresh doctors useful

immediately after graduation.

(h) Need For Specialists In Public Health And Family Medicine

In order to alleviate the actual shortage of medical personnel with specialization in the disciplines of public health and 'family medicine', the policy envisages the progressive implementation of mandatory norms to raise the proportion of postgraduate seats in these disciplines in Medical Training Institutions, to reach a stage wherein 1/4th of the seats are earmarked for these disciplines. It is envisaged that in the sanctioning of post-graduate seats in future, it shall be insisted upon that a certain reasonable number of seats be allocated to public health and family medicine. Since the public health discipline has an interface with many other developmental sectors, specialization in public health may be encouraged not only for medical doctors, but also for non-medical graduates from the allied fields of public health engineering, microbiology and other natural sciences.

(j) Use Of Generic Drugs and Vaccines

NHP emphasizes the need for basing treatment regimens, in both, the public and private domain, on a limited number of essential drugs of a generic nature. This is a pre-requisite for cost effective public health care. In the public system, this would be enforced by prohibiting the use of proprietary drugs, except in special circumstances.

(k) Urban Health

NHP-2002 envisages the setting up of an organized urban primary health care structure. The structure conceived under NHP-2002 is a two-tiered one; the primary center is seen as the first-tier, covering a population of one lakh, with a dispensary providing an OPD facility and essential drugs, to enable access to all the national health programmes, and a second-tier of the urban health organization at the level of the Government general hospital, where reference is made from the primary centre.

(l) Mental Health

NHP-2002 envisages a network of decentralized mental health services for ameliorating the more common categories of disorders.

(m) Information, Education And Communication (IEC)

NHP-2002 envisages an IEC policy, which maximizes the dissemination of information to those population groups which cannot be effectively approached by using only the mass media. The focus would therefore be on the inter-personal communication of information and on folk and other traditional media to bring about behavioral change.

(n) Health Research

The policy envisages an increase in Government funded health research to a level of 1 percent of the total health spending by 2005; and thereafter, up to 2 percent by 2010. Domestic medical research would be focused on new therapeutic drugs and vaccines for tropical diseases, such as TB and Malaria, as also on the sub-types of HIV / AIDS prevalent in the country.

(o) Role of The Private Sector

In principle, this policy welcomes the participation of the private sector in all areas of health activities – primary, secondary or tertiary.

(p) National Disease Surveillance Network

This Policy envisages the full operationalization of an integrated disease control network from the lowest rung of public health administration to the Central Government by 2005. The programme for setting up this network includes components relating to the installation of data-base handling hardware; IT inter-connectivity between different tiers of the network; and in-house training for data collection and interpretation for undertaking timely and effective response. This public health surveillance network will also encompass information from private health care institutions and practitioners. It is expected that real-time information will greatly strengthen the capacity of the public health system to counter local outbreaks of seasonal diseases.

(q) Health Statistics

The policy envisages the compilation of estimates for the incidence of the common diseases – TB, Malaria, and Blindness – by 2005. The policy proposes that statistical methods be put in place to enable the periodic updating of these baseline estimates through representative sampling, under an appropriate statistical methodology. The policy also recognizes the need to establish, in a longer time-frame, baseline estimates for non-communicable diseases, like CVD, Cancer, Diabetes; and accidental injuries, and communicable diseases, like Hepatitis and JE. NHP-2002 envisages that, with access to such reliable data on the incidence of various diseases, the public health system would move closer to the objective of evidence-based policy-making.

## National population policy (NPP) - 2000

In 1952, Indian became the first country in the world to launch a national program, emphasizing family planning to the extent necessary for reducing birth rates "to stabilize the population at a level consistent with the requirement of national economy". After 1952, sharp declines in death rates were, however, not accompanied by a similar drop in birth rates. The National Health Policy, 1983, stated that replacement levels of fertility rate (TFR) should be achieved by the year 2000.

On 11 May 2000 India had 1 billion (100 crore) people, i.e., 16 percent of the world's population on 2.4 percent of the globe's land area. If current trends continue, India may overtake China in 2045, to become the most populated country in the world. While global population has increased threefold during 20$^{th}$ century, from 2 billion, the population of India has increased nearly five times from 238 million (23 crores) to 1 billion in the same period. India's current yearly increase in population of 15.5 million is enough to neutralize efforts to conserve the resource endowment and environment.

The National Population Policy 2000 (NPP 2000) affirms the commitment of government towards voluntary and informed choice and consent of citizens while availing of reproductive health care services, and continuation of the target free approach in administering family planning

services. The NPP 2000 provides a policy framework for advancing goals and prioritizing strategies during the next decade, to meet the reproductive and child health needs of the people in India, and to achieve net replacement levels (TFR) by 2010. It is based upon the need to simultaneously address issues of child survival, maternal health and contraception, while increasing outreach and coverage of a comprehensive package of reproductive and child health service by government, industry and voluntary non-government sector, working in partnership.

**Objectives**

The immediate objective of the NPP 2000 is to address the unmeet needs for contraception, health care infrastructure, and health personnel, and to provide integrated service delivery for basic reproductive and child health care. The medium-term objective is to bring the TFR to replacement levels by 2010, through vigorous implementation of inter-sectoral operational strategies. The long-term objective is to achieve a stable population by 2045, at a level consistent with the requirements of sustainable economic growth, social development, and environmental protection.

**Targets**

In pursuance of these objectives, the following National Socio-Demographic Goals to be achieved in each case by 2010 are formulated :

(a) Address the unmet needs for basic reproductive and child health services, supplies and infrastructure.

(b) Make school education up to age 14 free and compulsory, and reduce drop puts at primary and secondary school levels to below 20 percent for both boys and girls.

(c) Reduce infant mortality rate to below 30 per 1000 live births.

(d) Reduce maternal mortality ratio to below 100 per 100, 000 live births.

(e) Achieve universal immunization of children against all vaccine preventable diseases.

(f) Promote delayed marriage for girls, not earlier than age 18 and preferably after 20 years of age.

(g) Achieve 80 percent institutional deliveries and 100 percent deliveries by trained persons.

(g) Achieve universal access to information / counseling, and services for fertility regulation and contraception with a wide basket of choices.

(j) Achieve 100 percent registration of births, deaths, marriage and pregnancy.

If the NPP - 2000 is fully implemented, we anticipate a population of 1107 million (110 crores) in 2010, instead of 1162 million (116 crores) projected by Technical Group on population Projections.

**Major Strategies in NPP - 2000**

(a) Decentralized Planning and Program Implementation.

(b) Convergence of Service Delivery at Village Levels.

(c) Empowering Women for Improved Health and Nutrition.

(d) Meeting the Unmet Needs for Family Welfare Services.

(e) Focus on Under-Served Population Groups.

(i) Urban Slums.

(ii) Tribal Communities, Hill Area Populations and Displaced and Migrant Populations.

(iii) Adolescents.

(f) Diverse Health Care Providers.

(g) Collaboration with and Commitments from Non-Government Organizations and the Private Sector.

(h) Mainstreaming Indian System of Medicine and Homeopathy.

(j) Contraceptive Technology and Research on Reproductive and Child Health.

(k) Providing for the Older Population.

(l) Information, Education and Communication.

**Operational Strategies**

(a) Utilize village self help groups to organize and provide basic services for reproductive and child health care, combined with the ICDS scheme.

(b) Implement at village levels a one-stop integrated and coordinated service delivery package for basic health care, family planning and maternal and child health related services, provided by the community and for the community.

(c) Wherever these village self-help groups have not developed for any reason, community midwives, practitioners of ISM, retired school teachers and ex-defense personnel may be organized into neighborhood groups to perform similar functions.

(d) At village levels, the Anganwadi centre may become the pivot of basic health care activities, contraceptive counseling and supply, nutrition education and supplementation, as well as pre-school activities. The Anganwadi centers can also function as depots for ORS/basic medicines and contraceptives.

(e) A maternity hut should be established in each village to be used as the village delivery room with storage space for supplies and medicines. It should be adequately equipped with kits for midwifery, ante-natal care, and delivery; basic medication for obstetric emergency aid; contraceptives, drugs and medicines for common aliments.

(f) Trained birth attendants as well as the vast pool of traditional dais should be made familiar with emergency and referral procedures.

(g) Provide wider basket of choices in contraception, through innovative social marketing schemes to reach household levels.

## National Rural Health Mission (NRHM)

The NRHM was launched on 12April 2005 by the Hon'able Prime Minister. NHRM would strive to achieve a set of Core and supplementary strategies to meet its goal of providing effective health care to the rural population especially the disadvantaged groups including women and children. Initial focus would be on 10 high priority states and to increase public health expenses from 0. 9% to 2. 3% of GDP.

### Core Strategies

The main focus in NRHM would be on the following issues :

(a) Decentralized village and district level health planning.

(b) Appointment of Accredited Social Health Activist (ASHA):- The selection criteria would be "women, resident of the concerned village, married / widow / divorced, 25-45 years age, formal education up to 8th, to be selected out of a panel by village health and action committee of Gram Sabha. Norm would be 1 per 1000 population, but this norm may be changed for different areas. No pay of honorarium but she will be given compensation for various health and sanitation services provided. They will be given a kit of suitable drugs. They would be guided by Anganwadi Workers (AWW) and ANM. In 4 years, 2.5 lakh ASHAs will be deployed.

(c) Strengthening the public health service delivery system particularly at village, primary and secondary level, by developing and implementing the Indian Public Health Standards; Developing CHCs as the First Referral Units (FRUs) by providing special care in Med, Surg, Obs & Gyn, and Pediatrics. Presently minimum standards of Indian Public Health for CHCs have been developed; later they will be developed for PHCs & subcentrie also.

(d) Mainstreaming of AYUSH (Indian Systems of Medicine).

(e) Improved management capacity to organise health systems and services in public health.

(f) Emphasizing evidence based planning and implementation.

(g) Prompting non-profit factor to increase social participation, promoting health behaviors and improving intersectoral convergence.

### Supplementary Strategies

(a) Regulation of private sector to improve equity and reduce "out of pocket" expenses.

(b) Foster Public – Private Partnership (PPP) to meet national public health goals.

(c) Re-orientation Of Medical Education (ROME).

(d) Raising health security / insurance for the poor.

### Organisational Stucture :

**Central level** – Mission steering group under Minister of H & FW.

**State level** – State Health Mission under CM.

**District level** – District Health Mission under Chairman Zila Parishad and covered by District Head of Health Department. It will control, manage and guide all public health institution in the dist & sub-dist level.

### Indian Public Health Standards (IPHS) in CHCs

As of Sept 04, there were 1, 42, 655 sub centres, 23, 109, PHCs and 3, 222 CHCs functioning. Each CHC is supposed to cover 1, 20, 000 population (80, 000 in hilly / tribal / difficult areas). Bureau of Indian Standards (BIS) has standards for 30 bedded Hospitals. These are at present not achievable as they are very resource intensive. Present IPHS standards for CHCs reflect requirements for the minimum functional grades. Further up-gradation will be proposed after these minimum requirements have been met.

The salient features of IPHS for CHCs include.

(a) Care of routine and emergency cases in Surg, Med and Obstetrics.

(b) 24 hrs delivery services including normal and complicated deliveries.

(c) Full range of FP services including laparoscopy.

(d) New born care, routine & emergency care of such children.

(e) Adequate surveillance under all national health programs.

(f) Referral Transport.

(g) Essential Lab Services.

(h) Blood Storage Services.

Specialists suggested at CHC level are Medical, Surgical, Obs-Gynae, Paediatrics, Anesthesia & Public Health manager. 1 Ophthalmologist for every 5 CHCs is also suggested. In addition, support staff is to be strengthened by addition of a Public Health Nurse (PHN) and one Auxillary Nurse Midwife (ANM) in all these CHCs in addition to the existing 21 to 22 support staff.

In addition norms for physical infrastructure for clinical services, support services, ancillary services and administrative services have also been specified.

A list of equipment needed at the CHC has been made. SOPs and standard treatment Guidelines (STGs) for management of routine and emergency cases have been made. A list of essential and emergency drugs for CHC has also been developed and Rogi Kalyan Samitee (Patient Welfare Committees) have been organised.

NRHM has been launched in 18 states, including 8 European Action Group (EAG) states (Raj, UP, MP, Bihar, Orissa, Uttaranchal, Jharkhand, Chattisghad), 8 North Eastern States, and 2 Northern states of Himachal & J&K.

### Progress Under NRHM

(a) State Health Missions have been constituted in all states.

(b) Total 3 lakh ASHAs selected till date.

(c) 2. 05 lakh ASHAs trained.

(d) ASHA training modules developed and revised.

(e) State / Distt. / Block level training completed.

(f) Over 1100 management professionals (CA/MBA) appointed in program management units (PMU) to support the programme management. This is being planed at the level of the block also.

(g) RCH- II launched and under implementation.

(h) IMCI started in 25 states.

(j) Legal changes brought about to allow ANMs to dispense medication and MBBS doctors to dispense anesthesia.

(k) JE vaccination initiated in 11 districts in 4 states and 93 lakh children immunized.

# Health Care

## Introduction

The term health care can evoke different meanings in different persons depending on one's perspectives. An industrial worker may think of health care as the treatment of loose motions with home remedies and a day off from work. To a surgeon, it may focus on the next patient being prepared for appendectomy. A public health administrator may consider it to be the immunization campaign scheduled for the next week, to the finance minister of a government, it may mean the health benefits package under planning to benefit a needy community. A town councilor may see it as the need to control the rising budget for purchase of medicines for the dispensaries in the municipality. Thus health care includes the systems of individual arrangements and social institutions through which health services of a personal nature are provided, organized, financed and controlled. It will refer to all types of personal health services provided to individuals by physicians, dentists, nurses, pharmacists and other health personnel. It includes promotion of health and prevention of disease, primary cure, diagnosis and treatment, rehabilitation and long term care. They are organized and financed under personal, private or public auspices (1).

## Evolution of health care

Till the turn of the 19th century, the western system of health care was being provided for the large numbers of ill persons unable to afford private treatment, by religious or philanthropic institutions or individuals who were motivated primarily to provide relief to the suffering of diseased persons, besides by governments. Knowledge of causes of disease and therapy were rudimentary as per current standards. Institutions were thus established for the poor and needy diseased persons who could not afford personal care for diseases. The stress was on Hospices for providing nursing care and relieving pain and sanatorium for convalescence. Initially, when the exact causes or sites of disease were ill-understood, attention was directed to amelioration of symptoms; i.e. medical care was 'symptom centered'. Later when the pathological changes in organs came to be understood, medical care became 'disease centered'. With the discovery of micro organisms as the cause of the pathological changes in organs and pathogenesis of the diseases, attention came to be fixed on to particular pathogens; first the animate and later, in course of time, the inanimate pathogens. Recognition of the fact that disease results from the interaction between the host and aetiological agent, and that its severity depends upon the reaction of the host as much as upon the quantitative and qualitative invasiveness of the aetiological agent, shifted the attention from disease to the sick person himself. The medical care then became 'patient centered' rather than 'disease centered'. In recent years, it has been appreciated that disease is an outcome of multiple factors favourable to the specific aetiology, to be found in the environment as an outcome of inter-relation between the host, environment and specific aetiology leads to recognition of the necessity of medical care of 'the individual within his community and environment' (2,3).

Disease exhibits what is called the 'iceberg' phenomenon. Ill people who actually seek cure represent only a small portion of the afflicted section of the whole community, like the visible portion of the iceberg. The submerged portion represents the vast section, which, owing to the environmental similarity with that of the overt portion, is vulnerable to the same pathogenic process. Thus apparent disease is a pointer to the existence of the vulnerable section, submerged in the community. Therefore, a study of individuals within the community and environment is important to uncover the submerged portion, along with the socio-economic and environmental factors favouring ill health (4).

Researchers in the field of diagnostics and therapeutics working in different parts of the world but primarily in Europe & America, started providing breakthroughs in the understanding and management of disease. Some of the discoveries were however expensive and the benefits could be availed by few. An appreciation by corporate world, that the diseased persons would be willing to pay for services provided, lead to setting up of hospitals on a corporate basis. The health care provided was of increasingly high quality but at a very high individual cost, beyond the reach of the multitude. Systems of provision of health care through purchasing health insurance by individuals was gradually established in the affluent nations. However, the increasing costs of medical care started becoming unaffordable even by affluent nations. It was gradually realized that preventing the onset of disease could be ensured by bringing about changes in the environment in which man lived and worked. Thus sowing the seeds of the new science of Public Health Care. (5,6 )

Rapid strides were made by nations in Europe and America during the 19th & 20th century in providing public health services to improve the health of its citizens. However, a realisation set in after the First World War and reinforced by events of the Second World War, that nations could not insulate their citizens or communities their members, if poverty and disease continued to flourish in populations, communities or nations in their immediate or even distant neighbourhood. No nation could also consider providing all facilities required to protect its citizens from acquiring diseases unilaterally and cooperation with other nations was necessary. Thus began the internationalization of public health. Developed nations organized themselves into groups for the collective good of their citizens to make concerted efforts to improve the state of health of their citizens. They also started providing aid or donations to those nations who were perceived to be of strategic importance to them in order to assist these nations to

improve their own public health services. In this respect, the league of Nations after the First World War and United Nations after Second World War, and their respective organs like WHO & UNICEF, were the organizations established to provide international cooperation, expertise and assistance to the member states. More and more nations, small or big, specially those which attained "freedom" from their erstwhile colonial masters in the 20th century, also joined these international organizations and provided a truly international spectrum to health care activities. The World Health Organisation (WHO), the health organ of United Nations spearheaded the international health activities and devised various strategies to enable developing countries with poor socio-economic profile, to provide a minimum level of health care to their citizens. "Health for all by year 2000" was the culminating strategy in recent years in this respect.( 7,8,9,10 )

Rapid progress by countries of the world was made on control of communicable diseases with simple and highly effective public health strategies like immunization and environmental sanitation under the umbrella of international institutions with the active collaboration of national governments. Increasing affluence of individuals and communities lead to adoption of certain ways of living, later broadly classified as "lifestyle", associated with this affluence by more and more individuals and communities. The increasing incidence of non-communicable diseases like hypertension, diabetes and coronary heart diseases were thus evidenced specially in these parts of the world. Improved methods of studying diseases through epidemiological methods identified the concept of "lifestyle" as the major aggravating factor causing this "epidemic" even in some not affluent countries which were still struggling to control communicable diseases. A new concept of "primordial prevention" to prevent the emergence of "risk factors" by means of public awareness campaigns to advocate healthy "lifestyle" over a period of decades, specially in the affluent societies and nations, along with vastly improved diagnostic and therapeutic measures have to some extent controlled the mortality, morbidity and disability associated with these diseases. (11,12,13 )

It was also realized that health could not be assured only by the medical fraternity. The relationship between health and economic status is well known. One of the principal impediments to economic development in many of the poorest developing countries is the widespread debility of the population due to extensive malnutrition and chronic impairment. Improvement in standards of living and working, which had many dimensions like education, social empowerment, sustainability of environment, industrialization and many others, were not only inevitably linked to disease but un-separable for the achievement of health and necessitated activities by all concerned for the achievement of "health" by all countries of the world as defined by WHO. The emphasis in the field of health care thus shifted from promising and committing necessary state level actions to provide primary health services for all citizens by member nations of United Nations under the "Health for All" campaign, to commitments by nations to implement as far and as quickly as possible, the expanded and comprehensive "Millennium Development Goals" which were inclusive of all those sectors of government and all organizations private & public who impacted on health. ( 14,15)

The realisation that governmental resources were inadequate to provide all necessary services to its citizens, that certain institutions in the private sector, called "voluntary health agencies" were already providing some of the desired services and the need to harmonize and synergize all actions to meet the determined goals and objectives in the stipulated time frame have lead to better appreciation for a public private partnership for the provision of services aimed at achieving "health" for all citizens of the world. ( 15,16,17)

### Concepts of Health Care

#### Health

WHO has defined health as "a state of complete physical, mental and social well being and not merely the absence of disease". This definition is utopian but can be attempted to be achieved. Control of disease, the causation of disease besides aspects of equality and human rights will need to be addressed to achieve the stated objective of health(18)

#### Public Health

The four major public health strategies for influencing health are preventing disease and promoting health, improving medical care, promoting health enhancing behaviour and controlling the environment. Public health considers medical care to be one means of protecting and improving the health of people. Curative services, however generally receive funding priority over preventive services on the grounds of urgency curative services cater for the immediate felt needs of the clientele while preventive services provide for the future which at times is not understood or appreciated by the clientele (19). Detailed discussion on Public Health have already been made in the "Curtain Raiser" chapter of this book.

#### Comprehensive health care

The concept of comprehensive services to cater for the needs of any human being from his "womb to tomb" was first used in 1946 in the Indian context by the "Report of the Health Survey and Development Committee" popularly known as "Bhore Committee" which assessed the health conditions and health institutions existing in British India. The recommendations of this document, available to India on achieving freedom, were loftily accepted as the benchmark for planning norms of public health but have been unable to be fully implemented even till date. This has been mainly due to the population growth outstripping the infrastructure provisions during successive five year plans of the government. (20)

#### Basic health services

In 1965, WHO UNICEF defined basic health service as a network of coordinated, peripheral and intermediate health units capable of performing effectively a selected group of functions essential to the health of an area and

assuring the availability of competent professional and auxiliary personnel to perform these functions. (21)

### Primary health care

In order to provide a minimum essential level of health care to the vast populations living in developing countries by their governments, appropriate technology was recommended to be utilised along with community participation to be provided to all the citizens. The concept of primary health care emanated from an important WHO conference held at Alma Ata ( USSR) in 1978. Primary health care is essential health care made universally accessible to all individuals and acceptable to them, through their full participation and at a cost the country can afford. (22,23)

### "Health for All by year 2000"

This slogan coined during the Alma Ata conference of WHO was coined to ensure achievement of an acceptable level of health throughout the world in the foreseeable future. It did not mean that all citizens of the world would be healthy but that they would have access to primary health care. It was aimed to achieve the stated goal by using the primary health care approach. Countries have committed resources to provide primary health care. However access to such services has remained a problem due to various operational and other factors. (15,24)

### Millennium Developmental Goals

A review of the state of health of the world population and affluence or lack of it resulted in world leaders adopting the United Nations Millennium Declaration in 2000, which committed them to pursue policies to ensure the development of their people and poverty eradication. These are now popularly referred to as the "Millennium Development Goals" and cater for aspects of poverty alleviation, overcoming illiteracy, provision of gender equality, providing access to clean water and reversing activities leading to environment degradation besides health related matters like reduction of maternal and child morbidity and mortality and control of communicable diseases. (25,26)

## Health Care in India

India under British rule had not reaped the benefits of industrialization which had affected positively the living standards of citizens of the ruling nation, enriched by raw materials forcibly taken away at very cheap rates from India and other colonies. Measures to provide health care in India were restricted to soldiers of the British army and civilians residing in and around the areas occupied by the ruling elite. It was only towards the end of British rule that concern for the common man was voiced by successive committees and commissions enquiring into the state of health of Indians. India became a free country in 1947 with a democratically elected government and adopted the constitution to become a Republic in 1950. The political leadership of this nascent democracy was fired with a zeal to provide radical change in the shortest possible time to the oppressed, impoverished, illiterate people lacking the basic amenities conducive to health. They chose a socialistic system of government to achieve these lofty ideals and copied from USSR to "plan" development activities with the meager resources available. To provide employment, food and other amenities, the route of planned industrialization through establishment of public sector industries and a command economy were visualized. The planning system was drawn up by the Planning Commission headed by the Prime Minister. Planning was for a period of 5 years commensurate possibly with the tenure of democratically elected governments. Stress on health sector was planned in consonance with the projections of health infrastructure made by the Bhore Committee and the realisation of need to attain population stabilization. India consciously chose to provide a system of socialized medicine which entailed upon the government to provide free health care services to all citizens. Health was placed on the "concurrent" list of subjects in the constitution with the basic responsibility resting with respective state governments to provide health care facilities. The role of the central government was to guide, coordinate and facilitate the activities of state governments and interact with international agencies in this respect. (21, 27, 28 )

However, the path to provision of an improved health care was adversely influenced by the need to finance the process of national integration, three major wars with our neighbours, the ever increasing needs of a burgeoning population, fledgling industry and over dependence on agriculture which had been rendered inefficient by persistent lack of modern inputs and strategies besides going through phase of land reforms. An impoverished yet proud nation hesitated to seek assistance from affluent nations from whose influence the nation had recently unshackled itself because this would have implied political aligning with these countries. Many methods, strategies and concepts were propagated by these countries as solutions to the ills of countries like India, based on their limited experiences. Some of India's academicians, technocrats and administrators who were deputed for training at institutions in developed countries on scholarships, fellowships, etc in fields of health and health related aspects received training on these aspects but attempts to replicate western models in India blindly, usually failed as they were not suitable to our needs.

However, the progress of the country in achieving for its citizens improvements in the sphere of health since attaining Independence though slow, has certainly been positive even though not as impressive as would have been hoped by the founding fathers. Indians on an average today, live better, eat more and nutritiously, have better chance of surviving to old age( life expectancy at birth increasing from 37 years in 1951 to 62 in 2001) and even poorly performing indicators of health like maternal mortality and infant mortality ( halved from 146 per 1000 live births in 1951 to 40 in 2004 ) have certainly shown a significant improvement. (29,30)

As a growing economy, India is fast learning to understand and address its problems. The Planning Commission in its approach paper to the 11$^{th}$ plan 2007-2012 has identified the need for a faster and inclusive growth. In this aim for all round development,

programmes like Sarva Shiksha Abhiyan and Rural Health Mission, which have been focused mainly on rural India, have been highlighted to provide the desired results by providing improved access and availability of quality health care, sanitation and nutrition (31) .

## Medical Care Of Armed Forces Personnel

In the Armed forces integration is inherent in its organization and administration of medical care is necessarily comprehensive. Services have no control over the individuals' heredity, intra-uterine life, prenatal hazards and life upto the age of recruitment. At the time of recruitment, however, a selection choice is available when persons with apparent or latent but detectable hereditary or acquired defects are eliminated. A medically suitable, probably a little undernourished but potentially sound bodied person, capable of being moulded into a fit serviceman, with adequate reserve against stress and strain of service, can thus be selected. The further responsibility of building up his health is that of the Armed Forces. In the process the recruit has to surrender some of his individual characteristics nurtured by parents and community from his very birth and assimilate certain unfamiliar new characteristics required for leading a close community life under regimentation, various disciplinary restrictions, and quite often, very strenuous, hazardous and emotionally stress producing life conditions. In order to enable him to withstand the metamorphosis from a civilian individual to a physically, mentally, emotionally and socially fit soldier, and thereafter to maintain his qualities at a high standard of fitness, the care of serviceman is well planned.

### Organization

In the Armed Forces "HEALTH" embraces all aspects which prevents disease and promotes physical, mental, and fighting fitness amongst all ranks and ensures their welfare and high morale. The important means to achieve positive health are provision of adequate and healthy accommodation, food and feeding arrangements, water and milk supplies, living and working conditions, clothing, environmental control and sanitation, personal care and health education of troops. Health and well being of personnel is the responsibility of the commanders. Medical services advise the commanders at all levels on all matters concerning health care and carry out treatment of ailments upto their rehabilitation. The Director General Armed Forces Medical Services (DGAFMS) is the head of Armed Forces Medical Services, and is responsible to the Ministry of Defence for overall medical need of the Armed Forces. The Director Generals of Medical Services (DGsMS) of Army, Navy and Air Force are the medical advisers to the respective Chiefs of Staff of the Army, Navy and Air force and are responsible for the day to day administration and proper functioning of the medical services under their control. The DGAFMS is kept informed of all general policies, decisions and directives issued by the three service headquarters (HQ). He is kept informed by the DGsMS regarding the planning of hospitals & research developments. A representative of DGAFMS attends all meetings and discussions where matters of medical policies and planning are under consideration by the three services. The important aspects of organization, charter of duties and functions of the armed forces medical services are enumerated in the Regulations for the Armed Forces Medical Services (RMSAF). **(32)**

In addition to provision of basic preventive, promotive and curative services, various National Health Programmes are also adopted in the Armed Forces in close coordination with the Central and State Health Services. The medical organization at the respective Service Headquarters coordinates all the personal care requirements, which include :

(a) Health care of troops and their families.
(b) Provisions of medical treatment and remedial regime.
(c) Advising on accommodation, nutrition, food, milk and water supply in Armed Forces.
(d) Health education of troops.
(e) Environmental control.
(f) Research on health and medical care, including matters affecting morale, fighting and functional efficiency of Forces.
(g) Health statistics.
(h) Medical categorization.
(j) Pathology services.
(k) Scrutiny of fatal case documents.
(l) Training of medical officers and paramedical personnel.

The various institutions involved in the planning, coordination and administration of the armed forces medical services include office of DGAFMS, Medical Services Advisory Committee and Armed Forces Medical Research Committee. Armed forces provide comprehensive health care in a three tiered format with single medical officer - Regimental medical officer (RMO) or a medical officer from the affiliated medical unit, designated as authorized medical attendant (AMA), providing primary health care at the unit level ; cases needing hospitalization or specialist attendance are referred to a field ambulance from an operational army area or to a peripheral or sub-zonal hospital in peace areas where secondary care can be provided. In case of necessity of highly skilled care, patients are referred to tertiary care centres located at zonal or command hospitals either through the intermediate channel of evacuation or even directly. The aspects of public health care are administered mainly through Station or Field Health Organisation ( SHO / FHO) who also coordinate provision of health care of the families of serving personnel through Maternal and Child Health (MCH) services and School health services. Ex-servicemen and their families are provided medical care through Ex-servicemen Contributory Health Services (ECHS) and also through military hospitals restricted to facilities locally available.

### Medical Services Advisory Committee

Medical Services Advisory Committee (MSAC), which consists of DGAFMS as the Chairman & the three DGsMS as members, is the highest policy making body as far as medical services are concerned. It deals with and decides all matters which have an inter services bearing. The proceedings of the Committee are approved by the Chiefs of Staff committee. The DGAFMS has therefore a dual role. In inter service matters, the chairman, MSAC is responsible to Chiefs of Staff Committee. In other aspects of his duties he is directly responsible to Ministry of Defence. Some of the important matters which are referred to MSAC for decision are :

(a) Initial training of AMC officers at Army Medical corps Centre & School.

(b) Specialist training & specialist pool, selection of officers for courses in India and abroad, study leave, grading/classification, appointment of advisors and consultants.

(c) Policy regarding ante-date of commission

(d) Policy regarding inter service transfer/attachment of officers and their deputation to other medical institutions.

(e) Recommendation for the appointment of honorary surgeons to the President and the grant of honorary commissions to civilian medical practitioners.

(f) Selection of officers to fill up appointments in the inter service organisations such as Armed Forces Medical Stores Depots (AFMSDs). However, the administration of AFMC is the sole responsibility of DGAFMS.

(g) Preparations and maintenance of regulations.

(h) Any other matter having inter service bearing.

**Armed Forces Medical Research Committee**

Armed Forces Medical Research Committee (AFMRC) was constituted under the Defence Research & Development Council in November 1963 with DGAFMS as chairman. The three DGsMS, DGHS (AF), Senior Consultants Medicine & Surgery, Scientific Adviser to Ministry of Defence, Commandant AFMC and other co-opted members or nominated representatives from ICMR, DRDO organisations etc. are members. Additional DGAFMS ( Medical Research ) is member secretary of AFMRC. In this connection, collaboration is maintained with the following organisations controlling health related activities in the country :

(a) Indian Council of Medical Research (ICMR)

(b) Council of Scientific and Industrial Research (CSIR)

(c) Medical Council of India.

(d) Directorate General Health Services.

(e) Planning Commission

(f) Indian standards Institute

The terms of reference of AFMRC are as follows :

(a) The Armed Forces Research Committee is under the Defence Research & Development Council & functions under its general authority & guidance.

(b) All medical research problems, before being taken up for investigations, are submitted to the Armed Forces Medical Research Committee which makes recommendations regarding the choice of problems and allotment there of to institutions for progress of research. Decisions on such recommendations are taken by or under the authority of the Defence Research and Development Council.

(c) The Armed Forces Medical Research Committee is responsible to over see the progress of medical research authorised by the Defence Council & such recommendations from time to time as may be necessary for the consideration of the Defence Research Development Council.

**Functions of DGAFMS**

The DGAFMS functions directly under the Ministry of Defence for the following :

(a) Convenor as well as the chairman of the boards for recruitment of medical, dental and nursing officers for three services of the Armed Forces.

(b) Terms and conditions of service of all categories of officers (medical, dental and nursing).

(c) Release, recall, invalidment, retirement, pension & gratuities of all categories.

(d) Reserve of officers for the three services.

(e) Maintenance of personal documents of Medical, Dental and Nursing officers. He records his remarks on the technical and professional capability of all officers of the rank of Colonels and above ( and equivalent rank in other services).

(f) Provisioning, procurement, storing including reserve, and issue of medical and dental equipment and stores as required by the three services.

(g) Standardization and development of medical, dental and non-medical equipment with a view to their inclusion in equipment tables.

(h) Arrange trials of stores and equipment in hospital and other units; convening equipment and scales panel committee meetings, preparations of medical scales and equipment tables publication of PVMS.

(j) Control and Supervision of AFMSDs and Artificial Limb Centre (ALC).

(k) Administration of AFMC and other research and training establishments attached to the institution. The Institute of Aviation Medicine will, however, be under direct control of DGMS(Air Force).

(l) Selection and appointments of instructional staff for above institution from the panels of the suitable names submitted by DGsMS.

(m) Inter service attachment or transfer of medical officers to meet the requirement of each service from the panels of names given by the DGsMS.

(n) Coordination, planning, directions and developments of research work carried out in AFMC and the institutions under the control of three services headquarters. The DGAFMS is be the Chairman of the Armed Forces Medical Research Committee and is guided by the direction given by the research & development council.

(o) Coordination of statistical works in the three services & compilation of annual reports including Annual Health Report of the Armed Forces.

(p) Recording recommendation on purely medical aspect of the cases for claims for disability pension for service personnel.

(q) Issue of technical & medical instructions on matters concerning three services.

(r) Rendering technical & medical guidance to Director General Ordanance Factories.

(s) Liaison with the Director General Health Services, the Defence medical organisations of foreign countries and the research institutions in India and abroad.

(t) DGAFMS is the Chairman for Selection Board for promotion of AMC, AD Corps and MNS to the rank Colonel & equivalent rank in the Navy & Air Force. He is member of Selection Board for promotion to the rank of Brigadier & above (equivalent rank in other services,) including the appointment of DGsMS in three services.

**Nutrition of Troops**

Nutrition is an important means of promotion and maintenance of health. However, its total organization is not the direct responsibility of the Medical Services. Ration scales are drawn up or amended by the respective service HQs in consultation with their Medical Directorates. Policy matters regarding ration scales are dealt with on an inter-services basis by the Armed Forces Health Sub Committee (AFHSC) of the Medical Services Advisory Committee (MSAC).

Research in food and food technology is usually carried out by the Defense Research Organization, routine inspection of food stuffs is carried out by Food Inspection Organization functioning under the Director General Supplies and Transport (S&T Directorate, Army HQ). A senior medical officer of the Army Medical Corps, a specialist in Preventive and Social Medicine is the head of the food inspectorate and is designed as the 'Deputy Director General Food Inspection' (DDGFI). He acts as the medical adviser in respect of assessment of nutritional values of food, and serves as the link between the Army Service Corps (ASC) and office of DGMS(Army) at the Army HQ. The DGsMS are consulted regarding nutritional aspect of the ration scales and foodstuffs included in them. The respective technical staff officers viz. Dir MS(H) for Army, Director (H) for Navy and Director (H) for Air Force, act as advisers to their DGsMS on these matters. DGAFMS is consulted on any matter regarding nutrition, ration or foodstuff problem common to all the three services. He may also order any research to be carried out on these matters through ADGAFMS(MR), R&D Organization and DGsMS.

**Health Statistics**

All statistical work pertaining to hospital based data in the Army for recording compilation and interpretation of medical data related to morbidity and mortality is carried out by the 'Management Information System Organization (MISO)' under the General Service (GS) Branch of Army Headquarters. One AMC officer, a specialist in Preventive and Social Medicine, oversees all the aspects pertaining to patient related data. These data are generated from the formatted reports received from hospital and other medical units concerned with patient care and after compilation, tabulation and analysis are provided to DGMS(Army). Computerisation of system of reporting has assisted in faster data management, analysis and feedback to the environment in the recent past. In the Navy and Air Force this task is done at their Medical Directorates. The Central Diseases Registry (CDR) is functioning in the Department of Community Medicine (PSM) of Armed Forces Medical College (AFMC). At present, it maintains records of all HIV/AIDS cases and cases of High Altitude Pulmonary Oedema. More diseases can be brought under registry/surveillance as per requirement of DGAFMS.

**Medical Boards and Fatal Documents**

Medical categorization( including invalidation) and scrutiny of the fatal case documents are important activities of the technical administration of health services. These functions are carried out by the medical staff posted at various HQs in the chain of command of the three services. The medical categorization ensures that a person with a disease or disability is kept under surveillance, there is continuity of remedial measures and provision of sheltered employment conditions away from possible hazards, which may aggravate the disease or disability. It also ensures that the task or work does not suffer due to the handicap of the performer.

Invalidation out of service of an unfit person, ensures primarily the fitness for combat and other duties of the armed forces personnel by eliminating the unfits or misfits and secondarily avoids the exposure of the disabled to the aggravating hazards associated with service conditions.

Scrutiny of the fatal case documents is a form of medical audit which brings out the lacunae in the comprehensiveness of health care, deficiencies in the curative regimes or even the restorative care. In these activities the specialists( including senior specialists like advisers and consultants) and senior administrative medical officers play a vital role. Corrective actions wherever required including professional counseling to the treating doctors or administrative officers are initiated by the appropriate medical administrative authorities.

**Pathology Services**

The Armed forces Pathology Services carry out all the clinical pathological examinations including biopsy examination of tissues, special diagnostic skin tests,

autopsies and histopathological examinations both for diagnostic and medico-legal purposes, public health examinations such as examinations of water and milk supplies and wall scrapings or samples for insecticides. Additional DGMS(H, PS & IT) at the Army HQs is adviser to the DGMS on aspects of Health, Hospital services and pathology services. At the peripheral levels there are hospital laboratories of varying capabilities depending on the size of the hospital where they are located. In addition to these, there are Departments of Pathology, Microbiology and Biochemistry at AFMC which are responsible for academic and research activities besides provision of pathology services to dependent clientele.

**Health Services**

Army

DGMS (Army )is responsible for all matters regarding health of the troops and their families to the Chief of Army Staff. The health services in the Army are the responsibility of the Addl DGMS (H, PS & IT) at the Army Headquarters. He is the head of the professional or technical section of Medical Directorate and is responsible for advising the DGMS on the health of the troops, the promotion and maintenance of positive health and prevention of illness. Addl DGMS (H, PS & IT) has two specialists, Director MS (PS) and Director MS (H) on his staff to assist him. The Senior Advisers in various specialities are available for consultation on matters pertaining to their respective specialities. All matters regarding health of troops, accommodation, clothing, nutrition, comprehensive medical care, control of communicable and some non-communicable diseases, pathology services, scrutiny of fatal case documents, medical examination and medical boards, entitlements of military and civilian personnel to medical care from Army sources and research, in fact all professional matters are dealt with by this section of the Medical Directorate. At the Command and Corps level the specialist in PSM, designated as Assistant Director of Health (ADH) and at the Area and Divisional level as Deputy Assistant Director of Health (DADH) are responsible to their administrative medical heads for all the duties of this section. Health activities are coordinated and executed by SHO / FHO as well as by Senior Executive Medical Officer (SEMO) where SHO / FHO are not available. The responsibilities in operational areas & peace areas are slightly different as follows :

**Field / Operational Areas**

In the operational areas, Deputy Director Medical Services (DDMS) of a Corps and Assistant Director Medical Services (ADMS) of a Division are responsible to their respective commanders for the medical administration and to the Major General(Medical ) of the Command for all medical, technical and administrative matters. Commanding Officer (CO) Field Ambulances (fd amb) works under the overall supervision, guidance and administrative command of the ADMS who is the 'Commander' of all medical units in the field formation. Conventionally each Division has two fd ambs. Each of these fd ambs are asked to provide medical and health cover, including establishing of Advanced Dressing Stations (ADSs) and Forward Surgical Centres (FSCs) to earmarked brigades / divisional troop units within the Division. The CO of the Fd Amb providing medical care to the respective Bde/ Div Tps unit is also designated as the SMO of that particular Bde/ Div Tps unit for all health related activities.

**Peace Areas**

In each large garrison station there is a hospital (Army, Navy or Air Force). Generally CO of the miltary hospital is the SEMO. (This concept does not exist in Navy & Air Force).However the DDMS/ADMS is empowered to nominate any medical officer to perform the duties of SEMO of a part or the whole of the military station. The SEMO is responsible to advise the local station Commander on all matters regarding health and sickness among troops and their families in the garrison or station and is the head of all the local medical establishments. He is also the Health Officer of the Cantonment and adviser to the Cantonment Board on all health matters. OC SHO, a specialist in PSM, assists in the comprehensive health care of troops and their families in station and in the Cantonment area. SEMO is responsible for all the local medical administrative and technical matters to the DDMS of the “Area HQ” and for administration of the hospital to the local Commander. AO 165/79 may be referred for detailed account of duties and responsibilities of various administrative and health authorities in relation to health of troops and their families.(33)

Navy

The Director Medical Services (Health) at the Naval HQ is responsible to the DGMS (Navy) on all matters concerning the Health of Naval personnel. DGMS (Navy) is responsible to Chief of Naval Staff (CNS) on all matters pertaining to health. At the Command level, the Command Medical Officer (CMO) is responsible to the Flag Officer Commanding in Chief (FOC-in-C) on matters pertaining to preventive, promotive and curative aspects of health care. He is assisted by the Staff Officer - Health (SO(H)) in exercising control and coordination of health related activities of ships /establishments in the area of responsibility. The Principal Medical Officer (PMO) of the ship / establishment (besides being the equivalent of RMO in the case of ships /establishments posted only single MO ) is the adviser to the Commanding Officer on all matters pertaining to health, hygiene and sanitation. Naval shore establishments have SHOs of varying size depending on the work load, similar in organization and function, to those in the Army. The SHO is responsible for ALL health promotional and hygiene activities in a station. They also provide pest control services to the ships of the fleet when located at a port station.

Air Force

The Director Medical Services (Health) at the Air HQ is the adviser to the DGMS (Air) on all matters affecting the health of air force personnel. DGMS (Air) in turn is responsible for the same to the Chief of Air Staff (CAS). Principal Medical Officers (PMOs) of all the Operation, Training and Maintenance Commands are similarly responsible to their own Air Officer Commanding in Chief

(AOC-in-C) and also to DGMS (Air). They are assisted by Deputy PMOs who are specialists in Preventive Medicine or Aviation Medicine. Operational Commands have both these specialists while other commands have either of them. There is a SHO of varying capability ( large, medium or small ) at all permanent IAF Stations. These organizations work directly under the supervision of the SMO or MO of the Stations. In large stations a specialist in PSM is in charge of this unit. The SHOs in other stations are functioned by medical personnel below officer rank (PBOR), who are trained in health and sanitation, under the overall command of SMO/MO of the station.

**Station Health Organization**

The Station Health Organisation (SHO) is a unit responsible for coordination and provision of public health services to the units located in the military station where they are located. Station Health Organisation (Large) is authorised at selected military stations based on garrison strength or on medical operational requirement. The erstwhile Station Health Organisation medium, small and unclassified authorised to smaller military stations have been merged with the local hospital with a view to reduce costs but their function is as before with direct control by CO of the hospital in his role as SEMO. They now function as the Health Section of the hospital. SHOs are responsible for the maintenance of healthy conditions of environmental sanitation, vector control including anti-malaria measures and disease prevention and control in the station. The OC of SHO (Large) is a classified or graded specialist in PSM who also functions as the Assistant Health Officer (AHO) of the Cantonment, when so formally appointed by the Command HQ. He is responsible to the Health Officer for the health of civilians and sanitation within the cantonment and to the SEMO for the health and sanitation within the Armed Forces lodger units and establishments in the garrison station. The OC SHO works in close collaboration with the Cantonment Board Authorities.

Functions of the OC SHO

The functions of the OC SHO are comprehensive and include inspectorial, advisorial, administrative and executive aspects of health care delivery. The detailed description is available in RMSAF & Army Order 165 / 79 which may be referred to. An outline description is as follows :

(a) OC SHO has four-fold functions to perform and his time is proportionately divided into the duties required of him to fulfill these. For all these four-fold functions he is responsible to the SEMO in station. In order to carry out these functions properly, the OC SHO is required to keep a close liaison with local civil health authorities and is also required to participate in all the National/local health programs that are carried out under their auspices.

(b) As AHO of the Cantonment, his duties are concerned with maintenance of health of civilian population with the main objective of keeping in check all the influences which might jeopardize the health of troops garrisoned in and around the cantonment and embrace the environmental sanitation; quality control of food, milk, water supply, disposal of sewage, sullage, refuse and industrial waste; control of communicable diseases; supervision of health of workers employed under the cantonment board; execution of health programmes as directed from time to time; licensing of catering establishments and market including hawkers; enforcement of cantonment regulations regarding abatement of public nuisance and environmental insanitation in commercial, industrial, residential and trade districts. On all these matters he is expected to render a monthly report for deliberation of the Cantonment Board of which the Health Officer (SEMO) is an important member.

(c) As MO in charge of the Cantonment General Hospital (CGH) he works under the administrative jurisdiction of the Cantonment Board. This hospital is intended to diagnose and treat the civilians in the Cantonment and serves as a 'pulse' of the health of the civil population. In order to extend the medical facilities and also get a better picture of the health, there may be established some outpost dispensaries or health centers. As a part of the professional supervision of the CGH the MO in charge is also responsible for general organization and administration of the hospital and execution of all instructions regarding the establishment, equipment and functioning of the hospital and has to make the annual budget of the hospital. The staff of the hospital is responsible to him for their duties, general conduct of professional work and holding charge of the equipment. Some of the cantonment hospitals have vastly extended their scope and provide much more specialized facilities.

(d) As SEMO's adviser on all matters regarding health of the troops, it is his responsibility to have a first hand knowledge of influences which might adversely affect the health of troops in station so that the SEMO is in a position to appropriately advise the OC Station, who is also the Chairman of the Cantonment Board. For fulfillment of this function, his duties include :

(i) Regular inspection of the garrison and unit lines;

(ii) Control and prevention of communicable diseases among troops.

(iii) To ensure proper execution of anti-malaria, anti-rodent and anti-fly measures.

(iv) To ensure safe water and milk supply; disposal of sewage and waste matters.

(v) Inspection of licensed catering establishments for permitting them to be put 'In bounds' for troops, and also periodical inspection to keep them on the approved list.

(vi) To maintain, interpret and report the vital and health statistics in respect of troops in the garrison.

(e) He is also to inspect the schools established for the children of service personnel.

(f) The OC SHO should carry out surveys on ailments found to be locally prevalent among troops, families or civilians in the cantonment, and garrison or neighbouring areas and submit them through the SEMO to higher medical authorities

(g) As OC of the unit, he is responsible for its administration and supervision of the work of the staff.

(h) As the permanent secretary of Station Health Committee he is required to correlate all the information available to him from the four-fold functions described above. The information is then presented comprehensively to the Station Health Committee, the inferences relevant to the health and well being of the troops are drawn and action to safeguard them against untoward influences are recommended. The committee consists of the Station Commander as the Chairman and OsC units in the station as members. The Garrison Engineer or his representative, the Supply Officer or his representative and the Cantonment Executive Officer are the co-opted members of this committee. The representative of local civil health authorities are also invited to attend the meeting. The Committee meets once a quarter or more often to discuss relevant health matters. The OsC units are then required to carry out the decisions taken at the committee meeting. The records are maintained and action pursued by the OC Station Health Organization in his capacity as the secretary of the Committee.

**Health Organization in Field Formation**

(a) DDMS Corps has an ADH as his adviser and assistant in all matters of health of troops in the formation and the lower formations. A FHO and Fd Amb are allotted to Corps HQ. Field Health Organisation (FHO) with all combatant manpower, is authorized for a Corps, to provide hygiene services along the line of march. During peace time they provide similar services as an SHO in certain stations where they are located. The role of FHO and health section of Fd Amb is to reinforce the existing sanitary resources in the field formations or its part deployed under such conditions, which threaten outbreaks of communicable diseases. The decision to deploy these units or their part in various location or formations is left to the DDMS Corps as advised by his ADH. He coordinates the matters on health of troops in the whole formation and its component formations.

(b) In a Division, the DADH advises and assists the ADMS at the Divisional HQ. The health section of a Fd Amb in a division provides the technical element consisting of two health assistant of rank of JCO / NCO. These personnel monitor the environmental aspects specially quality of water and vector control activities by units in their respective area of responsibility. They also assist the DADH in organizing health promotion activities. Normally, their requirements at particular places, sub-formations or units is assessed by the DADH, and decided upon by the ADMS. The Fd Amb is instructed to locate these personnel according to requirements. The detailed charter of their activities are as follows :

(i) Supervisory and Inspectorial

- Environmental sanitation measures in and around the units/sub-units, such as disposal of waste matter and pest control measures particularly against mosquitoes, house flies, bedbugs, mites, ticks and rats.
- Purification, chlorination, storage and distribution of water supply.
- Ration supplies, fresh, dry and tinned for their wholesomeness.
- Sanitary vigilance in civil areas around camps in collaboration with the local health authorites.
- Control measures against communicable diseases.

(ii) Instructional

- Assist DADH/SMO in conducting health courses for Regimental Officers, JCOs, NCOs and OR

(iii) Executive

- Technical assistance to rectify sanitary defects in the unit lines.
- Carry out disinfection and disinfestation whenever required.
- Periodic collection and dispatch of water, milk and food samples as and when required to laboratories for examination. This should also be done while establishing new water points.
- Assist DADH in collection of statistical data on health of troops by maintaining records and preparing periodical reports and returns.
- Help units in conduct of control measures in case of outbreak of communicable diseases, and high incidence of other preventable diseases.
- Assist units in implementation of national health Programs in the formation.
- Help DADH in carrying out investigations / health surveys when required.

**Unit Health Establishment**

The responsibility of maintaining hygiene and sanitation

in the unit and health of troops rests with CO of the unit with expert advice and assistance of the RMO. The principal means of preventing diseases are the maintenance of effective sanitation and personal care and hygiene. Therefore, knowledge of elementary hygiene, sanitation and the best means of preserving them are incumbent on all ranks. The unit health establishment enabling the OC to carry out his responsibilities for maintaining the effective fighting strength consists of the RMO, the unit hygiene officer, the unit hygiene and sanitation squad, and the medical section (consisting of dual tasked band personnel /stretcher bearers in infantry / mechanized infantry units ), AMC nursing assistants manning the MI Rooms/RAP and Battle Field Nursing Assistants (BFNAs) who are personnel of the unit trained in first aid duties. In a regimental training centre depending on its strength, there may be two or more RMOs, of who one can be graded/ classified specialist in Preventive and Social Medicine.

Duties of Unit Hygiene and Sanitation Squad (34)

In army units, a unit hygiene and sanitation squad is required to provide hygiene and sanitary activities in the unit area as per Army order 25 / 2004 /DGMS. A regimental officer is detailed by name to act as Hygiene and Sanitation Officer of the unit. The unit hygiene officer is mainly required to carry out the duties concerning maintenance of environmental sanitation, personal hygiene of all ranks and hygiene of cookhouses, dining halls and messes in the unit. He should be properly trained for these duties under local arrangements by the SEMO/SMO. He is also responsible to ensure that all the unit health documents, other than those that are to be maintained by RMO are upto date. A unit hygiene and sanitation squad consisting of 4 NCOs and 6 OR ( for major units) and 2 NCOs and 3 OR ( for minor unit) with 100% reserve are required to be trained by the RMO / under the arrangement of SEMO to carry out out the sanitary duties in a unit. The duties of the unit hygiene and sanitation squad are as under :

(a) Supervision of the sanitation of cookhouses, wet canteens, aerated water factory including proper disposal of waste products.

(b) Spraying of insecticides within unit lines.

(c) All anti-mosquito, anti-fly measures and anti-rat duties

(d) Supervision of personal anti-malaria measures.

(e) Acting as sanitary police to ensure general cleanliness and disinfection.

(f) Daily supervision of the water supply and its purification for drinking purposes.

(g) The care of all apparatus and stores connected with water supply of the unit

(h) Chlorination or superchlorination and testing for chlorine contents.

## Regimental Medical Officer (RMO)

He is the first medical officer in the chain of medical echelons through which a patient is passed from the time of contracting illness or sustaining injury. In order to perform his duties effectively, the RMO will have to be always abreast in his professional knowledge besides being conversant with rules, regulations, orders and instructions regarding all health matters and be able to apply his professional and administrative acumen for the attainment of optimal health of the troops who are placed under his care. As a practitioner of preventive and social medicine, he is required to perform the duties as laid down in RMSAF para 103 to 116 and AO 165/79. The unit MI Room functions as a miniature health center for the unit. All medical officers nominated by the SEMO / SMO to be in medical charge of units without RMOs (AMA) will also perform all these duties. These are briefly as under :

(a) He will be in medical charge of all personnel of the unit and the families entitled for medical attendance. He will advise the OC unit on all sanitary and medical matters pertaining to health of the troops.

(b) He will conduct morning sick parade at the MI Room/RAP at an hour fixed in consultation with OC unit and SEMO. Usually the sick parade is held at the time of the first duty parade of the day viz. physical training He should treat minor ailments in the MI Room and refer other cases to hospital for admission/investigation/consultation by specialists. He enters on "sick report book"- AFMSF -44 prepared in duplicate by the unit, the diagnosis of each case reporting sick, and the disposal of the case in the column of remarks in the following terms :

(i) Medicine and duty' (M&D) meaning treatment and return to duty.

(ii) Attend 'A' meaning attend for treatment as ordered and to perform ordinary regimental duties.

(iii) Attend 'B' meaning attend for treatment as ordered and to perform light duties only.

(iv) Attend 'C' meaning attend for treatment and to be excused all duties.

(v) 'Hospital' meaning admitted to hospital.

(vi) 'Duty' meaning reported sick unnecessarily without enough cause.

(c) He will carry out a detailed annual medical examination of all JCOs and OR and keep a record thereof in accordance with AO 3/ 2001.(35)

(d) He will carry out quarterly medical examination of all low medical category personnel and monthly medical inspection of all food handlers and keep a record of such examination.

(e) He will examine all men going out on Posting/Course and all men returning to the unit from temporary duty course, leave and hospital

(F) He will visit unit-run schools and carry out examination of school children and hygiene inspection of school premises.

(g) He will impart health education to the troops given regularly and repeatedly throughout the year. Unit

cinemas whenever available should display health education slides. Notice boards in unit lines should display salient features about major diseases and their preventive measures.

(h) He will arrange with CO of unit, training of requisite number of men in first aid, hygiene sanitation, water and anti-mosquito duties.

(j) He will be responsible for carrying out all preventive inoculations and vaccinations of all ranks, civilian employees and families under his charge.

(k) He will inspect every portion of the unit line including family quarters, cook houses, JCOs Mess, Officers Mess, clubs, institutes and civilian quarters within unit lines and report in writing of the defects to CO with remedial measures and suggestions. These will be recorded in a sanitary diary once a month.

(l) He should examine all families within three days of their arrival in station and ensure their immunization is completed and any disease/defect is attended to.

(m) He should execute all health programmes, surveys and studies as per national or regional health programmes or as per directions of medical authorities at local or higher armed forces headquarters and render reports as required.

(n) He should ensure that medical stores and equipments for RAP authorized vide RME scale, 37/64 as amended, are in perfect working order and should be checked once a month for any shortages, discrepancies or defects. He should ensure that replacement is demanded promptly from the medical units on which dependent. Equipment and material required for MI Room but not ordinarily authorized may be obtained on loan and kept in the MI Room. Outfit First Aid on sliding scale on authorized number of vehicle vide Medical Scale, IAF (M) 37/68 as amended, should be maintained.

(o) Ordnance stores authorized as per WET, medical comforts for patients as per Standard Ration Scales (SRS) and stationery articles from the unit should be obtained regularly.

(p) He should maintain an emergency cupboard for prompt attention of the emergencies on the lines laid down for Hospital MI Room in accordance with MAI 25/63.

(q) He should maintain the following registers in the unit :

(i) Barrack treatments, admission and discharge register

(ii) Infectious Disease Notification Register.

(iii) Malaria Register.

(iv) Register of water tested for free chlorine,

(v) Low medical category personnel register,

(vi) Record of health education lectures.

(vii) Record of eligible couples.

(r) He will advise the unit to maintain following records/registers according to existing orders :

(i) STD Register

(ii) Inoculation and Vaccination Register.

(iii) Yearly Medical Inspection Register.

(iv) Insecticide Spray Records.

(v) Sanitary Diary.

(vi) Blood Donors Panel Register

(vii) Register showing nominal roll of all ranks trained in hygiene and sanitation and water duties.

(s) He will maintain health records and charts, graphs or histograms of daily sickness, hospital admissions and incidence of infectious diseases.

(t) He will submit reports and returns to SEMO on health of the troops as required. Any case of infectious disease or unusual sickness is to be reported to SEMO without delay.

(u) With the concurrence of the CO unit he may be called upon to :

(i) Work in local military hospitals as and when required by the SEMO/ADMS to enable him to remain in touch with clinical procedures and hospital practice.

(ii) Visit the patients sent in for admission by him to follow up their diagnosis, treatment, progress and disposal;

(iii) Attend clinical meetings/ discussions and other professional training arranged by the SEMO.

**Summary of Duties of RMO**

- Advise CO on all health matters
- Immunisation
- Medical attendance of patients
- Supervise med, ord and other stores of RAP
- Med exam annual, food handlers, others
- Med exam of families
- Health education
- Maintain Records unit & MI Room
- Monthly Sanitary Round
- Other duties assigned CO /SEMO

## Health Education

Besides providing curative services as far as is possible within the constraints at the periphery, the medical officers (RMO / AMA) are principally concerned with

provision of preventive & promotive activities aimed at ensuring maintenance of good health by the troops and their families living with them in the military stations. The aspects of provision of health education to all ranks and their families, provision of maternal and child health care including family planning services, immunization and school health care services need to be appreciated by all personnel involved in the provision of health services.

It must be emphasized that personal habits contribute to the achievement of positive health, morale and well being and also reduce vulnerability to disease, both communicable and non-communicable. When men live in a closed community life they need to be more particular in practicing healthy habits to protect themselves and the community in which they live. Provided all the facilities to live healthy are offered, personal care demands active cooperation and action by the individuals themselves. This depends upon their will, efforts and education. Therefore, rationalization of his life pattern by health education is needed.

Health education as defined by National Conference of Preventive Medicine in USA is “a process that informs, motivates and helps people to adopt and maintain healthy practices and lifestyles, advocates environmental changes as needed to facilitate this goal and conducts professional training and research to the same end”. A more meaningful and dynamic definition arose from the Declaration of Alma Ata which defined health education as “ a process aimed at encouraging people to want to be healthy, to know how to stay healthy, to do what they can individually and collectively to maintain health and to seek help when needed”. Health education in the armed forces is necessary to enable the personnel to observe their own health care; get over wrong beliefs and replace them with rational ones; acquire correct and adequate knowledge regarding health and means of its promotion and maintenance; prevent ailments and take early care; convert illness consciousness into health consciousness for making 'health' their valued asset (37,38).

The conventional regimental method of enforcement of orders and instruction prove temporarily successful but do not yield lasting results. Health education sows healthy habits more permanently among the personnel and their families. Order and instructions regarding health are useful to a limited extent only because the code of conduct laid down through them is without the consent, knowledge or conviction of personnel. They do bring about some modification but do not necessarily produce a permanent change in the habits of personnel. As soon as laxity in enforcement of regulations occurs the disease rates rise. If personnel are induced by health education to incorporate these habits as a permanent component of their behaviour pattern, this laxity may not occur.

The serviceman's education also benefits his children in improving their health and inculcating healthy habits from the very childhood. It benefits the community when the serviceman returns to his rural environments and presents people an example of healthful living, thus, becoming a nucleus to spread the message of healthy living. Knowledge is very important, but merely imparting knowledge is not fruitful unless the attitude is favourable. That also may not make persons adopt healthy habits and surrender wrong beliefs unless motivation is created and group acceptance is ensured. After motivation has been created the newly acquired beliefs and practices should become permanent habits. Further, the 'felt needs' created have to be first fulfilled, and the habits made part of the whole culture-pattern, which is the end result of health education. Beliefs and practices acquired by people through past generations cannot be readily removed by implementing new ones unless they are willing to accept them and make these a part and parcel of their culture pattern. The benefits of the new habits over the older ones must be experienced by the people so as to take root.

The task of health education in an armed forces unit can be carried out by the RMO/ AMA, regimental officers and JCOs or paramedical personnel. It however demands patience, perseverance and hard work. It needs preplanning which includes preparation and use of appropriate audiovisual aids like charts, graphs, flash cards, film charts, pictures, posters and so on. Cinema films and filmstrips are very good adjuncts. Audiovisual aids should be simple and in a language easily understandable by the targeted audience. Group discussions help in convincing the personnel and families of the advantages and rationality of the new practices and beliefs and habits. The set hours for such education should be included in the formal training programme of the unit. But opportunities offer themselves to educate people during morning sick parade, health inspections, unit sanitation and hygiene inspections, during informal gathering, immunization and so on.

A high standard in the provision of health environments, sanitary facilities, catering arrangements, water supplies, living accommodation and so on provide an actual life experience of high educative value. Childbirth offers good opportunity for introducing the subject of family planning besides aspects of child rearing. Outbreak of diseases offers good opportunities though, at an avoidable health price to educate personnel and commanders on the necessary preventive measures.

The aspects which have been identified for health education activities are based on common experience of subjects which are of utmost importance for the achievement of health. The subjects include the following :

Personal Hygiene

The aspects of personal hygiene which are reinforced during health education are :

(a) Regular bowel habits are important for maintaining good health. It is cultivated by regularity in its act. It is necessary on the part of unit administration to provide enough sanitary facilities in the form of clean, well constructed, sanitary or deep trench latrines with adequate privacy to encourage personnel to use only the authorized latrines every time. Irregularity of bowel habits is often due to inadequacy or

unsuitability or lack of privacy and cleanliness of latrines. Moreover, such conditions also oblige personnel to foul the grounds near about the camp causing insanitary conditions, fly breeding, spread of intestinal diseases like viral hepatitis A, dysentery and ankylostomiasis. Personnel should also be educated and habituated to make use of latrines and not indulge in indiscriminate defaecation. Similarly adequate urinals of proper standards design should be provided by the unit and made use of by the personnel.

(b) A daily bath is the chief means to maintain a healthy skin and avert communicable skin disease. Excessive use of soap is not always good. After bath the body should be dried by rubbing with a moderately rough towel, such as the one provided as issue in the Armed forces. Adequate provision for washing and bathing should be made. Daily bath is beneficial not only for the cleanliness of the skin but brisk rubbing of the skin activates the surface circulation. This stimulates the cutaneous nerve ending making them more responsive, and clears the sweat and sebaceous pores. An elastic, clean healthy skin surface is an efficient safeguard against adverse effects of extremes of heat and also cold. The invigorating effect of a bath is due to stimulation of steroid secretions brought about by the mild stimulus produced by sudden contact of skin with water, cold in summer and hot in water. Cold and hot water baths respectively cool down the body in summer and warm it in winter.

(c) Hair should be washed regularly, if not daily, and properly groomed; they should always be kept cut short to avoid dirt accumulating in it and also for aesthetic reasons. Nails accumulate dirt and pathogenic organisms and introduce them to one's food if hands are not washed properly and in the skin if one happens to scratch it. They should be kept cut short.

(d) Teeth should be brushed preferably after every meal, but at least after the last meal of the day. A proper brush should be used for cleaning the teeth. The habit of using a toothpick is not good as it harms the teeth and gums.

(e) Eyes should not be rubbed too often or wiped with dirty hands. A clean handkerchief should be used for wiping the eyes and another one for clearing the nose, and while sneezing or coughing. Spitting indiscriminately or coughing, sneezing without use of handkerchief are bad habits, which help to spread the respiratory infection. Such habits must be discouraged. Fingers should not be used to clean nose and ears. It is bad habit and may damage the eardrum or nasal mucosa. The nose should not be blown too violently as it results in driving the mucous or serous discharge up the eustachian tube and may even rupture the ear drum.. All ranks must shave daily preferably with their own individual safety razor. Community shaving by a barber may cause HIV infection, Hepatitis B or fungal infections.

(f) Clothes must be washed and dried regularly; facilities must be provided to enable them to do so. They should not use each other's clothing, socks, shoes or boots or bed linen and blankets. As tobacco or betel chewing is not a usual habit in the Armed Forces, the habit of spitting can easily be curbed.

(g) Clean bowels, a good shave, brisk physical exercise, a good bath, brisk rubbing of the skin with a rough towel, a good nutritious breakfast and clean teeth and mouth in the morning before starting daily routine enhances efficiency in work.

### Food Habits

This indicates the habit of eating adequate nutritionally balanced food at fixed times, from healthy sources where it is well and hygienically cooked, preserved, protected and served. It should be eaten in sanitary surroundings without fly or dust nuisance or bad odours. It should be served by hygienic food handlers in a hygienic manner. Starvation does not harm a man as much as eating indiscriminately from unhygienic sources. Eating over and above the usual requirements even after starvation, also causes harm. Overeating harms more persons than under eating, especially among those above 35 years age. Hands and mouth should be washed before and also after eating. Over-consumption of oils, vanaspati or pure ghee is not beneficial as is usually believed. Service rations are well balanced and the various scales provide adequate quantities of calories and all nutrients to the servicemen for the particular area, types of activities and functions they are intended for. It is important that unit catering should be wholesome and sumptuous so that eating outside the unit is not felt necessary by personnel.

### Water Discipline

Water should be consumed in adequate quantity and from an authorized or a known safe source. Slackness in adhering to this habit may cause outbreak of gastrointestinal diseases. All ranks going out on patrol, convoy duties, tracking, route marches, on exercises, manoeuvers, reconnaissance, movement by transport or railway journeys should be habituated to carry full water bottles, individual water sterilizing outfits and to strictly adhere to the rules of water hygiene and discipline. Arrangements should be made to facilitate these habits and personnel should be trained to make use of the equipment given to them for water purification. It is quite impossible to train personnel to go without water, and any attempt to do so inevitably inflicts injury on the individual. The belief that soldiers can be hardened by forcing them to go short of water when undergoing training is irrational and dangerous. For troops undertaking hard work in hot weather, an ample supply of pure cool drinking water is essential to maintain fitness and to prevent effects of heat. True water discipline is enduring thirst and drinking when necessary from authorized sources, and when there is acute shortage of safe water, drinking only when ordered; it does not mean unnecessary water deprivation.

Water should be replaced when one has lost about 1.5 litre.

Regular Exercise

The aspects which need consideration are as follows :

(a) Human body requires regular exercise. Physical inertia leads to obesity, low catabolism, muscular laxity, low threshold for exercise, low vital capacity, low cardiac tolerance and low threshold for physical and emotional stress.

(b) Physical activity is a stimulus to the growth of children and adolescents and promotes mental relaxation in adults. It produces and enhances resistance against coronary disease, frost bite, trench foot, respiratory infection, prevents obesity, mental and physical lethargy. Exertion should, however, not be so excessive as to cause extreme fatigue as, like all stimuli, it becomes a stress-producing factor if it is excessive. It should be enough to produce pleasant fatigue demanding relaxation. Stage of recovery should follow exertion-causing fatigue.

Relaxation and sleep

Relaxation and sleep are necessary for recovery of the body from fatigue by eliminating biochemical products and physical and mental exertion. Sleep should be sound without any artificial aids. A sound sleep is ensured by freedom from ill health; good feeding and enough physical and mental exercise; comfortable thermal environments and freedom from pests like bedbugs, mosquitoes, sandflies, rats and so on; comfortable garments must therefore be provided to ensure sound sleep in barracks. Men should get used to sleeping with open windows and uncovered faces. In winter, reliance must be put on adequate clothing and blankets for warmth while sleeping than on closed doors and windows and artificial heat from fireplaces. A direct draught should, however, be avoided and guarded against. Enough rest and sleep are very necessary for accuracy in work, avoiding accidents, including traffic accidents and greater output of work. Some recruits like to huddle together under common blankets in winter. This habit spreads respiratory disease like meningitis, influenza and common cold. Provision of charpoy for each person, mosquito net, sufficient warm clothes and adequate blankets is to be made.

Leisure

Guidance in proper leisure time activities enable improvement in lifestyle and reduction of mental stress. The aspects to be considered are as follows :

(a) Recreation by inducing personnel to get interested in healthy outdoor or indoor games, recreational outings, visits to places of historical, cultural and religious interests, hobbies like painting, music, photography or handicraft, and other pastime engagements for using leisure in healthy pursuits produces a healthy attitude to life, inhibits temptation to indulge in unhealthy activities, aimless loitering, promiscuous tendencies, quarrelsome behaviour and provides relaxation without lethargy. All facilities should be provided and men should be induced to take full advantage.

(b) Religious, ethical and moral teachings keep the mind of people geared to healthy thought and action, provide a strong inhibiting factor in unhealthy pursuits like promiscuity and alcoholism or heavy smoking habits.

(c) General education, high degree of professional efficiency achieved by constant professional training and basic military training, a high standard of self discipline achieved without fear of punishment, and a high physical standard achieved by regular exercise, produce high resistance against unhealthy pursuits, habits and tendencies. All officers and JCOs should be educated to understand and practice these principles.

Smoking and Drinking

Excessive alcohol consumption has been traditionally associated with armed forces personnel possibly due to easier availability of alcohol and conditions of service life. Consumption of tobacco specially smoking has also been associated with armed forces personnel. The harmful effects of tobacco are well documented.

The policy adopted in respect of alcohol consumption and tobacco smoking in Armed Forces is one of moderation and of discouraging habitual or heavy indulgence. Neither of them have got any nutritional or health producing values and heavy indulgence has definite unhealthy effects, In order to discourage consumption of alcohol, an allowance in lieu of issue of alcohol in kind has been introduced. The token small amounts ( 60-120ml) issued 2-3 times a week at present for recreational purposes are not expected to produce addiction or lead to regular or heavy indulgence and are considered to be tolerable when issued under supervision within those limits. Medical officers should, however, always emphasize the uselessness and bad effects of immoderation in their use. The younger officers should be made a special target of such education as they are vulnerable to get addicted, need more nutrition which is likely to fall short of requirement due to heavy alcohol drinking; have to work harder to be alert and provide a good example to their troops. They are on their lowest rungs of their career and hence need guarding against bad habits. Medical officers themselves should provide good examples in this respect.

The aspects needing highlighting in this respect are as follows :

(a) Value of alcohol from the physiological and psychological point of view is not subject to a difference of opinion. It has some food value in the sense that yields energy. In any form it is definitely not essential for nutrition. It has an energy value of 25 to 29 Kj per ml. The addition of about 1.6 Mj from 60 ml. of rum is not significant.

(b) The psychological stimulant effect of the alcohol

in moderate doses as is issued to our troops at present, has been accepted over the ages. Alcohol produces a sense of well being and 'will do more' in our troops employed under adverse conditions. It is at present issued for this purpose to troops, more as a psychological booster than for any other reason.

(c) If alcohol is consumed in excess it may produce deleterious effects on the tissues particularly the liver, heart and central nervous system such as cirrhosis, peptic ulcers, delerium, tremor, psychosis, lowering of rational thinking, delayed reaction time increased irritability, lack of concentration and so on. These effects are mainly due to resultant avitaminosis from lack of proper diet of confirmed alcoholics or improper absorption as a result of chronic alcoholic gastritis. The troops should therefore, be educated in these aspects of alcohol consumption. The example set by regimental officers and JCOs in moderation, temperance or abstinence goes a long way to educate the OR, making them habituated to moderations.

(d) Heavy smoking is another harmful habit. Like drinking, this habit also often starts as a social accompaniment for relaxation under tense condition, for masking shyness or diffidence, as an escape from realities of life stress, or from the false beliefs in their beneficial values. The temporary relief is followed by irritation or lack of concentration and craving for further smoking. Just like tobacco chewing or alcohol drinking, this leads to compulsive smoking and then to addiction. Excessive smoking, especially if started in early life, causes increased incidence of lung cancer. It leads to a higher incidence of ischaemic heart disease, peptic ulceration, gastric carcinomatosis, tobacco amblyopia and tremors. Nicotine causes powerful vasospasm, thrombotic tendencies and reduced cardiac dynamics. Chronic bronchitis and pharyngitis are its constant accompaniments and dental staining is often seen. These points should be brought out to discourage troops from indulging in heavy smoking.

(e) It is said that the personality make up of people who take to heavy smoking and drinking is basically vulnerable to stress producing factors and hence smoking and drinking aggravate the fundamental effect of stress on such persons. Smoking causes increased vulnerability to frostbite due to vasospasm induced by it, and once it has set in, smoking should be prohibited. Withdrawal symptoms or denial of smoking to a person used to it are similar to withdrawal of any other substance of addiction i.e. restlessness, irritability, lack of concentration, delayed reaction time and delayed cerebration.

Family Welfare

Care of wife and children is the personal responsibility of each person; and a serviceman is not an exception to this. The welfare and health of the family affects the health, efficiency, wellbeing and morale of the troops directly and indirectly. Unit administration has a moral and ethical responsibility to ensure the welfare of all families in station. Medical Officers should educate and guide them and unit Commanders should arrange for proper facilities. Habits of the parents are likely to be picked up by the progeny, hence the personnel and their wives should practice correct health habits. Immunization schedule as mentioned in Chapter IX should be followed in case of children of all service personnel. Antenatal care, maternity, postnatal care, child welfare and family planning facilities should be provided under station and or unit arrangements. School health care should be provided to all children attending Armed Forces, Station or Regimental Schools. Families therefore, require health education to be able to gain from the comprehensive health care facilities made available.

**Suggested Subjects of Health Education**

- Personal hygiene
- Food habits
- Water discipline
- Regular Exercise
- Relaxation & sleep
- Leisure
- Smoking & Drinking
- Family welfare & Family planning

Family Planning

Family limitation is the greatest need at present from the national, community, family and individual point of view. For Armed forces personnel family planning and limitation of progeny is of vital importance because of the peculiar nature of their service requirements, condition and commitments. At least for half of their career, with the exception of extremely few categories, they have to remain away from their families and entrust their wives with all the burden of bringing up, education, and looking after the illness and other problems of children. This entails an extraordinary strain on wives besides the maintenance of a double establishment. If the serving person has to give his best to the service, he should remain free from the worries of his family while away from them (or living with them). It is therefore necessary that the size of the family should be small and manageable and within his means. All ranks should, therefore, be educated in rational beliefs and practices of planning and limitation of families. It is the responsibility of the RMO as well as the regimental officers to help the personnel in acquiring the knowledge and means to practice limitation and planning of the family.

## Health Care for Special situations

**During Moves** (34, 39, 40)

Care of personnel during a move is much more taxing than when they are static under well-controlled environmental living and working conditions. Movement in Armed forces is undertaken for administrative, logistic, strategic or operational purpose. It is accomplished by marching, by mechanical transport, by railway journey, by sea or air. The special taxing conditions during moves, depending on the mode of progression, are concerned with extra energy requirements, change in atmospheric, biological, physiological, physical and psychological environments, loss of sleep, change in body metabolism consequent upon the change in environs and mode of life, depletion of nutrition due to difficulties in food supply and water supply, difficulty in maintaining personal hygiene and environmental sanitation and so on. All the modes of movements require pre-planning and utmost care to ensure that personnel do not suffer from ill effects due to these conditions and arrive at their destination in a fit state to undertake further administrative or operational tasks without much delay or lack of efficiency. Trekking back to the base during withdrawal operations adds to all other stress producing factors. The various requirements and management of a move by marching, road transport, and railway are briefly described for the usual situations involved in the Army ; ie. Move by marching, move by rail, move by mechanical transport. The details need to be clearly understood by the medical officers required to plan provision of medical care during these moves which are as follows :

Marching

This is normal activity of troops undertaken for administrative logistic, tactical, strategic, operational and training purposes. Marching comprises orderly walking, wearing certain clothes in definite fashion, carrying a certain load disposed on the body in a particular manner, and moving together as a body of men at a regulated pace. It is interrupted by 'halts', the number and duration of which are directed by strategy. Further, this exertion may be prolonged for hours and days after physical and mental strain e.g. withdrawal operation in retreat. In short, marching is a community form of exertion. Training in the practice and habits of walking is, however, a prerequisite in every case. The aspects which need to be considered are as follows :

**Training for Marching**

Training for prolonged marching must be gradual and must be on full rations. Any attempt to force men in this preliminary training or train them to endure on inadequate rations will only result in a breakdown. Officers are responsible for instructing their men in march discipline, the care of their feet, personal cleanliness, water discipline and in march sanitation. The medical officer should give them technical advice on the physiology and hygiene of the march. He should also ensure that water duty personnel and the sanitary squads are thoroughly familiar with their duties, which will be required of them on the line of march.

**Preliminary Preparations**

A rapid survey of men should be made by the medical officer before the marching starts to eliminate those who are likely to be unfit to carry out the march. Only men who are in sound health should be allowed to start. Inspection of their feet, socks and boots is the duty of the platoon/ sub unit commanders in collaboration with the medical officer. Water trucks and receptacles for carrying water and all water bottles and cooking arrangements for the march should also be included within the inspection by the medical officer. Each person should know the route proposed to be followed and arrangement to keep in contact with and recovery of stragglers should be made. Alternative or escape routes, own camp positions and modes of communication when segregated must be known. Emergency and survival rations must be given to each individual and composite pack rations kept in reserve.

**Start**

The best time to start a day's march is the time at which the soldier would normally start his day's work in that particular season and climate. Marching in the very early mornings should be avoided as far as the military situation permits, as they involve much loss of sleep and greatly increase energy expenditure. The tactical situation may make it necessary to undertake a series of night marches. However, they cause considerable strain and result in loss of manpower and efficiency. In extremely hot weather the march should be finished before the worst heat of the day, by starting earlier in the morning, if necessary. Apart from this, the time to start should be late enough to allow men a reasonable night's sleep. This should always be impressed upon the force commander by the medical officers. Military necessity must of course govern the situation and each case must be considered on its merit. Before the march starts a light breakfast and hot sweet tea should always be issued.

**Rate**

The most economic rate with minimum energy wastage for the fully laden, trained infantry man on a fair, flat road is 90 metres in a minute with a pace of 75 cm. At this rate and including the usual allowance of a ten minutes halt for an hour marching, 5 km an hour for a smaller formation than a brigade and 4 km an hour for a division may be taken as very good marching on fair roads. In hilly or broken country the rate will be less. At altitudes above 3000 m the rate will be progressively reduced due to hypoxia. A faster rate either by increasing the number of paces per minute or the length of pace, become rapidly and progressively less economic and throws a strain on the troops and reduces their operational efficiency,

**Halts**

A halt of 10 min should be made at the end of the first 2 km for adjustment of equipment, and thereafter a 10 min halt every hour should be allowed. This is physiologically necessary. Long halts for an hour or more should always be allowed when the days march exceeds 25 km. At this halt the troops should be given a substantial meal. At every halt, short or long, every man should take off his equipment, lie down and raise his feet.

**Distances**

The distance covered is determined by the load, the climate conditions, the terrain or condition of the route, and the training and health of troops. For seasoned troops marching on six successive days, a speed of 24 km a day is good and 32 km a day very good. 'Forced marching ' at faster speed than this is only possible with a small number of specially picked tough and trained troops. One day's rest a week is essential. It is physiologically and psychologically much healthier to march 140 km in six days, with one day's rest than to cover that distance by continuously marching for seven days without rest. Forced marching leads to a great wastage from exhaustion and sickness and the tactical or strategic advantage contingent upon it may not, out weight the loss. But if the military situation demands a forced march, medical authorities should advise the force Commander on all possible steps to minimize the anticipated man power loss. The most important of these measures are the provision of full scale rations, an ample water supply, minimum load carriage and ensuring restful night's sleep.

**Load**

The physical stress associated with marching while carrying loads can lead to injuries besides fatigue. The aspects which need to b considered are as follows :

(a) Bones and ligaments take the main brunt of load during the static load carriage, but the main strain of energy expenditure during dynamic load carriage falls on the muscular system. The more the energy expended on carrying excessive loads the less there will remain to be expended on the distance marched and in fighting. Therefore, all possible means should be adopted to economize in muscular energy.

(b) For comfortable carriage, the body and the load carried on it should form one unit. In order to achieve even distribution and optimum stability and support, the load should be close to the body and over its centre; if loosely disposed, this causes friction and instability. If the load is further away from the body, the support has to be broad-based which causes more expenditure of muscular energy.

(c) A single load evenly distributed between the two shoulders and suspended by strapplings to the shoulders can be advantageously carried on the back, but large and irregular size loads are difficult to carry by this method. The load must be compact, preferably in an oblong cube shaped package.

(d) The weights of loads carried by infantry have varied considerably at different periods. Rationally the weight of load should have an optimum ratio with the body weight. A load of about 30 per cent of the body weight can be carried with most economical energy expenditure by an infantry soldier i.e. approximately 21 kg. For a man weighing 70 Kg., the effective maximum should be about 45 per cent viz. 32 kg for the same man. With loads of over 45 per cent of the body weight, the amount of energy expended increases to three times the increased load.

**Physiological Consideration**

The important physiological aspects which must be considered while planning the medical cover during marching are :

(a) The optimum body temperature for the efficient performance of muscular exercise is 38°C, above, which muscular efficiency becomes impaired; and if it continues to rise, heatstroke may result. The total body heat produced by a trained, physically fit, infantry soldier marching with full equipment on a level ground is 360 Kcal (1506Kj) per hour. Allowing for the heat of metabolism approximately 1000 Kcal (4184 Kj) of heat is required to be dissipated from his body during a straight forward march of 25 km over level ground at the atmospheric temperature of 21°C. As evaporation of approximately 2 ml of sweat dissipates one Kcal (4.184 Kj) of heat, the evaporation of about 2 litres of sweat is necessary to dissipate the excess heat. Heat produced will increase above 1500 Kcal (6276 Kj) in an untrained, unsuitably clad, tired person with sore feet, marching on a rough and hilly terrain with more than 18 kg of load and the speed above 90 m a minute. In addition as the atmospheric temperature rises above 21°C the evaporation of progressively increasing amounts of sweat from the skin is necessary to prevent a rise in body temperature.

(b) The total loss of water from the body will be at least 5 litres when the atmospheric temperature is 32°C, and 12 litres when it is above 40°C. Although the total water content of the average man's body is about 40 litres, a considerable portion of it cannot be drawn upon for the dissipation of heat without damage to the tissue structure. When he loses three litres, physical inefficiency becomes marked, and the loss of more than four litres brings him near to dehydration. Therefore in marching at an atmospheric temperature of over 38°C without water replacement, there is a risk of precipitation of heat effects. During 25 km march with the atmospheric temperature at 32°C, water should be consumed at the midday halt and when the atmospheric temperature is over 40°C it should be consumed at every halt.

(c) Physically fit, suitably clad, seasoned soldiers when adequately fed and supplied with water, suffer little ill effects from marching even in the hottest weather, if the march is not unduly long and the relative humidity not usually high. The amount of sweat produced does not necessarily indicate the amount evaporated.

(d) When the temperature and relative humidity are 32°C and 90 per cent respectively, an individual whose body is bathed in sweat is evaporating much less sweat from his skin than one with the

dry body when the temperature is 45°C and the relative humidity 20 per cent. The critical factors therefore are the high relative humidity with high dry bulb temperature.

(e) When the dry bulb temperature is above 38°C with the relative humidity above 85 per cent, there is a very real danger of a number of cases of heat exhaustion and heat stroke occurring among even the fittest marching soldiers.

(f) Under all the above conditions marches should be short, halts frequent, equipment and clothing light, drinking water liberally supplied and the worst heat of the day avoided.

(g) Evaporation of sweat is less in a humid and still atmosphere; therefore a hot and airless day is less suitable for marching.

(h) Effects of the heat are much more likely to occur among those who are over fatigued, debilitated and in poor physical condition.

(j) Profuse sweating also causes depletion of salt. While undertaking a 25 km march under atmospheric temperature of 40°C maximum a man loses about 15 to 20 g of salt. When undertaking hard work or longer marches in hot humid weather more salt may be needed.

(k) Also refer to humidity temperature chart in Chapter-II to determine heat risk of exercising/marching during hot weather.

(l) In mountain terrain at high altitude, the tactical and operational marches undertaken for long range patrol or tracking have some different physiological considerations as follows :

(i) The troops may be required to ascend a height above 3000 m and upto 6000 m ASL. Troops not fully acclimatized to high altitude are liable to suffer from altitude sickness and even pulmonary oedema. The danger lies in the possibility of its being mistaken for ordinary exhaustion and the real condition thus unknowingly progressing into irreversible physical breakdown and death. The progress of walking and its rate progressively diminishes at successive higher altitude. The danger is more for apparently stout or sturdy people who try to overdo the task of climbing with heavier loads.

(ii) The other danger is that of exposure to severe cold with blizzard, especially when swollen feet due to prolonged walking induce personnel to remove the boots and socks. Loss of water is caused by exhaling moisture saturated air at body temperature while inhaling cold air without much moisture. These conditions must be guarded against and personnel trained to recognise their importance and likelihood of danger.

(iii) For long range patrols, trekking and manoeuvers, oxygen cylinders may have to be carried.

(iv) Other side effects of marching in mountains terrain are foot injuries due to twisting, running or jumping and several injuries due to falls or land slides.

(v) Leeches in foot hills at lower altitudes may cause minor nuisance and snow or rain may retard the progress.

(vi) First aid equipment is always necessary while marching in mountainous terrain.

**Sanitary Arrangements**

Normally all people should have defaecated before the march begins. At short halts all that can be done is to ensure that those who must defaecate excavate, a shallow hole in the ground in which they deposit their faeces, afterwards covering them with earth, At a long halt, shallow trench latrines are dug by the battalion sanitary personnel who should always proceed with the advance party and leave detachment behind to cover the trenches and mark them properly for the succeeding trackers to be aware of the latrine area. Disposal of other waste matters should be carried out by burning or burying in shallow trenches.

**Personal Hygiene**

Men should get facilities each day for washing and changing. If it is not possible to wash the socks worn during the day's march, they should be turned inside out and hung up to dry in the sun. In hot weather, a campsite which allows washing arrangements should be chosen. At the same time the dangers of bathing in rivers or lakes which are polluted with sewage should be remembered. The danger of scrub typhus should be borne in mind when selecting resting sites, campsites and washing places.

**Procedures on Arriving at Camp**

On arrival at camp the men should get hot sweat tea. After tea, the necessary camp work should be performed and the men should attend to their personal hygiene. Finally the main meal of the day, which should be hot and substantial, should be served, but the issue of this should not be delayed too long, otherwise men who are overtired are apt to go to rest without food. In order to avoid a muscle bound condition men should not rest immediately but carry out light tasks or walk about for some time before lying down for complete rest. After the march is over for the day, the platoon commanders should carry out an inspection of boots, socks, feet and general condition of persons. The Medical Officer should assist in it and thoroughly examine the cases requiring his attention.

**Duties of Medical Officer on March**

The normal position of the unit Medical Officer is at the rear of the column so that he can attend to men who fall out. He should, however, once in each hour to go to the head of his battalion and allow it to march past him. By watching the appearance of the men as they file past him and speaking to each Company Commander, he can

guage the effect of the march on the men and supply his battalion commander with vital information. At halts he should attend to any minor ailments. At the long halt he should help the unit hygiene officer to select a site for the shallow trench latrines and ensure the refilling and purification of water in the water vehicles and containers. Immediately after the last short halt of the march, he should proceed forward to the site of the camp or billets and satisfy himself that sufficient latrines and urinals are ready for the immediate needs of his unit. He should also satisfy himself as to the suitability of the proposed sources of water supply.

**Care of Feet**

The soldier marches on his feet. It is obvious therefore that he must ensure adequate care of his feet and condition them to be able to bear with the physical stress of marching. The aspects needing consideration are as follows :

(a) Hardening of Feet

All men should wash their feet at least once a day, preferably in tepid water. After this they should be steeped in cold water for ten minutes. Soaking them in a solution of salt and alum, 100 g of each to 10 litres of water, is useful to harden very soft feet.

(b) Prevention of Sore Feet

It is useful to wear a pair of thin nylon or cotton socks under the regulation socks if the boots are large enough to allow this. If any particular part of the foot feels sore, a search should be made inside the boot for any roughness and projection of a nail; corns are due to nails pricking the sole of the foot. Changing into chappals at the end of the day's work is of great value. Those with a tendency to sore feet should dust their feet liberally each day with 'foot powder'(zinc oxide 10 per cent). It is an advantage to have the medical assistants trained in the elements of chiropody. At all halts on the march, and at the end of the march, he should attend to all those who are known to have tender feet. The feet must be kept scrupulously clean.

(c) Hyperhidrosis

Men who suffer from excessively sweaty feet develop inflamed and blistered feet. The best treatment for these conditions is to bathe the feet in 0.5 per cent solution of formaldehyde and dry them thoroughly, followed by dusting with 'foot powder'.

(d) Blisters

If the sore or irritation in the boot or socks is removed and the foot rested, the blister fluid will be gradually absorbed in four to five days. This can be hastened by draining the blister through a stout, sterilised long hypodermic needle, inserted into the blister through the surrounding sound skin painted with tincture of iodine. When the blister is empty, the skin over it should be carefully flattened down, but not cut away, and painted with iodine. Over this a piece of lint secured in position by adhesive plaster should be placed.

**Considerations for health care of troops during move by marching**

- Training for marching
- Preliminary preparations
- Start time
- Rate of march
- Halts
- Distances to be covered
- Load to be carried
- Physiological considerations
- Sanitary arrangements
- Personal hygiene
- Procedures on arriving at Camp
- Duties of MO during the march
- Care of feet
- Care of footwear

**Care of Footwear**

The aspects which need consideration are as follows :

(a) Boots

These should always be kept pliant and soft. The foot spreads about 1 cm in length and 1.25 cm in breadth under the weight of the full marching load. Therefore they should be fitted over regulation socks while the soldier is carrying his load and standing.

(b) Socks

A clean pair of socks should always be carried on the march for putting on after feet have been washed at the end of the march. Woolen socks shrink after being washed. New socks should therefore, be 2.5 cm long, and worn by the soldier while on duty in barracks. Two washes make them the right size for marching. Darning must be carefully done as holes in socks or badly darned socks cause blisters. Socks should be carefully washed and be kept clean at all times.

Move by Mechanical Transport

Precautions during moves in Mechanical Transport (M.T.) by road to be taken in addition to those mentioned above are as under :

(a) Movement should, as far as possible, be in the cooler hours of the day.

(b) Distance covered daily should not, as a rule exceed 160 km and there should be one day's rest after every 4 days driving.

(c) Every effort should be made to take the maximum benefit of available shade for halts, even if it means going some km further than scheduled.

(d) Canvas water bags (chaguls) filled with water

should be carried, slung on the outside of each vehicle for ensuring cool drinking water.

### Move by Rail

Besides all the usual measures to ensure the health, comfort, well-being and efficiency of the personnel required to be taken during a move, the following precautions to safeguard against health hazards should be taken when moving by rail :

(a) All electric fans in military coaches should be checked for their working.

(b) Overcrowding should be avoided in the coaches. These should be washed and sprayed with insecticides prior to occupation.

(c) A compartment, in addition to that for hospital accommodation, should be reserved and equipped for the treatment of men suffering from effects of heat.

(d) Entertainment should not take place overnight when the train is due to leave in the early morning; a long period cooped up in a stationery train in the hot weather is most uncomfortable and even dangerous.

(e) Ice containers are authorised and should be supplied at the scale of 5 per military coach and 1 per hospital compartment, officers compartment and kitchen cars.

(f) Ice is authorized at the scale of 35 kg per container or per 8 men at the beginning of the journey and a further 35 kg for replenishment later in the day.

(g) Adequate cold drinking water should be supplied to troops.

(h) Taking food, drinks or water from unauthorised sources at halts enroute should be prohibited. Halts for meals should be scheduled prior to starting and meals prepared by own cooks should be given.

### Disembarkation from a Ship

Men freshly disembarked possibly suffering from the after effects of sea sickness, and certainly soft from being on board ship, are susceptible to the effects of heat. They should on no account be subjected to a long march, moving heavy baggage, fatiguing works etc; until they have been fed and rested. Water points, shelters from the sun, and heat stroke centers should be provided at the docks.

## Provision of Maternal and Child Health Care in the Armed Forces

In the Armed Forces, Family Welfare Centers are organized on a station basis in all large, medium and small stations. Initially these centres were funded by the Ministry of Health and Family Welfare. However, at present, these centres are funded by the Ministry of Defence from their own budgetary allocation In large stations the establishment to provide health care for mothers and children is more elaborate than other stations. In addition to these centers some large units also run special health Centers exclusively for the care of family members of the service personnel. In the Navy, "Family Clinics" funded from non-public funds but under control of medical administrative authorities provide for comprehensive health care of families of naval personnel and are located at convenient places close to concentrations of family quarters. Antenatal, postnatal, under five clinics and family planning clinics are held on specific week-days at all these centers. Although a standard plan for staff and equipment is recommended for Family Welfare Centers, its implementation depends mainly on local resources, needs and enthusiasm. The OC SHO provides technical assistance and guidance on behalf of and under the general direction of the SEMO. The lady medical officer-in-charge is, however, the actual working head. In the case of unit run family welfare or health centers the RMO is responsible for the supervision of work in such centers. To enable the Medical Officers at various levels to carry out their duties in respect of provision of comprehensive medical care for the families of armed forces personnel, a brief resume of maternal and child health care is provided as follows :

### General

Mother and child has been recommended by WHO to be considered as one unit for provision of health care. In India, Women in the reproductive age group ( 15-44 years) who constitute about 19% of the population and children upto age of 15 years constitutes about 40% of the population and are considered a vulnerable group with high risk to life and health. Women carry a special risk to life and health during pregnancy, parturition and pueperium; the child bearing age shows higher death rates and morbidity rate in the female population. Infants are highly susceptible to infections, malnutrition, dehydration and environmental changes. The risk of life decreases as children grow up but they are still vulnerable to many adversities and infections. The pre-school and the school going children from one to ten years of age form 20% of the community; if adolescents upto 15 years of age are added to this, the total is about 40% of the community. In the armed forces, service personnel are invariably of younger age group as compared to the general population as they retire at a younger age. The proportion of families in the child bearing age group and children in the younger age groups will be more among service personnel as compared to the general population. However, a large percentage of service personnel are unable to or do not bring their families to the place of their posting due to various personal and accommodation problems. Hence they do not benefit from the comprehensive services provided by the armed forces and remain dependent on health services provided by the states or private practitioners (41).

### Maternal Mortality and Morbidity

Maternal mortality means the death of a woman while pregnant or within 42 days of termination of pregnancy, irrespective of the duration and site of pregnancy, from any cause related to or aggravated by pregnancy or its management but not from accidental or incidental causes.

Maternal mortality rate is expressed as maternal deaths per 1000 live births. At present it is 3.4 per 1000 live births. However, as compared with rates under 0.5 per 1000 live births in developed western countries this is still very high. Maternal morbidity is about 20 times the mortality. The commonest cause of maternal mortality in India are anaemia, haemorrhage, sepsis, obstructed labour, abortion, and toxaemia. Maternal morbidities are the anaemias, chronic malnutrition, pelvic inflammations, liver and kidney diseases. In addition, the pathological processes of some preexisting diseases, such as chronic heart diseases, hypertension, kidney diseases and pulmonary tuberculosis are aggravated by pregnancy and childbirth. A majority, of all the conditions causing maternal mortality and morbidity are preventable; by ensuring efficient antenatal, intranatal and postnatal care. (42,43)

### Child Mortality and Morbidity

Pre-school age child mortality means the deaths of children aged 1-4 years; 'infant mortality' means death of children upto 1 year of age; 'neonatal mortality' means death upto 28 days after birth; early neonatal deaths are the ones that occur upto 7 days after birth. Deaths from the 28th week of pregnancy upto 7 days after the birth, including stillbirths, are included in 'perinatal deaths'. Although perinatal period occupies less than 0.5% of the average life span, there are more deaths within this period than during the next 30-40 years. (44,45 )

The infant mortality rate in India which was 40 to 45 per 1000 of population at the beginning of last century has now fallen to 8.7 per 1000 on account of general improvement in environmental conditions, specific control of endemic communicable diseases, improved general nutrition and medical care, and health (or rather illness) consciousness of the people. Approximately half of the total mortality occurs among children below 5 years, half of the under five child mortality occurs below one year, and half of these die before they become one-month old.

Infant mortality in India halved from 146 per 1000 live births in 1951 to 40 in 2004. In developed western countries the infant mortality rates are uniformly below 10 per 1000 live births. At least 50 to 60 per cent of the child, mortality & morbidity can be prevented by efficient antenatal intra-natal and postnatal care.(29)

**Health of mother influencing maternal & child health**

The better the health of the mother during pregnancy and after delivery, the lesser will be the risk to her own life and health, and that of the infant; because the care of the mother before, during and after parturition contributes to the health of the foetus and infant as well. Maternal and child care as a combined service is thus an important constituent of the comprehensive health care of the community. Continuity of supervision is essential and the prenatal services can not be separated from the intranatal midwifery services from the infant and child welfare services. The aim of the combined services are;

(a) To further reduce the maternal mortality and morbidity during pregnancy, labour, puerperium.

(b) To ensure normal progress of pregnancy.

(c) To further reduce the perinatal, neonatal and infant mortality and morbidity.

(d) To ensure normal growth of children upto the time their health care is taken over by the school health service. The maternal and child health care programme includes antenatal care, maternity services and postnatal care, mother craft, under five clinics and family planning services. Various clinics may be held on different days of the week at the same premises and also the services may be extended to homes of the families.

### Antenatal Care

The antenatal service in the armed forces may be offered in the clinic by the lady doctor or extended to the home through Lady Health Visitor(LHV). The objectives of an antenatal care are to decrease the maternal morbidity and mortality before, during and after the child birth and to ensure the safe and healthy progress of pregnancy. Most of the causes of maternal morbidity and mortality can be rectified or avoided if detected early during pregnancy, if the nutrition of the mother is kept at its best during pregnancy and if diseases like syphilis, anaemias, hypertension, diabetes and toxaemias are treated early and kept controlled. Normally each expectant mother should be seen at least once a month in the clinic by lady doctor or LHV. To study environmental conditions and give practicable advice and demonstration, a proportion of the visits should be at the home. A minimum of three complete medical examinations are required. The first one should be before the 16th week. The second examination at the 32nd -36th week and the third examination during the 38th-39th week. A general review of the health of the mother and her mode of life accompanies each medical examination

The pregnant woman is usually first brought under antenatal observation about the 3rd month of pregnancy when she is thoroughly examined for any defects or diseases, approximate period of pregnancy is determined and in primipara the pelvic measurements are taken and recorded. The weight is recorded; blood is examined for VDRL, HIV, Hepatitis B,ABO & Rh grouping and for complete haemogram. Urine is examined for sugar, albumin and casts. Blood pressure is taken and recorded. Appropriate treatment for any defects or diseases is started. Immunization against tetanus should be given. Advice on personal hygiene in pregnancy and the instructions to return again after a fortnight /month or earlier if she feels unwell ( danger signs are explained) are given. By $32^{nd}$ to $34^{th}$ week the position, lie and presentation of the foetus should be ascertained and any remedial external measures, if considered necessary, can be carried out for correcting it. After the $36^{th}$ week the visit should be weekly and presentation checked. The head is generally fixed in the pelvic brim by the $38^{th}$ or $39^{th}$ week and prediction as to the absolute normality of labour can be made and case referred to the specialist if considered necessary..

### Maternity Service

The midwifery services can be a domiciliary or institutional service. The latter is particularly needed for prenatal and postnatal complications of abnormal labour, for normal labour in primiparas and for mother whose home surroundings are overcrowded or unhygienic. For the individual as well as an organization, institutional care is expensive where as domiciliary midwifery is less expensive and simpler to arrange. Domiciliary deliveries are safe for the normal confinement even where housing conditions are not ideal, but it is unsafe even for minor obstetric manipulations. For domiciliary work in urban areas one midwifery unit for every 100 birth in a year has been recommended. In rural areas where distances are great and communications poor one trained birth attendant in every village is necessary. The Health Worker Female (HWF) has all resources of the Primary Health Center and its staff behind her. She is supplied with the sterilised outfit and her knowledge is kept upto date by her contacts with hospital methods and practice. An institutional midwifery service in the armed forces scenario with hospital delivery is the preferred mode practised in the Armed Forces. It is run in conjunction with a family welfare centre for antenatal and post natal care.

### Postnatal Care

The postnatal care is also conducted either at the clinic on fixed days of the week or extended through paramedical healthcare workers at the homes. The postnatal rehabilitation of mothers, their mother craft training and inspection of babies for normality can be carried out simultaneously. The mother is educated regarding her own health and the health of the baby, and given advice regarding personal hygiene. Family planning clinic is attended by the mother about a month after the first child birth. IUD is usually inserted 6 weeks after child birth. After the second child, the couple should be advised to adopt permanent methods of family planning. In under five Clinic immunization schedule as given in Chapter IX should be carried out and the child examined for normality of growth nutrition; function of all organs and 'mile stones'. In the armed forces, post natal care is conducted in the family welfare centre with the lady doctor and LHV providing services of examination, advice and treatment if required. Home visits are also conducted by the LHV with family planning advice being rendered.

### Home Visiting

The paramedical health worker should visit each expecting mother and every infant once a month, and each child between 1 to 5 years once every three months. More frequent visits are desirable between the 36th and 40th week of pregnancy and the first month of the infant's life, which are the periods of maximum danger. Apart from 8 to 10 visits to each expectant mother and visits to every pre school child, each infant should be visited 12 times in the first year of life for teaching the mother to observe the normal developments and signs of departures therefrom, to manage feeding successfully, to supplements her own diet and to wean the child; deal with vaccination, clothing, bathing, teething habit training and prevention and treatment of minor ailments; educate against wrong customs and habits, to instill into her the elements of home and environmental hygiene, family budgeting, storage of food, and to help her to ameliorate social maladjustments. She has to demonstrate to the mother the preparation of suitable foods for the baby and to supervise the mother while she gains skill in carrying out treatment of minor ailments of the eye, ear or skin. Early visiting also enables the health visitor to register the pregnancy and directly or indirectly supervise the work of the dai or midwife in rural areas and to influence her methods and practices. In the armed forces, the LHV is entrusted with the task of home visits for all the above mentioned purposes. A schedule of visits is issued well in time to the units whose family accommodation is planned to be visited to gain logistical and administrative support.

## School Health Care

School health care is a link between the maternity and child health care and the general community health care. In 1953, the Secondary Education Committee emphasised the need for medical examination of school children and suggested a school feeding program. At the Central Ministry of health a special committee on school health care, "The National School Health Council ", has been established since Feb 1963 especially to plan and organise school children's health care.(46) Provisions have been made in the municipal, cantonment and state regulations for organization and maintenance of a school health service. Schools for children of Armed forces personnel are organised and maintained under the auspices of and financed from the Defense Ministry, Services HQs, local formation /Station HQs or regimental authorities. The RMOs and /or any MO detailed by the SEMO should regularly inspect the school premises located in the cantonment and the children studying in these schools and submit the report to the administrative authorities to enable them to arrange the remedial action for rectifying the defects and improve the health of children. The objectives of the school health care are as follows :

(a) Help children in this critical period of their physical and mental growth towards normal healthy adulthood.

(b) Maintaining working efficiency at a high level and improving mental assimilating power by :

  (i) Ensuring congenial working conditions.

  (ii) Keeping them physically and mentally fit at all times.

  (iii) Improving the general nutrition of the children.

  (iv) Reducing absenteeism and thus increasing average study hours/days.

  (v) Prevent spread of infections, reduce and detect minor ailments before they develop into major ones or permanent disabilities.

  (vi) Imparting health education and physical training to children.

(vii) Providing special arrangement for the education of handicapped children.

The aspects of school which may affect the health of the children and therefore warranting consideration by medical officers entrusted with the responsibility of coordination of school health services are as follows :

Healthful School Environment (47,48)

The environment at the school has an important influence on the health of the school children. General environs around the school building should be made healthy and sanitary by ensuring the following :

(a) The school should be located in areas free from crowded surroundings, away from bazars, butcheries, factories, disposal grounds for waste matters, public sanitary areas or enclaves, and such other places which may create a public health nuisance.

(b) There should be sufficient open space around the buildings.

(c) Enough playgrounds should be provided. Free muscular activity reduces mental boredom and strain and provides a stimulus for growth.

(d) There should not be any mosquito or fly breeding places around the school area.

(e) Traffic around the area should be restricted to the minimum so as to avoid noise, smoke and dust nuisance and mainly accidents.

(f) Accidents should be prevented not only on roads around school but also on the playgrounds and in class rooms. First aid should be taught to all teachers and senior pupils.

Seating Arrangement

These should be such as to allow adequate space, permitting freedom of movement for children on the bench so as to enable them to work without strain. The vertical and horizontal distance between seat and desk should be such as to permit children to write without raising their shoulders or stooping down on the desk. The distance of the seat from the floor should be such that the child is not required to either hang the legs down or raise the knees too high. Feet should rest on the ground while sitting on the seats without the popliteal space touching the seat i.e. the height of the seat should be an inch shorter than the leg from knee to the sole. An inclined foot-rest under the desk is the best device to achieve this. There should not be any obstructions to knee protruding under the desk. Normally the desk should be at elbow level when the child is seated. Its horizontal distance from the seat should not be more than 5 to 7 cm and vertical elevation such, that he is not required to lean forward while writing. The backrest should be adapted to the normal spinal curvatures. The black board should be at such a distance that the last student should be able to see the letters distinctly. Provision for keeping books and stationery should be made in the desk.

Drinking water

It should be procured from an authorized clean source, centrally stored and chlorinated. Laddles should be provided to take out water if taps are not possible. The ideal method is to provide water fountains which enable children to drink water without the use of cup or a glass. Common cups and glasses have the inherent danger of spreading upper respiratory tract infections.

Toilets and Urinals

Enough sanitary urinals should be provided at a central place but as near the class rooms as possible. Normally privies and urinals should be provided one urinal for 60 students and one latrine for 100 students. These should be kept clean at all times. Habitual use of clean sanitary urinals and latrines serves as a good medium for inculcating healthy habits in children. Toilet facilities should be separate for boys and girls.

Midday meals

These should be provided for supplementing the food available at home. These should provide about one third of the total daily requirements of calories, proteins, vitamins 'A' and 'B' complex and calcium. They should provide about 20-30 g of fat, 20 g of protein of which one-third should be of animal origin. Inclusion of milk in the meals will ensure this requirement. The schools meals not only aim at supplementing the nutritional requirement but also at inculcating healthy food and eating habits. In order to derive the greatest benefit the teacher must be trained in to elements of health and nutrition (49) .

Immunization

Children should be immunised against typhoid group of fevers, diphtheria and tetanus as a routine. If and when facilities exist immunization against poliomyelitis and tuberculosis by BCG should be carried out. Cholera inoculations should be given when the town is threatened by outbreaks.

Medical examination

All children should be thoroughly examined once a year or at least three times during the curriculum in addition to the one carried out at the time of entry. Results should be recorded in the health card and parents should be advised regarding remedial action. There should be a permanent register and health cards with column for remarks against examination of each system. The card is meant to be transferred to the institution the child may go after leaving one institution. A monthly, quarterly and annual report must be sent to the coordinating authority and medical authorities. The special points to look for are given below:

(a) Eyes for trachoma and vision (including tests for acuity of vision )

(b) Ears for perforated drums, otitis and power of hearing.

(c) Teeth for caries, non-alignment, mottling, gingivitis and so on.

(d) Nose and throat for adenoids and enlarged / infected tonsils & enlarged glands.

(e) Chest for lung involvement or congenital or

acquired cardiac defects.

(f) Abdomen for enlarged spleen, liver and any palpable lymph nodes.

(g) Genitalia for phimosis, undescended testicles or patent inguinal canal.

(h) Lower limbs for varicosity or other skeletal and muscular defects /deformities.

(j) Skin for ring worm, scabies and any depigmented patches.

(k) Hair for pediculosis, signs of malnutrition, etc

(l) Weight and height for normality.

(m) Any abnormal curvatures/ postures, delicate health, nutrition etc.

Minor Ailment Clinics

These should be provided and children should be encouraged to visit them whenever they feel unwell. It not only helps to reduce minor ailments from developing into major ailments or disabilities but also helps to detect any other major ailments or disabilities undetected in the incipient or early stages.

Referral Facilities

Facilities for reference of children to a specialist for investigation of ailments and their treatment/ hospitalisation should be ensured.

Physical Training

It is a major item of a school curriculum and should be insisted upon. Teachers should be trained in physical training or special instructors should be appointed.

Health Education

This should be part of the curriculum. It can be imparted either as an integrated part of curriculum or otherwise. Health education is also incidentally acquired by children through the experiences and observation of healthy school life as described above.

School health Committee

It should consist of the Headmaster or Principal as the Chairman and class teacher, health educator, school nurse, physical training instructor and the school medical officer as members. They should meet once a month or a quarter. A few parents should also be invited to attend these health committee meetings.

Parents Committee

# Assessment of Health in Armed Forces

## Introduction

The medical officer providing medical cover to the unit is very important in the scheme for provision of health cover in the armed forces. This could be the Regimental Medical Officer (RMO), if posted to the unit or Authorised Medical Attendant (AMA), if posted to some other unit but assigned responsibility to provide medical cover to personnel of a specified unit. In general, personnel specially young personnel posted to a unit are medically fit because they have been selected after a pre-placement medical examination. After being certified medically fit based on a thorough medical exam, young able bodied men are recruited in the services and thereafter undergo strenuous military training. The health of the troops under the care of RMO / AMA requires continuous monitoring right from the time of enrolment to enable maximum availability of combatants during war, operations or for peace time duties. The RMO / AMA is required to bring to the notice of the commanding officer (CO) of the unit any condition considered responsible for deterioration in health or likely to affect adversely the health, morale and welfare of the personnel of the unit. The further responsibility for rectifying such conditions rests with the CO under the advice of RMO / AMA. The Defence Services Regulations provide that the maintenance of health and prevention of disease among troops is a command function and commanders at various levels are responsible in this aspect while Medical Officers are responsible for rendering advise (1). In order to provide this advice, the RMO/AMA has to periodically conduct following activities :

(a) Conduct assessment of the environment - living and working conditions of the personnel by regular periodical inspections of the unit lines.

(b) Conduct assessment of the health of troops by regular periodical health inspections and examinations of the men under his medical care.

## Unit inspection

The RMO / AMA should make frequent inspections of the area under administrative control of the unit. These inspections should not be concerned only with the environmental sanitation. The inspections must include all the factors which combine to make up the soldiers' living and working environment, which in turn, determine his physical and mental efficiency, health and sickness, morale and welfare, and above all his fighting fitness. The unit hygiene inspections by the RMO / AMA are of four kinds :

(a) Periodic sanitary inspections for which detailed description is provided

(b) Inspections to check action initiated for rectifying defects highlighted

(c) Special inspections on occurrence of any disease in epidemic form. For this purpose expert help from a preventive medicine specialist must be sought at the earliest to pinpoint source of infection and institute remedial measures.

(d) Inspection for siting and locating the unit and its sub units upon its move into a new area. All aspects of hygiene and sanitation needs of a body of troops need to be considered and advice provided for adequate planning and meticulous execution through the CO of the unit. Details are available in the relevant chapters, for prevention of common infectious diseases.

## Periodic Sanitary inspection

General Principles. Regulations for the Medical Services of the Armed Forces 1983 in para 114 lays down that the RMO / AMA should visit every part of the barracks and camp at least once a month (2). The descriptions enumerated in the succeeding paragraphs pertain mainly to army units. However, with minor alterations in procedure they also apply to navy and air force ships/ units / installations. The concept of "monthly sanitary round" does not mean that only one day during the course of a month should be set aside for complete unit inspection. Indeed, such an inspection thoroughly carried out would occupy the whole day. It is much better to hold weekly inspections so planned that every part of the unit is covered once a month. In that case, a set day and time each week should be allotted to the inspection. This procedure has been sometimes contended to be faulty on the grounds that it removes the element of surprise, which would have enabled the medical officer to see the conditions as they always are rather than when specially prepared for inspection. The advantages of fixing date and time outweigh this objection. Firstly, this procedure ensures that such officials as the second in command (2IC) and quartermaster (QM) of the unit accompany the RMO/ AMA on his round. Secondly, it guards against the possibility of the medical officer missing the inspection in a particular month and finally, it has an educative value for all personnel on how the environmental conditions should ideally exist.

A definite scheme should be drawn out in detail on paper and closely followed to ensure that nothing is overlooked. The plan will naturally depend upon the topography of the camp. After taking over medical charge of the unit, the RMO / AMA should obtain or make a map of the camp and unit showing the location of all departments, buildings, huts, roads, latrines and so on. Army units are structured to possess a number of sub units called company (infantry or engineers) / battery (artillery) / squadron (armour) or other such sub units which function with some degree of cohesion and independence within the unit. The accommodation is usually distributed to these sub units which function their independent cookhouse and dining hall (approximately for a strength of 100-150 persons). The locations of all these sub units should be studied and

the plan of visit closely followed at the first few weekly inspections until the RMO / AMA becomes fully conversant with the location of every part of the unit and camp, including the layout of the water supply and drainage system. It is also important for him to know the sanitary problems which had arisen in the past and the way they had been dealt with from a study of the previous reports and the "Unit Sanitary Diary".

It will be appreciated that for units which are operationally deployed specially in mountainous terrain or during "training exercises" which simulate operational deployment, the sub units are at some times at considerable distances from the main headquarters of the unit and will need to be visited by RMO / AMA in a deliberate manner to appreciate the living conditions and conduct sanitary inspection.

As per page 51 of AO-27/2004/DGMS, the medical officer should also be accompanied on his inspection round by the unit sanitation and anti-malaria officer (usually QM is so designated by CO) and any other individual specially required (3). In some units a designated officer instead of the 2IC is detailed by CO to accompany the RMO / AMA. It will usually be found that once the RMO / AMA has secured the confidence of his CO, the attendance of the 2IC, at least occasionally, can readily be obtained. Before starting on the inspection the RMO / AMA should always visit the CO. This offers an opportunity for discussing with the CO such important points as the number of cases of sexually transmitted diseases (STD) , malaria, viral hepatitis and other preventable infectious diseases among unit personnel and any other matter having bearing on the health and welfare of personnel.

During the inspection minor defects should be commented upon verbally and not included in the written report. The more serious defects may, however, be noted for subsequent report to the CO in the sanitary diary. A suggested format for the "Unit Sanitary Diary" is enclosed as **Appendix** at the end of the chapter. This format helps the RMO / AMA to focus attention on those aspects which need attention and need to be commented upon. It should be borne in mind that the "Unit Sanitary Diary" is produced for annual administrative inspection of the unit. The endorsements should therefore be appropriate to the importance of the document. The inspection should be carried out systematically. The list of places to be visited during the "Sanitary Round" are enumerated below. All the areas however may not be applicable for every unit.

(a) Living accommodation - barracks, huts, tents
(b) Cook houses
(c) Dining halls
(d) Bath houses / Bathrooms
(e) Latrines
(f) Officers' and JCOs' messes
(g) Barber shop
(h) Dhobi Ghat / Washing places
(j) Water supply point
(k) Recreation room / Information room
(l) CSD canteen
(m) Wet canteen
(n) Regimental school
(o) Offices, QM stores (specially ration stores and store for hygiene chemicals & spray equipment)
(p) Guard rooms / Quarter guard
(q) Gymnasium & swimming pool
(r) Medical Inspection Room (MI Room)
(s) School
(t) Rubbish and waste matter disposal area
(u) Animal lines or private animal farm
(v) Slaughter houses
(w) Aerated water factory
(x) Family accommodation of other than officers

Living Accommodation

The requirements of ventilation, lighting and so on have been described in chapter IV. The permanent location of a unit is as per Key Location Plan (KLP). As an interim measure units may be located for a short duration, which may continue for several years, at a place which is specified in the Interim Location Plan (ILP). Units located in KLP location are authorised permanent accommodation as per specifications in "Scales of accommodation" of Military Engineering Services (MES). Unfortunately it takes years, sometimes decades, for proper accommodation (as per authorization, MES specification and design) to be built. During this period adhoc accommodation as available is allotted under arrangements of the Station Commander. Over a period of time, units use their own funds as well as through MES sanctioned construction works, to make themselves reasonably comfortable. However, the accommodation may be far from ideal design or teaching. The RMO / AMA must bear this in mind while conducting the sanitary inspection and forwarding subsequent comments or suggestions. RMO / AMA must however familiarize himself with the "scales of accommodation" which are available with Garrison Engineer of MES, Station Headquarters or formation headquarters - Quartermaster General Branch and suggest construction of deficient accommodation affecting hygiene and sanitation of the unit.

Whatever accommodation is allotted needs however to be kept in proper state of repair and as clean as possible. Compliance with all such requirements, including the state of general hygiene should be scrutinized by RMO / AMA. The general cleanliness of the place should be meticulously maintained. Floors, walls and ceiling should be in good state of repair to avoid harbouring of pests. Daily sweeping and /or mopping should be encouraged. The unit sanitation and anti-malaria squad should carry out their duties efficiently and regularly; their work in respect of spraying insecticides in all accommodation should be checked from time to time. Every barrack, hut, or tent should display on the wall at a prominent place the record of residual insecticide spraying. Detailed assessment of mosquitogenic conditions and anti -

malaria measures should be made. Guidelines are available on page 54 of Army Order 27 / 2004 / DGMS - Prevention of Malaria & other mosquito borne disease (3)

The RMO / AMA should inspect the arrangements for fixing mosquito nets, stringing of charpoys, cleanliness of beds, bug infestation and so on. The individual "kit", containing all items of personal clothing issued to every individual, is laid out during the inspection to enable assessment of the state of clothing of the personnel. Randomly, a few dining plates should be inspected for cleanliness ; water bottles should be checked for fungus, mould and cleanliness; few mosquito nets should be examined for tears and proper repairs by patching (and not stitching or tying) ; and boots for the state of repair and likely chance of causing corns / callosities. Barrack inspection thus affords an opportunity to go into many details of the living conditions of troops. In areas where impregnation of bed nets is advised, the RMO / AMA has a duty to check that the impregnation with recommended chemical (as specified by the medical authorities like Officer Commanding Station Health Organisation (OC SHO) or Deputy Assistant Director of Health (DADH) is properly done on the mosquito nets.

**Accomodation**
- KLP / ILP
- Adequacy
- Repair state
- Cleanliness
- Lighting
- Ventilation
- Personal kit

Feeding Arrangements

It is an old saying that "an army marches on its stomach". Provision of safe, adequate and tasty meals under all circumstances is the aim of all units. Adequacy and suitability of space, ventilation and lighting for the cooking and serving of the meals must be considered during inspection and all the standards should be taken into account. In general, the inspection can be grouped into that of the cookhouse - where food is prepared, and that of the dining hall - where food is served and partaken by the personnel. Detailed sanitary guidelines are available on page 20&21 of Army Order - 25 / 2004 / DGMS - Prevention of Food and Water Borne Diseases (4). The under mentioned points should be observed and commented upon :

**Cookhouse / Dining hall**
- Adhoc / as per scale
- Cleanliness
- Lighting / Ventilation
- Rat & Fly proofing
- Smoke nuisance
- Chapatti basket / utencils
- Meat box / chopper
- Rations dry & fresh
- Hyg of cooks / immunization
- Clothing of cooks /

(a) State of repair which may affect sanitation, fly and rat proofing, cockroach nuisance, ventilation, lighting, smoke nuisance and so on.

(b) Inspection should be carried out of the raw foodstuff, especially the fresh items, and their cooking from the point of view of any loss of nutritional values, digestibility, palatability and possible contamination or deterioration of cooked food.

(c) Inspection of personnel working in cookhouse and handling food for personal hygiene, especially cleanliness of clothing and hands, personal cleanliness, trimmed finger nails, clipped hair and any skin conditions.

(d) Inspection of food items for taste, palatability and acceptability in general. Food should also be tasted to ascertain these points.

(e) Availability of fresh water supply and its protection.

(f) Inspection of dining hall from the point of view of adequacy of space, comfort, fly and rat proofing, seating and eating arrangements, plate washing arrangement and disposal of left over food, meat bones, etc.

The following documents on public display should be checked:

(a) Cook house rules including authorisation of rations.

(b) Nominal roll of food handlers and their monthly medical examination and immunisation records.

(c) Bill of fare (weekly menu).

(d) Store room for rations (dry & fresh) from point of view of general hygiene, fly and rat proofing and quality of rations.

(e) Samples of food preparation of each of the three meals served in all cookhouses should be preserved in refrigerator wherever the facility exists for at least 24 hours, preferably 48 hours, and the containers should be properly marked. This assists in proper diagnosis in the event of an outbreak of food poisoning.

**Sanitary Annexes**
- Bathing facilities
- Adequacy
- Hot water arrangements
- Latrines
- Adequacy
- Cleanliness
- Repair state
- Dhobi ghat
- Availability
- Waste water disposal

Washing and bathing Arrangements

All permanent accommodation are designed to house the dormitories for men, cookhouse & dining hall as well as sanitary annexes (bathroom & latrines) in the same building. However, in adhoc or older constructed accommodation, dormitories are separate from bathing spaces & toilets. Inspection should be carried out to see the adequacy, cleanliness, surroundings, disposal of wastewater, shelter from wind,

arrangements for drying and arrangements for provision of hot water (specially in winters).

**Bathing Arrangements**

Each unit should have a definite arrangement for providing men a daily bath, and at least two hot baths a week during winter. The unit medical officer should make himself familiar with the system of bathing of the men of his unit and should make it his duty to see that it is adequate.

Dhobi Ghat and Shop

Arrangements should exist for washing of the clothes of the personnel by the individual himself for his clothes, under garments and socks and centrally through the services of washer men (dhobis) for articles of uniform, arrangement for drying of clothes and ironing of clothes by washer man. These should be established as far as possible near the unit lines. Washed and unwashed clothes should not be allowed to be mixed. Water used for washing should be clean and no water-logging of waste water should be permitted. Waste water should be drained well away from the unit area after removal of the soapy scum.

Latrines

Common latrines are the norm for lower ranks of the armed forces which are usually part of sanitary annexes located at the end of the building housing the dormitory / in separate annexes. Water carriage system is provided in permanent accommodation with flushing system. In case of water shortage or malfunctioning of flushes, hand flushing is resorted. A water storage masonry tank or other adhoc arrangement for storage of water for ablution and flushing is provided wherever 24 hours water supply is not possible (which is the usual system). Blockages of the latrines due to inadequate availability of water for flushing is a recurrent occurrence specially in older accommodation. Servicability and cleanliness of the latrines are of prime importance to prevent fly nuisance. RMO/ AMA should also carry out an occasional inspection of the condition of latrine seats and urinals. In case they have lost their glaze, become pitted or are no longer cleanable due to prolonged use, they can be recommended to be replaced by MES as per existing provisions. An "unhygienic certificate" is required by MES to be rendered by medical authorities, Officer Station Health Organisation in a large station or even RMO / AMA in a small station, to facilitate the replacement action.

Officers' and JCO's Mess

It is often experienced that the kitchens of officers' and JCO's messes are far below the standard demanded of the cookhouse serving the lower ranks. They are usually never inspected and are neglected. These messes should neither be overlooked nor any lower standard accepted. The points to be considered are exactly the same as enumerated above

Water supply

Chapter on water supply describes methods of provisioning of safe and wholesome water to troops. Details of the source, system of purification and distribution must be always known to the RMO / AMA. Where water supply is piped to the unit from a water point, water samples at various points of delivery in the unit and sub-units should be examined for the presence of free chlorine at frequent intervals (preferably daily) and records maintained. It must be noted that chlorine rapidly evaporates if exposed to sunlight and air. Therefore tests should be conducted only when "fresh water" is being supplied and not from water drawn from overhead tanks of a building. These tests should be conducted regularly, preferably on a daily basis. If chlorination is not done centrally at the water point or in the unit after getting it, the method of chlorination at sub-unit levels should be checked, not only during monthly inspection but more frequently and records maintained. Absence of "free chlorine" at the consumer end leads to suspicion of leakage / sewage contamination in the distribution water pipelines and needs to be immediately investigated to prevent outbreak of water borne diseases. Any likelihood of pollution at any stage before its consumption should also be ascertained. The tests are conducted and records of daily chlorination maintained by water duty personnel at various sub-units which should be scrutinized during the monthly round.

**Barber shop**

- Space adequacy
- Cleanliness
- Instruments
- Waste disposal
- Hygiene of barbers
- Clothing

Barber shop

Barber Shop Detailed instructions for cleanliness of Barber shop has been laid down in AO-247/73 (5). This can become a focus for dissemination of HIV, Hepatitis B, skin infections like sycosis barbae, Tenia barbae or Tenia capitis through infected instruments and also respiratory infections to the personnel due to close contact, which is unavoidable during shaving or hair cutting. During inspection the following points should be checked :

(a) The shop, furniture and equipment should be kept clean at all times.

(b) No bedding or unauthorized clothing should be kept therein.

(c) A nominal roll of all employees showing the date of monthly medical examination, inoculation and vaccination under the signature of the medical officer should be displayed in the barbershop.

(d) Arrangements for frequent washing of hands of the barbers and adequate water supply should be provided.

(e) All barbers should wear clean overalls and aprons when at work.

(f) Shaving or hair cutting of men suffering from skin disease is prohibited.

(g) Clean towels and sheets are used in the shop.

(h) If a 'barber's chair' is provided, its headrest should be protected by clean paper; a fresh piece being used for each individual.

(j) A bucket or a tin is provided for used cotton wool and clipped hair. The tables are provided with sunmica, zinc sheet or marble top and kept clean.

(k) Combs, razors and clippers are kept immersed in 2.5 per cent cresol, dettol, or chlorosol solution when not in use during working hours. Before use they are washed with clean water. The rest of the time they are cleaned and protected with Vaseline excepting combs which are cleaned and washed with soap and dried. Shaving brushes after each shave are washed in a solution of savlon /dettol and then rinsed in clean water. Razors are wiped on a clean towel kept for the purpose. It is better to encourage use of changeable blade razors. The blade should be used once and then disposed. The used blades should be disposed by deep burial after disinfection in a strong bleach solution (5% strength for half an hour). In general, shaving by barbers should be discouraged where possible and individuals be encouraged to shave themselves.

| Canteen |
|---|
| As for cookhouse |

(l)All cuts are swabbed with tincture of iodine.

Canteen

The wet canteen in army units is run by a civilian contractor appointed by the unit and is an important adjunct for the unit personnel who partake of the tea and snacks prepared. The canteen should be inspected exactly in the same way as a cookhouse, but probably with a more detailed scrutiny. Sanitary control of canteens is extremely important, as laid down in page 22 of Army Order - 25 / 2004 / DGMS - Prevention of Food and Water Borne Diseases (4).

Recreation and Information Rooms

The standards recommended for space, ventilation, lighting and furniture should be ensured. Overcrowding in a recreation room, specially for viewing the very popular entertainments beamed by television channels, is as dangerous as it is in living barracks. Therefore, space and ventilation are important factors. Moreover, the rooms should be adequately warm in severe winter and cool in summer. The function of the recreation room is to provide healthy recreational facilities in order to promote the mental well being, to break the boredom and divert attention from the temptation of visiting civil areas. Attention should be paid to general cleanliness.

Regimental School

Regimental school caters for lower ranks to improve their basic educational qualifications and is different from the school for children. With the change in minimum qualification standards of soldiers to matric level, the utility of such schools has greatly reduced. Nevertheless, if they exist, adequacy of space, ventilation, lighting and general cleanliness should be examined. The seating arrangements and the relative position of black board and teacher must be checked.

Office Rooms and QM Stores

These places also require inspection for ensuring adequacy of accommodation, maintenance, lighting, heating/cooling and ventilation from the point of view of health. Clothing and ration stores must be examined for rat and fly proofing. Working comfort of the staff in office and rat proofing of stores are also important and must be ensured. As the RMO / AMA is concerned with the correct storage and issue of hygiene chemicals and serviceability of spray equipment, these must be checked during the inspection. Preferably all hygiene chemicals (which are obtained from Army Service Corps) must be demanded as per the size of the container provided by the manufacturer. Storage in adhoc containers can be dangerous due to accidental misuse. All items must be stocked as per requirement. Hygiene chemicals are demanded and consumed based on medical advice. Usually OC SHO controls the issue action at station level so all units have to route their hygiene chemical indents through him. RMO / AMA with more intimate advance knowledge of training commitments of the unit can ensure adequate and timely stocking of hygiene chemicals for use when the unit or detachments are deployed in un-controlled areas for operations or training. State of repair of spray equipment is also required to be monitored and repairs / demands for new items placed well in time on Army Ordnance Corps units (Divisional Ordnance unit / Ordnance Depots) to enable appropriate spraying activities. The authorisation of spray equipment is laid down in page 44 of Army Order - 27 / 2004 / DGMS - Prevention of Malaria and other mosquito borne disease (3-4)

| Offices / Stores |

| Lighting |
| Repair state |
| Cleanliness |
| Hygiene chemical store |

| Quarterguard |
|---|
| As for accomodation |

Guard room / Quarter guard

Large units like infantry battalions are authorised a Quarter guard which provides ceremonial guard to the unit and is a showpiece where the regimental flag, “colours” and other valuables including cash of specified amounts are stored temporarily. The quarter guard also has prisoner cells to house offenders who have been awarded “imprisonment” for their offence as per Army Act. The cells are required to be of such construction as to be conducive to healthy living for an offending soldier undergoing a spell of imprisonment. His health should not deteriorate during the imprisonment due to the conditions prevailing. Hence, aspects of environment applicable to living accommodation except provision of fans are catered. The prisoner is under observation at all times and is conducted by the duty sentry for bathing and calls of nature for which sanitary facilities are provided. These aspects are also inspected by the RMO / AMA during his round.

| Family Lines |
|---|
| As for accommodation |
| Also CILQ accn |

Family Lines

In a military station where units are located in peace time, married accommodation is built as per specified design and

scales and are available to all ranks. Usually, units are allocated blocks of such accommodation in single or multi storied construction for better coordinated maintenance. The accommodation allotted to Personnel below officer rank (PBOR) should be included in the inspection as the health and hygiene of families and their living standards influence the health of the soldier also. Their health is as much the responsibility of the CO as the health of personnel he commands. The same uniformly high standard in the ordinary married quarters as in the men's barracks cannot be expected. Everything possible should be done to raise the level of living conditions of the soldier's family by lectures and talks delivered during inspection as well as by using the forum of Family Welfare Centre of the unit. An attitude of helpfulness should be adopted during these inspections. It should be realized that the average soldier's wife with duties of house-keeping and care of the children has her hands full in keeping her home even reasonably clean. The important points on which to lay stress are the condition of the food storage, water supply, waste disposal and drainage, ventilation and general cleanliness of the house and health of the children.

The MES constructed married accommodation available in a station is usually insufficient to meet the requirements of all those who may wish to avail of this facility. To overcome the shortage, a provision of providing allowance as "Compensation in lieu of quarters" (CILQ) , has been authorised by the government. Any PBOR wishing to hire a house on CILQ is required to have the house inspected for both medical and security aspects. Station Headquarters sanction CILQ based on medical inspection reports of OC SHO. However, the continued maintenance of hygiene and sanitation condition of the hired accommodation is the responsibility of CO of the individual. RMO / AMA must therefore focus attention on houses hired on CILQ by PBOR of his unit and advise corrective actions if required. The aspects which need attention are the condition of living rooms, kitchen, bathroom, latrine, water supply, waste disposal and general sanitation of surroundings.

### Family Welfare Centre (FWC)

Traditionally army units have maintained a Family Welfare Centre to impart some skills to the wives of PBOR who are invariably with the unit only for a brief period of the entire career of the husband. The FWC is actively supervised by the wife of CO or in her absence a senior lady to ensure adequate patronage and logistical support. At least once a month there is a unit level organization of "family welfare meet" during which all available ladies including wives of officers of the unit attend, interact and discuss ways and means of improving the status of the wives of all ranks. In the earlier days the skills imparted by the FWCs mainly pertained to housekeeping but over the years this has also evolved to equipping the wife of PBOR with economically viable skills like computer education, handicrafts manufacture, etc.

One of the duties of RMO / AMA is to appropriately use the opportunity provided by this forum to stress on healthy lifestyle and other health related information to enable the ladies to provide a healthy environment, proper nutrition and correct upbringing for the entire family including their children and their husband, besides themselves. Of late with instances of mental stress related problems (marital discord, substance abuse, delinquent children, problems of adolescent child, etc) arising in the increasing nuclear families of PBOR, the opportunity to sensitise the ladies about the various aspects of mental health or illness should also be utilised by RMO / AMA. In this he may seek professional assistance with support of CO. Often a full time or a part time lady doctor is appointed by large units for day to day work pertaining to health care of wives and children of PBOR of the unit. Appropriate support and supervision of the activities of the lady doctor by RMO / AMA will greatly assist in provision of comprehensive maternal and child health services.

| School |
|---|
| As for accomodation |
| Medical examination |

### Children's School

Some large units, as a welfare measure, have started schools for small children - usually for pre-school age children. These should be inspected frequently, preferably, once a month due to the very high chance of infectious diseases among the vulnerable young children. General cleanliness, adequacy and the state of sanitary conveniences, water supply arrangements, programme for health and physical education and the general state of health of the children should be checked. Once a year all children should be subjected to a proper medical examination to enable early detection of disabilities which can be corrected and facilitate the learning process. Necessary records must be maintained in a systematic manner.

### Aerated Water Factory

Many units run their own aerated water factories. Sometimes, the natural desire to bring down the production cost tends to a lowering of the hygienic standards of production. As a principle, the hygienic standards of the aerated water should be the first criterion in its manufacture; and low cost, although desirable, should be of secondary consideration. The premises in which the factory is located should have concrete floors and impervious walls. The personnel employed in the factory should be directly under the unit medical control and supervision. Special clothing for use during working hours should be supplied to all workers. Chlorinated water from a piped supply from a central water works can be used. When such is not obtainable, clarified water should be chlorinated and used half an hour after chlorination. Strict attention should be paid to the cleanliness of the bottles and the method of washing them. The satisfactory method of washing bottles is first to scrub them inside and outside with a brush,

| Aerated water factory |
|---|
| As for cookhouse |
| Cleaning of bottles |
| Raw material |
| Hygiene of staff |
| Testing samples |
| Documents |

then steep them for 30 min in a bleaching powder solution (30 grams to 5 liter) and then in running chlorinated water, and finally allow them to dry on a draining board without wiping with cloth. The method of preparing and storing the syrups and flavouring agents for lemonade, colas, and other sweetened aerated water should be hygienic. These products are attractive to flies and the possibility of contamination by this means should be guarded against. From time to time (preferably once a month) , samples of all types of aerated water made in the factory should be sent to the laboratory located at nearest military hospital for bacteriological examination. The health standards expected of personnel employed in the factory are the same as those for cooks of unit kitchen. All concentrates used should be certified by ISI / FPO / AGMARK and the labels be appropriately endorsed to indicate appropriate processing and use of safe preservatives, colouring or flavour agents. Guidelines given in pages 22 & 23 of Army Order - 25 / 2004 / DGMS - Prevention of Food and Water Borne Diseases should also be referred (4).

| Abattoir |
|---|
| As per cookhouse |
| Scaffolding |
| Waste disposal |
| Hygiene of butchers |
| Instruments |

Abattoir

When slaughtering of animal is carried out under unit arrangements, the RMO / AMA should inspect abattoir thoroughly for hygienic standards, as it becomes a source of health hazard to personnel. Fly breeding and contamination of meat are the two hazards. Special notice should be taken of the floor and general cleanliness of places where the carcasses are dressed. Floor should be of impervious concrete and interior wall of smooth concrete which should be lime washed frequently. Concrete channels should drain all liquid manure from the lairs and the slaughter room to a place of disposal outside; semisolid manure should be dealt with in the same way as manure from a dairy. The slaughter room should be fitted with scaffolding having chrome plated hooks for dressing of animals, be fly proof, have an adequate water supply and be provided with a suitable means of dealing with blood, offal and waste animal products. Where it can be arranged, all liquid waste should be run into a water carriage sewer, and all solid refuse should be burnt in an incinerator. Above measures, however, are rarely possible because slaughtering under unit arrangements is usually necessary in the operational service when live animals designated meat-on-hoof (MOH) is supplied. The best method of disposal then is daily burning of all refuse and offal in the beehive incinerator. On rare occasions when burial method is adopted, the pits should be well limited and the offal covered by a layer of mud. Once the pit has reached its maximum capacity, a layer of oiled earth should be arranged on top and firmly rammed in. Special covered receptacles for holding blood and offal pending incineration or burial should be provided. The carcass hanging room should be well ventilated and fly and rodent proof.

There is a chance of contamination of slaughtered meat from the dirty hands and clothes of meat handlers. In order to reduce contamination of meat, all personnel handling meat must wear clean clothing, must have their nails clipped short, be free of any communicable diseases and be protected against enteric group of fevers. All implements used in cutting meat like choppers, knives, etc must always be boiled for 20 mins after use and wooden blocks cleaned with salt powder. Meat is kept in meat safes and stores which are fly and dust proof, are well ventilated and are cool. Detailed guidelines on meat hygiene are laid down in pages 17 & 18 of Army Order - 25 / 2004 / DGMS - Prevention of Food and Water Borne Diseases (4)

| Animal Lines |
|---|
| State of repair |
| Hyg / sanitation |
| Rat / fly |

Animal Lines

Animals - mules, horses, dogs, etc are authorised to animal holding units like Animal transport battalions of Army Service Corps and Dog units and veterinary hospitals of Corps of Remount and Veterinary Corps. In addition, some units may also maintain Dairy animals for the welfare of the troops located in some inaccessible or hilly areas where fresh milk may not be easily available. The chief sanitary problem of the animal lines is the collection and disposal of animal litter in such a way as to prevent fly breeding. RMO / AMA must visit the animal lines frequently to maintain vigilance on the method of removal and storage of animal litter pending final disposal as it is a potential fly-breeding place in a unit. The floors of animal standing and for their litter should be made of sound concrete; otherwise it is difficult to deal with fly menace. The RMO / AMA should satisfy himself that at no place in the system of removal and disposal of animal litter there is any possibility of fly breeding. The grain stores for feeding the animals should be examined specially with a view to ensure that they are rat-proof.

| Waste disposal |
|---|
| **Sewage / sullage** |
| Type & serviceability |
| Blockage / overflow |
| Potential water contamination |
| **Refuse** |
| Disposal type |

Disposal of Waste

This should be inspected at the end of the tour. The methods of disposal are described in Chapter V. Military sewage disposal plants in large stations are under central control of Military Engineering Service (MES) ; the RMO / AMA during sanitary round has little role to play in this aspect. However, in small stations a sewage disposal plant may come under the unit's sanitary control and should be inspected by the RMO/ AMA for its efficiency. The RMO / AMA should proceed as follows to ensure the efficiency of methods adopted :

Excreta Disposal

Temporary systems of excreta disposal (shallow / deep trench latrines) are constructed for use for short durations upto a year These latrines require strict monitoring to ensure maintenance in hygienic condition. RMO/ AMA

may need to make a daily inspection of these latrines. The points to be noted are cleanliness of latrine seats, oiling of the rammed down earth surrounding the latrine seats and daily spray of insecticides to prevent fly breeding (Dichlorovos (Nuvan) 100ml in 10 litres of water can be sprayed over 500sqm surface).

**Water carriage system**

If a water carriage system connected to main municipal drainage is in use, very little attention is needed except to ensure that the latrines and urinals are clean, the flushing system is working efficiently and that there are no leakages, breakages and blockages in the whole system. In cantonments, garrison stations and permanent camps this is the method of choice. At the time of construction, the sewage pipelines are laid below the level of water distribution pipelines. However, it is likely that due to blockages, raw sewage may overflow and lead to sewage accumulating in areas through which water pipes are passing. In case of leakages in the pipelines providing intermittent water supply, there is a strong chance of contamination of water supplies due to negative pressure in the pipes when there is no water in the pipes and an outbreak of water borne diseases like gastro-enteritis, viral hepatitis, enteric fever, etc can occur. It is necessary to be aware of the layout of water and sewage pipelines in the unit area. Monitoring of any sewage overflow from manholes and prompt corrective action through MES are necessary. RMO / AMA plays an important role in early detection of such overflows during his periodic visits to different parts of the unit and educating the personnel on necessity to report such overflows immediately to QM and himself.

**Septic tanks**

Wherever septic tanks are used their efficacy and maintenance should be checked. Effluents from septic tanks are usually connected through perforated pipes to the soil after a period of treatment. This enables aerobic digestion and ultimate disposal as water and carbon dioxide. The septic tanks need periodic maintenance by MES. Bailing out the sludge at the bottom of the tank as well as the scum on top and disposal by burying in pits ensures that the septic tank is in appropriate state of functioning. In case the septic tank fills up in spite of periodic maintenance, the fluids can be pumped out after digging appropriate pits and burial. It is a sign however, that new septic tank is required to be constructed.

Refuse Disposal

Control should be kept over refuse collection and disposal in a hygienic manner. Unit hygiene and sanitary squads must be properly trained to construct and maintain the sanitary appliances. The beehive incinerator is ideal for any camp except the purely temporary camp in which proper drum incinerators should be used. All cook house refuse should be appropriately disposed as it is a source of fly nuisance. In military stations refuse disposal is usually entrusted through a conservancy agreement to Cantonment Board. Refuse is to be conveyed to designated garbage points / bins under unit or station responsibility. Cantonment Board conservancy staff remove the refuse from these points for final disposal periodically - usually on alternate days. Burial as a method of refuse disposal is superior to burning if properly conducted with a layer of mud covering the day's refuse. Dumping as a method should not be adopted except as a last and temporary resort. It attracts rats and flies, breeds cockroaches and creates general unhygienic conditions around kitchen. Bio-degradable refuse may be disposed by vermi-composting or other such methods of in situ disposal.

Sullage Disposal

In permanent camps, garrison stations and cantonments, underground drainage connected with the main sewage system is ideal; otherwise disposal in large streams or soakage pits should be resorted to. In every case grease traps and gully traps should be properly constructed and maintained.

Animal Litter

It should be disposed off by trenching, composting, tight packing or incineration according to the facilities available, amount of litter, and duration of the camp.

Medical Inspection Room (MI Room) or Regimental Aid Post (RAP)

Promotion and maintenance of health of troops being the concern of the CO of the unit, it is incumbent upon the unit administration to make provision for a suitable, centrally located, Medical Inspection Room (MI Room) /Regimental Aid Post (RAP) where detection of illness and adequate treatment for needy soldiers can be provided by the RMO / AMA conveniently and comfortably. The MI Room is a peace time designation while in operational areas or during War the term RAP is used. The authorisation of medical and ordnance stores are however the same for both. It should be kept meticulously clean, neat and tidy. It should be well equipped with all the medical and ordnance equipment as authorized. The work should be well organized and all equipment should always be in working order. The staff, nursing assistants and unit personnel trained for such duties (Battle field nursing assistants (BFNA) ) should be courteous and caring towards the sick and infirm seeking their assistance and be professionally competent to discharge the designated health care activities. Disposal of bio-medical waste generated from the MI Room / RAP has assumed an added importance in recent times with the greater awareness among all of the dangers posed by improper waste disposal on the lay population as well as health care workers.

**Action after the unit Inspection**

After the inspection, the CO of the unit inspected should be given a verbal report mentioning all defects and measures advised for their rectification. A severely critical written report should, except in very exceptional circumstances, be avoided as this usually leads to misunderstanding and defeats its objective which is to rectify the potential hazards identified. The written report, which also indicates the state of immunization of the troops and average daily sick attendance, is endorsed in

the sanitary diary which should be submitted to the CO as soon as possible after the inspection. The sanitary diary should be a large substantial book, which is not likely to be lost, and which allows a record of the sanitary state of the unit to be maintained over a long period. Its upto date maintenance is the unit's responsibility. A sample is enclosed as Appendix with pages ruled into three vertical columns as per page 25 of Defence Services Regulations headed 'Points to be commented', 'Remarks of RMO', CO's remarks and 'Action taken' (usually by QM) (2). The report should conclude with a summarization of the general sanitary condition of the camp as, for example, 'excellent'. 'good', fair' or 'poor'. Comments should always be constructive and the observation of a defect should invariably have a concrete recommendation for its rectification. It must be remembered that all actions connected with the inspection are for an official purpose and lack of appropriate action / response from any official should not be construed as a personal affront by RMO / AMA. The motive of unit inspection is to achieve a progressive improvement in environmental conditions for maintenance of high standards of health and battle-worthiness of the unit at all times and should be accordingly appreciated by all concerned. The inspection note should provide a valid guide to the CO for assessment of the health of troops, their morale, and living conditions. After the CO has scrutinized it and rectification recommended are carried out by the regimental officers concerned or the reasons for not carrying them out are given, the sanitary diary should be forwarded by the unit to the SEMO through OC SHO by the 10th of every month as per page 12 of Army Order - 25 / 2004 / DGMS - Prevention of Food and Water Borne Diseases (4). The report serves as a guide for the SEMO to further advise the CO of the unit and keep the formation commander / station commander informed. Therefore, difficulties experienced by the unit also should be mentioned. The RMO should, whenever necessary, obtain advice and help from the DADH, and OC Station health Organisation. The RMO should also advise the CO and Regimental Officers to go through the simple procedures on elementary hygiene as given in DGAFMS publication on "Elementary Hygiene" (6).

**SEMO / SMO Visit**

Senior Executive Medical Officer (SEMO) is usually the CO Military Hospital. However any other officer may be designated SEMO by ADMS / DDMS for whole or part of a station. He visits the units under his jurisdiction in the unit once in a quarter and informs the Station Commander of any shortcomings. He is responsible to ensure that RMOs and OC SHO carry out their duties and responsibilities. He must keep the ADMS / DDMS also informed about all matters affecting the health of troops in station. In stations where no military hospital is located the ADMS / DDMS of the field formation whose troops are located in station may detail a medical officer to carry out the duties of SEMO. Such an officer is designated as Senior Medical Officer (SMO) for the units entrusted to his care (7, 2).

**Assessment of Health**

General considerationsThe armed forces select persons who are medically FIT besides physically strong to subject them to grooming and conditioning in training centres for transforming them to "trained" soldiers / sailors / airmen. A group of physically and medically fit individuals are thus available to the Commanding officer (& to his RMO / AMA). The armed forces attempt to provide good nutrition and a reasonably safe environment for their peace time duties and conditions them (acclimatization) for adverse conditions on need basis to ensure availability of fit combatants for war. The RMO / AMA gets some idea of the state of health (or extent of ill health) and morale of personnel in the unit under his medical care from the "daily sick report". However, this only reveals the state of illness. It does not automatically follow that those who are NOT reporting ill are healthy. The thoroughly carried out, regular, periodical medical inspections are more revealing. This is a reliable method of keeping himself informed of the state of health of unit personnel. The RMO / AMA is required to carry out the medical inspection of the following :

(a) All food handlers once a month. (4)
(b) All ranks newly posted to the unit. (2)
(c) All ranks before proceeding on courses of instruction/ leave/ temporary duty
(d) PBOR returning from courses of instruction/ leave/ temporary duty (2)
(e) Recruits posted to the unit from regimental centres (2)
(f) All ranks joining their units after serving abroad / proceeding abroad (2)
(g) All unit personnel yearly (8, 9)

Such medical inspection enables the RMO / AMA to detect a disease early in an individual and the rising incidence of any disease / condition in the unit, early enough to enable him to take prompt action and to advise the CO on the control measures to be adopted.

Food handlers

The detailed instructions for food handlers have been enumerated in page 9 of AO 25/2004/DGMS. All food handlers are medically examined with a view to detect harbouring of infections by food handlers which can be communicated through food or drinks. "Food handlers" will include any person concerned with the collection, storage, purification, cooking, serving or distribution of food or water and maintenance of cook house / kitchen equipment. This term therefore refers to NCO i/c cook house, cooks, masalchis, mess waiters, bar tenders, all personnel working in wet canteen and aerated water factory and any civilian staff or PBOR employed in cook house / mess. Special care should be exercised to also ensure that such staff are not returned to food handling duties after an episode of diarrhoea, jaundice, furunculosis or boils or unexplained fever (which could be enteric fever). Similarly, working parties detailed for episodic requirements like for parties / barakhana or as cookhouse working detail should not be suffering from the above mentioned diseases (4).

Newly posted personnel or personnel reporting to unit after course of instruction / leave/ temporary duty

These personnel may be harbouring an infectious disease in mild manner, in its incubation period or in convalescent stage. Early detection and segregation / isolation are needed to prevent an outbreak of the disease among personnel of the new unit. Common examples are conjunctivitis or a respiratory viral infection. Such personnel may also be harbouring vector borne diseases like malaria (on suppressive therapy). A proper history taking and examination followed by appropriate action by RMO / AMA will prevent introduction of the disease among the unit personnel.

Personnel proceeding on courses

All personnel proceeding to attend courses of instruction are required to be in acceptable medical category compatible with the requirement of the course. A medical certificate is required to be issued accordingly by the RMO / AMA after conducting a general examination and verifying that the individual is protected from diseases by immunization and is not due for recategorisation of medical category (if in low but acceptable medical category). In case found to be not fit for the course, the individual must be referred to the concerned specialist at the nearest MH for opinion regarding fitness to attend the course. Institutions conducting the course lay down specific instructions which are available in the joining instructions issued to the individual.

Recruits joining the unit

All recruits joining the unit are screened for presence of a communicable disease as well as any visible disability which may have been acquired during the training period or during transit period.

Personnel proceeding abroad/returning from abroad

Personnel proceeding abroad are required to be medically fit. They are therefore medically examined as per stipulations laid down periodically which include ECG, Chest - X-Ray, blood examinations (including HIV). Administration of appropriate immunizations at an appropriate date and initiation of chemo suppressive therapy for malaria or other diseases if recommended also form part of the medical examination at such an occasion.

Personnel may be harbouring exotic diseases acquired abroad including sexually transmitted diseases like HIV. It is mandatory that all such personnel are therefore screened immediately after return.

Annual medical exam

Yearly medical inspection of all personnel implies a thorough inspection of a person for fitness. A detailed record is to be maintained of such inspections and the health record card filled up. Detailed instructions on methodology of annual medical examination for officers (Army order 1 / 2004 / DGMS) and for PBOR (Army order 3 / 2001 / DGMS) has been laid down. In view of the increasing incidence of chronic diseases like Diabetes mellitus and IHD affecting PBOR in the Army, a system of Periodic Medical Examination (involving a more detailed medical examination) has been started for JCOs during 41st year of age or within one year of becoming Naib Subedar (8, 9).

Civilians

In order to protect the health of service personnel, as few civilians as possible should be employed or allowed into the unit lines. Certain civilians are employed as regular civilian government employees / temporarily for leave relief, etc as per laid down policies. These civilians provide logistic assistance where combatants may not be authorized. Vendors and hawkers of food articles should not be allowed in the unit area. All civilians employed or permitted to work in unit lines should be under strict medical supervision. The following precaution must be taken by RMO / AMA to ensure that no civilian entering unit lines conveys an infection to personnel :

(a) Before any civilian is engaged he should be medically examined by the unit medical officer. If passed as fit, he should be inoculated against the enteric group of fevers.

(b) All civilians employed in the unit for duties involving food handling should be regularly inspected once a month in same manner as for cookhouse staff. They should all be re-inoculated when due.

(c) Before a civilian returns to duty after an absence for any cause, he should be medically examined; and if the absence has been due to illness, this should be kept in mind before passing him fit to return to his work.

(d) Civilians in dairy farms, canteens, cookhouses, messes, butcheries and barber's shop should be employed on a permanent or long term tenure and always more thoroughly examined.

(e) Short term hiring for few days of persons of unknown past medical history should be discouraged, specially for tasks like cooks or food handlers.

Inspection of school children

Medical examination should be carried out preferably once a year for all children studying in schools run by armed forces or for armed forces. School children are specially vulnerable to develop diseases or conditions which adversely affect their scholastic performance. However most of the disorders if detected early are curable / correctable and hence the importance of medical examination of school children. OC SHO is responsible to organize the medical examination of school children in a station. Resources required for conduct of the medical examination can be provided by SEMO. Some schools organize the medical examination from their own funds, however, coordination of activities, record keeping and follow up actions are required to be ensured by OC SHO in conjunction with school authorities.

A complete examination should be made of the children with the assistance of school teachers. The points to note are the general appearance and demeanour of each child, height, weight, eye sight (near & distance vision) teeth, tonsils & adenoids, & the intelligence and systemic examination. The teacher in charge of each class should

# Hospital Administration in Armed Forces Hospitals : An Overview

## Introduction

Hospitals are complex matrix organizations. In provisioning of effective patient care it is essential that both clinical and administrative issues are considered. A holistic understanding of these is essential for efficiency of the hospitals. It is important that Medical Officers (MOs) and specialist officers, in addition to their clinical skills, are also well versed with the important administrative issues in the hospitals. Important managerial and administrative issues likely to be encountered by MOs / specialists in the hospitals are discussed in this chapter.

## Ward Management

### Functions and Responsibilities

MO Incharge (I/C) ward is the overall in-charge of the ward. He is responsible for efficient performance of the staff placed under his charge. His duties / responsibilities include the following :

(a) Ensure that the prescribed medication is given to the patient.

(b) Ensure dangerous drugs are kept under safe custody.

(c) Ensure medicines are properly indented, checked, stored and accounted. He should check the expense book of drugs at least once a month.

(d) Ensure correct distribution of diet/extras to patients.

(e) Ensure functionality of equipment in the ward at all times.

(f) Supervise and take measures for maintenance of furniture and fittings.

(g) Ensure general cleanliness and upkeep of ward.

(h) Ensure visitors visit during authorised hours only.

(j) Ensure availability and updation of following documents and records in the ward:

(i) Day and night report book.

(ii) TPR recording book.

(iii) Treatment / Injection book.

(iv) SIL/DIL register.

(v) Instructions / Round book.

(vi) Controlled and local purchase drugs accounting book.

(vii) Dangerous drugs book.

(viii) Inventory Register.

(ix) Breakage / loss book.

(x) Lab report (Advance report book).

(xi) DMO call book.

(xii) Input and Output chart record.

(xiii) Demand book for various stores.

(xiv) Out pass book for inpatients.

(xv) Complaint book.

(xvi) Suggestion book.

(xvii) Admission and discharge book.

(xviii) Register for diets and extras.

(xix) Fire orders.

(xx) Expense book.

(k) Ensure timely diagnostic investigations of patient as advised.

(l) Ensure timely specialists opinion for patient management.

### Management of SIL/DIL patients

The salient features to be considered are:

(a) Patients admitted to service hospitals are placed on Dangerous ill list (DIL) or Seriously ill list (SIL), if they are brought to the hospital / MI Room in grave or serious condition or their condition worsens while being treated in the hospital to an extent that intense monitoring becomes necessary. Placing a patient on DIL/SIL is purely based on clinical judgment of a medical officer or specialist.

(b) The progress of SIL/DIL cases on the case sheets must be written once a day for SIL cases and twice a day for DIL cases.

(c) Reporting of the DIL/SIL patients to higher formation must be done as per policy guidelines (1).

(d) Relatives of personnel placed on DIL are authorised free conveyance (2). The various provisons available on the subject are :

(i) Two persons are entitled free conveyance by Rail / Road in the same class as entitled to patient.

(ii) If traveling by air only one person is entitled free conveyance. The second person may travel by rail / road. The second individual may be allowed to accompany the relative by air subject to the following conditions:

- Where the relative is a lady.
- Where the relative is a male but is over 60 yrs of age or is infirm/physically handicapped.

(iii) The return journey is to be performed by rail/road and will be limited to the same persons who are provided free conveyance for the onward journey.

(iv) Airlift by service aircraft for hospitals in areas inapproachable by any civil means of conveyance (3).

(e) Free of cost ration may be issued at the scale laid down in Table-1, SRS/AI dt. 10/3/76 to the relatives of patients of the rank of JCO/OR and equivalent ranks in Navy/Air Force placed on

SIL/DIL in Service Hospitals not exceeding 02 in number for each patient. This concession is admissible only to the relatives of patients who are admitted is Service Hospitals which are located beyond a distance of 02 kms from the market (4).

Medical Ethics and Medico Legal Issues

The important points to be considered are as follows. Further details are given in the next chapter.

**(a) Misconduct**

MO I/C ward should ensure that there is no abuse of professional position by committing improper conduct with patients or by maintaining an improper association with patients. A male medical officer should examine a female patient only in the presence of husband/female attendant.

**(b) Consent**

The rights of the patient must be respected. Patients must be informed about their treatment and illness details. Written consent must be taken especially for the following :

(i) Surgical procedures.
(ii) Anaesthesia.
(iii) Disposal of tissues/organs removed during operation.
(iv) From NOK for autopsy examination in cases other than the medico-legal.

**(c) Refusal of treatment**

When the patient refuses treatment or insists on discharge from the hospital against medical advice after he has been explained the consequences, a certificate must be taken from him that he is seeking discharge/refusing treatment. The unit of the individual and CO/Registrar of the hospital should be immediately informed.

**(d) Discharge in Absentia**

If the patient leaves the hospital without having been discharged, the patient should be discharged in absentia and following to be informed immediately (5).

(i) CO/Registrar
(ii) CMP
(iii) Civil Police
(iv) NOK
(v) Unit concerned
(vi) Higher authorities

However all efforts to find the patient should be made before discharging a patient in absentia.

Medical Officers / Specialists should be conversant with the provisions of the following

**(a) Consumer Protection Act, 1986**

The Government of India enacted the Consumer Protection Act in the year 1986 with a view to provide simple, speedy & inexpensive redressal for consumer grievances related to defective goods, deficient services 7 unfair trade practices. A doctor can be held liable under the Consumer Protection Act, 1986 for deficiency of service. The National Consumer Disputes Redressal Commission and later the Supreme Court of India in the case of Indian Medical Association V/s V.P. Shantha, (AIR 1996 SC 550) has held that the services rendered by the medical practitioner is included and covered under the definition of services as per Section 2 (l)(o) of the Consumer Protection Act, 1986.

**(b) Right to Information Act 2005**

The Right to Information Act enacted in the year 2005, provides for setting out the practical regime of right to information for citizens to secure access to information under the control of public authorities, in order to promote transparency and accountability in the working of every public authority. The Public Information Officers (PIOs) are to provide timely information to person seeking information. Information such as that available to a person in his fiduciary relationship or which relates to personal info the discharge of which has no relationship to any public activity is exempt from disclosure. The Armed Forces are also under the purview of this act. The guidelines for providing information in the Armed Forces have been elucidated vide Human Right Cell, Addl Dte Gen Discipline and Vigilance, AG's Br, AHQ vide letter No 17732/6/Info Act/AG/DV-1(c) dt 18 Nov 2005. The PIO in the Armed Forces at various levels are as shown in Table 1. In the O/o DGAFMS, Director, AFMC (Coord) is the PIO for various sections and the DGHS (Armed Forces) is the Appellate Authority (Auth : DGAFMS, DG 1 (c), Army HQ, New Delhi letter No 43244/RTI/2006-07/Gen/DG-Ic dt 07 Dec 2006.

**(c) Medical Termination of Pregnancy Act, 1971**

Table - 1 : Public Information Officers in Armed Forces

| Formation | PIO | SOs of 'A' Br |
|---|---|---|
| Integrated HQ of MoD (Army) Command | Additional Director General of Public Info Brig | **Appellate Authority** DGD.C & W/AG's Branch |
| Corps/Area/Sub Area | 'A' (D & V) Col A | Chief of Staff |
| Stn HQ/Units/Est | | |

The MTP Act of 1971 lays down the condition under which a pregnancy can be terminated, the person(s) who can perform such termination and the place where such termination can be performed. Written consent of the guardian is necessary before performing abortion in women under 18 years of age.

**(d) Prenatal Diagnostic Technique (Regulation and Prevention of Misuse) Act and Rules. 1994 (amended 2002)**

Diagnostic Techniques (Regulation and Prevention of Misuse) Act, 1994, was enacted and brought into operation from 1st January, 1996, in order to check female foeticide. The Act prohibits determination and disclosure of the sex of foetus. It also prohibits any advertisements relating to pre-natal determination of sex

and prescribes punishment for its contravention. All hospitals/medical establishment in AFMC having Ultra sonography medicines are to be registered (Auth : O/o DGAFMS letter No 20028/PNDT/DGAFMS/DG-3A dated 28 Jul 2002). The various action, reports and returns that are to be furnished are detailed in the letters.

### Issue of Medical Certificates

All medical and medico-legal certificates and reports issued from a hospital are to be issued by the Administrative Authority of the hospital i. e. CO/Registrar/Administrative Officer. MO I/C ward should not issue certificates of such nature. A record of issue of such certificates to be maintained in the hospital.

### Bio Medical Waste Management

In wards should be done as per guidelines issued by O/o DG'sMS (6). Ward SOPs should be prepared for the management of biomedical waste. These should be in consonance with the hospital SOPs and guidelines issued by O/o DG'sMS . Accident reporting should be as per Appx `B' of DGMS (Army) letter and maintenance of records as per Appx 'C' of the ibid letter. Periodic bio waste audit should be done for improvement in processes and procedures. Details of Bio Medical Waste Management is discussed in a separate chapter.

### Fire Safety

One fire point is authorized for a ward having 24 beds (7). All patients must be briefed on actions to be taken in case of a fire in the ward / hospital. Appropriate structural and functional actions to be undertaken by the hospital. Regular fire fighting practice make the staff alert and prepares them to take appropriate action during fire hazards.

### Inpatient Death

All cases of hospital in-patient deaths will be attended by the Medical Officer-in-charge (MO I/C) of the ward during working hours or by the Duty Medical Officer (DMO) once the working hours are over. When death is declared by the Medical Officer, following actions are required to be undertaken by him :

(a) Death certificate AFMSF-93 (Part-I) is to be issued, mentioning diseases/ conditions directly leading to death, along with the antecedent causes, giving rise to such conditions. If the MO has examined the person before death and is sure of the cause of death and has no doubt about the death he should issue the death certificate (AFMSF-93, Part I) immediately. Cases of unnatural deaths (suicidal, accidental and homicidal) or when there is suspicion about death being natural, are to be reported to police for investigations as a medico legal case (MLC). Commandant / CO of the hospital must be kept informed.

(b) Arrangements should be made for speedy disposal of dead bodies from the wards to the mortuary. The Chief Ward Master and the mortuary duty staff should be immediately informed for this purpose.

(c) The Stats Section of the Hospital / Duty Clerk is instructed to pass a telegraphic message / signal to the NOK of the deceased and to others concerned, as per laid down policy.

(d) In medico-legal cases, the civil police is to be informed in writing.

(e) Detailed case notes should be written in the medical case sheets. Details of incidence leading to death of the individual, the clinical findings and the course of management, undertaken before death of the individual, are required to be mentioned.

(f) In case of `Sudden Death' in the hospital, Medico Legal Case (MLC) should be initiated in all cases and civil police to be informed.

### Accounting of Drugs and Stores (8)

The do's and don'ts for accounting of drugs and stores in wards is given in Box - 1.

**Box 1 : Do's and don'ts for accounting of drugs**

**Do's**

Following must be strictly accounted for in expense books.

- All NIV items.
- Expensive and easily pillferable items.
- Schedule E (Narcotics and Dangerous Drugs) of Drugs Act1940.
- Prepare indents in triplicate.
- Tally quantity issued by Medical Stores and quantity received by wards.
- For routine indents frequency of indenting should be:
  - ICU - weekly
  - Acute wards - fortnightly
  - Chronic wards - monthly
- Intimate Medical Stores of drugs/expendable items likely to expire at least 3 months before date of expiry.
- Maintain inventory for non-expendable items.

**Don'ts**

- Overstock drugs in wards.
- Place urgent indents too frequently.
- Countersign handing-taking certificate for

### Indices of Measurement of Hospital Utilisation

Hospitals generate various types of information from its various wards and departments. Hospital utilisation indices are one of the important data generated within a hospital. Some of the important indices related to hospitals are as follows:

**(a) Bed Complement**

The bed complement of a hospital is the total number of hospital beds available for use by in patients. In the Armed Forces it is called authorised beds.

**(b) Hospital bed**

A hospital bed is the one which is regularly maintained and staffed for the accommodation and full time care of a succession of in-patient and is situated in wards or areas of the hospital in which continuous medical care for inpatients is normally provided. This does not include healthy babies in maternity wards but includes incubators and bassinets for premature babies.

**(c) Admission**

Admission refers to the number per year of acceptances by a hospital of a patient who is to receive medical care while in residence therein and who is expected to remain in hospital for one or more nights. Healthy, newborn babies should not be counted as inpatient admissions, but babies requiring special care should be included among the admissions.

**(d) Discharge and Deaths**

The annual number of discharges includes the number of patients who have left the hospital (cured, improved, etc.) , the number who have transferred to another health or social institution and the number who have died.

**(e) Bed days or patient days**

"Bed day" or Patient day" is the unit of measure denoting the service rendered to one in patient in the hospital census between one day and the succeeding one. Sometimes the day of admission and the day of discharge are counted as one day. In other cases, a full day is counted only when admission is before mid day or discharge after mid-day. Thus, the data given should be the annual total of the daily census of occupied inpatient beds throughout the reporting year.

**(f) Average Length of Stay (ALS)**

This index indicates the average period in hospital (in days) per patient admitted. This figure may be calculated by adding cumulative number of bed-days of all discharged patient (including those dying in hospital) during one year divided by the number of discharges and dead patients. The hospitals holding patients of general nature as well as chronic cases should calculate the ALS separately. e.g. Patient "A" is discharged from hospital after staying in a hospital for 10 days, patient "B" died after 4 days of admission and patient "C" left hospital on transfer after 4 days of stay. The average length of stay of these patients would be ( (10+4+4)/(2+1))=6days

**(g) Bed Occupancy Rate (BOR)**

This figure expresses the average percentage occupancy of hospital beds. It is calculated by dividing the daily average number of beds occupied (obtained from the daily census of occupied beds) by the bed complement (nominal number of beds in the establishment) and multiplying by 100. e.g. If 130 beds are occupied of the total 200 beds, the bed occupancy rate for the said hospital would be 130/200 x 100 = 65%.

**(h) Hospital Care Evaluation Statistics**

There are certain other statistical values in addition to patient mortality and morbidity indices given above which reflect on the quality of care rendered by the hospitals. These are used in comparing the standard of work performed in different hospitals or in the same hospital at different periods. These are enumerated below :

(i) Post operative infection rate.
(ii) Post operative complication rate.
(iii) Caesarian section rate.
(iv) Autopsy rate.
(v) Rate of normal tissue removed.
(vi) Percentage of disagreement between final and pathological diagnosis.
(vii) Gross result of treatment i. e. patients discharged, recovered, improved and not relieved.

The do's & don'ts for ward management are given in

Box - 2 : The do's and don'ts for ward management

**Do's**

- Ensure correct and timely medication to patients.
- Ensure timely diagnostic investigations of patients.
- Ensure correct availability / accounting of drugs.
- Keep dangerous drugs under lock and key.
- Ensure functionality of equipment.
- Update documents timely.
- Measure hospital indices.
- Take appropriate consent from patients especially prior to surgical procedures. Keep the Registrar/ Commandant informed of any untoward incident in wards.
- Dispose biomedical waste as per guidelines. Ensure fire safety for patients and staff.

**Don'ts**

Box-2

**Out patient department (OPD)**

Out patient department is a section of the hospital where a person is given general or emergency diagnostic, therapeutic or preventive health service on an ambulatory basis, at regular hours by qualified personnel. OPD is rightly called the "Shop window" of the hospital. It makes the first impression on the visitor, as it is the first contact point. It is most important that adequate facilities are provided in this area. Some of the suggested measures for judging the performance of OPD are listed in following paragraphs :

(a) Workload

A record of the workload of OPD attendance, admission etc. provides the backdrop against which performance should be judged. Emergencies should be reflected separately, since they consume more time, effort and resources.

(b) Waiting Time

This is the most important factor in patient satisfaction. The shorter the waiting time in an OPD, the better is the state of satisfaction. Some waiting is unavoidable in a busy OPD. However, no patient should be expected to wait for more than 30 min for consultation.

(c) Comfort and Conveniences

Provision of appropriate facilities in OPD go a long way in improving image of the hospital, e. g. toilets, drinking water, cafeteria, music, TV, spacious lobby, waiting area, telephone, etc.

(d) Transport

Ambulance must be on standby 24 hours under control of MO I/C. At least one ambulance should be equipped with life support equipment.

(e) Behaviour of Staff

Most complaints against hospitals are due to rude behaviour of the staff. It is the responsibility of the MO I/C to inculcate the correct behaviour pattern in his/her staff and also to remain vigilant towards any breach of etiquette.

(f) Turnaround Time

This is the time taken for reports of Laboratory tests / other investigation reports / X-Rays to become available to patient. Efforts should be made to give patients their reports on the same day.

(g) Availability of Staff

Absence of doctors or paramedical staff from their place of duty is a significant factor in patient dissatisfaction. It should be ensured that doctors reach the OPDs in time and do not leave their duty station for trivial reasons.

(h) Availability of Equipment

Absence of needed equipment, or non-functioning equipment, is not only bad for the image of a hospital but can cost a patient his/her life. Hence all equipment must be functional at all times.

(j) Grievance Redressal System

Patient should know whom to approach in case he/she has a problem. The presence of a"May I Help You" counter may serve this need. Suggestion books or suggestion boxes must be provided to enable patients to express their views, complementary or otherwise, about the department.

(k) Patient Satisfaction Survey

To know the patients perception of services being provided, surveys to know their views/suggestion must be conducted. The results of these must be analysed and improvement in process / procedures / infrastructure incorporated.

Intimation of Medico Legal Cases to Civil Police

MO I/C MI Room / DMO is responsible to inform all cases of accident, suicide & homicide to the police, as required under Sec 39 of Cr PC. MO I/C MI Room / DMO / Specialist who order the stomach wash in suspected cases of poisoning is responsible for safe custody of the fluid obtained till it is handed over to the police. Same is the case with other substances like vomitus, stools, container of poison etc. (Sec 201 IPC). A careful labeling of these specimen hold legal importance.

Found Dead (BID) Cases

The following actions are to be taken in case of found Dead / Sudden Death Cases:

(a) The deceased to be examined in detail by the MO I/C MI Room / DMO and death confirmed.

(b) The identification marks to be recorded accurately,

(c) The circumstances leading to death to be ascertained from the person (s) bringing and identifying the body.

(d) All particulars of the person (s) bringing the deceased to be noted in the case sheet and statement given by them will be endorsed in the case sheet.

(e) Civil police to be informed in writing

(f) MO I/C MI Room / DMO to inform Comdt, Sr Registrar, Stats Sec/Duty Clk and CMP immediately.

(g) Body to be sent to mortuary for preservation.

(h) If no clearance is given by the police, the body to be handed over to them for further disposal, after taking proper receipt.

(j) In case the body is sent for postmortem to civil hospital, a brief summary of the case to be given to civil police. Under no circumstances the fatal case documents are to be handed over to civil police.

(k) The body will not be handed over to NOK without clearance of civil police in writing.

(l) The following documents will be initiated by MOIC MI Room/DMO:

(i) Flimsy (AFMSF 8A)

(ii) Case sheet (AFMSF 7)

(iii) Death Certificate (AFMSF 93 Part I) in red ink

(iv) Record of summary in Medico Legal Register

Case of Alleged Rape

Rape being a serious criminal offence, the nearest police station should be informed immediately and necessary examinations of accused and the victim to be carried out by authorised Medical Officer.

Do's and Dont's for OPD are given in Box - 3.

**Medical Stores**

Armed Forces Medical Services has a well-organized system of provisioning and procurement of Medical stores and it is undertaken by DG-2 group at the officer of DGAFMS.

Classification of Medical Stores

The Medical Stores are divided into the following categories

(a) **Expendable Medical Stores** : Depending on the life of pharmaceutical product these are further

**Box - 3 : Do's and don'ts for OPD management**

**Do's**

- Examination of female patients should be done only in the presence of husband/female attendant.
- Plan for accessibility to various facilities for patients/visitors with disability.
- Plan to ensure design follows function.
- Design to cater for future expansion.
- Plan effective signage system.
- Design for unilateral flow of patients and visitors.
- Plan to cater effectively for peak hours.
- Specify the role of MI Room / OPD in Disaster Management.
- Do maintain a separate medico legal register and ensure its safe custody.
- If patient is in a dying state and is giving a statement, record the dying declaration. Two witnesses should also be incorporated. Treatment should precede all legal formalities.

**Don'ts**

- Do not refuse emergency treatment to non-entitled cases.
- Do not throw away bullets/pellets/clothing of patients in medico legal cases.

categorized into:

(i) Short life, having shelf life of 2 years

(ii) Long life having shelf life more than 2 years

(b) **Non-expendable medical stores** : These consist of electro medical and non electro-medical equipment.

Important Terminologies

The following are some important terminologies regarding Medical Stores:

(a) **Medical Equipment Scale (ME Scales)** : This is the list of Medical Store items authorised to units and forms the basis for indenting.

(b) **Priced Vocabulary of Medical** : Stores (PVMS). This is a catalogue of government-approved list of Medical Stores in common use. Introduction / deletion of items is done by Drug Review Committee, which generally meets once a year under the chairmanship of DGAFMS.

(c) **Not in Vocabulary (NIV) Items** : These are items not included in the PVMS list. These are usually recently marketed drugs/equipment which have yet not been introduced in the PVMS.

(d) **Monthly Maintenance Figure (MMF) :** It is the average consumption of pharmaceutical products and forms the basis for calculation of requirement in indents. Availability of the product needs to be considered while calculating the requirement.

Disposal of surplus stores

The stores held in units may become surplus either due to change in authorisation or change in the requirement. Hospitals should intimate Command HQs, dependent depots and O/o DGAFMS to give disposal of surplus drugs/drugs nearing expiry date. As per the policy in vogue, DDOs may ask firms to replace unconsumed stocks 03 months before date of expiry free of cost. (9)

Disposal of Stores suspected of Toxicity

Drugs and other Medical Stores found to be defective should be disposed off in accordance with DGAFMS policy on the subject (10). The use of suspected product should be suspended immediately. Office of DGAFMS/DG-2E and the concerned Medical Stores Depot should be informed immediately and specimen of the suspected product should be sent to Controller of Quality (CQA), Kanpur for testing. The suspected product should be segregated and stored till clearance is received from O/o DGAFMS/CQA. Records of such cases should be maintained.

Table - 2 : Financial Powers of Competent Financial Authorities

| CFA | Without Consultation | With consultation with IFA |
|---|---|---|
| Maj Gen | Rs. 1, 00, 000/- | Rs. 2, 00, 000/- |
| Brig | Rs. 50, 000/- | Rs. 1, 00, 000/- |
| Col | Rs. 30, 000/- | Rs. 60, 000/- |
| Lt Col | Rs. 20, 000/- | Rs. 40, 000/- |

Financial Power of the CO/ Commandant

Financial Power of the CO/ Commandant of Hospitals for Local Purchase. The financial powers of the various CFAs is given in Table 2: (11)

Direct Demanding Officers (DDOs)

The salient features of the policy guidelines on the subject are as follows (9):

(a) Rate Contract (RC) powers for both PVMS and NIV drugs and consumables upto a value of Rs. 5 crore have been delegated to DGAFMS.

(b) Hospitals commanded by Brigs and above and four hospitals of Navy and Air Force commanded by Col and equivalent have been made Direct Demanding Officers (DDOs) to empower them to obtain their supplies of drugs and consumables directly from the vendor with whom RCs have been concluded by DGAFMS.

(c) Procurement against Rate Contract (RCs). Important points are as follows:

(i) Drugs and consumables with an annual turnover of more than 20 lakhs are to be progressed for Rate Contract.

(ii) DDOs must submit correct MMF every year to DGAFMS based on which DGAFMS will decide

on the quantum of drug/consumables for RC.

(iii) In case of non supply/delay in supply against central supply order and whenever deemed essential, DDOs may place supply order on Rate Contract holder directly under intimation to DGAFMS.

Local Purchase of Medical Stores by DDO

The following are the salient points for the local purchase:

(a) **Registration of suppliers :** Firms from where the purchases are to occur should be registered by a Board of Officers, duly approved by DDO. Item wise database should be maintained which should be reviewed ever year.

(b) **Tendering** : Two-bid system should be followed for all procurements. Bids should be asked, evaluated and selected first on fulfilling technical specifications and then being the lowest in financial terms. Details of tendering including preparation of Tender Enquiry, quantity to be procured, tender opening, preparation of Comparative Statement, Price Negotiation, placement of Supply Order, Acceptance of Contract, repeat orders, delivery and inspection of stores and payment of bills should be done meticulously. The essential requirements are:

(i) Tender Enquiry must include full details of the item required, delivery date, terms and conditions including payment terms.

(ii) The quantity to be procured should be calculated so as to ensure optimal availability.

(iii) The supply order should contain the name and address of contractor, contractor's quotation number and date, inspection authority, place of delivery, date of delivery, specifications of the pharmaceutical product/equipment, labeling particulars and packing details. Supply order should incorporate a cause that products supplied should have a minimum of 5/6th of balance shelf life at the time of supply.

(iv) Repeat orders should ensure:

- Items ordered in the original order have been delivered successfully.
- Repeat orders quantity is to be restricted to a maximum of 50% of original quantity.
- Placed within one year from date of supply against previous order and only once.
- Items are obtained at the same price as before and there has been no reduction in the price.

The important do's and don'ts of indents of medical stores are given in Box-4.

**Box - 4 : Do's and don'ts for indents of medical stores**

**Do's**

- Do indent item s of the same group and same PVMS section in the same indent sheet. Do quote the authority for indenting (ME Scale / GOI letter etc.)
- Do write the correct six /seven digit PVMS number in the indent.
- Do mention the correct NRS (Nearest Railway Station) in the indent sheet. Do forward requisite copies of indent sheet.
- Do reflect the correct MMF.
- Do submit the schedule of indent along with the indent.
- Do forward the sample signature of the indenting officer to the Depot.

**Don'ts**

- Do not mix up items of different group (special/short life/long life) in the same indent sheet. Do not place an indent at a wrong period.
- Do not exceed the number of items in a single indent

## Equipment Management

Effective management and efficient maintenance of hospital equipment have an impact on all aspects of patient care. Equipment management includes need assessment, procurement, inventorying, utilization, maintenance repairs, condemnation and disposal. An effective equipment maintenance plan saves lives, contains costs and ensures patient and staff satisfaction.

AO 5/99 and AO 12/2004 (12) gives details for procurement, stocking, issue, repair and maintenance of medical equipment. As per this AO medical equipment is categorized into the following:

(a) **Electro-Medical equipment :** Equipment listed in PVMS sections 25 and 28. Some equipment from other sections including NIV equipment are also categorised in this group.

(b) **Non-electro Medical equipment :** All mechanical, electrical and optical equipment not listed as electro-medical equipment or imported equipment are categorised as non-electro medical equipment.

(c) **Imported equipment :** These equipment are highly sophisticated in technology and procured either through foreign firms directly or through their Indian agents.

(d) **Gift equipment :** These are equipment received from non-public funds or as gift stores.

On receipt of the equipment from the AFMSDs it must be ensured that :

(a) Spares and accessories are received as per the equipment schedule of the manufacturer.

(b) Technical documents like the service/repair and maintenance manuals are available.

Maintenance of Equipment

The following are the salient aspects for effective maintenance of equipment:

**Box - 5 : Equipment maintenance objectives**

- Maximum availability, reliability of equipment.
- Useful life of equipment is extended.
- Safety of operations.
- Prevention of wastage of consumables.
- Maximum return on investment

(a) Equipment Maintenance Objectives (13) are listed in Box 5.

(b) Levels of maintenance are as follows

(i) First level. Maintenance carried in unit/ by operator of equipment.

(ii) Second level. By EME personnel in Station Workshop.

(iii) Third Level. By EME personnel in workshop (CRC) / AFMSD Pune / Equipment manufacturer)

(c) Classification of Types of Maintenance of equipment :

(i) Preventive Maintenance. This is the maintenance carried out at predetermined intervals or according to prescribed criteria and intended to reduce the probability of failure of functioning of an item.

(ii) Breakdown Maintenance. This is the maintenance carried out after fault recognition and is intended to put equipment into a state in which it can perform a required function.

Repair of Equipment

The following are the salient features regarding repair of equipment.

(a) For sophisticated / costly equipment. These will be maintained and repaired by the firm by undertaking the Annual Maintenance Contract.

(b) Non-electro equipment not under AMC is sent for repairs to the dependent EME workshop. If the repairs cannot be done equipment is labeled "Beyond Economical Repair (BER)".

(c) Electro-medical equipment not under AMC is sent to workshops designated as nodal repair workshops. If the repairs cannot be done the equipment is labeled "Beyond Local Repair (BLR)" and sent to nominated Command Repair Cell (CRC) or AFMSD, Pune

(d) If the equipment cannot be repaired at CRC or AFMSD it is declared BER. If the repairs cannot be under taken through workshops it may be carried out through a civilian firm. The financial powers for repairs are given at Table 3 : (12, 14)

Table - 3 : Financial Powers for Repair of Equipment

| Designation | Financial Powers |
|---|---|
| Commandant / COs Upto Col | Rs. 5, 000/- per repair |
| Brig & above | Rs. 25, 000/- per repair |
| Commandants: AFMSDs / AFT | CRs. 25, 000/- per repair |
| DGAFMS | Rs. 1, 00, 000/- per |

(e) The following maintenance performance indices may be utilised to determine the maintenance state of equipment:

$$\text{Downtime Index} = \frac{\text{Downtime hours}}{\text{Service hours}} \times 100$$

(i) $$\text{Maintenance Cost Index} = \frac{\text{Maintenance Cost}}{\text{Capital Cost}} \times 100$$

(ii)

(f) Log Book : This should be maintained for all important / costly equipment to facilitate maintenance state. This should include the following details :

(i) Name of equipment

(ii) Date of purchase

(iii) Cost of equipment

(iv) Name, address, fax, e-mail and phone Nos of supplier

(v) Date of installation

(vi) Spare parts of Inventory

(vii) Technical / users manual / circuit diagrams

(viii) AMC details

(ix) Warranty period

(x) Breakdown details

(xi) Repair details

(xii) Preventive maintenance details

**Box - 6 : Do's and Don'ts for Equipment Management**

**Do's**

- Do follow the guidelines and instructions for equipment management as given in AO 5/99 and policy letters of O/o DGAFMS.
- On receipt of equipment from AFMSD ensure that spares and accessories are received as per the equipment schedule of the manufacture along with service, repair and maintenance manuals.
- Do follow preventive maintenance.
- Do utilise the equipment performance indices.
- Do maintain log book for critical/costly equipment.
- Do utilise Armed Forces as well as authorized civil, repair facilities for early repair of equipment.

**Don'ts**

- Do not follow only breakdown maintenance for equipment (preventive maintenance is must).
- Do not get equipment repaired through unauthorised sources.
- Do not let a equipment be non functional for want of repair. Take prompt actions and follow up for early

The important do's and don'ts for equipment management are given in Box - 6

**Fund Management**

Funds constitute the finances available with an institute, formation or an unit which are either allocated by the Government or raised through the contributions from the serving personnel, canteen profit or rebates from regimental contractor / institute (15).

These are of two types :

(a) Government Funds. These are further sub divided into:
  (i) Public funds
  (ii) Imprest Account
(b) Regimental fund & Private funds

Public Funds

These include all funds, which are financed entirely from public money. Unspent amount is refunded to Government (in the event of it not been utilised within the same financial year). Following funds are included in this group :

(a) Annual Training Grant (ATG)
(b) Educational Training Grant (ETG)
(c) Library Grant
(d) Amenity Grant
(e) Incidental & Miscellaneous Grant (I & M) / Annual Contingency Grant (ACG)
(f) Civ Pay & allowance
(g) Hospital Stoppage Rolls (HSR)

**Annual Training Grant (ATG)**

This is a grant meant for Trg Aids and Eqpt. It is allotted by DGMT (GS Br) to Command and Formation HQs. It is then sub-allotted by the Formation HQs to units under their administrative jurisdiction. The management of this fund is governed by AIs 26/79 as amended vide AI 29/80 (16). Items which may be purchased from ATG include trg items, which are not in WET e. g. hiring tpt for training purpose, weapon-trg stores, training aid-audio visual, map reading stores and stationery can be purchased through these funds.

**Education Training Grant**

The grant is meant for periodicals, newspaper and magazines for troops. The claim is submitted to the CDA on contingent bill quarterly, based on actual posted strength present in the unit on the last day of every quarter. Items that can be purchased from this grant are – Educational items for unit school e. g. books, periodicals and stationery and other items for info rooms. The management of ETG is governed by provisions of AIs 9/84 and 24/91.

**Amenity Grant**

This grant facilitates expenditure on welfare of troops and patients. Its allotment is made out of Defence Service Estimates based on strength of troops. It is claimed in two equal installments, in Apr & Oct of year from the Regional Controller of Defence Accounts.

**Annual Contingency Grant (ACG) & Annual Stationery Grant (ASG)**

Earlier known as Incidental and Miscellaneous (I&M) grant. Contingent expenditure comprises of all those charges which are incidental to the management of a unit / establishment / office and include the cost of postage, telegrams etc. telephone charges, advertisements, office rent, books and periodicals, charges on hot weather appliances, liveries to office peons, repair of furniture, local transport charges on duty connected with the unit, garden impliments and other similar petty charges.

**Hospital Stoppage Roll (HSR)**

Money charged from dependent & family members of Offr, Para Military personnel, non entitled cases, Officers PSO and retd officer and their family members for hospitalisation period, is deposited in Government treasury.

**Imprest Account**

Imprest is advances of public money issued in bulk to certain nominated officers termed as 'Imprest Holders'. Imprest is maintained on IAFA-125 (Cash account book). All transactions, i. e. receipt / payments will be supported by vouchers i. e. acquittance rolls / MROs / Contingent bills. Expenditure from the imprest account can be undertaken for the following :

(a) JCOs/OR Pay & allowance.
(b) TA/DA advances to officers in exceptional cases when move is on short notice and money cannot be drawn from CDA (O)
(c) Condiment allowance of personnel.
(d) Rum & Cigarette allowance.
(e) Payment of funeral allowance.
(f) LTC adv JCO/OR.
(g) Urgent special investigation/treatment of patients in civil.

**Regimental Funds**

Regt funds are welfare funds of army which are raised through contribution by serving army personnel, canteen profits & rebates collected from regimental contractor. CO is trustee for regimental funds and is responsible for proper utilisation of funds. These funds are used for welfare activities and benefit of personnel and unit. It comprises of :

(a) All funds other than public funds mainly by unit, which are, financed either wholly or partly by public money.
(b) Private funds are those, which are not solely financed by public money. They are part of Regt funds.
  (i) Partly or wholly financed by public funds - Condiments allowance, Civ Labour welfare fund, Ex-Servicemen Fund.
  (ii) Privately financed funds – Unit funds, Sports

funds, Canteen profits, Religious institutes fund, Barrack damage fund, Officer Mess fund, JCO Club fund, Patient Comfort fund.

**Cash Books**

There are two types of cash books IAFA-125 & IAFA-811. History of the funds or source of income with scope of expenditure of all sub heads should be typed out and pasted on the first page of each book. Rate of Regt subscription and details of monthly remuneration as approved by CO will also be recorded on the first page. Cash books of Public and Regt funds are to be maint separately but on similar pattern. The following points must be remembered while writing cashbooks :

(a) There must be a separate book for every fund e. g. columnar cash book (IAFA-811) & cash acct book (IAFA-125) for Regt and Public funds.

(b) All entries must be in 'ink' with initials of accts officer.

(c) There should be no overwriting or erasing. Incorrect entries must be struck off with 'red ink' in a a straight line and correct entry inserted above it, duly attested by the officer (Auth: FR-II rule 46).

(d) At end of the month, the cashbook must be closed and balanced.

(e) Balance statement and balance sheet must be written in ink and bank reconciliation statement must be recorded monthly on the cashbook.

(f) Separate cashbook (IAFA-811) must be maintained by the cashier.

Box – 7 : Do's and don'ts for fund management

**Do's**

- Maintain separate cash accounts for Public and Regimental funds in RTC.
- Exercise supervision on all financial transactions. Sign only after studying and understanding the contents of financial documents. Keep cash in bank / RTC. Make entries for all transactions in cash books promptly. Surprise check of cash in RTC. Check details of sundry debitors and creditors.
- Prepare balance sheets monthly. Prepare conciliation statement between bank and unit account books.
- Expend the funds within stipulated time.

**Don'ts**

- Keep excessive cash balance in RTC.
- Exceed payment of pay and allowance beyond entitlements. Do unauthorised transactions between different funds.

The important do's and don'ts for fund management are given in Box - 7

Conclusion

In a hospital there are multiple and diverse administrative and managerial issues which emerge in provision of patient care activities. It is essential that MOs and specialists are acquainted with the likely issues/problems that may arise and the various options for dealing/solving them. Understanding and application of these is a major step in achieving patient satisfaction and continuous

# Legal Aspects of Health Care

## Medico-legal case

### Definition

A Medico-legal Case (MLC) is a case of injury or illness where the attending doctor, after eliciting history and examining the patient, thinks that investigation by law enforcement agencies is essential to establish and fix responsibility for the occurrence of injury or illness in accordance with the law of the land.

Section 39 of Cr PC gives the list of incidents, which must be reported to the police by every citizen, including the medical officer, irrespective of the outcome of the incident.

The following cases are to be registered as medico-legal cases:

(a) Vehicular accidents, factory accidents or any other unnatural mishaps.

(b) Suspected or evident homicides, suicides including attempted ones.

(c) Suspected or evident poisonings.

(d) Burn injuries due to any cause.

(e) Injury cases where foul play is suspected, if the doctor thinks that the patient is an accused or a victim in a crime

(f) Injury cases where there is likely hood of death in near future

(g) Suspected or evident sexual offences

(h) Unconsciousness when the cause of unconsciousness is not clear.

(j) Medico-legal Deaths – as elaborated in the subsequent chapters.

However the list is not exhaustive. Hence the above-mentioned general principle is the best guide.

If the MO fails to report ML Case to the police authorities he can be punished under Section 202 & 176 of Indian Penal Code (IPC) with imprisonment of either description for a tem which may extend to six months, or with fine, or with both.

### Registration of a medico-legal case - procedure

(a) In all medico-legal cases that are not brought by the Police, written intimation must be sent to the Police Station in whose area of jurisdiction the hospital or heath care center reporting a case is located.

(b) It is the legal duty of the first doctor who attends the case – Sec 39 of Cr PC.

(c) In case where a casualty medical officer has not labeled a case as medico legal but a treating physician in the ward feels that a case needs to be registered as a MLC, he should inform the hospital administrative authorities for such action.

(d) There is no stipulated time period beyond which a MLC cannot be registered. A case can be reported as MLC not only at any time of its stay in the hospital but also after death.

(f) Referred / Transfer cases – Although legally not mandatory to re-register in the new station, it is advisable to report the case to the local police authorities in the new station to avoid problems if the patient dies in the new hospital.

(g) At the time of discharge/transfer of the case the police station with which the case is registered as MLC should be informed, preferably well in advance.

### Medico-legal cases brought by the police

Whenever the police bring a person for medical examination, a requisition to that effect by the Investigating Officer (IO) or the Station House Officer (SHO) giving a brief description of facts pertaining to the case is submitted to the medical officer specifying the purpose of the examination. This requisition constitutes authority for the examination and issue of a medico-legal report/certificate.

A police constable must accompany the person to be examined to identify the examinee to the medical officer as well as to prevent impersonation.

The report/certificate is to be submitted to the concerned IO in a sealed envelope.

The MO must retain a copy of the certificate/report submitted.

These medico-legal certificates/reports are legal documents and hence need to be prepared with great care after thorough examination of the person. They are to withstand legal scrutiny subsequently during the court proceedings.

### Consent for medico-legal examination

Informed Consent of the examinee is a must for all medico-legal examinations.

The legal provision that the examinee is at liberty not to consent and submit himself to examination, even if he is the accused, should be brought to his notice. This provision is based on the general legal principle that no individual, including the accused, can be compelled to give evidence against himself. He should also be informed that the findings of the medico-legal examination will be presented in the court and they may turn-out to be against his interest.

If the individual refuses to consent, the refusal should be obtained in writing, witnessed and the individual is sent back to the IO. Forcible medical examination should never be carried out.

However, where a person has been arrested for committing an offence and produced for medical examination under Sec 53 of the Cr PC, he can be

examined under force even if he refuses to give consent. The police is asked to make him ready for examination after his refusal is recorded.

Consent for medico-legal examination should always be a written expressed consent irrespective of the nature of examination.

As far as possible, the examination of a female should be conducted by a female registered medical practitioner. A male registered medical practitioner should examine the female, only in the presence of a female attendant.

#### Hospital death of medico-legal case

Should a case admitted and reported to the police as medico-legal case die in the hospital, the dead body should be sent to the mortuary and intimation regarding death is sent by the hospital administration to the police. Medical Certificate of Cause of Death will NOT be filled up by the ward MO/DMO. Under no circumstances the dead body should be handed over to the relatives directly. The concerned police officer (IO) will take over such body for inquest and will hand over the body to the relatives only after he decides that the same is no more required for any investigation/examination.

The same procedure is to be followed by the RMO for non-institutional medico-legal deaths.

#### Medico-legal report

A Medico-legal examination report must be prepared in the appropriate format by the attending doctor or Casualty Medical Officer (CMO). The report should be written by a doctor in his own handwriting. Particular care must be taken to ensure that the writing is legible and neat. Specific formats for different ML Case Reports should be available in the MI Room.

The general format of a medico-legal examination report is similar to that of a medical case sheet, with necessary minor modifications. It has three parts:

(a) Part I – Particulars of the Case

(b) Part II - Findings/Observations.

(c) Part III - Opinion

The following points are to be kept in mind while expressing opinion:

(a) Opinion expressed should be based on observations recorded.

(b) Opinion need not be expressed immediately following examination. The MO, at his discretion, should reserve his opinion till additional information becomes available to him like reports of investigations ordered by him.

(c) Despite all efforts if the MO is unable give definitive opinion about the issues under question, he should not hesitate/feel ashamed to say so, eg. Negative Autopsy.

The MO must retain a carbon copy of the report in his file for future reference.

Any samples (exhibits) collected by the MO for further forensic investigations should be mentioned in the report and handed over to the IO/his representative in sealed containers, ensuring Chain of Custody of Evidence.

#### Medico-legal certificate

A medical certificate issued and used for legal purposes is called Medico-legal Certificate. Like all other certificates, it is a brief, precise document in which the medical officer expresses opinion about a fact, eg Age Certificate, Medical Certificate of Cause of Death etc. The accompanying words- "I hereby certify"- require the issuing MO to be absolutely certain about the opinion expressed. Thus the evidential value of a medico-legal certificate is more than that of a medico-legal report.

It is mandatory for the issuing MO to mention his registration number below his signature in a medico-legal certificate.

Approved formats of the commonly issued medico-legal certificates should be readily available in the MI Room.

#### Dying declaration

Although not a medico-legal document, the MO should have some knowledge of it as he may be involved in recording it.

Dying declaration is the statement, written or oral, made by a dying person, with the knowledge that he is going to die shortly, about the circumstances that have been responsible for his imminent death under criminal circumstances.

Ideally a magistrate is to be called to record it, but if the death is too imminent the medical officer should himself record it. Dying declaration recorded only with the dying person in compos mentis (normal mind) will be held valid. A certificate to that effect by the doctor is essential. The doctor should record dying declaration in the same words as narrated by the dying person and in the presence of two witnesses. Police officer in-charge of the case should not be present during the recording.

After recording the declaration, the MO should send it to the magistrate in a sealed envelope.

#### Conclusion

Carrying out medico-legal examination and issuing a medico-legal report/certificate when requisitioned by the authorities concerned, is one of the mandatory legal duties of a MO. Avoiding or performing this duty casually/inefficiently may land the MO on the wrong side of the law.

## Medico - legal aspects of poisoning

#### Introduction

Medical officers might have to deal with cases of poisoning in the course of their professional duties. Poisoning might be accidental, suicidal or homicidal. It results in death on many occasions. All cases of poisoning need to be investigated by the police. Hence it is an essential legal duty of all medical officers as registered medical practitioners to report all cases of poisoning to the police.

#### Definition

Poison is a substance which if introduced in the living body or brought into contact with any part thereof, will

produce ill health or death, by its systemic or local effects or both. Very often it is the intended use rather that the inherent nature of a substance that meets the legally accepted concept of a poison. For instance a pharmaceutical agent which is beneficial in therapeutic doses might act as a poison if administered in higher doses with intention of causing harm.

**Role of medical officers in a Case of Poisoning**

(a) The patient should be immediately hospitalized and resuscitated.

(b) Case should be registered as medico legal case.

(c) Under Sec 39 Cr PC, all cases of poisoning are to be informed to the police by the medical officer. Non-compliance is punishable under Sec 202 IPC.

(d) Material for chemical analysis, like vomits, stools, urine, suspected article of food / drink, stomach-wash fluid etc. to confirm the diagnosis, should be collected by medical officer. These should be handed over to investigating officer in a sealed labeled container.

(e) Failure to preserve any suspected article, with intention to protect accused from legal punishment is punishable under Sec 201 IPC.

(f) Arrangement should be made to record dying declaration, if condition of the patient is serious.

(g) The medical records should be kept meticulously.

(h) In case of death of the patient, the medical officer, should not issue medical certificate of cause of death. The dead body should be handed over to the police for further investigations.

**Collection and Dispatch of Biological Materials for Chemical Analysis to the State Forensic Lab**

Body fluids and tissues collected either ante-mortem or post-mortem is handed over to the investigating officer for chemical analysis in Forensic Science Lab, ensuring chain of custody.

Since the biological material is likely to undergo decomposition, suitable preservative is to be added to the containers.

(a) Equal volume of rectified spirit is the ideal preservative for vomits, stools and viscera in all cases, except in cases of poisoning by alcohol. However, saturated solution of common salt, in equal volume, can be used for all cases except for cases of mineral acid poisoning.

(b) Blood is preserved by adding Sodium Fluoride and Potassium Oxalate to it. Usually 5-10ml blood is collected in ante-mortem situations and about 50ml in post-mortem cases. The preservative for 10ml blood is a mixture of 30mg potassium oxalate and 10mg of Sodium Fluoride.

(c) Urine is preserved by adding a few crystals of thymol or drops of dilute HCl to it.

(d) The containers used should be of adequate size and should not be filled more than 3/4 capacity to avoid spillage. They should be made of glass only.

(e) The container should be sealed and labeled.

(f) The specimen should be accompanied by a duly filled requisition form bearing the ink impression of the seal used, in addition to the clinical details.

## Medico-legal deaths

**When are deaths to be treated as Medico - legal ?**

As a rule the following deaths are reported as ML deaths:

(a) Un-natural Deaths

(b) Un-identified Deaths

(c) Un-diagnosed Deaths

(d) Un-attended Deaths (including Found Dead & Sudden Death Cases.)

(e) Deaths due to industrial occupational diseases, food poisoning etc too are reported as ML deaths as these are not naturally occurring diseases.

(f) All operation room, labour room and post invasive procedure deaths, where death is directly linked to the procedure.

The list is not exhaustive. It is the discretion and responsibility of the medical officer diagnosing (declaring) death to decide whether the death needs to be reported as medico-legal.

Battle Casualties and Battle Accidents are not ML deaths, hence are not reported to the police. However all Physical Casualties are ML deaths - A.O. 1/2003/MP refers.

Death of a military person in an accident involving military aircraft is exempted from the purview of Cr PC 174 and hence need not be reported to civil police. (Auth- Govt of India, Ministry of Home Affairs letter No. 8/179/71-GP A.1 dated 25 Nov 1972).

**Action by the Medical Officer**

(a) Examine the person and declare death after resuscitation is unsuccessful.

(b) Inform the (Civil) police by telephone followed by letter.

(c) Take custody of the dead body and preserve it in the mortuary till the police arrive and take over the body.

(d) DO NOT issue Medical Certificate of Cause of Death.

A case can be declared medico-legal by any medical officer at any stage of hospitalization. Though in routine practice, the MO IC MI Room handles the bulk of these cases, at times the circumstances of a case may become apparent only during hospitalization. In these cases the treating specialist or MO IC ward can declare a case to be medico legal.

**Investigation of ML Death: Cr PC Sec 174**

Inquest

An Inquest may be defined as a legal inquiry by an authorized agency to establish the cause and circumstances surrounding the death of a person, where death has occurred under illegal or suspicious

circumstances .

Investigating agency

Cr PC sec 174 vests the power of investigating ML deaths with Police. An officer of the minimum rank of Sub Inspector is empowered to carry out the official inquiry called "Inquest".

In special circumstances like death in custody, death due to police firing, dowry deaths the magistrate carries out the inquest as per Cr PC Sec 176.

Military Court of Inquest (AO 20/2001/DV)

(a) The formation commander can also order a military inquest under the authority of AO 20/2001/DV.

(b) Findings and opinion of military inquest will have the same legal authority as the police/magistrate inquest when it has been held in lieu of police/magistrate inquest provided prior approval of the civil authorities has been obtained for holding the military inquest. This step is usually undertaken in areas where civil administrative set-up to carryout the inquest is not available.

(c) The disposal of dead body will take place only after concurrence of the presiding officer of the court of inquest has been obtained.

(d) A copy of the court's proceedings is forwarded to the magistrate of the area.

**Conclusion**

It is again emphasized that the MO or the hospital administrative authorities should not hesitate to declare deaths as medico-legal and report the same to the civil police. This is not only a legal requirement but also help in establishing all the facts about that death.

## Medical Certification of Cause of Death

Mortality Statistics forms an integral part of the vital statistic system. They are one of the basic components of population growth. Cause specific mortality rates are key indicators of the health trends in the population and are provided by the system of medical certification of cause of death.

The law requires all births and deaths occurring within India, to be registered with the Registrar of births, and deaths in accordance with the provisions of the Registration of Births and Deaths Act, 1969. Registrar General of India is the highest official.

In India as per the provisions of Sec 10 (3), Registration of Births and Deaths Act, 1969 every medical practitioner is duty bound to issue, without charging any fee, a Medical Certificate of Cause of Death (MCCD) in cases where he has attended to a person during his last illness and where he is satisfied that the death was due to natural causes.

(a) Medical officer should not delay, issuing death certificate, once he is sure of the cause of death.

(b) He can not charge any fee for issuing death certificate.

(c) He should not withhold issuance of death certificate even if his dues are not cleared by the relatives.

(d) No medical officer should sign death certificate in advance or without viewing and examining the dead body personally.

**MCCD should NOT be issued in any of the following situations**

(a) Where a practitioner is called to see a person who has died suddenly and whom he had never examined before.

(b) When he has some suspicion as regards the cause of death

(c) Where there is the slightest suspicion of violence, even in the presence of serious natural disease.

For battle casualties and battle accidents, the decision of commanding officer and RMO, as regard the cause of death is final. As per Army order 1/2003/MP, death certificate in case of battle casualties is issued by AHQ AG's branch.

**Instructions for filling Medical Certificate of Cause of Death**

The first part consists of particulars (identity) of the deceased including age and date and time of death.

The second part is the medical part. Its format has been standardized and approved by WHO. It consists of two parts:

(a) First - Immediate, Antecedent and Underlying Causes (Primary / Direct cause).

(b) Second - Other significant (secondary) conditions that contributed to the death.

Abbreviations should not be used while filling up the certificate and the diseases have to be mentioned as per ICD-10 along with their code numbers.

Part - I

Only one cause is to be entered on each line of Part I. The underlying cause of death should be entered as the lowest line in this part. The underlying cause of death is the condition that started the sequence of events between normal health and the immediate cause of death.

**(a) Immediate cause**

The direct or immediate cause of death is reported on line (a). This is the disease, injury or complication that directly preceded death. It can be the sole entry in the statement. There must always be an entry on line (a)

Mode of dying such as cardio respiratory failures, heart failure should not be entered at all. In the case of violent death enter the result of the external cause (e.g. fracture of skull, crushed chest).

**(b) Antecedent Cause**

If the condition on line (a) was the consequence of another condition, record that in line (b) as antecedent cause. This condition must be antecedent to the immediate cause of death, both with respect to time and etiologically or pathologically. Violence or circumstances of accident antecedent to an injury entered on line (a), should be entered on line (b). (e.g. Road Traffic Accident, fall from height).

**(c) Underlying Cause**

The condition which gave rise to the antecedent condition on line (b) is to be reported here. If the condition on line (b) is the underlying cause, nothing to be entered on this line.

(d) The original format, approved by WHO, had only (a), (b) and (c) under I, but as per recommendations of 43rd World Health Assembly, 1990, an additional line (d) has been added below (c).

Part- II

Diseases or conditions believed to have influenced the course of the morbid process and thus contributed to the total outcome but which were not related to the disease or condition causing death.

After completing the form the certifier signs the certificate giving his name, qualification, designation and registration number. The date and time of signature will be the same as in the beginning of the certificate, except in cases where the cause of death has been certified after an autopsy.

**Conclusion**

Medical Certificate of Cause of Death is the back bone of mortality and morbidity statistics of a community, based on which National Health Policy is formulated. Hence it is essential that every medical officer should be careful in providing the information through MCCD.

## Consent in medical practice

**Introduction**

A successful relationship between a doctor and his patient is based on mutual trust. To establish trust a doctor must respect patient's autonomy - the right to decide whether or not to undergo any medical intervention. A patient must be given sufficient information, in a manner that he / she can understand, to enable him / her to exercise the right to take an informed decision about the care they are to receive.

**Definition**

Consent means voluntary agreement, compliance or permission. As per the Indian Contracts Act, Section 13, two or more persons are said to consent when they agree upon the same thing in the same sense.

To be legally valid, the consent that is given must be intelligent, informed and with free will. Consent is not free when it is produced by coercion, under influence, fraud or misrepresentation and intoxication. (I.P.C. Sec 90)

**Types of Consent**

(a) Implied
(b) Express
  (i) Verbal
  (ii) Written

Implied Consent

An implied consent is indicated by the patient's co - operation and conduct. It is the most common variety of consent in medical practice. The patient implies consent to medical examination by registering with the doctor, narrating his symptoms and providing other information asked by the doctor in connection with his disease etc. It is sufficient for only external clinical examination involving not more than inspection, palpation, percussion and auscultation.

Verbal Express Consent

The patient expresses his consent verbally to a specific oral question by the doctor. This grade of consent is a pre-requisite for internal clinical examinations, giving intra-muscular injections and other non-invasive procedures. Ideally it is to be obtained in the presence of a disinterested witness.

Written Express Consent

For all procedures involving threat to life or limb, invasive diagnostic and treatment procedures, blood transfusion etc a written express consent is to be obtained. In these circumstances the consent has to be a fully Informed Consent. Consent for medico-legal examinations as far as possible has to be a written express consent, except where the person is in police custody.

**Informed Consent**

The consent obtained after providing complete information to the patient about the modality of treatment being adopted or investigative procedure being carried out is called Informed Consent.

A fully informed consent is a good defense available to the doctor against blame of medical negligence on the ground of failure to inform a patient of the risks associated with a procedure.

**Who Should Obtain Consent?**

Ideally it is the duty of the doctor providing treatment or undertaking an investigation, to discuss it with the patient and obtain consent.

Consent Under Special Circumstances

**(a) Consent of Persons subject to Army / Navy / Air Force Act**

When a person in uniform refuses to give consent for any investigation or treatment, the medical administrative instructions provide for placing the person under Medical Category 'C'(Permanent) for that ailment. Under no circumstances treatment/investigation should be carried out without consent.

**(b) Consent in cases of emergency where the patient is conscious and competent**

Consent is implied in all cases of emergency.

**(c) Consent in medico-legal case (MLC)**

Consent is required to examine a person even for medico-legal purposes. However, when the person is in police custody as an accused and examination is being carried out under Sec 53 Cr PC (on the orders of the police official/magistrate), necessary force may be applied to carry out the examination if he refuses to give consent for the same.

**(d) Consent for examination of children**

In India the legally accepted minimum age for giving valid informed consent for medical examination and routine

treatment is twelve years. Age of consent for treatment involving danger to limb or life is eighteen years.

**(e) Consent for examination of insane persons**

In case of insane persons, the guardian is the person, legally competent to give consent.

**(f) Illegal actions and consent**

Consent is invalid in illegal procedures like criminal abortion, euthanasia etc.

**(g) Spousal consent for procedure likely to cause sterility/impotence:**

Sterility and impotence do not constitute grounds for divorce when acquired after marriage. However these conditions have a material importance in the nature of conjugal relations. Therefore it is essential that spousal consent should be taken, where treatment induced sterility, impotence or other factors affecting the marital rights of either spouse are involved.

### Conclusion

All MO should be aware of the various aspects of consent. Practice of medicine without due application of various aspects of consent is not only un-ethical but also illegal. A well informed consent is a very good defence should the doctor be blamed for negligence, in these days of 'patient autonomy.

## Injury report

### Introduction

Any medical officer may be called upon to examine an injured person.The doctor who examines an injured person has the responsibility of not only treating but also to prepare and issue the Injury Report, if asked by the police. This may be followed by giving expert evidence in the court of law. All details of examination of injured person should be entered in medico legal/Accident register maintained in the casualty of all hospitals.

Definition: As per Sec 44 IPC, injury is "Any harm whatever illegally caused to any person in body, mind, reputation or property."

### Medical Classification of Injuries

(a) Mechanical Injuries
  (i) Blunt Injuries:
    - Abrasions
    - Contusions
    - Lacerations
  (ii) Incised Wounds
  (iii) Stab Wounds
  (iv) Firearm Injuries

(b) Thermal Injuries:
  (i) Due to Cold
    - Frostbite
    - Trench foot
    - Immersion foot
  ii) Due to Heat
    - Burns
    - Scalds

(c) Injury due to Energies
  (i) Due to Electricity
  (ii) Due to Lightening
  (iii) Due to X-rays
  (iv) Due to Radioactivity
  (v) Due to Explosions

### Legal Classification of Injuries

(a) Simple Injury
(b) Grievous Injury

Sec 320 IPC defines Grievous Hurt.

The following kinds of injuries are designated as "grievous";

(a) Firstly- emasculation.
(b) Secondly- permanent privation of the sight of either eye.
(c) Thirdly- permanent privation of the hearing of either ear.
(d) Fourthly- privation of any member or joint.
(e) Fifthly- destruction or permanent impairing of the powers of any member or joint.
(f) Sixthly- permanent disfiguration of the head or face.
(g) Seventhly- fracture or dislocation of a bone or tooth.
(h) Eighthly- any hurt which endangers life or which causes the sufferer to be during the space of twenty days in severe bodily pain, or unable to follow his ordinary pursuits.

### Recording & Interpretation of Injuries

Any medical officer may be called upon to examine injured person. Injuries should be examined without delay at any time of day or night, as any lapse of time will modify the features of the injury. All details of examination of injured person, whether admitted into hospital or treated as outpatient, have to be entered in an Accident Register, to be maintained by all hospitals and clinics. A detailed and accurate record should be made by the doctor at the time of examination. The doctor will be required to issue injury report when asked by the police. The format of Injury Report and the method of filling it up is given in **Appendix** at the end of this chapter.

(a) The first four columns of the table are for recording of the findings of examination of the injured person. The next three columns are for recording the opinion on various aspects of the injury. The remarks column is for providing other relevant medico-legal information.
(b) Every injury is to be given a serial number and described separately. However, when injuries are minor, of same type (nature) and are located as a group they can be described as a group – e.g. multiple abrasions over the back.
(c) In the column for Nature of Injury the name of the

wound as per the medical classification of injuries- i.e. abrasion, contusion, incised wound, etc., should be noted.

(d) Meticulous recording of the shape and size of the wound is essential to compare with those of the suspected weapon and opine about the possibility of infliction of the wound by a weapon of those dimensions.

(e) For imprints, shape of the imprint (preferably in the form of a diagram) and various dimensions of the imprint are recorded.

(f) Column for "Situation over the body", should mention the exact situation of the wound with reference to anatomical landmarks e.g. the mid-line, a joint, the navel or the nipple etc. Orientation of the wound i.e. horizontal, vertical, oblique, etc. should also be noted.

(g) While describing all the features of the wound technical (medical) terms should be avoided. As far as possible, common English terms understandable by the police and judicial officers should be used.

(h) The medical officer will opine on the following medico-legal aspects of the wound, based upon the above mentioned (observed and recorded) features of the wound:

(j) Legal Type of Injury (simple, grievous or grievous – dangerous)

(k) If the nature of injury and extent of injury cannot be made out at the time of first examination e.g. when a fracture is suspected and expert opinion of the x-ray of the part is awaited; abdominal injuries with vague symptoms awaiting investigation/operation results, etc. the injury report should not be given hastily.

(l) However, if considerable delay is anticipated in obtaining the required information – e.g. awaiting reports of certain investigations or clinical course, prognosis and outcome of the injury - it is advisable to issue the injury report keeping the particular opinion pending. The final opinion can be given at a later date when the necessary information becomes available.

(m) Kind of Weapon: The kind of weapon/instrument possibly responsible for infliction of the injury should be mentioned.

(n) Weapons causing injury are grouped into:

(i) Hard and blunt weapons e.g. stick, stone, fist, etc.

(ii) Light sharp weapons e.g. knife, scalpel, razor blade, sword.

(iii) Heavy 'sharp' weapons e.g. axe, hatchet, saber, etc.

(iv) Firearm

(o) Opinion about the kind of weapon is expressed as per the following guidelines:

(i) Blunt Injuries (Abrasions, Contusions, and Lacerations) are caused by Hard Blunt Weapons.

(ii) Incised Wounds are caused by Light Sharp Weapons

(iii) Heavy Sharp Weapons invariably cause Chop wounds as they are invariably used as clubbing weapons.

(iv) Stab injuries are caused by thrusting of Weapons with Long Blade.

It is to be noted that the nature of injury depends not only upon the kind of weapon but also upon its manner of use.

(p) In some situations the particular injury can be linked to suspected weapon of assault more closely. If the dimensions of the wound exactly tally those of the alleged weapon, e.g. Signature Fracture produced by a Hammer, the opinion can be "The possibility of wound having been caused by the weapon of similar nature can not be ruled out."

(q) In the column for opinion about Age of Injury, the possible time lapsed since occurrence of the injury should be given. This is assessed by noting the stage of blood clotting process, chronological changes of inflammatory reaction, changes due to healing process etc.

(r) The remarks column is for recording observations about the condition of clothing, the clinical condition of patient, the investigations carried out to confirm/diagnose the nature of injury and their results, any trace evidence collected from the wound like broken glass piece, broken tip of knife, grease, pieces of cloth, bullet, wad, etc. Similarly information whether the injured person is hospitalized should be provided.

(s) Having prepared the injury report in duplicate according to above guidelines, the medical officer affixes his signature and other details at the bottom of the report. Original copy is handed over to the authorized representative (constable) of the investigating officer after obtaining his signature for receipt of the same on the report. The second copy is maintained by the medical officer for future requirement when summoned as expert witness in the case. Any trace evidences collected during the examination are handed over to the police constable, maintaining "Chain of custody of Evidence", for forensic examination.

(t) If an injured person comes directly to the medical officer, it is his legal duty –under Sec 39 of Cr PC - to send a written intimation to the police station in whose area of jurisdiction the hospital or health care center is located.

### Introduction

Medico – legal aspects of patient care is receiving considerable attention in all health care delivery systems. In the Armed Forces Medical Services, health care establishments are located in all parts of the country. Law and order being a state subject, subtle differences in legal procedures do exist from one state to another.

Every MO should bear in mind that the legal procedures followed in a particular state have to be followed in handling cases that fall within the medico legal domain. Guidelines given hereafter are generally applicable all over the country. Nevertheless in specific cases, it would be advisable to familiarize oneself with current rules and regulations that apply to a particular place.

### Medical Certification and Competence

Every MO is a registered medical practitioner. Therefore in law, he / she is treated as being technically qualified to carry out all medico – legal work, including medico – legal autopsies. Medico – legal work is carried out in only those centers that have been authorized for the purpose by the State Govt. Within the Armed Forces, only AFMC, Pune is authorized to carry out medico – legal work. However all health care establishments have to handle cases that have medico – legal implications. Therefore a correct approach to a case is essential for all MOs.

Nowadays there is reciprocity between MCI and State medical councils. Therefore MOs in the AFMS can carry out their professional work all over the country, irrespective of their State of registration. Nevertheless in cases of professional misconduct they would be subject to the jurisdiction of the State Medical Council that has originally granted them recognition.

### Medico – Legal Duties of MO

This Section aims at making all the MOs of AFMS aware of their medico-legal duties and responsibilities. Unlike the clinical management of a case, the medico – legal duties involve interaction with non – medical agencies such as the Police and Courts of Law. Therefore fulfilling legal requirements related to the investigation and trial of a case places an additional responsibility upon the MO attending to a case.

### Approach

The different chapters of this section will focus on common medico-legal scenarios that a MO is likely to face in his professional work. This is a very basic guideline. A more detailed ML Manual for AFMS is being published shortly by the Dept of Forensic Medicine & Toxicology, AFMC, which will address all issues of pertinence in greater detail.

Presently the following topics will be briefly discussed :

(a) MLC – Medico – legal Case – Report
(b) Medico – legal Aspects of Injuries
(c) Medico – legal aspects of Poisoning
(d) Medico – legal Deaths
(e) Death Certification
(f) Consent in Medical Care
(g) Medical Negligence
(h) Consumer Protection Act

### Conclusion

It is again emphasized that MOs of AFMS are NOT IMMUNE from any of the laws applicable to medical practice in the country. Since they are employees of AFMS, any legally wrong practice of medicine by them will bring disrepute, including legal action, not only to the particular MO but also to AFMS. Commanding Officers of Military Hospitals have a great legal and administrative responsibility in ensuring that medicine is practiced legally and ethically.

## Medical negligence

### Introduction

Medical officers may be sued by patients for Medical Negligence claiming hefty compensation. This has become more likely due to awareness of patients about their rights and applicability of acts like Consumer Protection Act to the medical profession. Since doctors of AFMS are employees of Ministry of Defence, the blame will partly be on the employer, leading to adverse administrative action too against the MO. Such incidences will tarnish the image of the AFMS. Hence it is essential that all MOs of AFMS must be aware of the issue.

### Definition

Want of reasonable care and skill or willful negligence on the part of a medical officer while treating a patient with whom patient doctor relationship has been established so as to cause bodily harm or mental agony.

### Civil & Criminal Negligence

Difference between the two lies mainly in the degree of harm caused. If the negligent act has resulted in death of the patient then the loss can not be compensated monetarily alone and the act amounts to "causing death due to rash and negligent act". Such gross negligence is termed as Criminal Negligence. All other cases of negligence where the damage can be compensated monetarily are labeled as cases of Civil Negligence.

Negligence is to be proven by the patient by establishing the following points-

(a) That the defendant (doctor) owed a duty of care to the plaintiff (patient)
(b) That the defendant was in breach of duty.
(c) That the plaintiff suffered damage as a result.

Duty of Care

The contract between the patient and the doctor gets established the moment the doctor accepts the individual as his patient and lasts till the cure of the particular illness or till it is terminated by either party, whichever is earlier.

Breach of Duty

A doctor is not liable for error of judgement either in diagnosis or treatment, so long as he applies a minimum reasonable standard of skill and care. A doctor can misdiagnose and mistreat a patient without being

negligent, even if another practitioner of greater skill would have had more success. A doctor does not guarantee to provide the best possible care, but only care consistent with his professional qualification.

A doctor is not liable for error of judgement either in diagnosis or treatment, so long as he applies a minimum reasonable standard of skill and care. A doctor can misdiagnose and mistreat a patient without being negligent, even if another practitioner of greater skill would have had more success. A doctor does not guarantee to provide the best possible care, but only care consistent with his professional qualification.

Damage suffered by the patient - Examples,

(a) Loss of earnings.
(b) Expenses.
(c) Reduction in expectancy of life.
(d) Reduced enjoyment
(e) Pain & suffering
(f) Death

**Precautions Against Medical Negligence**

(a) Good rapport with patient and his relatives
(b) Informed Consent
(c) No guarantee of accurate diagnosis & cure
(d) Follow Approved Modalities of Management.
(e) Duty to be Well Informed.
(f) Duty to communicate with other doctors-consultants
(g) Duty to obey summons for attendance.
(h) Do not omit to institute routine and basic measures like immunisation, sensitivity testing, proper use of antibiotics etc.
(j) Don't operate when unwell / unfit.
(k) Accurate and Legible Medical Records.
(l) The following are certain guidelines for the medical officers to avoid subsequent problems for self as well as for fellow practitioners-
    (i) Do not criticize fellow practitioner in the presence of patients or relatives.
    (ii) Do not make a statement constituting or admitting fault on your part.
    (iii) Refrain from over optimistic prognosis.
    (iv) Check instruments and equipment and keep them in a state of readiness, especially emergency equipment.
    (v) No experimentation without patient's informed consent, even if it is for therapeutic purposes.
    (vi) No procedure to be performed beyond ones skill.
    (vii) To avoid administration of wrong drug, the medical officer should personally read the label on the drug container. Treatment instructions to the subordinate staff should be issued in writing and never telephonically.
    (viii) All male medical officers must ensure presence of a female attendant while examining female patients.

**Common Causes of Negligence**

(a) Failure to Attend

The doctor is blamed on this count due to the ambiguity about the termination of the patient doctor relation. Some authorities feel that the contract lasts till the present illness is cured but others feel that it exists till either party terminates it. The doctor is supposed to attend the call from the particular patient till the existence of the contract.

(b) Casualty Dept

Any lapse on the part of any staff of the casualty dept is likely to invite litigation due to the nature of circumstances and out come of the cases in question.

(c) OT Deaths

Operation theater/labour room deaths and deaths following invasive procedures are bound to give rise to doubts of negligence. Hence these cases should be ideally reported as medico-legal deaths, so that an inquiry by a third party (police) is carried out to clarify all aspects of the incidence.

(d) Therapeutic Hazards

The doctor is likely to be blamed for such mishaps if the consent obtained is not an informed one.

(e) Failure of Communication

A consultant is likely to be implicated if the patient suffers damage due to communication gap between him and the family physician.

**Conclusion**

Medical Negligence is a legal entity. All blames of negligence are considered by the judiciary keeping all aspects of the situation and intricacies and uncertainties involved in the practice of medicine. However all MOs should take due precautions to avoid blame of Medical Negligence.

## Consumer protection act as applicable to medical profession

**Introduction**

Consumer Protection Act was enacted by the Parliament of India in 1986 to protect the rights of consumers. Difference of opinion existed even among the legal luminaries till 1995 as to its applicability to the medical practice. However in 1995, the Supreme Court of India ruled that the act is applicable to medical profession in the land mark case, Indian Medical Association Vs V P Shantha .

**Summary of Supreme Court Judgement - 1995**

(a) Service rendered to a patient by a medical practitioner (except where the doctor renders service free of charge to every patient or under a contract of

personal service) would fall within the ambit of 'Service' as defined in the Act.

(b) The fact that medical practitioners belong to the medical profession and are subject to the disciplinary control of the Medical Council of India and/or State Medical Councils would not exclude the services rendered by them from the ambit of the Act.

(c) A “contract of personal service” has to be distinguished from a "contract for personal services". The service rendered by a medical practitioner to the patient cannot be regarded as service rendered under a "contract of personal services" and is not covered by exclusionary clause of the definition of 'service contained in the Act.

(d) The expression "contract of personal service", can not be confined to contracts for employment of domestic servants only and the said expression would include the employment of a medical officer for the purpose of rendering medical service to the employer. The service rendered by a medical officer to his employer under the contract of employment would be outside the purview of ' service' as defined in the Act.

(e) Service rendered free of charge by a medical practitioner attached to a hospital/nursing home or a medical officer employed in a hospital/nursing home where such services are rendered free of charge to everybody, would not be 'service '. The payment of a token amount for registration purpose only at the hospital/nursing home would not alter the position.

(f) Service rendered at a non-government hospital/nursing home where no charge whatsoever is made from any person availing of the service and all patients (rich and poor) are given free service is outside the purview of the expression 'service'. The payment of a token amount for registration purpose only at the hospital/nursing home would not alter the position.

(g) Service rendered at a non-government hospital / nursing home where charges are required to be paid by the persons availing of such services falls within the purview of the expression 'service '.

(h) Service rendered at a non-government hospital / nursing home where charges are required to be paid by persons who are in a position to pay and persons who cannot afford to pay are rendered service free of charge would fall within the ambit of the expression ‘service’, irrespective of the fact that the service is rendered free of charge to persons who are not in a position to pay for such services. Free service, would also be 'service' and the recipient a 'consumer' under the Act.

(j) Service rendered at a government hospital/health centre / dispensary where no charge whatsoever is made from any person availing of the services and all patients (rich and poor) are given free service-is outside the purview of the expression 'service '. The payment of a token amount for registration purpose only at the hospital/nursing home would not alter the position.

(k) Service rendered at a government hospital/health centre / dispensary where services are rendered on payment of charges and also rendered free of charge to other persons availing of such services would fall within the ambit of the expression 'service ', irrespective of the fact that the service is rendered free of charge to persons who do not pay for such service. Free service would also be 'service' and the recipient a 'consumer ' under the Act.

(l) Service rendered by a medical practitioner or hospital/nursing home can not be regarded as service rendered free of charge, if the person availing of the service has taken a insurance policy for medical care where the charges are borne by the insurance company and such service would fall within the ambit of 'service'.

(m) Similarly, where, as a part of the conditions of service, the employer bears the expenses of medical treatment of an employee and his family members dependent on him, the service rendered to such an employee and his family members by a medical practitioner or a hospital/nursing home would not be free of charge and would constitute 'service' under the Act.

**Note :** As on date Consumer Protection Act is not applicable to hospitals of AFMS. However the ambit of the act is being expanded regularly. ESI hospitals have been brought under its ambit following a recent (May 2007) Supreme Court of India judgment.

**Conclusion**

The medical professionals have become apprehensive of frivolous allegations and loss of reputation following the applicability of the act to medical practice. However there is no cause for worry as the same legal principles as applied in civil courts are applied while deciding the issue of medical negligence in Consumer Fora also. However all MOs need to be more vigilant to avoid blame of negligence.

**Appendix**

Injury report

To,

The Investigating Officer,

Police Station----------

Ref your letter No ---------- dated ----------

Sir,

I am forwarding herewith the report of examination of:

Name of the Injured ----------

son/wife/daughter/of----------

Resident of ----------

Brought by PC---------- No ---------- PS----------

Consent for examination----------

Identification marks

1. ----------

2. ----------

History in Brief:

---

# Health Management during Disasters

## Introduction

Disasters have existed ever since the existence of mankind and no community is immune to the emergencies caused by natural and manmade disasters. Worldwide, natural disasters have been known to be one of the major problems in terms of mortality, number of people adversely affected and economic losses. There is no evidence to suggest that frequency of natural disasters will alter significantly in immediate future. Natural disasters have tended to be more destructive in last few decades as they affect larger concentration of population due to increased urbanization, and settlements in disaster prone areas.

The spectrum of occurrence of disasters indicates that the Asian region is one of the most disaster prone regions as 60% of the major natural disasters reported in the world occur in this region. India is amongst the most disaster prone countries in the world due to high vulnerability to natural disasters like floods, earthquakes, cyclones and droughts. In India, flood affects over 9 million hectares area annually, 56 % of landmass is vulnerable to seismic activity of varying degree and 5700 kms long coastline is prone to severe cyclones with very severe loss of life and economic damage. Besides the natural disasters, India is also vulnerable to manmade disasters like transportation accidents, chemical and technological disasters and other such events.

It is evident from the spectrum of occurrence that adequate procedures to deal with disaster situations are necessary. Disaster management requires well-coordinated public policy for disaster prevention, mitigation, preparedness, emergency response and reconstruction. Health care in disaster is one of the critical elements (1). The issue becomes even more relevant since proper foresight and planning is of considerable importance for disaster management. Often, in disaster situations, a lot of resources have been wasted due to improper planning and impulsive actions (2).

## Definition

The concept and definition of disasters have altered over times in accordance with changing concepts concerning their cause and effect. The definition of disasters have reflected this change, with increasing attention being given to the social aspects of disaster situations and collective ability to meet the requirements of these situations. Disasters have been defined in various ways on the basis of degree of physical impact of the event, magnitude, disruption of public safety, disproportion of resources and in terms of special efforts required and controllability of events.

(a) Pan American Health Organization (PAHO) has described disaster as "an overwhelming ecological disruption occurring on a scale sufficient to require outside assistance."

(b) Sociologically "A disaster is an event in time and space which produces the condition whereby the continuity of the structure processes of social units become problematic."

(c) Commonly disasters are defined as an 'overwhelming ecological disruption which exceeds the capacity of a community to adjust and consequently requires assistance from outside. W Nick Carter defined it as 'an event, natural or manmade, sudden or progressive, which impacts with such severity that the affected community has to respond by taking exceptional measures' (3)

(d) As per the Disaster Management Act 2005, 'Disaster' means a catastrophe, mishap, calamity or grave occurrence in any area, arising from natural or manmade causes, or by accident or negligence which in substantial loss of life or human suffering or damage to, and destruction of property, or damage to, or degradation of environment, and is such a nature or magnitude as to be beyond the coping capacity of the community of the affected area (4).

## Classification of Disasters

Disasters have been classified in various ways, but the most convenient method used is division of disasters in two distinct categories according to their causes i.e. natural and manmade. The understanding of classification helps in short-listing the hazards existing in the area for planning and preparing the facilities for optimum response

### Natural Disasters

These include the following

(a) **Meteorological Disasters**: Storms, cyclones, hailstorms, hurricanes, tornados, typhoons, snow storms, cold spells, heat waves and droughts.

(b) **Topological Disasters**: Earthquakes, avalanches, landslides and floods

(c) **Biological Disasters** : Epidemics of communicable diseases and insect swarms (e.g. locust swarms)

### Manmade Disasters

(a) **Accidents**: Transportation accidents (land, air, and sea), collapse of buildings, dams and other structures, mine disasters, and technological failures such as mishap at a nuclear power station or leak at a chemical plant causing pollution of atmosphere (5).

(b) **Civil disturbances**: Riots and demonstrations.

(c) **Warfare**: Conventional warfare (Bombardment, blockage or siege): Non-conventional warfare: (Nuclear, Biological and Chemical warfare, Guerrilla warfare including terrorism).

(d) **Refugees**: Forced movements of large number of people usually across the frontiers.

## Spectrum of Disaster Management

The spectrum of disaster management involves disaster prevention, mitigation, preparedness, response and recovery.

### (a) Disaster Prevention

It covers those measures, which are aimed at impeding the occurrence of a disaster event and / or preventing such an occurrence having harmful effects on communities. It is concerned with the formulations and implementation of long-range policies and programs.

### (b) Disaster Mitigation

Measures aimed at reducing the impact of a natural or manmade disaster on a nation or community.

### (c) Disaster Preparedness

Measures, which enable governments, organizations, communities and individuals to respond rapidly and effectively to disaster situations. Preparedness measures include the formulation of viable disaster plans, the maintenance of resources and the training of personnel. Organizing, planning coordinating, resource planning and training are its major concerns.

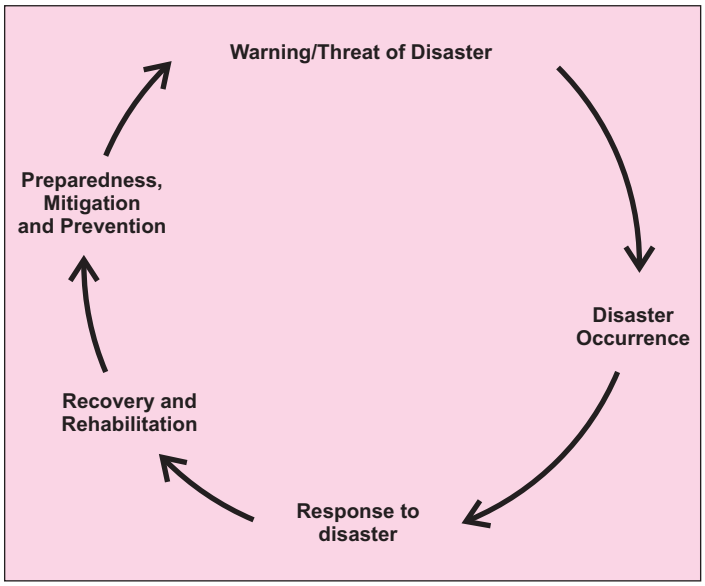
### (d) Disaster Response

Response measures are those, which are taken immediately, prior to and following disasters. Such measures are directed towards saving life and protecting property and dealing with the immediate damage caused by the disaster. Its success depends vitally on good preparedness.

### (e) Disaster Recovery

Recovery is the process by which communities and the nations are assisted in returning to their proper level of functioning following a disaster.

Fig - 1 : Process of Disaster



Disaster situation has been conceptualized as a process with differing phases. In each different phase, the information needed, the action required, the problem encountered and people involved may be quite different. A better understanding of disaster process and inter relationship of these different phases is important for emergency response. The different phases in disaster process are preparedness, warning, threat, impact, assessments, rescue, immediate action, initial recovery, long-term rehabilitation and prevention (Fig 1). Each phase will vary according to the type of disaster event with different time element. Some researchers divide the disasters into three phases, pre-disaster, disaster emergency and post disaster phases.

## Special Characteristics

Disasters are considered phenomena in themselves and have profiles with some special characteristics. Understanding these basic characteristics is essential for its management.

The geographic divisions of area concerned with disaster were conceived in order to classify the arising problems and to help manage them. Three major divisions are in vogue, Impact Area, Filter Area and Community Aid Area. Impact Area is where disaster has struck causing damage; Filter Area is undamaged zone surrounding the impact area from where immediate aid by community starts; The Community Aid area is immediately outside the filter area from where the organized rescue and relief flows.

Analysis of various disaster situations of differing magnitude and its consequences confirm that there are many common pattern of human and organizational behavior in emergency situation. The psychology of disaster involves some distinct facets like victim before, during and after disaster, of the volunteer helper, trained professionals and onlookers. Behavior pattern and disaster psychology must be understood in order to cope with the problem.

Convergence is observed to be a common problem in most disaster events and it has an important bearing on disaster management. Convergence characterized by the spontaneous movement of large number of people, large amounts of material towards the zone of impact and communication convergence are the common problems. Convergence cannot be completely blocked but it can be channeled.

Disaster management implicates different sectors at different times, therefore need for cooperation and coordination amongst various agencies is never more apparent than in the case of disasters, hence there is a need for multidisciplinary approach in disaster planning and preparedness.

## Principles of Disaster Planning

Disaster Management means a planned and systematic approach towards understanding and solving problems in the wake of disasters. Disaster planning cannot prevent disasters but its effects could be minimized by

appropriate plans and preparedness. Some of the general principles of disaster planning are universal and can be applied in all the situations. The foremost requirement is that it should be a continuous process, it should reduce the unknown in a problematic situation, and it should be based on valid knowledge. Other important facts are that it should evoke appropriate action, focus on general principles, and it must be tested.

Disaster plans and preparedness to deal with disaster situation are necessary for every community and particularly the health care system with its critical component, the hospitals which are to be prepared consistently to mobilize all their facilities for maximum use. Realistic, well-rehearsed and properly coordinated disaster plan executed by well-trained system is essential to meet the challenge of disasters. The key issues in disaster management are communication, coordination and control. Important issues in pre-disaster management are prediction, prevention, planning and preparedness. The critical issue when disaster event occurs is the immediate response, rescue, relief and rehabilitation.

## Disaster Management in India

In India the Central Government and State Government share the responsibility for disaster management. The primary responsibility for disaster planning, preparedness, rescue and relief is of the State Government. The States are supported by Central Government by providing informational, financial, technical, material and training support. In the State Government plans, the district, which represents the basic administrative unit, is the focal point of disaster management.

The Disaster Management Act, 2005 was enacted on 23rd Dec 2005 (4). The Act defines disaster management as a continuous and integrated process of planning, organizing, coordinating and implementing measures which are necessary for

(a) Prevention of threat of disaster.
(b) Mitigation of risk of any disaster.
(c) Capacity building.
(d) Preparedness to deal with any disaster.
(e) Assessing the severity.
(f) Evacuation / rescue / relief.
(g) Rehabilitation & reconstruction.

Prime Minister is the Chairperson of the National Disaster Management Authority which has been constituted under the Act. Apart from the Chairperson, the National Disaster Management Authority has Members, Advisory and Executive Committees. Parallel organization structure and authorities also exists at State & District level (4, 5).

The Armed Forces are the key resource and response organization for relief and rescue. The Armed Forces Medical Services are a critical element in the emergency response. In order to be effective and efficient during disaster, event pre-planning and co-ordination with various government organizations and health care institutions in the region would be necessary. Therefore, during preparedness phase, the role, responsibilities, and coordination of health care become very essential at all levels from Formation HQs to the Medical Establishments and upto the RMO level.

## Critical Elements of Preparedness and Response

The preparedness and response depends upon various critical elements. The information of the disaster plans from State Level to District Level, role and responsibilities of various resource organizations, mechanism for coordination, control and practice are some of the critical issues. The preparedness will depend upon appropriate disaster plans for regional / local area based on risk, hazards and vulnerability analysis, and the resources available.

The coordination at various levels of government by the appropriate Formation HQ and at local level by the Medical Establishment based on the anticipated role and responsibility is a critical issue for rational response during disasters.

The disaster plans preparedness and response is dependent on the State Government policies, legislation, organization, disaster plans, resource organization, role and responsibilities of various agencies, logistic plans, coordination, evacuation and shelter plans, training, public awareness and drills. The State Government plans become the baseline for the matching Formation HQ Plans, to provide the support expected in disasters. The Formation HQ plans at various levels will include all the elements of resource organization to meet the demand of anticipated disaster event. The role and responsibilities allotted for health care becomes the total point for preparedness and developing health care plans. Each Medical Establishment then prepares its plans based on the overall objectives, roles and responsibilities and resources available.

## Health Problems Related to Disasters

Though all disasters are unique in that, they affect areas with different social, medical and economic backgrounds, there are still similarities between disasters, which, if recognized, can optimize the management of health relief and use of resources. The following points in this context need to be noted:

(a) There is a relationship between the type of disaster and its effects on health.
(b) Some effects are a potential rather than an inevitable threat e.g. Population movements and other environmental changes may lead to increased risk of disease transmission.
(c) The actual and potential health risks after disaster do not all occur at the same time. Instead, they tend to arise at different times and vary in importance e.g. casualties are greatest when there is crowding and standards of sanitation have declined.

(d) People generally recover quickly from their immediate shock and spontaneously engage in search and rescue, transport of the injured, and other relief activities.

Table - 1 : Short Term Effects of Disasters

| Effects | Type Of Disaster | | | |
|---|---|---|---|---|
| | Earthquakes | High Winds (without Flooding) | Tidal Waves (flash Floods) | Floods |
| Death | Many | Few | Many | Few |
| Severe injuries requiring extensive care | Overwhelming | Moderate | Few | Few |
| Increased communicable diseases load | Potential risk following all major disasters (Probably rising with overcrowding and declining sanitary conditions) | | | |
| Food scarcity | Rare | Rare | Common | Common |
| Population displacements and movements | Rare | Rare | Common | Common |

## Short Term Effects of Disasters

The various short term effects of disaster is shown in table - 1

### Health problems common to all disasters

(a) Social reactions

These could be grouped as follows:

(i) Spontaneous behavioral reaction e.g. generalized panic or stunned waiting.

(ii) Widespread looting.

(iii) Rumors regarding spread of epidemic.

(iv) Population displacements leading to excessive burden on relatives and friends, parks, city squares, vacant lots and government buildings and urban areas where public services can't cope resulting in increased morbidity and mortality.

(b) Climatic exposure

The need to provide emergency shelter varies greatly with local conditions.

(c) Food and Nutrition

Food shortages in the immediate aftermath may arise in two ways. Food stock destruction within the disaster area may reduce the absolute amount of food available, or disruption of distribution systems may curtail access to food even if there is no absolute shortage.

(d) Communicable Diseases

The transmission of communicable diseases after natural disasters may be influenced by following factors:

**(i) Pre existing Disease in the Population**

The risk of epidemic after a disaster is related to the endemic levels of disease in the population. Where a disease agent did not exist in a population before a disaster, there is generally no risk of an outbreak occurring. These include diarrhea and dysentery, cholera, measles, whooping cough, meningococcal meningitis, tuberculosis, malaria, intestinal parasites, scabies and other skin diseases, louse borne typhus and relapsing fever.

**(ii) Ecological Changes Resulting from Natural Disasters**

Natural disasters may alter the potential for disease transmission by altering the ecological conditions. In this context, the most important diseases are those transmitted by mosquito vectors and by water. The breakdown in living conditions following disasters may increase the hazard of transmission of plague, louse borne typhus and relapsing fever. The incidence of dog bite and risk of rabies may increase as neglected strays come in close contact with persons living in temporary shelters.

**(iii) Population Movements**

Population movements may influence the transmission of diseases by increasing population density causing burden on the water supply and other services in the receiving areas and / or introducing susceptible population to a new disease or disease vector. The important diseases to occur in temporary settlements are diarrheal diseases and dysentery, viral hepatitis, measles, whooping cough, malaria, tuberculosis, scabies and other skin infections.

**(iv) Damage to Public Utilities**

Damage to water supplies and sewage disposal systems may increase water borne and excremental diseases.

**(v) Interruption in Public Health Services**

The important services interrupted in this context are vector control programs, which might lead to resurgence of malaria and other vector borne diseases; routine immunization programs against measles, whooping cough, poliomyelitis, tuberculosis and diphtheria.

**(vi) Altered Individual Resistance to Diseases**

Protein Energy Malnutrition, which affects children in poorer population of most of the developing countries, increases susceptibility to many communicable diseases including malaria and tuberculosis.

**Prevention & control of communicable diseases**

The prevention and control measures of communicable diseases should be on the following broad principles (6, 7):

(a) Setting up a Surveillance System

It is established to collect, collate and interpret the data. It will need the services of an epidemiologist / public health specialist, paramedical and health personal and clerical staff.

(b) Disease Surveillance

The objective of disease surveillance after disaster is to identify disease outbreaks, in order to investigate them and to instigate appropriate disease control measures. The diseases considered for surveillance include those known to be endemic to the area, those, which represent a serious health hazard, and those, which are amenable to control. A more focused, system based surveillance system should be instituted. These symptom complexes, which might be important, include fever, fever and diarrhea, fever and cough, trauma, burns, measles etc. These data should be analyzed, interpreted, and presented to the higher authorities (6, 7).

(c) Laboratory Services

Lab for basic diagnostic tests of stool and blood may be established by field reporting units but for specific bacteriological and virological tests, the referral labs in nearby cities or areas will have to be marked (7, 8, 9).

(d) Vaccination and Vaccination Programs

Mass vaccination campaigns against the following diseases will be helpful, as well as some other vaccines for specific diseases, depending on the threat perception ( 7 – 9) :

(i) Tetanus
(ii) Measles

However mass vaccination campaign against typhoid and cholera should be avoided because of the following reasons:

(i) Offer low and little individual protection.
(ii) Complete coverage of population is probably impossible.
(iii) Require large number of workers who could be better employed elsewhere.
(iv) Could lead to reuse of inadequately sterilized needles that may transmit Hepatitis B / HIV.
(v) May lead to false sense of security about the risk of disease and to neglect of effective control measures.

**Environmental Management**

The measures will entail actions in the following areas:

(a) Water Supply

A survey of all water points will have to be made, giving priority to drinking water distribution system. It will have to be determined, if the water supply has been contaminated by sewage or chemical contaminants. If bacterial contaminants are found, the water supply should be disinfected before distribution by increasing residual chlorine. It is recommended that all repaired mains, reservoirs, treatment tanks or other units should be properly cleaned and disinfected (10, 11). The mass distribution of water sterilizing tablet, bleaching powder or liquid disinfectants should be carried out. Individuals in limited and controlled groups may be given such disinfectants to purify small amounts of drinking water for one or two weeks.

(b) Basic Sanitation (10 – 13).

These include the following

(i) Making of emergency latrines.
(ii) Development of solid waste collection and disposal facilities. Burying or burning solid wastes is recommended.
(iii) Health education

(c) Vector Control (7, 14).

Essential vector control measures in disaster are as follows:

(i) Elimination of breeding places by water management and not allowing stagnant pools i.e. by draining, filling and overturning receptacles.
(ii) Enforcement of personal protective measures by people.
(iii) Indoors spraying with 0.1% pyrethrum.
(iv) Outdoors spraying with malathion / fogging.
(v) Control of houseflies by regular spray of Nuvan on dumping sites and around cooking places.
(vi) Prevention against rodents by improving environmental sanitation, storing food in closed areas, early and safe disposal of solid wastes and use of rodenticides like zinc phosphide.

(d) Personal Hygiene (7)

These include:

(i) Provision of washing, cleaning and bathing facilities.
(ii) Avoidance of overcrowding in sleeping quarters.
(iii) Health education.
(iv) Personal safety and protective measures must also be observed by all those involved in disaster relief operations (15).
(v) Burial / Disposal of the Dead

Bodies are unlikely to cause outbreaks of diseases such as typhoid fever, cholera or plague, if death resulted from trauma. However, they may transmit gastroenteritis or food poisoning syndrome to survivors if they contaminate water sources. Despite the negligible risk, dead bodies represent

a delicate social problem. The normal local method of burial or cremation should be used although mass cremation requires large amounts of fuel. Before disposal, bodies must be identified and the identifications recorded.

## Organization of Medical Care for Disaster (3, 16, 17).

The medical care in disaster situation has two distinct facets : pre-hospital care and hospital care. The pre-hospital care involves dispatch of the medical team, care at site and evacuation of victims to definitive care facilities. The hospital care involves triage, emergency care and continuation of treatment, intensive care, diagnosis, treatment and rehabilitation.

The principles of mass casualty management are universal and can be applied in any mass casualty situation natural or manmade. The importance of triage, first aid, life saving measures, transport and evacuation for definitive care to hospital has been recognized the world over. The mass casualty management demands standard simple therapeutic procedures and standardized drugs & medical supplies. On site care demands establishment of a command post triage team, first aid team, mobile hospital (if required), evacuation team, transport and communication.

Hospitals play a crucial role in medical care of the disaster victims. All hospitals must be prepared to meet the challenge of disasters by having an appropriate disaster organization, pragmatic disaster plan, clearly defined role and responsibilities of various staff, laid down plan for each department, accident and emergency department, critical services like OT, ICU, Laboratory, diagnostic, blood bank and other supportive services.

### Disaster Preparedness

The preparedness is the next crucial stage where the following aspects are to be given attention by the Formation HQs and Medical units. Contingency plans prepared by Govt of India for various contingency situations may be referred to (5). In addition, plans for stocking and distribution of medical supplies should be given special attention (18).

(a) Development of disaster plans – which is realistic and adaptable and it is harmonized at all levels. It must be clearly written and periodically tested.
(b) Resource plans for health care.
(c) Role and responsibility of resource organization.
(d) Logistics, equipment and supplies required.
(e) Arrangement for communication, transportation, evacuation.
(f) Coordination and control
(g) Disaster drills.

**Preparedness addresses the following important issues:**

a) Arrangements for on site medical help include the following:
   (i) Alerting and dispatch of mobile help team.
   (ii) Staff, equipment, transport and communication.
   (iii) Arrangements for onsite coordination for rescue and relief.
   (iv) Triage, First Aid and Evacuation Team.

**b) Hospital Disaster Plans. The disaster preparedness includes the following aspects:**

(a) Alert, recall, deployment system.
(b) Triage, First aid, Emergency care arrangements.
(c) Critical area response like OT, ICU etc.
(d) Support services like Blood Bank, Radio diagnosis, Pharmacy, CSSD etc.
(e) Expansion and creation of facilities for disaster victims.
(f) Sustaining the plan and matching resource allocation.
(g) Mock Disaster drills.

### Role of Hospital in Disasters

Hospitals play a major role in the management of all kinds of disasters . They must be organized to respond in a timely and efficient manner to the complex needs arising from a mass catastrophe which may occur within or out side the hospital.

Internal or External Disaster

An internal disaster is an emergency situation that occurs within an institution that may interrupt services, threaten the lives of staff, patients and visitors and may necessitate mass evacuation. Internal disasters may be caused by fires, building, collapses, explosions and others. An external disaster occurs outside the hospital, induced by natural causes or by human activities.

### Objectives of a Hospital Disaster Plan

The main objectives of the hospital disaster plan should be as follows :

(a) To prepare the staff for peak performance during a disaster.
(b) To optimize the available resources during disaster.

### Characteristics of a Hospital Disaster Plan

Irrespective of a hospital's characteristics, complexity and resources, every hospital plan should have the following characteristics :

(a) It should be functional and flexible. The nature and extent of disasters can not be predicted hence the hospital plan should have inbuilt flexibility to cope with varying dimensions of disasters.
(b) It should clearly establish roles and functions as well as lines of authority and command.
(c) It should be applicable for managing internal and external disasters.
(d) It should be part of a regional disaster plan.
(e) It should be comprehensive and should

Box - 1 : Principles of a Disaster Plan

| |
|---|
| **Simple:** Should be simple and operationally functional |
| **Flexible:** Should be able to be executed for various forms / discussions of disasters |
| **Concise:** Should specify various roles and responsibilities. |
| **Adaptable:** For internal and external disaster. |
| **Part:** of a regional plan. |

encompass roles & responsibilities during disaster management.

The main principles of a hospital disaster plan are shown in Box-1

**Phases of Hospital Disaster Plan**

Box - 2 : Phases of Hospital Disaster Plan

**Preparation** : Development of plan

**Alert**

- Notify personnel
- Prepare for immediate action
- Expand hospital capacity
- Organize incoming patient area
- Assure safe transportation
- Provide information

**Emergency**

- Activate the plan contingency plan as per.
- Type
- Magnitude

**Reestablishment**

- Return to normal activities
- Critical evaluation of plan
- Steps for improvement

The plan should be comprehensive from its inception to activation. The essential phases of the plan are shown in Box 2.

Preparation phase

This should include formation of a Disaster Management Committee. Each hospital / medical unit should have a standing committee for disaster management which should be responsible for preparing, disseminating, follow up, update, training and coordinating. The following may be included in the Committee :

(a) Commandant/CO of hospital
(b) Senior Registrar/Registrar/ Administrative Officer
(c) Head of Departments
(d) MO I/C MI Room
(e) Quarter Master
(f) Coy Cdr
(g) Principle Matron
(h) OIC Medical Stores
(j) Chief Ward Master
(k) OC SHO
(l) MES Representative
(m) Representatives from other support and utility services as required.

**The main functions of Disaster Management Committee include the following**

(a) Develop hospital disaster plan
(b) Develop departmental plans
(c) Allocate duties to hospital staff
(d) Develop standards of emergency care.
(e) To conduct and supervise training
(f) Supervise drills to test the hospital plan
(g) To improve and revise disaster plan regularly
(h) To prepare a comprehensive Disaster Manual

All MOs / RMOs must be fully trained in life support management, familiar with signal communication requirement / procedures, air evacuation procedures triage and other related protocols processes & procedures. They must be aware of the disaster plan of the MH.

**Communications** : Effective communications are critical in disaster management. Internal system of communication the hospital various wards and departments of the hospital must be established.

**Signage** : The hospital should have effective and appropriate signage particularly for exits to be used in case of an emergency , entry/exit points for vehicles and ambulances. Directional signs for use during day and night should also be available for the interior and exterior areas of the hospital.

**Reserve Medical Stores** : All hospital should have a reserve of expendable and non- expendable medical stores including OT clothing and sterile surgical instruments. These should be periodically check and replaced if required.

**Standing Operating Procedures** : All hospital should have standing operating procedures

**Staff Training** : Ongoing training must be provided to all the staff. Drills must be practiced at least once in 03 months and the plan continuously improved. The main functions of a hospital disaster drill are as follows.

(a) To test the hospital response.
(b) To determine the effectiveness and efficiency.
(c) To train the staff of the hospital.
(d) To detect errors or flaws in the plan.
(e) To minimize the response time required by the hospital to react to disaster situations.

**Disaster Facilities :** These should be specified in the disaster plan of the hospital.

These should include the following area

(a) Reception Triage area. The word 'triage' is of French Origin and means selection or categorization. The concept of triage in a disaster situation means classifying victims in order to assign priorities for medical care and transportation .A triage area is the area where victims are immediately placed after rescue/received in hospital and undergo a physical examination in order to assign priority for treatment and transportation to hospitals.

(b) First aid station

(c) Primary treatment areas for managing immediate, urgent and non urgent cases

(d) Secondary care areas such as wards, ICU, OTs and Radio imaging

(e) Information centre , A pre designated officer only should release any information to the media on the details of casualties and or disaster situation.

(f) Relatives waiting area

(g) Morgue : If the hospital morgue does not have sufficient capacity, the plan should designate in advance a site where dead bodies may be kept temporarily.

Hospital in-patient bed capacity may be increased through selective discharges, transferring patients to other hospitals, suspending normal OPDs and postponing non-emergency scheduled surgeries.

**Hospital Disaster Plan** : The following are the important provisions that must be incorporated into a hospital disaster plan.

(a) An efficient system of alert and staff assignment.

(b) Conversion of a usable space into clearly defined areas for triage, patient observation and immediate care.

(c) Removal of casualties to more appropriate and definitive medical care facilities.

(d) Security arrangements.

(e) Establishment of a public information centre.

(f) Evaluation of hospital services and its sources of electricity gas, water, food, and medical supplies.

(g) Identification method for patients who are immediately dischargeable or transferable.

(h) Disaster medical record keeping and medical training.

(j) Planning use of OT, Radio imaging, blood bank, laboratory and critical care facilities.

(k) Effective communication.

Pre hospital Management

The objective of pre hospital care is to render first aid to victims at the disaster site and their safe transportation to the nearest health care facility Pre hospital trauma care should have the characteristics of effectively and efficiency, It may be represented by the acronym TRAUMA as shown in Box 3.

Box - 3 : Characteristics of Pre Hospital Trauma Care

T - Tailored to the requirement.
R - Response coordinated.
A - Active including medical management of casualties.
U - Urgent reactions.
M - Methodical approach.
A - Authority, roles and responsibilities well defined .

The principles of pre hospital care include.

(a) Competent and safe extrication, if required.

(b) Primary examination and resuscitation if required.

(c) Effective evaluation.

(d) Level of care as per status of first responder.

The officer first receiving communication about the disaster must seek all available information including the type/severity of incident and its location. The essential details which may be sought may be represented by acronym ETHANE and in given in Box 4

Box - 4 : Essential Disaster related details to be sought from Source of Information

E - Exact location (Grid reference).
T - Type of incident.
H - Hazards - present and potential.
A - Access and egress routes at disaster site.
N - Number and severity of casualties.
E - Emergency services present or not.

**Disaster Response**

The rapid disaster response is heavily dependent on appropriate disaster plan and preparedness. The initial response is hinged on the rescue and relief. Rescue in specific disaster requires trained personnel and special equipment like rescue in case of earthquake to find survivors in debris / collapsed buildings. The important feature of the response includes the following:

(a) Mechanism for rapid survey and assessment to determine immediate and medium term needs & measures required for rescue and relief.

(b) Mobilization and deployment of resources.

(i) Extrication and rescue.

(ii) On site medical care.

- Mass casualty care.
- Triage, First Aid, Evacuation.

(c) Transportation for definitive care at designated hospitals.

(d) Hospital care

(i) Immediate life saving.

ii) Definitive care.

(e) Long term rehabilitation

**Suggested Format for a Hospital Disaster Plan**

No plan can be made to fit every emergency but a general schedule of enunciated activities will prove to be extremely useful, if executed in a coordinated and disciplined fashion.

(a) Organization and Operations

The disaster management services of the hospital should have elements of quick medical response, effective pre hospital care and efficient definite hospital care. Plan must be comprehensive and holistic. It should incorporate SOPs for management of internal and external disaster. It should include pre hospital and hospital components. It should incorporate the following

(b) Disaster Management Committee

The composition and functions of the Committee have been enumerated above.

(c) Alert Activation

Intimation regarding the disaster may be received by the MO I/C MI Room/ DMO/Sr Registrar/ Adm Officer/ CO/ Commandant or anyone else. The information should immediately be conveyed to the CO / Commandant. Depending on time availability CO / Commandant may instruct the Sr Registrar/ Adm Officer to activate the Plan or he may hold an emergency meeting with the Disaster Management Committee.

(d) Control Center

A control center must be established to coordinate and monitor the various activities. Sr Registrar/ Adm Officer should be operationally functional from this center.

(e) Reception Center

This center receives casualties. Traffic, vehicular as well as human, to the center must be effectively directed and controlled. The center should be managed by DMO /MO I/C MI Room. Stretcher squads, stretchers and trolleys should be readily available.

(f) Disposal of Dead Bodies

In case any patient is declared dead on arrival his body will be shifted to the Morgue.

(g) Collection of Valuables

All belongings of the patients including valuables should be collected, and deposited with the Assistant Registrar / Chief Ward Master. A proper accounting of the same should be done. Arms and ammunition should be deposited in Kot and proper records maintained.

(h) TRIAGE System

A predetermined TRIAGE should be undertaken to classify the casualties. Manpower permitting and for a large number of casualties the TRIAGE team should incorporate a surgeon, an orthopedic, a physician and an anesthetist. After first aid the casualties should be sent to various wards and departments as per priority allocation. A functional TRIAGE As follows may be utilized

(i) Priority I - Needing immediate resuscitation. These casualties should be sent to ICU / acute wards.

(ii) Priority II - Needing immediate surgery. These casualties should be sent to OT.

(iii) Priority III - Needing first aid and possibly surgery.

(iv) Priority IV – Needing only first aid. These may be discharged after first aid.

(j) Death Cases

Brought in dead and those who die while on medical management should be sent to morgue. Details of dead bodies with correct identification mark, sex, physical characteristics and preferable with photographs should be maintained .Dead bodies should be handed over to the NOK after completion of medico-legal formalities.

(k) Additional Bed Space

Disaster casualties may require additional beds. The crisis expansion beds should be utilized. If required the convalescing patients, elective surgery patients and patients who can have domiciliary care/daycare/OPD management should be discharged.

(l) Emergency Blood Bank

Blood of all groups should be stocked to meet emergency requirements. List of potential blood donors should be available and they should be requested to report to the hospital as and when required.

(m) Staff

In addition to members of clinical staff, para and preclinical disciplines should render assistance in managing the casualties. Duty roster for standby staff should be available in the Duty Medical Officers' room.

(n) Nursing staff

A list of nursing staff who may be made available at short notice to render nursing assistance should be available in the Duty Medical Officers Room

(o) Other Staff

Duty roster including those on standby duty of other hospital services like radiology, laboratory, house keeping/sanitation service should be available with the DMO.

(p) Hospital Security

Security of admitted patients, their belongings, hospital staff and equipment is essential. It should receive attention during planning execution of disaster plan.

(q) Dietary Services

The dietary services should be capable of handing additional loads during disaster situations. Acquisition of raw materials and supply of appropriate meals for staff patients should be planned.

(r) Transport Services

Intramural and extramural transport services should b e predetermined and coordinated for disaster situations.

(s) Information Services

An officer should be designated to issue details of casualties to media etc. He should obtain prior clearance from competent authorities before issuing information.

(t) Engineering and Maintenance Services

These services should ensure uninterrupted supply of water and electricity during the management of disasters. Standby generators should be inspected and maintained in operationally serviceable condition.

## Recommended Duties For Disaster Management In Hospitals

### Senior Registrar / Registrar / Adm Officer of Hospital.

He should be the chief coordinator for all arrangements to ensure effective execution of the Disaster Management Plan. His duties should include the following:

(a) To ensure the entire staff of the hospital is fully aware of the disaster plan and their respective duties in case of a disaster. He should ensure that the job cards for every appointment/individual associated with the plan is available and known to the concerned. He should also ensure that the plan is updated regularly.

(b) He should ensure regular practices drill of the plan.

(c) On getting the information of the Disaster, he should inform the CO/Commandant of the disaster and depending on their instructions should either activate the disaster plan or arrange for a meeting of the Disaster Management Committee.

(d) If required to be should instruct the Quick Reaction Team to leave for the disaster site.

(e) He should ensure that the manpower is detailed / beefed up in areas/department/wards as per the Disaster Plan. All those who are not on duty and in station including officers. JCOs and ORs should be instructed to report to their respective duty places.

(f) To ensure that wards/department are ready to receive casualties as early as possible.

(g) To ensure availability of comfortable shelter / accommodation and food / refreshments for relatives of patients.

(h) If required to augment manpower and material resources from other local hospital/units.

(j) To prepare and forward reports and returns regarding details of casualties to all concerned.

### Principal Matron

The duties of the Principal Matron should include the following:

(a) To ensure optimum availability of Nursing Officers in wards and departments.

(b) To ensure wards are ready to receive casualties.

### Coy Cdr.

The Coy Cdr should mobilize and optimally distribute the available manpower to the various departments and wards.

### Quarter Master

The QM should ensure availability of additional requirement from the stores to the wards/departments. If required, he should issue stores for crisis expansion of beds.

### Officer-in Charge Medical Stores

He should ensure that medical kit for QRTs and Disaster Management are ready at all times. The items in the kits should be periodically turned over to avoid expiry of pharmaceutical products.. During disaster management he should ensure interrupted and speedy replenishment of supplies to the wards and department.

### Officer-in-Charge Laboratory

In managing disaster the Pathologist, in addition to his duties may also be designated as the Officer-in-Charge of Mortuary. His duties include the following:

(a) Collect additional stores, if required, for blood grouping and other investigations.

(b) Intimate the blood donors from the station units to report for blood donation.

(c) Arrange for alternative place for keeping of dead bodies if sufficient place is not available in hospital mortuary.

(d) Ensure security of the dead bodies.

(e) Ensure preservation of dead bodies till final disposal.

(f) Ensure proper identification system of dead bodies.

(g) Ensure proper record of dead bodies.

(h) Ensure proper handing/taking over of dead bodies to NOK/Police.

### Chief Ward Master

Chief Ward Master plays a crucial role in effective management of casualties in disaster situations. His duties include the following:

(a) To provide additional nursing staff to various wards and department in consultation with the Principal Matron.

(b) To ensure proper documentation of casualties.

(c) To maintain record of casualties.

(d) To ensure timely handing over of dead bodies to their NOK / Unit / Police after correct documentation and procedures.

(e) To ensure safe custody of patients belongings and valuables.

### Training for Disasters

Training is the essential aspect of the preparedness and it will determine the outcome of the response as well. Training needs attention at all levels of Formation HQs, Medical units and up to the RMO level. The factors to be considered are:

(a) Creating awareness of the Risk, Vulnerability and Hazards.

(b) Dissemination of Disaster Management Plans.

(c) Awareness of role and responsibilities of various functionaries. Teamwork yields better results (19)

(d) Arrangements for mobilization and its practice.

(e) Training of hospital staff in operational zing the hospital disaster plans (20).

## Disaster management plan for natural disasters : A Blueprint

Though all disasters are unique in that they affect areas with different social, medical and economic backgrounds, however there are certain peculiar problems associated with floods, cyclones and Tsunami. These are essentially due to increased load of communicable diseases, food scarcity and mass population displacements and movements. Therefore disaster management includes good site planning; provision of basic clinical services, shelter, clean water and proper sanitation; mass vaccination against specific diseases (and chemoprophylaxis if required); a regular and sufficient food supply; and control of insect vectors of diseases. Table 2 lists the main diseases and disease groups targeted by such interventions.

### Organisation of medical setup

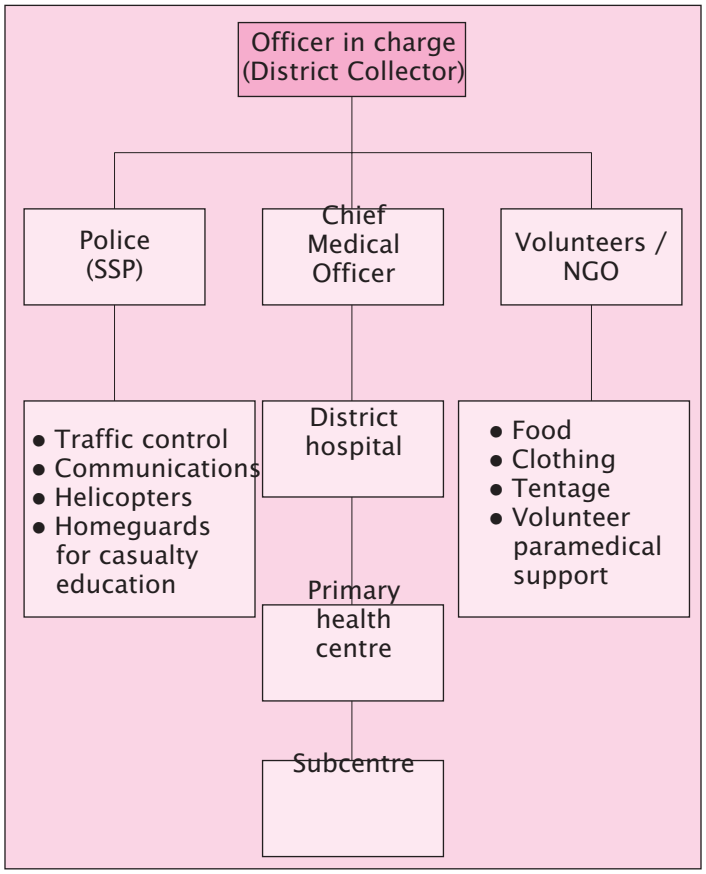
The State Chief Secretary should be overall incharge of Disaster Management in the State. The medical aspects will be coordinated by the State DGHS. He will ensure that adequate manpower reserves are rushed from non affected areas in the State to those which are worst affected so that medical manpower is properly augmented (Fig. 2).

Table - 2 : Main Diseases

| Preventive measures | Impact of spread on |
|---|---|
| Site planning | diarrhoeal diseases, acute respiratory infections |
| Clean water | diarrhoeal diseases, typhoid fever, Hepatitis A and E |
| Good sanitation | diarrhoeal diseases, vector-borne diseases, scabies |
| Adequate nutrition | tuberculosis, measles, acute respiratory infections |
| Vaccination | measles, meningitis, Japanese encephalitis, diphtheria |
| Vector control | malaria, plague, dengue, Japanese encephalitis, other viral haemorrhagic fevers |
| Personal protection (insecticide-treated nets, clothing, shoes) | malaria, leishmaniasis, leptospirosis |
| Personal hygiene | louse-borne diseases: typhus |
| Health education | diarrhoeal diseases |
| Case management | cholera, shigellosis, tuberculosis, acute respiratory infections, |

At the District Level, the District Collector will be the Chief Executive of the Disaster management cell. He will be in a position to coordinate all relief effort with various departments including ensuring NGO participation. The medical team will be headed by the Chief Medical Officer (CMO) of the district. The various programme officers under him like the District Malaria Officer, the District Immunisation Officer, etc will ensure availability of equipment, stores and manpower required for disaster activities. The District hospital will be responsible for providing referral services for curative care as well as outreach teams to be deployed at short notice in affected remote areas. These teams should have medical officers, surgeon, anesthetist, and adequate paramedical staff.

Fig - 2 : Disaster management organisation at district level



The nodal peripheral unit for providing medical relief will be the PHC of the area and the MOi/c PHC will coordinate all effort and seek assistance of the CMO as and when required. The Subcentre staff will support him in all the activities.

### Medical relief

Pre planned medical bricks comprising essential drugs and equipment for management of casualties will be located at the district hospital. This will be issued to the affected relief teams under the directions of the CMO.

Each medical brick should be capable of managing approximately a population of 1000 persons for a period of 30 days. The suggested drugs and equipment are listed at Appx 'A' for one medical brick. However, the same is not exhaustive and can be modified as per local needs and health problems of particular districts.

**Public health aspects**

In the case of natural disasters like floods, tsunami and cyclones it is important to plan the public health activities so that one is prepared for proper management of the disaster. The important aspects include provisioning of appropriate shelter for displaced population, potable water supply, food and nutrition and sanitation. Some suggested norms are shown in Table - 3.

Shelter

In natural disasters, the displaced population must be sheltered in temporary settlements or camps. The selection of sites must be well planned to avoid risk factors for communicable disease transmission, such as overcrowding, poor hygiene, inadequate water supply, insanitary disposal of excreta vector breeding sites and lack of adequate shelter. Such conditions favour the transmission of diseases such as measles, meningitis and cholera. Critical factors to consider when planning a site are: water availability, means of transport, access to fuel and access to fertile soil. The surrounding environment may also pose a threat to health in the form of vectors not encountered in the population's previous place of residence. In order to reduce such risks it is essential that site selection, planning and organization be undertaken as soon as possible. The following criteria should be considered when assessing site suitability; other criteria may also be relevant in specific situations.

Water supply

The availability of an adequate amount of safe water has proved in practice to be the single most important criterion for site location. The water source should be close enough to avoid transporting water by trucks, pumping it over long distances or walking long distances to collect insufficient quantities.

Space

There must be enough space for the present number of emergency-affected population, with provision for future influxes and for amenities such as water and sanitation facilities, food distribution centres, storage sites, hospitals, clinics and reception centres.

Topography and drainage

Gently sloping sites above the flood level is preferred in order to provide natural drainage. Flat areas, depressions, swamp, river banks and lakeshore sites should be avoided. Windy sites are unsuitable, as temporary shelters are usually fragile.

Soil conditions

The soil type affects sanitation, water pipelines, road and building construction, drainage and the living environment (in terms of dust and mud). The most suitable soil type is one that will easily absorb human waste.

Access

The site should be accessible at all times (e.g. for food deliveries, roads during rains).

Vegetation

The site area should have good vegetation cover if possible. Trees and plants provide shade, help to prevent soil erosion, allow recharge of the groundwater supplies and help in reducing dust. It may sometimes be necessary, however, to destroy poisonous trees or plants, for example where populations are accustomed to collecting berries or mushrooms. Table 3 gives the site planning norms.

Water

Water and sanitation are vital elements in the transmission of communicable diseases and in the spread of diseases prone to cause epidemics. Diarrhoeal diseases are a major cause of morbidity and mortality among affected populations, most being caused by a lack of safe water, inadequate excreta disposal facilities and poor hygiene (see Table 4). The goal of proper water and sanitation facilities is to minimize risks to the health of a population, particularly one caught up in the difficult circumstances of an emergency with its attendant displacement and dangers. Such a programme is an integral part of preventive health activities. The main focus of such a programme is on :

(a) The provision of a safe and sufficient water supply,

(b) Provision for excreta disposal and the establishment of other waste control and hygiene measures,

(c) A programme of public education for the affected population on the issues of hygiene and water use.

In a natural disaster, the affected populations need immediate access to a water supply in order to maintain

Table - 3 : Site planning norms

| | |
|---|---|
| Area per person for collective activities | 30 $m^2$ |
| Shelter space per person | 3.5 $m^2$ (4.5–5.5 $m^2$ in cold climates) |
| Distance between shelters | 2 m minimum |
| Area for support services | 7.5 $m^2$/person |
| Number of people per water point | 250 |
| Number of people per latrine | 20 |
| Distance to water point | 150 m maximum |
| Distance to latrine | 30 m |
| Distance between water point and latrine | 100 m |
| Firebreaks | 75 m every 300 m |
| | |

Table - 4 : Diseases caused due to unsafe water

| | |
|---|---|
| Diseases that occur owing to a lack of water and poor personal hygiene | Skin infections: scabies, impetigo<br>Ophthalmic infections: conjunctivitis, trachoma<br>Louse-borne diseases: typhus |
| Diseases that occur owing to poor biological quality of the water | Caused by faecal pollution: cholera, typhoid, other diarrhoeal diseases, hepatitis A, hepatitis E, schistosomiasis<br>Caused by the urine of certain mammals: leptospirosis |
| Conditions that occur owing to poor chemical quality of the water | Poisoning |

health and to reduce the risk of epidemics. If the emergency-affected populations have to be sheltered in temporary settlements or camps, water supply is an essential consideration in choosing the site location. An adequate amount of safe drinking-water must be provided for the entire displaced population. The first objective is to provide sufficient water; quality can be addressed later. Sufficient water of low quality is better than very little water of high quality. During the rapid assessment of a proposed site it is essential to protect existing water sources from possible contamination. If the population has already moved into the area in question, then immediate measures should be taken to isolate and protect the water source, if it is on or near the site. Table 5 gives the recommended doses of Chlorine tablets that can be distributed to the affected populations to prevent diarrhoeal diseases. Location of water distribution points are given in Table - 6 :

Sanitation

The aim of a sanitation programme is to develop physical barriers against the transmission of disease, in order to protect the health of the disaster affected population. These barriers include both engineering measures and personal hygiene measures. The provision of latrines and the development of methods of waste disposal are essential elements of the programme. These measures are only fully effective, however, when complemented by a sanitation education programme. The efficient and safe disposal of human excreta is as important as the provision of water in its positive effect on the health of the emergency-affected population. Human excreta is more likely to transmit disease than animal waste. It contributes to the transmission of numerous diseases (which can be particularly when combined with low levels of nutrition) and can also be a breeding ground for flies and other insects. In the acute phase of an emergency, any form of excreta disposal is better than none. The simplest and quickest methods should be adopted; these can later be improved on and changed. Initially, speedy action is important in averting human catastrophe.

Excretion fields must be prepared on the first day. Indiscriminate defaecation needs to be controlled. Areas where defaecation cannot be permitted are:

(a) Near rivers, streams and lakes and within 30 metres of any water source or water point

(b) Near water storage facilities

Table - 5 : Recommended dilution and use of Aquatabs

| | | Type of water and source | | | |
|---|---|---|---|---|---|
| | | Clear Piped water | Protected tube wells, ring wells, clear rain water | Unprotected wells and cloudy water : filter before purifying | Water known to have faecal contamination : Filter before purfying |
| Tablet size | Chlorine per tablet | Volume of water treated per tablet (Litres) | | | |
| 8.5 mg | 5 | 5 | 2.5 | 1 | 0.5 |
| 17 mg | 10 | 10 | 5 | 2 | 1 |
| 67 mg | 39.41 | 39.41 | 19.7 | 7.88 | 3.94 |
| 340 mg | 200 | 200 | 100 | 40 | 20 |
| 500 mg | 294 | 294 | 147 | 58.8 | 29.4 |
| Free available chlorine content after treatment (Residual) | | 1 mg / Litre | 2 mg / Litre | 5 mg / Litre | 10 mg / Litre |

Table - 6 : Location of water distribution points

| | |
|---|---|
| Location | Water distribution points must be set up in suitable places around the camp. A good location is an elevated spot in the centre of a living area. If the water points are from ground sources, no sanitation facilities should be within 50metres, and definitely not closer than 30 metres. If the water point is too far away, people will not collect enough water or may |
| Design | When designing water points consider the following:<br>✎ Traditional water-carrying methods,<br>✎ The containers used: for example, a raised area is suitable for people who carry the bucket on their heads,<br>✎ Who collects and carries the water (it is usually the women and children),<br>✎ The availability of spare parts.<br>There should be enough space on the concrete slab around the water point for laundry and bathing areas. If sanitation is compromised, it may be felt necessary to locate bathing and washing areas away from collection points. However, traditional practices and habits need to be accommodated as much as possible. Animals must certainly be kept away. If they are mobile herds, watering facilities should be established some distance away and a fence erected around the water point. |
| Number | One tap per 200 - 250 people is the ratio recommended by the United Nations High Commissioner for Refugees (UNHCR). The more people there are per tap, the more wear and tear there is. Nobody should have to wait longer than a few minutes; if collection takes a long time, people will return to old, contaminated but quicker sources. |

(c) Uphill of the camp
(d) Uphill of water sources
(e) Along public roads
(f) Near feeding centres, clinics, food storage depots and distribution centres.

These areas should be fenced off and guarded where necessary. The use of water for anal cleansing may explain defaecation near water sources. Water must be provided in alternative locations to control this practice effectively. These measures must be announced throughout the camp with the assistance of the community leaders, and displayed on signs, using both words and pictures.

As a short term measure Deep trench latrines (DTLs) used by the army would serve as a very effective and simple measure providing one seat (of 5 latrines for 50-75 people) staying in the camp. Adequate seats and digging material should be procured for this purpose.

Food and Nutrition

Food shortages and malnutrition are common features of emergency situations. Ensuring that the food and nutritional needs of an emergency-affected population are met is often the principal component of the humanitarian response to an emergency. When the nutritional needs of a population are not met, this may result in protein–energy malnutrition and micronutrient deficiencies such as iron-deficiency anaemia, pellagra, scurvy and vitamin A deficiency. There is also a marked increase in the incidence of communicable diseases, especially among vulnerable groups such as infants and young children, and these contribute further to the deterioration of their nutritional status. The nutritional requirements of a population must be assessed to:

(a) Identify the nutritional needs of individuals, families, vulnerable groups and populations as a whole,
(b) Monitor the adequacy of nutritional intake in these groups,
(c) Ensure that adequate quantities of safe food and appropriate food commodities are procured for general rations and selective feeding programmes.

Table 7 below summarizes the main daily requirements used to calculate the average content of emergency rations.

Non Governmental Organisations can be effectively utilized for providing nutritional support under a coordinated manner.

Vaccination

The major outbreaks expected during natural disasters would be of feco oral group of diseases namely typhoid and cholera. It is therefore essential that vaccines should be procured in advance so that they could be used in the eventuality of an outbreak. Vaccination for typhoid would also assume priority in non immunized populations. However, if there is a strong routine immunization programme in vogue then there is no need to do the same during epidemics. India unfortunately does not have a free child or adult immunization programme against typhoid. It is important to therefore formulate a national

Table - 7 : Nurtitional requirements

| Food Type | Quantity |
|---|---|
| Energy | The mean energy requirement is 2100 Kcal /person /day |
| Fat/ Oil | 17-20% of the energy should be in the form of edible fats or oils. |
| Proteins | 10-12% of the energy should be in the form of proteins.<br>Recommended daily protein intake : 46g from an avarage mixed diet of cereals, pulses and vegetables. |

strategy for routinely immunizing our population against typhoid as is done in the Armed Forces. The use of cholera vaccine is recommended only in stable post-emergency situations.

The other major vaccines used in such situations are those against measles. Measles vaccination is one of the highest priorities in the acute phase of an emergency if vaccine coverage rates in the affected population are below 80%. The main objective of a measles vaccination programme is to prevent an outbreak of measles with the high mortality rates often associated with this disease in emergency situations. In this way, the measles vaccine provides one of the most cost-effective public health tools. Once the acute phase of the emergency is over, plans should also begin to re-establish the Expanded Programme on Immunization (EPI) to routinely immunize children against tetanus, diphtheria, polio and tuberculosis. This should be integrated with the national EPI programme using national vaccination policies, and it is important to involve the national EPI programme from the start of any plan or activity. The organization of a vaccination campaign requires good management ability and technical knowledge. Responsibilities for each component of the vaccination programme need to be explicitly assigned to agencies and persons by the health coordination agency. The national EPI of the host country should be involved from the outset. National guidelines regarding vaccination should be applied in emergency situations as soon as possible.

**Mass vaccination strategies**

To implement a mass vaccination campaign in emergencies, there are two main strategies.

(a) Vaccination can be carried out at the screening centre on arrival at a camp. This is possible when the screening facility has been set up and the influx of refugees is steady and moderate.

(b) Vaccination sites can be set up in different sections of the target area and mass vaccination carried out by outreach teams. This is necessary when the population has already settled at a site or the influx has been too rapid to organize a screening facility.

The list of essential vaccines and cold chain equipment to be maintained at the District Level for rushing into affected areas is given as Appx 'B'. However, they need to be given to the populace only after taking into considerations all epidemiological aspects.

Vector control

The purpose of vector control is to reduce disease transmission by rendering the environment unfavourable for the development and survival of the vector. Prevention is better than cure, and when the planning and construction of camps is undertaken, preventing the development of vector problems should be taken into account. Complete eradication of a vector is rarely possible but the vector population and its life expectancy should be kept to a minimum. Early diagnostic and treatment are needed to prevent severe forms of the disease (especially for malaria) when transmission control is needed to reduce incidence. Both are complementary and two essential components of any effective vector borne disease control programme. The major biological vectors are mosquitoes, sand flies, ticks, fleas, lice, mites. Important carrier reservoirs or intermediary hosts are rodents. The diseases most commonly spread by vectors are malaria, dengue fever, typhus, leptospirosis and plague. The main methods of vector prevention and control can be classified as personal protection; environmental control; campsite, shelter and food store sanitation; community awareness; and chemical control such as residual or space spraying, insecticide-treated traps, selective larviciding and the use of rodenticides. Vector control is very specific to the ecology of the vector, the epidemiology of the disease, the human and social environment as well as resources locally available (e.g. technical staff, structures, logistics). For mosquito control it is essential to have an adequate stock of antimalarial drugs, repellents, and hygiene chemicals for antilarval spray. Cases of dengue need to be isolated immediately. When camps are there for long duration, fly nuisance is bound to set in and can lead to diarrhoeal diseases like shigellosis and salmonellosis. ORS packets should be available in abundance and sanitary control by community education and proper disposal of garbage is to be ensured. The Surat plague occurred immediately following the floods in the city leading to panic. Advanced planning and proper dissemination of information can prevent panic in such situations. Leptospirosis is another common health problem envisaged after the floods. Prompt diagnosis and wearing of proper clothing by the rescue teams (anklets in the case of soldiers) can prevent this disease.

The hygiene chemicals and equipment for vector control is given as Appx 'C'.

Readiness for chemoprophylaxis

The current epidemiological situation will decide whether to give chemoprophylaxis to the entire population or a select sub population or to health care workers involved in relief operations. The common diseases for which chemoprophylaxis should be readily available are:

| | | |
|---|---|---|
| Leptospirosis | - | Doxycycline |
| Cholera | - | Doxycycline |
| Meningitis | - | Rifampicin |
| Malaria | - | Chloroquine |
| Plague | - | Doxycycline |

Surveillance

Surveillance is the ongoing systematic collection, analysis and interpretation of data in order to plan, implement and evaluate public health interventions. The word surveillance means "watching over". A surveillance system should be simple, flexible, acceptable and situation-specific. It should be established at the beginning of public health activities set up in response to a disaster.

The objectives of a surveillance system in a disaster are to:

(a) Identify public health priorities;

(b) Monitor the severity of an emergency by collecting and analysing mortality and morbidity data;

(c) Detect outbreaks and monitor response;

(d) Monitor trends in incidence and case-fatality from major diseases;

(e) Monitor the impact of specific health interventions (e.g. a reduction in malaria incidence rates after the implementation of vector control programmes);

(f) Provide information to the Ministry of Health, agency headquarters and donors to assist in health programme planning, implementation and adaptation, and resource mobilization.

Experience from many disaster situations has shown that certain diseases / syndromes must always be considered as priorities and monitored systematically. In the acute phase of an emergency, the major diseases/syndromes that should be reported are:

(a) Bloody diarrhoea

(b) Acute watery diarrhoea

(c) Suspected cholera

(d) Lower respiratory tract infection

(e) Measles

(f) Meningitis

After the second / third week the following diseases should be added on:

(g) Malaria

(h) Dengue/ DHF

(j) JE

(k) Leptospirosis

(l) Septic dermatological complications

Lab for basic diagnostic tests of stool and blood may be established by field reporting units but for specific bacteriological and virological tests, the referral labs in nearby cities or areas will have to be marked.

### Critical elements of preparedness and response

The preparedness and response depends upon various critical elements. The information of the disaster plans from State Level to District Level, role and responsibilities of various resource organizations, mechanism for coordination, control and practice are some of the critical issues. The preparedness will depend upon appropriate disaster plans for regional / local area based on risk, hazards and vulnerability analysis, and the resources available. The coordination at various levels of government by the appropriate State HQ and at local level by the Medical Establishment based on the anticipated role and responsibility is critical issue for rational response during disasters.

The disaster plans preparedness and response is dependent on the State Government policies, legislation, organisation, disaster plans, resource organisation, role and responsibilities of various agencies, logistic plans, coordination, evacuation and shelter plans, training, public awareness and drills. The State Government plans become the baseline for the matching District HQ Plans to provide the support expected in disasters. The District HQ plans at various levels will include all the elements of resource organisation to meet the demand of anticipated in disaster event. The role and responsibilities allotted for health care becomes the total point for preparedness and developing health care plans. Each Medical Establishment then prepares its plans based on the overall objectives, roles and responsibilities and resources available.

**Medical brick for a population of 1000 for 30 days**

| S.No. | Nomenclature | Qty |
|---|---|---|
| 1 | Inj Lignocaine | 02 |
| 2 | Inj Atropine | 02 |
| 3 | Tab Common cold | 2,000 |
| 4 | Inj Morphine | 50 |
| 5 | Inj Ranitidine | 10 |
| 6 | Inj Fortwin | 50 |
| 7 | Inj Adrenalin | 30 |
| 8 | Tab Cetrizine | 800 |
| 9 | Tab Periactin | 100 |
| 10 | Tab Dexamethasone | 200 |
| 11 | Inj Dexamethasone | 10 |
| 12 | Inj Hydro Cortisone | 20 |
| 13 | Inj Avil | 20 |
| 14 | Tab Avil | 400 |
| 15 | Inj Phenargan | 20 |
| 16 | Inj Diazepam | 20 |
| 17 | Anti inflammatory | 1000 |
| 18 | Antibiotics | 5000 |
| 19 | Antipyretics | 1000 |
| 20 | Anti malarials | 2000 |
| 21 | Antitussives | 10L |
| 22 | Antispasmodics | 300 |
| 23 | ORS | 1500 |
| 24 | Hydrogen Peroxide | 5.000L |
| 25 | Liq Antiseptic | 1.000L |
| 26 | Eye Drops cifran | 15 |
| 27 | IV Fluids NS | 576 Bott |
| 28 | IV Fluids DNS | 576 Bott |
| 29 | IV Fluids 5% Glucose | 1,104 Bott |
| 30 | IV Fluids R/L | 2,256 Bott |
| 31 | Haemaccel | 900 Bott |
| 32 | IV Set | 576 Bott |
| 33 | IV Catheter | 576 |
| 34 | Cotton Absorbent | 10 Kg |

### C

**List of hygiene chemicals and entomological equipment**

| S.No | Nomenclature | Qty |
|---|---|---|
| 1 | Thermal fogger | 01 |
| 2 | Knapsack sprayer (16 L) | 02 |
| 3 | Compression sprayer (12 L) | 03 |
| 4 | ULV fogger | 01 |
| 5 | Malathion EC 50% / DDT WP | 300 L/Kg |
| 6 | Temephos/Baytex EC | 10L |
| 7 | Aquatabs (17 mg) | 1,00,000 |
| 8 | DMP oil | 25L |
| 9 | Impregnated bed nets* | 600 |
| 10 | Bleaching powder (33% Available Chlorine) | 30Kg |
| 11 | Cresoli Black | 150L |

* 6L of commercial Deltamethrin containing 2.5% of AI will be required for 600 bed nets.

### B

**List of essential vaccines and cold chain equipment for a population of 1000**

| S.NO | VACCINE | Doses |
|---|---|---|
| 1 | Typhoid oral | 600 |
| 2 | Cholera | 400 |
| 3 | Measles | 250 |
| 4 | Japanese Encephalitis | 250 |
| 5 | Tetanus Toxoid | 300 |
| 6 | Tetanus immunoglobulin | 300 |
| 7 | Meningococcal vaccine | 300 |
| 8 | Vaccine Carrier | 15 |
| 9 | Cold boxes | 10 |

# Principles of Health Education

Public Health is the science and art of preventing disease prolonging life, and promoting health and efficiency through organized community efforts. In earlier periods, public health dealt with the sanitation of the environment and the control of communicable diseases enforced by law if found necessary. However stimulating and helping people to assume responsibility for themselves needs understanding people's behaviours and the factors influencing it. Health education attempts to influence the health related knowledge, attitude and behaviour of individuals and communities. In fact, in contemporary public health practice, providing health education, with a view to achieve positive changes in health related attitudes and behaviour from community members is the most important requirement, be it prevention and control of HIV / AIDS or lifestyle (non-communicable) diseases or prevention of infectious diseases and so on.

### Definition

Health education can be defined as a process with intellectual, psychological and social dimensions relating to activities which increase the abilities of people to make informed decisions affecting their personal, family and community well being. This process, based on scientific principles, facilitates learning and behavioral change among both, individuals & communities (1).

### Information Education Communication (IEC)

IEC is a broad term comprising a range of approaches and activities. Visible component of IEC is frequently the material produced and used. Effective IEC makes use of a full range of approaches and activities. IEC activities are grounded in the concepts of primary health care, concerned with individual behaviour change and changes in social or community norms. IEC can be defined as an approach which attempts to change or reinforce a set of behaviour in a target audience regarding a specific problem in a predefined period of time. It is multidisciplinary and client centered in its approach drawing from the field of social marketing behaviour analysis and anthropology.

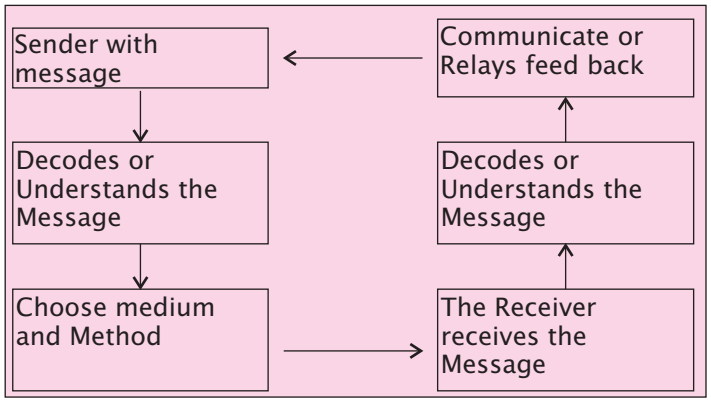
### Communication Process

In health communication we communicate for a special purpose to promote improvements in health behaviour through the modification of the human, social and environmental factors that influence behaviours. It is necessary to understand how communication works. The various components involved in the process of communication are depicted in Fig. - 1.

Components of the Communication process

It is apparent that several elements are involved in the process of communication. It will also be appreciated that communication is two way process. This implies that just as the sender (source) is communicating with the receiver; so also is the receiver communicating with the sender. The components are :

Fig - 1



### The Sender

Sender is the source of Communication. The following aspects need to be particularly considered with regards to the sender :

(a) His own competence and expertise in the subject.

(b) His own convictions about what he speaks.

(c) His own mannerisms, which include non-verbal communication skills.

### The Receiver

Also called the audience who are receiving the message sent by sender.

### The Message

This refers to the information which he/she desires to communicate and must possess the following attributes :

(a) Message should be precise, accurate and to the point.

(b) The ambiguity in the message may create more harm than good.

(c) The information should vary from person to person or from group to group depending upon their background.

(d) The message must necessarily contain clear, concrete suggestions for action in day to day life of the receiver.

### The Medium (Channel)

The communication channel through which the message moves from the sender to receiver is the medium. These include the various methods (as lecture or exhibition) and the "aids" (as slides, slide projector) which are utilized to communicate the message.

**Encoding**

This process includes the language expression, gestures and actions utilized for the purpose of making the information intelligible to the receiver. Obviously the receiver must be familiar with the code.

**Decoding**

The process by which receiver understands or interprets the message is called decoding.

**Feed back**

The part of the receiver's response that the receiver communicates back to the sender.

**Propaganda and Advocacy**

Propaganda is merely a publicity campaign aimed at presenting a particular concept in a favourable light in such a way that public may accept it without thinking. It is a deliberate attempt planned with a view to altering and controlling ideas and values along predetermined lines. The widely employed techniques are an appeal to emotions, feelings and sentiments. It prevents or discourages thinking by readymade slogans. The knowledge is spoon-fed and passively acquired. As a mass-communication activity, propaganda tends to have short-run situationally-defined aims with an appeal to diverse population on the basis of immediate interests, fears or desires. The objective is to not so much influence the individual deeply as it is to win his support for some immediate issue.

The aim of ADVOCACY is to place health problems issues on the political agenda and effectively reach the influential group of policy makers, elected representative, professionals and other interest groups to formulate and implement policies to create pressure groups and supportive systems in order to respond appropriately to the health problems. It helps in identifying potential allies and building alliances and relevant policy and decision making channels. The information concerning position on the issue is collected and provided. A common understanding among stakeholders concerning issue is created through advocacy and negotiating action on the basis of common understanding is taken.

**Barriers in Communication**

Unplanned distortion during the communication, resulting in the receiver obtaining a different message than that sent by the sender, is referred to as or barriers in communication (also called as "Noise" or "distortions" in communication. These can be :

(a) Physiological – Difficulties in hearing, expression.

(b) Psychological – Emotional disturbances.

(c) Environmental – Noise, invisibility, congestion in the classroom, etc.

(d) Cultural – Level of knowledge, understanding and receiver's beliefs, etc.

All barriers should be identified and removed for achieving effective communication. One of the main challenges in the design of effective health communication programs is to identify the optimal contexts, channels, content, and reasons that will motivate people to pay attention to health information.

**Communication skills**

Communication skills are required to make communication effective. These include greeting skills, speaking skills, listening skills, questioning skills, and summarizing skills. In short communication process would be effective if the communicator has skills in introduction, skills in presenting and skills in conclusion.

**Non-verbal communication**

Non-verbal communication is the way in which human beings influence each other without words. In health communication, non-verbal communication plays an important role. It also affects the communication process. Body language is an important constituent of non-verbal communication and consists of gesture, postures, facial expressions, eye contact, manipulating the eye brows etc.

**Behaviour Change Communication Process (BCC)**

This is depicted in Box – 1 & Fig. 2 :

**Components of Health Education Process**

Health Education has three broad components :

Box - 1 : Process of Behaviour Change

**Informed / Aware -** Initially a person is unaware that a particular behaviour may be harmful. The first step in a behavioural change programme is therefore to make people aware through various channels using mass media, group methods and through interpersonal communication.

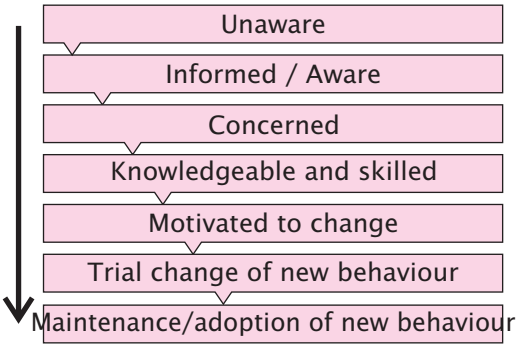
**Concerned -** Information must be given in such a way that the audience feels it applies to them i.e. the audience becomes concerned and people are motivated to evaluate their own behaviour. Targeted communication and interpersonal approaches are more useful.

**Knowledge & skill** - Once concerned, individuals may acquire more knowledge and develop skills by talking to peers, social workers or healthcare providers. More interpersonal communication are needed at this stage, specially training programmes to build and develop skills

**Motivated and Ready to change -** Individuals might now seriously begin to think about the need and importance of new health message and measures. Positive message from peers are particularly effective.

**Trial change of Behaviour -** the individuals decide and try

Fig - 2



(a) Levels of Health Education
(b) Methods of Health Education
(c) Activities undertaken in individual methods

Levels of Health education

Health education is carried out at three main levels, viz., individual and family, group level and general public (mass) level.

**Individual and Family Health Education**

There are plenty of opportunities for individual health education. It may be administered during personal interviews in the consultation room of the doctor or in the health centre or in the homes of the people. The individual comes to the doctor or health centre because of illness. The opportunities are utilized in educating him on matters of interest – diet, causation and nature of illness and its prevention, personal hygiene, environmental hygiene etc. Topics for health counseling may be selected according to the relevance of the situation. By such individual health teaching, we will be equipping the individual and family to deal more effectively with health problems. The patient will listen more readily to the physician. A hint from the doctor may have a more lasting effect than volumes of printed words. The nursing staff has also ample opportunities for undertaking health education. Public health supervisors are visiting hundreds of homes; they have plenty of opportunities for individual teaching while working with individuals. The health educator must create an atmosphere of friendship and allow the individual to talk as much as possible. It is useful to remember, "An effective communicator is not the one who talks too much but one who listens too much."

An effective method of individual education is **Counseling,** which is defined as a confidential dialogue between a client and a health care provider aimed at enabling the client to cope with stress and take personal decisions related to disease. The counseling process includes an evaluation of personal risk of disease transmission and facilitation of preventive behaviour. The aim of counseling must always be based on the needs of the client. The purpose of counseling is three fold : to help clients manage their problems more effectively, to develop unused opportunities to cope more fully, and to help and empower clients to become more effective self helpers in the future. Helping is about constructive change and making a substantive difference to the life of the client. However, ultimately, it is only the client who can make the difference. The counselor is merely an instrument to facilitate that process of change. In the short-term, counselors use basic skills to help clients make personal decisions about their behaviours.

**Group Health Education**

Our society contains groups of many kinds – school children, mothers, industrial workers, patients, etc. Group teaching is an effective way of educating the community. The choice of subject in group health teaching is very important as it must relate direct to the interest of the groups health. The methods in group health education are focus group discussions, health talks, demonstration, panel discussions and workshops. The group health education methods are effective in promoting behavioural change, influence opinion, develop critical thinking and increase motivation. Use of "aids" to education greatly facilitates group education. Examples of commonly used "AIDS" are given in Box – 2.

**Focus group discussions (FGD)**

Box - 2 : "AIDS" in health education

**Auditory :** Audio cassettes, tape records

**Visual :** Text Books, Posters, Charts, diagrams, film strips, comic strips, pamphlets, internet

**Audio-Visual :** Movies, lectures combined with slide presentations, Television.

A Focus group discussion is a group discussion of 6-20 persons guided by a facilitator during which group members talk freely and spontaneously about a certain topic or health problem. The purpose of a focus group discussion is to obtain in-depth information on concept, perceptions and ideas of group on a particular topic.

**Education of the General Public (Mass education)**

For education of the general public we employ "Mass Media" of communication. Mass media are generally less effective in changing human behaviour than individual or group methods because mass communication is one way. Nevertheless they do have quite an important value in reaching large numbers of people with whom there is no contact, in a short period of time. The continuous dissemination of information and views about health through all the mass media contributes in creating awareness and raising of the level of knowledge in the community. Examples of Mass-Media are given in Box – 3.

Box - 3 : Examples of "mass media"

- Television
- Radio
- News Paper
- Films
- Health Magazines
- Posters
- Health Exhibitions
- Health Museums
- Printed Materials

For effective health education mass media should be used in combination with other methods. Television, News Paper, and Radio are the most basic channel of health information communication. The internet and other advance communication technologies such as mobile telephone message and satellite television are important channel for health information communication. They have had more influence in the younger generation and in urban community. These communication channels are emerging and being adapted rapidly in the movement toward modernization.

**Methods of Health Education**

Methods are generic descriptions of how change is to be brought about within the target group; for example, mass media and community development are two terms being

used to describe a host of health education activities. While planning health education programs, it is not that any method can be used (as delivering lectures to all concerned) but rather the method most suited for the topic and the target audience should be selected. The commonly available methods are listed in box - 4. (2)

**Activities in Health Education**

Box - 4 : Commonly Used Health Education Methods

- Individual Instruction(as counseling, patient instruction)
- Lecture – Discussion
- Educational Television / Computer (Use of television, computer and internet for viewing of prepared programs)
- Audio-Visual Methods (see earlier box)
- Mass Media Methods (see earlier box)
- Peer Group Discussion / Focus Group Discussions
- Programmed learning (use of teaching machines, or programmed texts)
- Simulation & games (games, dramatizations, role playing)
- Inquiry Learning (an approach in which students formulate and test their own hypothesis)

The various methods of health education, as enumerated above, are utilized through different activities, depending on the objectives and the type of target audience. For example, a small group / focus group discussion can be undertaken using a LCD projected slide show, or through a flip chart, or may be simply an open multi-way discussion without using any teaching aid. Similarly, mass education process may be through the activities of traveling through the streets with a loud speaker or by inserting TV footages or through a documentary cinema. The appropriateness of the method and how this method is going to be processed (i.e., the activities) should be decided by the health education planner.

# Planning and Implementation of Health Education Programmes

In contemporary public health practice, health education of the community (whether small groups or large masses) or of individuals (patients or healthy individuals) is one of the most important health care activity. Medical officers, specialists in various medical disciplines and specialists in Community Medicine (Public health and Preventive Medicine) in particular, should therefore be well versed in the various steps to be undertaken while planning, organizing, implementing and evaluating health education programmes. This involves a series of scientific and sequential steps, which are being explained in this chapter, duly illustrated with an example in the settings of Armed forces.

### Step 1 - Situational Analysis

The first, and one of the most crucial steps in health education programme planning is "Situational Analysis", also known as "Community Analysis" or "Needs Assessment". This is the essential step for gaining insight into the health problems, so that programmes can be developed and directed towards conditions which are significant issues for the community members. This step of community analysis consists of following five sequential steps, viz, analyzing the community backdrop, analysis of the health status of the community, analysis of the health care system of the community, analysis of social systems of the community, and SWOT analysis. After these five sub-steps, we move to the next vital step, i.e., community diagnosis". We discuss each of these steps, as follows.

(a) Analyzing the Community Backdrop

The first thing is to get to know the area and the community under your jurisdiction (or the community for which you are planning the health education program), very well. Drive (preferably walk) around the entire area. Find out where are the work places, location of various governmental and non-governmental offices, location of various military units, markets, eating joints, recreation facilities, training areas, schools, hospitals, other health care facilities (as Medical Inspection (M I) Rooms), family residential areas, etc. See for yourself the minute details, as what are the roads and other communication systems, the pattern of residential accommodation, water supply system, night-soil disposal system, solid-waste disposal system, and environmental conditions. Don't forget to find out about sensitive issues like defined red-light areas, clandestine sexual avenues, tobacco kiosks, alcohol shops and so on.

After the initial inspection, define some tentative boundaries that can demarcate the larger area into smaller, more homogenous aggregates. The most obvious choices are the major physical boundaries as major roads, rivers, or government boundaries as those delimiting the village or Taluka or district. In armed forces, a well established method is to divide the area into five "sectors" which all Station Health Organizations (SHOs) undertake for purpose of various preventive health care activities. Having done this detailed exercise, make a detailed "spot map" showing all these various aspects, as described above. In armed forces, developing and regularly updating such spot maps is, in any case, an indispensable duty of the Officers Commanding SHOs. Whenever you take over as the OC, SHO or as DADH of a formation HQ, the first thing you should do is to undertake a detailed, on ground assessment of your area under health cover and update the spot maps. MOs and RMOs should assess the details and update the spot maps for their respective areas. Listen to the local radio and see the local television programmes, which would further assist you in getting an insight into the community backdrop.

Find out the details of the socio-demographic characteristics of the community under your health care. Find out the total population, distribution according to social status (rank structure in armed forces), according to age groups, according to families and children, and further according to the different geographical sectors that you have made to demarcate the community. See the main occupations, industry and business patterns. Now write down the details in a textual form, complemented by the spot maps, tables of various demographic characteristics and other graphics. It is important to develop a written document at this stage since it will come very handy later on while implementing the health education programme. In any case all OC SHOs and DADH should always keep such a written document, duly updated, since it will be an essential and basic document for planning all health care activities including health education; the document can also be placed by the OC SHO / DADH, before the Senior Advisors, as and when they visit them (Box - 1).

(b) Analysis of Community Health Status

In this step, the data related to important epidemiological parameters is collected from various sources as hospital records, official reports, and, if required by a quick sample survey (Details of important epidemiological parameters and sources of epidemiological information have already been covered in the section on "Principles of Epidemiology"). The main parameters, depending upon requirements include Birth rate, death rate, IMR, MMR, Neonatal MR and death rate according to major socio-economic categories (as social class, sex, rank status, etc.). Thereafter, mortality and hospitalization rates per 1000 (or per lac) population are worked out, for the past 3 years, for the leading 10 or 15 causes, separately for males, females and children (preferably for different age groups). These rates give us a clear idea of the leading causes of death and disease for various age and sex groups. These rates are then compared with the rates for

Box - 1

This is a hypothetical example of planning, organizing and implementing a community health education program. Maj 'X' was posted as the OC, SHO of "Juliet" (J) station, immediately after passing M.D. in PSM and being graded as a specialist. Soon after taking over, she went through the existing details regarding the location, physical, socio-demographic & sanitary characteristics. She decided to update these details by making an extensive physical visit to the entire area of 'J' station. Her findings, in brief, were as follows.

'J' is located somewhere in central Indian plains, connected by train and road but not by air. It is a large civilian township and District headquarters, besides being a very old and large cantonment. The civil set up has a population of about 1 million, with a large district hospital having all basic specialties. The civil society is generally a conservative society and lives in harmony. Main source of water supply is a large perennial river. J is also a large educational centre of central India. Climate is subtropical with heavy rainfall during July / Aug, and extremes of ambient temperature during Dec / Jan and May / June. General terrain is undulating, with few hillocks and generally fertile agricultural land. Main occupation of people is retail business in textiles & domestic-ware, governmental jobs and educational industry. No natural disasters or civil strife had been noticed in the city for the past many years.

'J' has a well demarcated cantonment, occupied primarily by the army. It is a peace location, predominated by training centers. There is a formation (Area) headquarters and their troops. There are 3 very large regimental training centers, a brigade group, and two a large ordnance depot. Health facilities include a large (zonal) military hospital commanded by a Brigadier (who was also the designated Senior executive Medical officer(SEMO) of the station, 4 central MI Rooms one in each centre and in the Ordnance depot, a large SHO for public health and preventive medicine cover (of which 'X' is the OC) and a 100 bedded cantonment hospital for civilian population of cantonment. For the sake of preventive health care the area had already been divided into 5 sectors, serially numbered from 'A' to 'E'. Sector 'A' had the Area HQ, their units, the military hospital and family accommodation for all ranks. 'B' had two Regimental training centers; 'C' had the brigade along with their family accommodation; 'D' had the third regimental centre and accommodation for officers, while 'E' had the Ordnance establishment along with separated family accommodation. Water supply was through ten deep borings and supplied as central piped supply. Sewage disposal was by large septic tanks; a new central sewage system was being planned. Road communications within the cantonment area were quite well planned. The Senior most commandant of the 3 regimental centres also officiated as the Station Commander. Sectors 'B' to 'E' had a well established central MI Room each, manned by 1 to 2 Medical officers and Nursing Assistants.

There were a total of 20,000 troops (including recruits in the regimental training centres) and approximately 9000 families (including 2800 ladies and 6200 children). One of the centre was predominantly for recruits drawn from J&K, Himachal and Punjab; the second had recruits mainly from Rajasthan, Haryana and adjoining parts of UP. The third centre catered to recruits from all over the country. All troops and families, irrespective of the place they belonged to, were able to communicate in Hindi language. Though the regimental centres were authorized lesser capacity, at that time, a large number of recruits (total 9000) were present in the 3 regimental centres due to increased recruiting drive as a consequence of operational reasons. There was, thus, definite overcrowding in the training centres, with excessive load on water supply and night-soil disposal facilities. Local markets were available in the cantonment area, catering for eatables and other day to day use items. There was no particularly

various leading causes of death and hospitalization that have occurred, overall, in the state or in the country, to see if there is any particular difference in the leading causes of ill health between the area where we are planning our health education activities and the overall state or country. The data should be arrayed in simple tables, showing the diseases in the first column, the rates per 1000 (or per lac) in the second column and the overall rates in the state / country in the third column.

Sources which need to be explored to obtain this information include census office, Registrar of vital events, civil hospital and private hospital records, and interviews with civil practitioners / government Doctors. In case of Armed Forces, the important sources include military hospital admission and discharge data, monthly health reports initiated by SHOs, Records of outbreak investigations with SHO, Disease notification forms (AFMSF-73) and strength details about troops and families available with Station HQ and individual units.

An additional and extremely important part of this step is to also obtain data on health-behaviour related aspects of the clientele. This is best done by undertaking a cross-sectional and quick survey from a representative sample, obtaining data on leading lifestyle factors (diet, exercise, tobacco and alcohol use, obesity, and sexual practices), personal hygiene and protection (use of road safety and occupational safety devices, protection against insect vectors of diseases, bathing, hand washing and oral hygiene), and on water and food hygiene practices. This quick survey may bring forth some very important issues, (which may not be evident by simple comparison of routine mortality / morbidity data) and which need to be tackled by health education programmes (Box - 2).

(c) Analysis of Community Health Care System

The third step in situational analysis (community analysis) is to collect and analyze data describing the resources for

Box - 2

In our example:- Maj 'X' obtained the basic population data regarding the strength of troops and families according to the five sectors, and sub-distribution according to rank (Officers, JCOs, NCOs, OR and Recruits) and as per age groups for ladies and children, from the Station HQ and respective units. She obtained the data on leading ten causes of deaths and hospitalization during past 3 years from the Military hospital A&D book. In addition, she obtained the details from monthly health reports which were initiated by her SHO, as also AFMSF-73 from local formation HQ. She also had detailed discussions with the RMOs / MOs of central MI Rooms as regards their opinion of leading causes of ill health. Finally, she took the SEMO, Station Commander, Brigade Commander and Centre Commandants into confidence and carried out, in the next 4 weeks, a baseline survey on a convenience sample of 150 recruits (50 from each centre), 30 Officers, JCOs and 90 NCOs / Sepoys (5 offrs, 10 JCOs and 20 NCOs / Sep each from the Area HQ / Area Units, Brigade group, 3 centers, and Ordnance establishments) and 75 ladies (randomly selecting 25 officers wives and 50 JCO / NCO / OR wives). She developed a simple one-page structured Performa to obtain information about lifestyle factors, personal hygiene and personal protection and food / water hygiene. Another one page questionnaire obtained data on knowledge regarding HIV / AIDS & other STDs, attitudes towards sexual promiscuity, and sexual practices; this Performa was administered only to recruits and Officers / JCOs / NCOs Instructors from training centers.

Maj 'X' worked out the rates per 1000 strength of ten leading causes of death / hospitalization separately for serving personnel, recruits, ladies and children. In an adjoining column, she displayed the rates per 1000 for the entire Indian Army (average of past 3 years) to get a quick visual comparison. She could make out that the maximum morbidity problems were with the recruits; among them the leading causes were chicken pox, URTI, LRTI, mumps, gastro-enteritis, viral hepatitis A and E, enteric fever, training related injuries, nervous breakdown and lastly, STDs. There was no significant difference in the rates of various diseases or their pattern between 'J' station and the overall rates seen in Army. Among ladies and children, the mortality and morbidity was very low; the major causes of ill-health were malaria and gastrointestinal infections. Among serving personnel also, the rates of morbidity and mortality were quite low, with malaria, mild gastrointestinal infections, overweight, hypertension, road accidents being the leading health issues.

The results of quick sample survey showed interesting results. Substantial percentage of JCOs / NCOs showed low levels of organised physical exercise, a definite problem of overweight and habit of tobacco use. While indulgence in promiscuous sex was not reported by this category, they did demonstrate an attitude of "permissiveness" relating it to manliness and something that could be condoned in a soldier. Officers and ladies were well aware of basic lifestyle and personal protective factors and were positively inclined. Recruits showed a concerning proportion of tobacco use (they started the habit only after joining as recruits), were largely unaware of HIV / AIDS / STDs, and did show an inclination in indulging in sex, mainly due to inquisitiveness as well as due to the tacit condonation which was likely to be given to them by the immediate superior NCO / JCO instructor if they indulged in promiscuous sex. However, actual indulgence in promiscuous sex among recruits was very low.

On further studying the available research project reports, 'X' realized another interesting phenomena : that the level of HIV seropositivity among recruits wass extremely low (0.045%); however, the highest proportion of HIV cases was among the young personnel, aged between 20 to 29 years. Is it possible, then, that attitudes which lead a young person towards promiscuous sex are developed during the recruit period and these actually indulge in promiscuity once they become full fledged soldiers. If that be so, education and motivation for healthy behaviour during recruit period may be of much value in preventing indulgence in promiscuity (and resultant HIV/STIs) later on? There

providing health care (both curative as well as preventive) as are available to the community. This is undertaken by describing, firstly, the formally recognized health institutions (as government and private hospitals, dispensaries, health centers, sub-district hospitals, preventive health care programmes and institutions executing them). Secondly, informally recignized practitioners as those of traditional systems are described. The medical and paramedical manpower is thereafter described, as number of physicians, surgeons, according to sub-specialties, nursing personnel, health / sanitary workers, laboratory trained personnel and so on. The organization of service delivery, referral systems, and local health departments are studied. Finally the "grey areas" in health care, including communities / locations which are underserved or disadvantaged are identified. The last step is important since community groups who are actually in maximum need of health education are usually also the ones who are underserved / disadvantaged or living in inaccessible areas (Box - 3).

(d) : Analysis of Community's Social Organization and Support System

In this step, the social structure and the social support systems are studied and analyzed. The overall organization of the community, the major community groups, the interaction between various community groups, the peers / leaders, the opinion formers, and the political climate is studied. In addition, the various "Support Systems" available in the community (Voluntary organizations, NGOs, agencies which can organize

Box - 3

In our example : Maj 'X' undertook a detailed assessment of the health care facilities available for personnel and families in her area of responsibility. She noticed that Health facilities in 'J' station are fairly well organised and include a large (zonal) military hospital commanded by a Brigadier (who was also the designated Senior executive Medical officer(SEMO) of the station), 4 central MI Rooms, one in each centre and in the Ordnance depot, a large SHO for all duties pertaining to public health and preventive medicine cover (of which 'X' is the OC) and a 100 bedded cantonment hospital for civilian population of cantonment. For the sake of preventive health care the area had already been divided into 5 sectors, serially numbered from 'A' to 'E', as already described. The casualty department of military hospital was functional 24 hours. Road communications are good and each sector had ambulance / modified vehicles for transporting patients to the hospital and back. All MI Rooms also had an ambulance each. However, there were problems regarding transportation for the families living in separated family quarters, with no particular unit being made responsible to organize the transport and other welfare measures for separated

financial assistance, charitable organizations, and so on) are studied, with a particular reference to how these can be gainfully utilized in relation to the proposed health education programmes.

(e) Analysis of Strengths, Weaknesses, Opportunities and Threats (SWOT)

Strengths are advantages that are of a permanent nature and exist in the community ethos or in the general environment, and they must be gainfully utilized by the health provider; e.g., conservative attitude of a community is a strength for anti-alcohol educational programme. Weaknesses are disadvantages of permanent nature in the community ethos or environment which will need to be neutralized or bypassed for success of the programme; e.g., conservative attitude in the community may be a disadvantage while launching a sex education programme for school children. Opportunities are temporary, often flitting occurrences which the health provider should always be on the look-out for and utilize them to her benefit; e.g., if an outstanding sportsperson becomes the mayor of the city, it is an opportunity to contemplate launching a community educational program for healthy lifestyle and physical fitness. Threats are temporary phenomena which may be inimical to the programmes; recent occurrence of vaccine related adverse effects among children may be a threat to educational program for promoting vaccination coverage and this would need to be either circumvented or else tackled energetically (Box - 4).

**Step – 2 : Making the "Community Diagnosis"**

This is a vital step, wherein we identify the "target populations" and their health problems. The first step in making the community diagnosis is to summarize the

Box - 4

The overall social organization in 'J' station was similar to any other military station. The Area commander was the senior most Officer. The 3 centers, military hospital and ordnance depot was under the control of Area Commander while the brigade group was under his control only for local administration. There was cordial relationship between all the senior officers and among the units. The senior officers were, in general, well disposed to preventive health care. The Commandant of military hospital, who was also the SEMO had made a good reputation through good provision of medical care. The Army Wives welfare association (AWWA) was very active in the station and was mainly organizing vocational classes for wives of jawans. The lady wife of Area commander was the President AWWA. Common platforms for meeting all senior officers were a monthly social get together in officers institute, the station commander's monthly conference, the annual sports meet of Kendriya Vidyalaya, and raising days of individual units. The training centers had hectic schedules, especially due to excessive strength of recruits, which gave very little time for any other health education or even any other welfare activity

In general, the social climate was commensurate with the overall ethos of the Indian Army, i.e., to keep troops and families in the best state of health and physical fitness and to prevent disease. The new Area Commander had recently arrived on posting. He had particular liking for healthy lifestyle, particularly physical exercise and abstinence form tobacco. His lady wife was greatly interested in organizing preventive health care activities for ladies and children. She had particular interest in AIDS prevention, and had earlier worked as chairperson of a NGO undertaking AIDS prevention activities. During one of the social get together, Maj 'X' had an informal discussion with the Area Commander and his lady wife, who got quite impressed and promised her all help in any preventive health care activity that she wanted to undertake in the station. However, Maj 'X' also realized that there were some stumbling blocks, in that the society was quite conservative and not quite open at discussing about AIDS, especially in the forum for school children. She also knew that one of the staff officers dealing with AWWA was known for his "obstructionist" and "delaying" attitude. With this totality, Maj 'X' summarized the SWOT as

**Strengths :** The organization ethos accepting healthy and fit life as essential and motivation towards disease prevention; The cordial relationships between the various senior officers and various units.

**Weaknesses :** Hectic training schedules, leaving little available time for recruits to be available for health education; conservative climate tending to inhibit school health education on sensitive issues.

**Opportunities :** Highly motivated Area Commander and his lady wife; Good reputation of the SEMO as medical administrator.

findings of the earlier step of "situational analysis" (community analysis), through sub-steps 1 (a) to 1 (e). This summary will give us an idea of the "needs" of the community. The needs so identified are of 2 categories; firstly the "professionally assessed needs" i.e., those needs which are worked out by the health care provider, based on community analysis data. This would include the leading causes of morbidity and mortality (as, chicken pox, hepatitis, injuries, etc.) and leading determinants of diseases (as smoking, inadequate levels of physical exercise, dietary patterns, sexual promiscuity, etc.). Secondly, equally important are the "felt needs" of the target population, i.e., those areas of concern which are articulated most commonly by the target population. These felt needs are the most pressing problems experienced by groups and individuals in the target population and usually reflect the problems currently in focus (1 - 4) (Box - 5).

In short, in the step of community diagnosis, we clearly define the following aspects. A consolidated statement clarifying these under mentioned issues would serve as the basic guideline for further planning of our health education programme :

(a) What are the "target communities" which are to be addressed by our proposed health education, or by other health care programmes or by a combination of health education and health care programmes? Delimiting the target audience (s) will define premises of our proposed programme and help us focus our entire energies on to these defined groups, with a view to get the maximum results. Target communities are those groups or subgroups which have the maximum ill-health (mortality, morbidity or unhealthy lifestyle) and are likely to give significant results if concerted health education programmes are focused on them.

(b) What are the major health problems as assessed by us which need to be addressed by health education programmes or health care programmes?

(c) Besides our assessed needs, what are the other "felt needs" of the target audiences, which also need to be addressed either by health education or other health care programmes.

**Step – 3 : Defining the "Premises" and "Goal" of the Proposed Programme**

Premises are the outer boundaries within which our proposed programme will function; we will not be going out of these limits in so far as the particular programme is concerned. Thus, this helps us focus our attention our programme and our goal and not mix up our actions with other issues. Premises are generally defined in terms of the population characteristics, place, time and the broad issues which will be the concern of the programme. While defining the premises and the goal, one should be clear that while a number of issues may be identified as major "needs", it is not necessary (and also not usually feasible) to address all these identified needs through health education programmes. Some of the needs would be better resolved using public health or other medical care approaches. It is therefore important to clearly delineate at this stage, which of the needs will be addressed by health education programme and which would be addressed by other public health / medical care steps.

Once we have defined the premises and sorted out the

Box – 5

Continuing with our example : Having collected and analysed the information form the first step of situational analysis, Maj 'X' finally summarized the community diagnosis as :

**Primary Target Audience** : Firstly, the highest amount of morbidity was noticed among recruits. Secondly, there were a very large number of recruits in 'J' station. Thirdly, was the fact that recruits are actually adolescents, who have just left their traditional family life and whose health related behaviour and lifestyle is in the formative process. Thus a concerted and focused health education programme for recruits was likely to pay rich dividends. For these reasons, the "primary target Audience" for the proposed programme was defined as "Recruits undergoing training in any of the 3 training centers in "j" station.

**Secondary target Audience** : While primary target audience was identified as "recruits", it was realized that without providing the knowledge and obtaining favourable changes in attitudes of those who were the "Instructors" for recruits at the training centers, the results may be limited. These instructors were not only teachers but also formed a "peer group" for the recruits and their own behaviour was likely to have much impact on the development of attitudes and practices by recruits. "Therefore, a secondary target audience was also identified as "JCOs and NCOs Instructors posted at the 3 training centers". In addition, the lady wife of the Area Commander as well as the DDMS of the Area HQ were of the view that a programme for education the ladies in the station as regards food and water hygiene, healthy lifestyle and HIV / AIDS should also be launched. Thus, another secondary target audience was identified as "Wives of serving personnel, including separated families, staying in 'J' station".

**Professionally Assessed Major Health Issues** : The major health issues which required action, either by health education programme or by public health improvements or a combination of both were gastrointestinal infections due to overcrowding and consequent load on existing water supply, sanitation and accommodation facilities. In addition, keeping in view the low level of knowledge and young age of recruits (when lifestyle habits are formed), lifestyle factors related to sexual promiscuity and tobacco use were also identified as important issues.

**Additional Felt Needs of target Audience** : Various Officers, JCOs and NCOs, during the survey had also suggested that overcrowding, adequate water supply and increase in sanitation facilities was a pressing requirement. Hence, these aspects were also noted for

"needs" according to which all will be addressed by our proposed health education programme, we enunciate the overall "goal" of the programme. Goals are broad statements which reflect the end result that we desire to achieve, i.e., they are the intended consequences of the program (5). Program goals should not be confused with "educational goals", which will be discussed later under step – 6 (Box - 6).

Box - 6

Continuing with our example:- After going through various details, Maj 'X' could make out that the needs related to improvements in overcrowding, water supply and additional sanitary facilities would need major engineering efforts and sanction of works, and additional public health surveillance efforts, for which she would need to constantly undertake advocacy with the commanders and engineering authorities. Health education program for this need may not be an effective approach. On the other hand, an IEC program addressing Lifestyle, particularly HIV / AIDS, food / water hygiene, and tobacco use would adequately address one of the major identified needs. The ideal target audiences for such an educational program would be all recruits, all JCO & NCO Instructors and all ladies. With this conviction, she defined the premises of her proposed health education programme as " IEC program for lifestyle and behavioural factors concerning Sexual Health (particularly HIV / AIDS), Personal Hygiene (particularly food and water hygiene) and tobacco use, proposed to be undertaken among all recruits, all JCO & NCO Instructors, and all wives of serving personnel posted at 'J' station, over a two year period from Jan 2001 to Dec 2002".

Having defined the premises of her proposed programme, Maj 'X' defined the goals as "to provide universal knowledge regarding hazards of sexual promiscuity, transmission and prevention of HIV / AIDS, hazards of cigarette smoking and elements of food and water hygiene, and to achieve a positive change in the attitudes among the target populations, as regards HIV /

**Step – 4 : Consolidating data on knowledge, attitudes and behaviours**

It is apparent that the ultimate goal of any health education program is to increase the knowledge and obtain a favourable change in attitudes and behaviour by the target population. Hence, we will need data as regards the current state in respect of the knowledge, attitudes and behavior, for the goals that have been identified. Behaviour should be assessed in terms of "events" and "outcomes". An event is the actual behaviour (e.g., smoking, sexual promiscuity); an outcome is the result of that event (e.g., IHD, AIDS). A sample survey of the target population, if the same has not been done in step 1 (b), should be now undertaken and data on current levels should be recorded (6 – 9) (Box - 7).

**Step – 5 : Assemble the Planning Group / Coordination Council**

Community health education cannot be accomplished by a single health educator. All representatives form the community, especially those who can facilitate the program should be approached to consent being a part of the planning group (also sometimes called as coordination council or governing board). From this step onwards, all plans are discussed and finalized, progress monitored and difficulties sorted out by personal involvement of members of this group. This group should include the public health / health education specialist, who should be the secretary of this group. The chairperson is usually an eminent / influential political or administrative person. The members include technical specialists, administrators, and above all, representatives of each of the target populations identified earlier.

Box – 7

Continuing with our example :- Maj 'X' had already collected data on relevant headings during step -1 (b). However, some data was further required and the same was collected through a sample survey on 50 subjects from each of the 3 target populations. Analysis of the data revealed that approximately 30% of the recruits, 50% of the ladies and 70% JCO / NCO Instructors were aware about the seriousness and transmission modalities of HIV AIDS. 100% ladies, 65% JCO / NCOs and 75% recruits looked at sexual promiscuity as UNDESIRABLE; Only 30 to 40% of all the 3 target audiences could list 5 common and serious diseases caused by tobacco use. 10% recruits and 45% JCO / NCOs were using tobacco in some form or the other. Only 20 to 30% of all the 3 target audiences could correctly narrate

Once a planning group has been constituted, all members should be given an initial briefing to orient all members as regards the various aspects of the program. This activity is relevant since many of the members may not be very aware about the technical intricacies of health education and medical care, as also about the details and sequence of planning process (Box - 8).

**Step – 6 : Reconfirming the program goals, enunciating the educational goals and the objectives**

Once a planning group has been formed, one of the first activities to be undertaken by this group is to firstly, reconfirm that the original program goal (vide step – 3) is finally acceptable or else it needs to be changed. Secondly, the group should enunciate broad statements, for different identified "needs" and different target groups, as to what the educational process aims at finally achieving. The overall program goal should be kept in mind when formulating the educational goals. The educational goals should be stated in precise language so that all members of the planning group thoroughly understand the exact intention of the statements (5,10).

Having specified the educational goals, the educational objectives are enunciated. As compared to goals, which are generalized & broad statements, objectives are precise statements which indicate as to how the goal will be realized. For one goal, there could be a number of objectives. Objectives should be specific, measurable and

Box – 8

Continuing with our example : Maj 'X, by now, was ready with the basic data, list of identified target populations and the broad goals which she had kept for the proposed health education program. She first of all personally briefed the SEMO, the DDMS of Area HQ and the Station Commander with an outline of the program. Having convinced and obtained assurance of their support, she took an appointment with the lady wife of the Area Commander, who asked her to come in the evening at tea time. The Area Commander, DDMS, Station Commander, and Col 'A' were also present during tea. Maj 'X' briefed them on her laptop computer, backed up with hard data from the survey, the broad goals and a outline of the proposed health education activities. All were very impressed and the Area Commander directed all to extend support to Maj 'X' as regards the programme. A programme steering council was also drafted out, which included DDMS Area, SEMO, Station Commander, Commandants of the 3 centers, Brigade Commander, lady wife of Area Commander, and lady wives of Brigadiers in the station. Thereafter, a "program planning committee" (PPC) was worked out, which included the Station Commander as chairman, the SEMO, the Col 'A', Maj 'X' (secretary), Deputy Commanders of the training centers and the Brigade, lady wives of Commanding Officers of training battalions and Infantry battalions, 2 JCOs and 2 NCOs Instructors from each training centers. This PPC was empowered to develop and implement the program and to meet once a fortnight to review the progress. The Area Commander asked Maj 'X' to brief him and his wife once a month as regards the progress of the program. The PPC met after 3 days during which Maj 'X' gave detailed briefing about the current situation, the target groups, the identified educational goals and the tentative plan. Finally the PPC promised an "in-principle" support and asked Maj 'X' to develop the draft objectives, the possible methods and activities, the time-table and details of implementation, to be discussed in the next

quantifiable in terms of magnitude of change and time-line. Within each objective, the parameter which will measure change is called the "indicator" and the magnitude of change proposed to be achieved is called the "target". For example, in an objective "Proportion of persons who are smokers should reduce from current 45% to 25% in next 2 years", the statement "Proportion of persons who are smokers" is an indicator while the part "reduce from current 45% to 25% in next 2 years" is a target (Box - 9).

**Step - 7 : Resource Analysis**

The important issue at this stage is how we can convert the desired objectives into an effective "action plan" so that the objectives can be achieved. For this purpose, we have to now analyze our resources, i.e., what all do we have to take action. In general, resources are analyzed in terms of 3 broad headings, viz., men, money and material. Resource analysis for manpower would include the

Box – 9

Continuing with our example : The PPC reviewed the broad program goal initially developed by Maj 'X' and generally agreed with the same. Having verified the program goals, the planning group defined the **educational goals** as :

- All the 3 target audiences to be made fully aware about the hazards of sexual promiscuity, and about mode of transmission, seriousness and prevention of HIV / AIDS.
- The recruits and JCO / NCO instructors should develop a healthy change in their attitudes, and genuinely identify sexual promiscuity as an undesirable lifestyle which should not be condoned, and definitely not encouraged.
- All the three target audiences should be aware of the health hazards of tobacco use; there should be significant decline in the proportion of tobacco users among JCO / NCO Instructors; there should be significant decline in the proportion of recruits starting tobacco habit;the target audience of ladies should talk to their husbands & children about hazards of tobacco use.
- All the 3 target audiences should be aware of the basic principles of food and water hygiene.

Against the background of these stated educational goals, the group developed the following **objectives** (timeline for all objectives was Jan 2001 to Dec 2002) :

- At least 90% of recruits, JCO and NCO instructors should be aware of the diseases transmitted by sexual route, the sequelae of HIV / AIDS infection, the modes of transmission and preventive measures as against a current level of 30% among recruits and 70% among JCOs / NCOs
- At least 90% of the recruits, JCO and NCO instructors should identify sexual promiscuity as UNDESIRABLE (current level 65% among JCOs / NCOs and 75% among recruits)
- 100% of all 3 target audience should be able to name 5 common and serious diseases due to tobacco use (current level 30 to 40%)
- Proportion of tobacco users should come down to less than 25% among JCOs / NCOs and less than 5% among recruits (current levels 45% and 10%).
- 100% tobacco users should voluntarilty agree that tobacco use is an undesirable habit (current level not known).
- At least 80% of all 3 target audience should name 5 basic principles of water and food hygiene. (current level 20 to 30%).

medical and paramedical personnel, and other key personnel as epidemiologists, trained health educators, data operators and statisticians, along with their locations, who would be available for the health education program, either full-time or part-time. This aspect of

manpower also includes the 'supportive manpower" as political leaders, administrative authorities and peers who would support the program. Money refers to assessment of funds / finances which will be required for development of health education material, training material, communications and transport, purchase of health educational and medical equipment if required, payment of salaries, etc. The source of finances could be government (public funds) or funds generated by voluntary / non-governmental organizations. Finally, material refers to technical equipment, expendables and logistics. This would need assessment of various aspects like availability of class-rooms, lecture halls, buildings, electricity, announcement systems, projection systems as slide / overhead projectors, computers, LCD projectors, mobile panels, posters and charts for exhibitions, models, and so on. In addition, equipment pertaining to "logistics" as vehicles for transportation of target population, petrol, tentages, generators, etc., would also need to be assessed, as required. It is only after making a detailed assessment of resources (already available and expected over reasonable period of time), that the program planner would be able to decide as to how best can an action plan be drawn to meet the objectives; at this stage, it may also be a consideration to drop one or two objectives if adequate resources are not available (Box - 10).

### Step – 8 : Identify Methods and Activities for Health Education

In the earlier chapter, we have deliberated on the various types of methods (as lectures, focus group discussions, exhibitions, mass media communication methods, etc.) and the activities that are conducted within each of these methods. Detailed decisions should now be taken to see which particular method(s) will be most appropriate to address the objectives for different target groups, and

Box - 10

**Continuing with our example**

Having drawn a list of goals and objectives, Maj 'X' undertook a detailed analysis of the resources, which she listed as follows :

**Technical manpower** : Maj 'X' was herself a well qualified specialist in PSM, having required training in epidemiology, statistics, health education and program management. The SEMO was a highly qualified super specialist in Immunology. The military hospital had 10 general medical officers and 10 specialists in all basic specialities. There were 6 Regimental Medical Officers (RMOs), one in each centre, two in the brigade group and one in the ordnance establishment, who were ready to get involved in the program in their respective locations. The SHO, which Maj 'X' was commanding had 4 sanitary inspectors and one lab assistant, all well trained in health education and program implementation. Each of the centre , brigade group and ordnance establishment had, besides RMOs, 2 to 3 trained nursing assistants, who could also be drawn into the program.

**Other manpower** : A potential source of Non-medical manpower were the JCO / NCO instructors of the various centers a total of approximately 100 in strength, who were responsible for giving military instructions to recruits and could be trained as trainers. Higher level "manpower support systems" included the Area Commander, DDMS of the Area, Station Commander, SEMO, Center Commandants and Brigade Commander, who had all assured Maj 'X' of their full support. Within her SHO, Maj 'X' had a clerk and Store Keeper and Drivers, besides various other supportive manpower who could help in organizing office procedures & physical assistance in laying out health educational venues.

**Finances** : There was no formal governmental funds available for the program. Maj 'X' had visualized that she would need to run the program within existing resources of manpower and logistics, though the lady wife of the Area Commander had promised that upto Rs 10,000/- would be made available out of welfare funds for miscellaneous expenses. One of the Centre Commandant had assured that any printing of technical pamphlets would be done free at the press which his centre was running. All Centre Commandants and the Brigade Commander had promised that tea and snacks would be served to all participants, after the educational sessions, out of their resources.

**Technical Equipment** : The SHO at 'J' station had been upgraded by the DGAFMS into an "IEC node". As result, the SHO had been equipped with a computer system, slide projector, overhead projector. Mobile panel-boards for exhibitions, and a large variety of health educational material including booklets, posters, charts, flip charts, pamphlets, transparencies, slides and hand bills for AIDS prevention. The computer was equipped with various software including software for developing educational material in Hindi and other regional languages, thus making educational material other than AIDS also quite feasible. In addition, she also had a well laid out health museum with various charts and models on prevention of various diseases as a part of her SHO.

**Other Equipment and logistics** : Maj 'X' had a dedicated light vehicle as well as a heavy vehicle in her SHO, thus facilitating movement of her personnel and health educational equipment. The Station Commander, Brigade Commander & Centre Commandants had also assured her that personnel and families who would be attending he health education program would be transported to the venue and back under their arrangements. All the Centres and the Brigade had large lecture theatres fitted with computer and LCD projection systems and their availability was assured to Maj 'X'. Besides, 2 open air theatres and a large central "Mela Ground" were also available for holding exhibitions

Box - 11

In our Example : Maj 'X' reviewed the target audiences (step-2) and the objectives (step-6) that had been decided, and matched them with the assessed resources (step-7). She then concluded that the following methods and activities should be used for different target audiences :

**For Recruits, in respect of all the three educational objectives (HIV / AIDS, Tobacco, and food & water hygiene) :**

- Respective Centre RMOs to give lecture of 20 minutes followed by 10 minutes of two-way discussions, for 100 to 125 recruits, according to training battalions / companies, so as to cover all recruits once in two months. Posters developed by AIDS Control Organization of Armed forces and distributed by SHO to be utilized. Lectures to include hazards of sexual promiscuity, sequelae of HIV infection for individual, family and community, modes of transmission and methods of prevention; hazards of tobacco use and methods of giving up tobacco use; basic principles of food hygiene.
- JCO / NCO Instructors, after being trained, within two months of start of programme, to talk daily for 5 minutes to their respective recruits, during their training schedules, on all the three aspects. They will use flip-charts, to be provided by OC SHO, for such informal talks.
- Central exhibition during station mela, during Diwali and Holi festival times, organised by Station HQ. OC SHO to be given two stalls in these melas (festival camps) to put up an exhibition on all these 3 areas, using appropriate charts and models. The mela is organised for 3 days and is attended by all personnel and families in the station.
- Maj 'X' to be invited by respective unit commanders / training battalion commanders to speak for 10 minutes on the three aspects, during their monthly sainik sammelans for recruits / for all ranks. After 3 months of work experience in the program in question, the RMOs may, at times give the talks during these sammelans, instead of OC, SHO.

**For JCOs / NCOs Instructors and JCOs / NCOs of Infantry Brigade Units in respect of all the 3 educational objectives :**

- Maj 'X' to hold centre-wise Focus group Discussions of 30 to 45 minutes duration, for groups of 20 to 25 JCO / NCO instructors, within the location of each centers or infantry units, so as to cover each centre once a month, on all the three aspects outlined above. Computer projection system will be used as training aid. Power-point projection program in Hindi / Roman Hindi to be developed by Maj 'X'.
- Talks during sainik sammelans by Maj 'X' and exhibition during central mela to be additionally utilized by all JCOs / NCOs.

**For ladies in the Station**

- Each training centre / brigade group / ordnance establishment to constitute a "Core Resource Group (CRG)" of 20 to 25 ladies from within their respective resources. The ladies should be educated till 10th standard and should be communicative and socially motivated. Lady wife of Dy Commander, Lady wives of Commanding Officers of battalions, 1 young lady wife of an officer, 5 to 7 JCOs wives and 8 to 10 NCOs / Sepoys wives to be part of this group.
- The ladies to collect at a central place in their respective centre / brigade once a month, on a fixed day (Thursday) at 1400 hrs. Maj 'X' along with her team and educational aids to reach the concerned location and undertake focus group discussion on the three objectives, as also on various other aspects of health and disease prevention, for about 1 hour. Power-point projections, charts and handbills to be used as aids.
- The 20 to 25 ladies of the CRG to become "Resource Persons" and visit families within their respective centre / units during the next one month (i.e., till the next educational session with Maj 'X') and educate other ladies as regards what they have learnt, by personal discussions and small, domestic level groups. They will also carry pamphlets and handbills, provided to them by OC SHO, for distribution to the ladies.

**For the Peers, Supporters and Program Functionaries**

- Briefing on the progress & difficulties, for all senior officers involved with the program. To be undertaken once a quarter by Maj 'X' during the quarterly station anti-malaria and health committee meeting, to be chaired by station commander and attended by Colonel 'A', Dy Commanders of the training centres and commanding officers of all other units. Circular to be issued by Maj 'X' and records of proceedings to be maintained. Teaching aids : powerpoint presentation and LCD projector in station Commanders office, followed by minuted record of the meeting.
- Briefing of senior ladies, including lady wives of following senior officers : Area Commander, Centre commandants, brigade commander, commandant of ordnance establishment & commanding officers of major units in station. To be held once a quarter. Briefing by Maj 'X'.
- Monthly meeting of medical functionaries. To be chaired by SEMO and attended by Maj 'X', all

within each method, what all educational activities will be undertaken. The details of the decided methods and activities for each target group should be written down (Box - 11).

**Step – 9 : Writing and disseminating the Action Plan (Implementation plan)**

Having clearly enunciated the methods and activities, a detailed action plan should be written down. This is a detailed document which clearly specifies as to who will do

what, to whom all, where, in what manner and how frequently. The document should specify all details of :

(a) Dates / days of the week or month and timings, on which the educational sessions will be held for the duration of the program.

(b) The locations at which the sessions will be held.

(c) Who all will attend the sessions at the particular locations, dates and time?

(d) Who will be administratively responsible for ensuring that the target audience reaches the particular location of educational session, well in time?

(e) Who will conduct the session

(f) Who will be responsible for technical aspects of the session.

(g) Who will be the overall coordinator for the educational activities?

The details should be discussed by the program planning committee (PPC) and then issued by a senior administrative officer to all concerned (Box - 12).

**Step - 10 : Implementation and Evaluation**

Once the instructions for implementation have been issued, the health educator's responsibilities further increase since he is now not only responsible for providing health education to the various target populations but also often responsible for coordination of the various administrative aspects, to see that all aspects of the program progress as scheduled in the action plan. In real

Box - 12

Continuing with our example : Maj 'X' developed the draft action plan for implementation as follows :

- Total duration of the health educational program will be two years (Jan 2001 to Dec 2002).
- Respective RMOs of the regimental training centers and battalions of the brigade group will give lecture on the stipulated educational areas on every Saturday after the drill period, to a company strength of recruits/infantry personnel. Thus, all training companies of the centers/infantry companies on brigade group will be covered once in a month. Audio-visual aids as stipulated (in step-8) will be collected by the RMOs from the SHO. Adjutants of the battalions will be responsible to ensure that the concerned company of recruits / soldiers is made available for health education at the designated location and time.
- All Training battalions/infantry battalions will invite Maj 'X' to deliver a lecture of 10 minutes duration during the monthly sainik sammmelan on the decided topics. Arrangements for conveyance of Maj 'X', her team and educational equipment will be of the concerned Commanding Officer.
- All JCOs/NCOs Instructors will talk to their respective student recruits informally, daily for about 5 minutes on the decided topics, starting from April 2001. The Subedar Majors will give a weekly confirmation on this aspect to their respective adjutants.
- All training battalions/infantry battalions will invite Maj 'X' to deliver a talk to their Instructor JCOs/NCOs, once a week on every Wednesday, between 1200 to 1300 hrs. This will be done in rotation, covering the JCO/NCO instructors of a particular training company on a given Monday. The rotational program will be prepared by Maj 'X' and forwarded to the battalions at least 3 months in advance. Responsibility of ensuring that the JCOs/NCOs are available at the location and/for transportation of Maj 'X', her team and equipment will be of the concerned battalion commanders, who will also ensure that a proper lecture hall with LCD projection system is made available.
- Respective lady wives of centre commandants and brigade commander will select a core resource group of 20 to 25 ladies (as per details discussed in step-8). Maj 'J' will issue a program according to which she will discuss the educational aspects of selected topics with the ladies of core resource group, in rotation on every Thursdays, from 4 to 5 p.m. The location will be a central hall of the concerned centre/brigade. The respective centre adjutants/Staff captain of Brigade will ensure that the core group of ladies are provided transport and reach the venue well in time on the decided date and also provide transport for conveyance of Maj 'X' , her team and equipment.
- Maj 'X' to keep lady wife of Area commander and other senior ladies duly apprised about the progress of educational activities for ladies. Senior ladies may also visit the venue and participate, once in a while, as desired by them.
- Station HQ will earmark a place for SHO, during Diwali and Holi station melas, where Maj 'X' will put up the health exhibition. Logistic requirements will be catered to by station HQ.
- Once in 3 months, a evaluation test will be taken from all recruits and JCO/NCO instructors, by Maj 'X'. For ladies of Core resource Group, Maj 'X' will take a oral test to monitor progress.
- All instructions will be issued by Col 'A' of the Area HQ, on behalf of the Area Commander. Coordination of all activities and regular feed back on technical and administrative matters will be drafted by Maj 'X' and forwarded once a month to Area HQ and Station HQ for information of Area Commander & Station Commander respectively.

The above draft action plan was approved by the SEMO, Station

life scenarios, everyday there will be problems, which would need an action and to be rectified. Sometimes the vehicle may not turn up to ferry the health educators team and equipment, sometimes the officer responsible for administrative coordination for one of the target populations may simply forget that there was a session planned for that day; sometimes a holiday may be announced suddenly on the day of planned session. All these issues need to be visualized and addressed. In health education programmes, and for that matter in any public health program, perseverance and determination always pays.

Along with implementation of action plan, evaluative process also needs to be planned and conducted. As explained in detail in the section on principles of epidemiology (planning & evaluation of programs), evaluation is undertaken for six different aspects, viz., relevance, adequacy, process, and outcome (including efficacy, effectiveness and efficiency). In the usual settings of health education programs, evaluation is undertaken for "process" (i.e., whether the activities are being undertaken as planned) and for outcome (i.e., to what extent the objectives have been met). Evaluation for process is to be undertaken concurrently, say once in 3 months for a program planned for 1 to 2 years. Outcome evaluation is undertaken both, concurrently (e.g., what percentage of target population have shown improvement in knowledge and behaviour) and terminal evaluation at the end of the program (whether targets as envisaged at the planning stage have been achieved). It should be remembered that evaluation should always be an analytic process, with the drawbacks / deficiencies noticed further analyzed and change in program actions undertaken to rectify defects that have been identified(Box - 13).

**Step – 11 : Writing the Final Report** : Once the program has been completed or terminated for whatsoever reasons, the program planner must write down a detailed report of the program, including the background, the target audience, the educational and program objectives, the action plan,

Box - 13

Continuing with our example : Maj 'X' continued to collect data on each and every activity that was planned in the action plan, including the administrative aspects. Any acute deficiency (e.g., one of the days the target group of recruits were diverted to some other place for working, at the last moment) was immediately brought to the notice of the concerned commanding officer, personally, with an element of advocacy for his personal directives in ensuring that the details of action plan are complied with by all concerned. As another part of process evaluation, Maj 'X' compiled and analysed the ongoing data about changes in the health awareness level among different target groups, along with difficulties observed, and gave briefings to members of PPC, during the quarterly conferences. In addition, she also constantly kept the lady wife of Area Commander informed as regards the progress and the difficulties, on a monthly basis, with a request for her help, which, quite obviously was forthcoming since the lady wife of Area commander had herself given a very high priority to the program. After initial "teething problems", all concerned became convinced about the usefulness of the program and their motivation to make the program a success increased.

In Oct/Nov 2002, I.e., two months before the program was scheduled to end, Maj 'X' undertook a sample survey of the target population and obtained data on the knowledge and attitudes regarding sexual promiscuity, transmission and prevention of HIV / AIDS, hazards and prevention of tobacco use, and food / water hygiene. She analysed the data and compared the results with the baseline (which she had earlier collected in step-6). The results showed that there was tremendous success achieved. The program had achieved uto 80 to 90% of the stipulated targets. Another important result that happened and which was, in fact, not visualized earlier was that all the training centres and brigade group were finally so impressed with the program that they identified the program as an essential training and welfare need and incorporated the program action plan in their respective training and welfare Standing Operative Procedures (SOPs). Thus the program became an automatically operated program with little requirement of coercion from the side of Maj 'X'. Soon thereafter, the Area Commander was posted out; Maj 'X' was also posted out and so were the various centre

## Socio-Behavioural Sciences and Health

Social, cultural, psychological and behavioural factors are important variables in the etiology, prevalence and distribution of disease. The way the people live, their habits, beliefs, values and customs are significant determinants of individual and collective health. The behavioural sciences (sociology, social psychology, cultural anthropology) have made significant role in developing better understanding about the social etiology of health problems. It is recognized that causation and spread of a disease does not depend entirely upon biological organism. The cultural and social factors which govern human behaviour also have dominant role to play in the disease process.

### Sociology

Sociology is the science concerned with the organization of social groups. It studies the kinds and cause of variation in social structure, and the processes by which intactness of social structure is maintained. Sociology deals with the study of society. Society is a group of individuals who have organized themselves and follow a given way of life. The behaviour of man depends very much upon his relationship with other fellow beings. Man is a subunit of a small group; the family, while the family is the basic unit of society. Man's behaviour is affected not only by his physical and biological environment but also, to a larger extent by social environments represented by his family.

### Community

In the simplest terms, a community can be defined as a group of people who have some common characteristics and are bound together by "WE" feeling. This sense of 'we' feeling (i.e., shared togetherness) may be due to a place where they all stay or due to some other common interest.

Accordingly, communities can be either "structural" or else, "functional" communities. Functional communities are non-geographical aggregates which are bound together by some common factor other than geographical place of residence or work; e.g., religion (as, Hindu community), occupation (as medical community), special interest (as cricket lovers) or need (as socially backward communities). Structural communities are organised by geographical or political boundaries. It could be as small as an "indoor patient's community in a hospital" or increasingly larger, according to a "Mohalla", village, slum, city, district, state or even a nation.

Community affiliations often provide a source of support for individuals and groups. The sense of group identity creates motivation. For this reason the community is ideal for focal point of programme.

### Culture

Culture is defined as learned behaviour which has been socially acquired. Culture includes all that man acquired in the mental and intellectual sphere of his individual and social life. It is a product of human societies. Culture is necessary for human being; it makes life worth living and socializes man. A culture denotes total way of life. It is recognized that cultural factors are deeply involved in all the affairs of man including health and sickness. The cultural factors such as customs, beliefs values and religious taboos create an environment that helps in the spread or control of certain diseases and affect health of the community. The various causes for sickness, as understood may be classified in two categories : Supernatural causes and Physical causes. Supernatural causes include diseases caused by (a) breach of taboos e.g. leprosy, sexually transmitted diseases; (b) wrath of god and goddesses e.g. small pox and chicken pox ; (c) spirit intrusion, ghost intrusion and evil eye. The physical causes include excessive heat or cold, wrong combination of foods and impurity of blood etc. Prevention of disease and bringing improvements in the health conditions in any society is dependent upon our ability to understand and improve the social or environmental factors.

### Family

The family is a primary unit of all societies. A family can be defined as a group of individual biologically related to one other, staying under a common roof and eating from a common kitchen. It can also be defined as :

"The Family is a group defined by a sex relationship precise and enduring to provide for the procreation and upbringing of children" (MacIver).

Family is the reproductive nucleus of society, a fundamental and social institution whose primary and essential task is to socialize the new born so that they may be placed in life as mature and independent. Through the family, human beings maintain physical continuity by reproduction and maintain social and cultural continuity through training and education.

#### Family in Health and Disease

The health of the child is bound up with the family's internal and external environment even before it is born, and the foetus in the womb can be harmed by the health, nutrition and behaviour of the mother. Subsequent experiences in infancy, in the quality of feeding and method of training for instance may further influence development, physique, stature and personality.

The members of family share a pool of genes and a common environment as well as common modes of thoughts and behaviour and family material and social environment which includes housing, sanitation and diet. A damp overcrowded house encourages streptococcal infections and Tuberculosis. It is not only infective agents that pass between the members of a family. Parents may transmit distorted cultural perceptions and behavioural norms to their children, and thus create deviant behaviour and failures of adaptation among them.

#### Family life cycle stages

(a) Married couple - beginning of family

(b) Child bearing family

(c) Family with pre- school children
(d) Family with school age children
(e) Family with teenage children
(f) Middle age
(g) Aging family members/ retirement

As families enter each new developmental stage, transition occurs. Events such as marriage, childbirth, releasing members as adolescents and young adults, and continuing as a couple or single person and aging years move families through new stages. Each new developmental stage requires adaptation and new responsibilities. Each new stage presents opportunities for health promotion and intervention. There are certain functions which are relevant to health behaviour, and are important from the medical sociology point of view, as follows :

**Child rearing**

one of the important functions of the family with which medical and health workers are concerned, is the physical care of the dependent young in order that they may survive to adulthood and perpetuate the family. It is important to note that child care (e.g. feeding, nutrition, hygiene, sleep, clothing, discipline, habit training) are passed on from one generation to another.

**Socialization**

The second responsibility of the family is to socialize the stream of new-born barbarians. By socializing is meant teaching the values of society and transmitting information, culture, beliefs, general codes of conduct, by example and precept, in order to make them fit for membership in the wider society of which the family is a part. It is the family which imparts practical education to children concerning the customs in society, preservation of health, love, sympathy, cooperation etc.

**Personality formation**

The capacity of an individual to withstand stress and strain and the way in which he interacts with other people is to a large extent determined by his early experience on the family. The families acts as a placenta excluding various influences, modifying others and pass through it and contributes some of its own in laying foundation of physical, mental and social health of the child.

**Care of dependent adults**

The family is expected to provide care during sickness and injury of adults and dependents. From the public health point of view care of women during pregnancy and childbirth is an important function of the family. The family also provides support, security and encouragement to the aged and handicapped.

**Stabilization of adult personality**

The family provides an opportunity, both for adults and children, for release of tensions so that the individual can attain mental equilibrium and strive to maintain a stable relationship with other people. The family has an important function in stabilization of the personality of both adults and children, and in meeting their emotional needs.

Problem families

The factors in most problem families are usually those of personality and of relationship, backwardness, poverty, illness, mental and emotional instability character defects and marital disharmony. These families are recognized as problems in social pathology. There is a need to render useful service in rehabilitating such families in a community.

**Common terms used in sociological applications in health**

Social pathology

Social pathology is the systematic study of human disease in relation to social conditions and disease process outside the human body. The cause is to be found in the society. These include Social Problems (namely, poverty, destitution, illiteracy and ignorance, migration, lower status of women, child neglect and child abuse, child labour, drug abuse, juvenile delinquency); social conditions (as housing, environmental sanitation, crime and corruption, stress, suicide) and social circumstances (stigma, social isolation, vulnerable populations). The causes of social problems, conditions and circumstances which affect the health of the people are to be understood and actions are to be taken to prevent such problems through health education and rehabilitation.

Social Diagnosis

This is made by socio-medical surveys and by study of domestic and social conditions of individuals. This is a statement of the aberrations that are likely to result from the identified social pathologies.

Social therapy

Social therapy offers holistic therapeutic and support services. The approach addresses and supports the total social, emotional and educational needs of young and the entire family. Clinical treatment of any disease with drug should be supplemented with social therapy. Social security measures, link between hospital and community, health education and legislation serve as supportive measures.

Knowledge

Education is a process of learning undergone by individuals for gaining knowledge, developing attitudes and acquiring skills. Knowledge is the basis of health education where a person gets of information by many modes which becomes his knowledge.

Attitudes

Attitudes are mental habits acquired from social experiences that predispose us to react to specific objects, persons or situations in a definite way. They are the crystallized habits of thoughts that we develop relative to social situations and that set us to respond in a certain manner. An attitude is an enduring system that includes a cognitive component, an emotional (feeling) component and an action tendency.

Practices

Practices are application to particular and personal

situation. The individuals modify their behaviour and maintain the change for the rest of their life. E.g. the individual stops smoking after changing attitude.

Community's social support system

In medical practice the ability of a family and community to provide social support and material aid to dependent members is important.

Social assistance implies provision of relief to individuals at critical times without having received any contribution from them. Social assistance is a non-contributory benefit extended to vulnerable groups including women, children and aged.

Social environment

The social environment includes all those things which arise out of social relationships such as customs, traditions, institutions social conduct, rituals, diet, way of life and economic status. Health is profoundly influenced by the social environment which acts in many ways to shape the contours of disease, in populations as well as individuals. For promotion and protection of health and prevention and control of disease social environment should be free from harmful agents. Important measures for providing healthy social environment as :

(a) Social security against fear and want (ESI scheme, old age pension, life insurance, provident fund and health and medical facilities.)

(b) Fair distribution of food and other amenities of life such as housing

(c) Facilities for exercise and leisure

(d) Facilities for education for all

(e) Propagation of healthy customs, freedom of expression and thought

(f) Protection of property, life and honour

(g) Safe work place which involves establishing a stimulating work environment and making sure that the work place creates social contacts which do not interrupt the family networks.

**Non-Governmental Organizations (NGOs) and Voluntary organizations**

NGOs form a bridge between the government and community and provide platform for people's participation NGOs are many and diverse. There scale may be large, medium, and small. Their support may come from external sources, from their own fund raising or from government. Their principal activity may be direct service to those in need in the community, health education or research. Voluntary organizations could be defined as those organizations which are non- governmental and non profit making in character and not fully funded whether directly or indirectly only by government. Most voluntary organizations have four primary purposes

(a) Raise money to fund research and programmes

(b) Provide education to both professionals and the public

(c) provide services to individuals and families affected by the disease and health problem (iv) to advocate for beneficial policies, laws and regulations. (e.g. VHAI, Indian Red Cross Society, Hind Kusht Nivaran sangh, Tuberculosis Association of India etc.)

**Social Security**

Social security means public programmes designed to protect individuals and their families from income losses due to unemployment, old age, sickness or death and to improve their welfare through public services (e.g. medical care) and economic assistance. The term may include social insurance programme health and welfare services and various income maintenance programmes.

**Rehabilitation**

Rehabilitation has been defined as "the combined and coordinated use of medical, educational and vocational measures for training the individual to the highest possible level of functional ability". The following areas of concern in rehabilitation have been identified

(a) Medical rehabilitation - Restoration of function

(b) Vocational rehabilitation - Restoration of the capacity to earn a livelihood

(c) Social rehabilitation - Restoration of family and social relationships

(d) Psychological rehabilitation - Restoration of personal dignity and confidence

**Social class**

Socio-economic standard of people is conventionally expressed in terms of various social classes in which people are distributed which are referred to as social stratification. Social stratification is a horizontal division of society into several socio-economic layers : each layer or social class has a comparable standard of living and life style. Social class is determined on the basis of three parameters of development, namely education, occupation and income. Education determines the knowledge, attitude, and value system of individuals and their socio-economic growth potential. Occupation determines the income generating capacity of individuals and their life style, Income determines the purchasing power of individual and their socio-economic status. On the basis of these parameters populations are divided in to social classes—upper, upper middle, middle, upper lower and lower.

(a) The socio-economic status scale (urban) developed by Kuppuswamy attempts to measure the socio-economic class of family in urban community. It is based on three variables - education, occupation, and income. A weightage is assigned to each variable according to seven point predefined scale. The total of three weightages gives the socio-economic status score which is graded to indicate the five classes. The level of income is generally updated on the basis of consumer price index (CPI). Current income group, as given in Textbook of community medicine,2007, by Dr (Brig) Sundarlal are taken in Kupuswamy's scale.

Kupuswamy's scale

| Education of head of household | | Occupation | | Income Per Capita per month | |
|---|---|---|---|---|---|
| Educational level | Weigh | Occupation | Weigh | Range | Weigh |
| Professional degree or Hons / MA & above | 7 | Professional | 10 | Above Rs 20000 | 12 |
| B A or BSc degree | 6 | Semi-professional | 6 | Rs 10000 to Rs 19999 | 10 |
| Intermediate or post high | 5 | Clerical, shop-owner, farm- | 5 | Rs 7500 to Rs 9999 | 6 |
| HSC | 4 | Skilled workers | 4 | Rs 5000 to Rs 7499 | 5 |
| Middle school certificate | 3 | Semiskilled workers | 3 | Rs 3000 to Rs 4999 | 4 |
| Primary school or literate | 2 | Unskilled workers | 2 | Rs1001 to Rs 2999 | 2 |
| Illiterate | 1 | Unemployed | 1 | Below Rs 1000 per | 1 |

**Total Score is calculated as**

Education(A) + Occupation(B) + Income(C). Depending on the score, the status is as follows :

**Total Score**

| | |
|---|---|
| 26 – 29 | I (upper class) |
| 16 – 25 | II (upper middle) |
| 11 – 15 | III (lower middle) |
| 5 – 10 | IV (upper lower) |
| Below 5 | V (lower) |

**(b) Dr. B G.Prasad's social classification**

The income group can be used by applying P Kumar's conversion factor i.e.

$$\frac{\text{Value of CPI X 4.93}}{100} = (\text{conversion factor})$$

Value of all India consumer price index in 2003 was 496

$$\frac{496 \text{ X } 4.93}{100} = 24.45$$

This 24.45 conversion factor is multiplied by Rs 1000 of social class I income of 1991 data to get corresponding value of social class I in 2003 i.e.Rs 24450. Likewise it can be calculated in other income group also.

Dr. B G.Prasad's social classification

| Social class | Updated by 1991 | By applying conversion factor (2003) |
|---|---|---|
| I | 1000 and above | 24450 and above |
| II | 500-999 | 12225-24449 |
| III | 300-499 | 7335-12224 |
| IV | 150-299 | 3667-7334 |
