The conventional organisational structure in the form of pyramid, with head of the institution at the pinnacle and the grassroots level workers at the bottom has been widely perceived as the ideal method of balancing the needs of the health sector as far as specialists and generalists are concerned. Thus at the bottom were the specialist managers, fleshly recruited from management. With the passage of time this manager gains experience, acquires additional knowledge and is ready to expand his sphere of

functioning, at which point he is considered fit to be promoted up to understand and specialize in an ever widening sphere of the organisation's activities and simultaneously is also forced to take a broader view of the business perspectives. The process is repeated time and again till the manager reaches the pinnacle.

The pyramidal structure presupposes the breaking down of the organisation into a series of manageable units work generally based on functional requirements. When integrated, these functional units form the core of the organisation.

Decisions are but interpretations of available information and the conventional organisation structure assumes that as one moves upwards in the organisational hierarchy, the decision makers automatically have access to more channels of information and hence are in a position to take better decisions. Thus delegation of authority is invariably designed to ensure that the more important a decision the higher authority who takes it. Thus the head of the institution is expected to take the most important decisions, and down the line, decisions of lesser importance are taken till we reach the very bottom where the most mundane things will be decided upon.

1.4 ORGANISATION EFFECTIVENESS

Organisations as you know are social systems with "Specific Purposes". Therefore, effectiveness of organisation is a measure of its ability for goal attainment. For example a sub-centre which has to provide MCH Services and has a high immunization coverage and low incidence of vaccine preventable diseases would be considered an effective organisation. Similarly a hospital which has provision of curative services as its goal and which successfully treats the patients, would be considered as an effective organisation.

You will notice that clarity of goals or objectives become important if one has to comment on the effectiveness of an organisation. Effectiveness says something about how well an organisation is doing in achieving its objectives.

You can recall a myriad of variables which implinge on effectiveness of an organisation. Variables, which may contribute towards effectiveness, include productivity, adaptability, flexibility, motivation, conformity etc. The variables or the determinants must tell us something on the present state of the organisation, the capability of the organisation to keep up with the changing environment, and the capacity of the organisation to meet unforeseen situations. Presence of these attributes in some measure or the other should determine the effectiveness of an organisation both from the view of the output and its ultimate potential.

Having known the objectives, you should familiarise yourself with the determinants of organisational effectiveness. The core variables, which contribute towards effectiveness, are:

- Productivity
- Adaptability
- Flexibility

Productivity: It deals with the present state of the organisation in terms of output. Effective organisations are those that produce more and higher quality outputs most efficiently. Thus, maximisation of output and minimisation of input will be a measure of the efficiency of an organisation. But the output must contribute towards goal attainment. The output or the product could be anything such as number of children immunized, number of deliveries conducted by trained health personnel or the number of patients admitted and discharged.

Adaptability: You will appreciate that no organisation operates under static conditions. There is constant flux in the environment. The ability of an organisation to monitor this change and keeping pace with this change would be a measure of its adaptability.

Survivability of any organisation depends on its adaptability. An organisation should be endowed with a structure, which can monitor the change in the environment and to

take suitable action to modify organisational activities to meet the change. Adaptability does not only mean coping with change but also anticipating change. You will agree to that in an era of competition, it pays to be pro-active than to be reactive.

Flexibility: Another important determinant of organisational effectiveness is flexibility in the structure to meet the challenge of unforeseen situations. Situations do not arise as expected. The future is uncertain. The arrival of unforeseen situations are stochastic in nature. Not only the arrival is stochastic, the very nature of situations may be different. When is the unusual demand going to occur, and what kind of demand would that be? Both would require the flexibility of an organisation to cope with unusual demand. If this flexibility is found wanting, naturally the organisation cannot keep up with its goal-attainment. Therefore, it is necessary to have inbuilt flexibility mechanisms within the organisational structure.

Thus the criteria for effectiveness can be summarized as follows:

a) Organising the centers of power for routine services (productivity) which includes:

- The quality of the product/service,
- The quantity of the product/service, and
- The efficiency with which it is produced.

b) Organising Centres of power to change routines (Adaptability) which includes:

- Anticipating problems in advance and developing satisfactory and timely solutions to them.
- Staying abreast of new technologies and methods applicable to the activities of the organisation.

Factors Influencing the Core Variables

An organisation high on productivity is meeting to some degree its goal-attainments. Similarly organisations high on adaptability and flexibility have the potential to meet the threats of the environment and thus contribute to organisational effectiveness on a futuristic basis. It can be said that productivity decides how well you are doing at present, but adaptability and flexibility decide whether you can survive or not i.e. can you cope with change and unpredictable situations?

Each of these core variables get further enhanced or reduced by impact of many other factors such as centralisation. Let us examine how is centralisation related to the core variables? Centralisation may be functional to productivity for routine jobs but dysfunctional in coping with unforeseen situations (flexibility). Therefore, many factors are functionally or dysfunctionally related to the three core variables discussed above. This issue can be further complicated, if we consider that centralisation, say for example, is functionally related to productivity and dysfunctionally to flexibility. Then, is a high degree of centralisation desired? Simply, which is more important productivity or flexibility? This would depend on the goal of the organisation. Ideally maximization of all the three core variables should lead to high organisational effectiveness, but the constraints of resources will limit the necessity to maximize all the three.

Some of the important factors often encountered in an organisation are as follows:

- Leadership
- Centralisation
- Conformity
- Motivation
- Communication
- Autonomy
- Mobility

Factor-variable Interaction

Now you will learn about step by step analysis of the factors vis-à-vis the variables.

Leadership

You have already learnt about various types of leadership styles. On one end of the continuum you have the high-task and low-people style. The high-task, low-people style obviously is suitable for short-term increase in productivity. Therefore, a positive correlation exists between high productivity and this style of leadership particularly for short term. In the long term, productivity is bound to come down as the morale of the workers is also likely to suffer under the influence of the high-task, low-people relationship. Hence the high task, low people have more dysfunctions than functions towards productivity in the long run. But this style may be suitable during high overloads of work. That means when overloads of work arise temporarily this style is likely to be functional. Any number of such arguments can be developed, and the style most suited will be determined by the organisation goals itself. For example, a high people, low task style will enhance motivation but unless that motivation leads to a spurt in enthusiasm to work more, it has very little to contribute to the effectiveness of an organisation.

Centralisation

A high degree of centralisation has been found to be positively correlated to routine type of jobs. That is, where the job is of a routine nature, a high degree of centralisation enhances productivity by optimizing use on resources. But, where the job is more contingent than routine, high centralisation becomes dysfunctional as the managers have very little flexibility in decision making. Thus centralisation affects flexibility. For example, in an organisation where routine jobs exist side by side of a research laboratory, high centralisation may be desirable in the former case but decentralisation is a must in the latter. Therefore, the degree of centralisation should be determined depending on the type of job people are doing. In the same organisation, this aspect may have to be varied, depending upon the level of the subordinates.

Conformity

Conformity implies the degree to which performance corresponds to norms. The implications are high degree of conformity at the activity level will result in higher productivity for routine jobs. Where jobs are specialised conformity will restrict independent action thereby depriving qualitative changes. Where qualitative changes are desirable, like research laboratories, specialised hospitals etc., the consequences would be dysfunctional to productivity. Similarly, at higher levels, conformity will breed 'yes men' rather than honest advisors. Not only the restricted field of action likely to cut into flexibility, adaptability is also likely to suffer. Conformity also tends to affect morale which in turn affects productivity. Nevertheless, in health organisations, conformity at the lower levels is a desirable trait. Further questioning of orders and instructions of superiors under emergency situations, will without doubt curb operational success. At the directional and conceptual levels, any kind of pressure to ensure adherence to norms is likely to frustrate individual opinion, and consequently growth of our organisation.

Motivation

Motivation as you have learnt in Course-1 may be defined as the degree to which individual motives are gratified. Rates of turnover, absenteeism and sick reports are common measures of motivation. Low motivation arises out of repetitive jobs and, therefore, dysfunctional to productivity when routine jobs are concerned. Its functional aspect relates to the dexterity and job competence that is developed by the worker. On the whole, dysfunction is more predominant where the job content is of a routine and repetitive nature. Low motivation essentially has dysfunction running through all the core variables, viz. productivity, adaptability and flexibility. The only time when low motivation gets positively correlated to flexibility during routine overloads of jobs when the manager has to resort to High Task-Low Relationship approach.

Communication as you know may be defined as the transmission of information with the intent of changing the recipients' knowledge, attitudes or overt behaviour. Free flow of communication gets negatively correlated to productivity due to information overload at the decision nodes. Communication which is spontaneous at the work place is found functional to the core variables. Organisational structures, which attempt to break the information overload at the decision nodes often, resort to vertical organisations. This also becomes dysfunctional due to the distortions at the many interfaces of the organisational hierarchy. It has been found that highly centralised organisations imbibe the practice of vertical flow of communication from "Top" to "Bottom". In such situations, you will notice communication gets positively correlated to productivity of routine kind of jobs. Also the flexibility for routine overloads of work increases. The dysfunction due to top to bottom approach of communication manifests itself in the area of flexibility for situational context. In such situations authority and responsibility needs to be delegated to the peripheries of the origination where lateral and vertical communication flow play a vital part. Horizontal communication on the other hand, is positively correlated to adaptability as it permits free and quick exchange of information. Open Organisation Systems permit a lot of lateral communication to react to environmental changes.

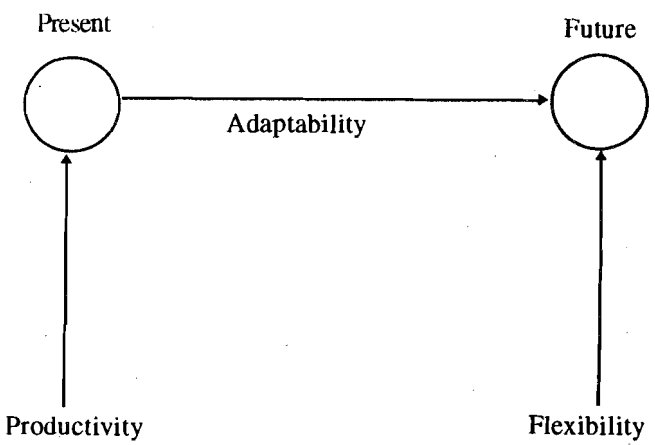
Autonomy

Autonomy may be defined as the degree to which a social system has freedom to make decisions with respect to its environment. The autonomy of an organisation is related to its centralisation. Whenever centralisation is high autonomy decreases. Therefore, autonomy is negatively correlated to productivity for routine jobs and flexibility on routine overloads. Autonomy is positively correlated to adaptability and flexibility for contingent situations. Predominantly autonomy at work increases productivity due to higher morale of the workers.

Mobility

There are two kinds of mobility. The first one involves changes of location coupled with change of job and the second one relates to change in location and continuation of the same job. The first type of mobility which we will call type A and the second type, the type B. Type A mobility is functional for semi-skilled jobs since shift in ability helps in contingent situations. However where jobs are specialized, type A becomes dysfunctional to all the core variables, type B mobility is functional. The degree, to which an organisation can mobilize itself to achieve the goals, is a measure of its organisational effectiveness.

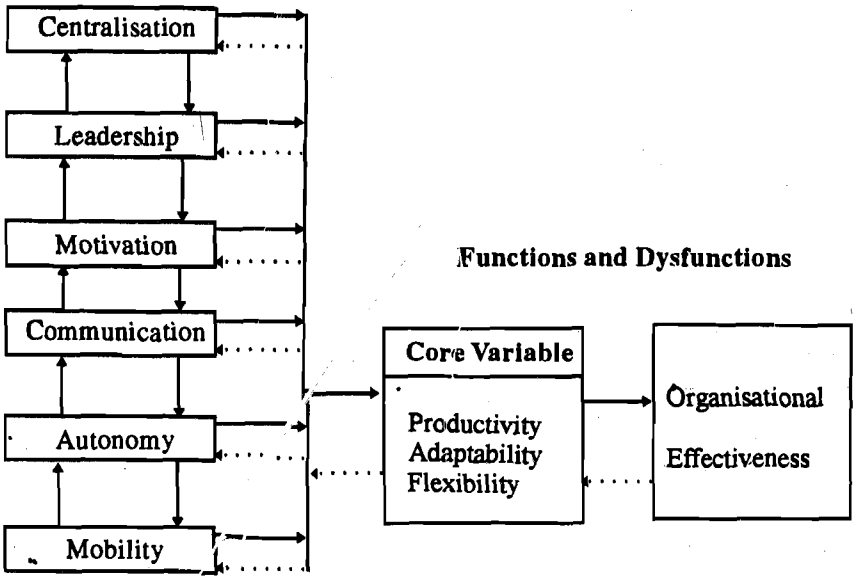
The effectiveness measure has to be seen from the point of view of the present state, the future and the potential to handle unforeseen situation. The relationship among the three core variables can be understood by the following model:



Productivity is concerned about the present state, flexibility is concerned about the potential of an organisation to handle unpredictable situations in the future, and adaptability is the line joining the present and the future adaptability would safeguard the very survivability of an organisation. The line demarcating adaptability and flexibility is indeed thin. Flexibility essentially is a special case of adaptability.

Flexibility implies temporary changes to meet a contingent situation, after which the organisation returns to its original state. Adaptability is seen as a long term change forced by the environment. You will agree that for hospitals, both adaptability and flexibility are essential if hospitals have to meet the people's expectations in changing health scenario and rapid advancements in medical technology.

The core variables determine the effectiveness of an organisation. But these core variables are affected by many factors like centralisation, motivation, autonomy etc. Therefore, the relationship between the factors, the core variables and organisational effectiveness is interdependent in nature. This will be clear by the following model:



The factors are functionally or dysfunctionally related to the core variables. A factor may functionally contribute to productivity but dysfunctionally to flexibility. Another factor may do quite the reverse. Therefore, the interaction among the various factors will finally shape the total effect on the core variables and consequently the organisational effectiveness.

The maximisation of the core variables should lead to maximisation of the organisational effectiveness. But constraints of resources will force a compromise in their mix from level to level in an organisation, depending upon whether the level is an activity, directional or conceptual.

1.5 LET US SUM UP

In this unit you have learnt about the existence of an organisation, types of organisations, organisation structure and its effectiveness. You have also learnt about the core variables and factors affecting the effectiveness of an organisation. You have also learnt how the intervention of core variables and factors affect the effectiveness of the organisation.

1.6 ACTIVITIES

To understand the organisation and functioning of a health institution and to fulfil the objectives of this unit of practical manual, you should perform the following activities.

- Enlist the aims and objectives of the selected hospital/health organisation.
- Enumerate the functions/services being provided.
- Ascertain from the staff members of the organisation, if they have defined job functions, do they have defined job responsibilities with them in the form of manual or guide book.

- ☞ Draw an organisational chart showing hierarchical relationship.
- ☞ Study the various factors responsible for organisational effectiveness.
- ☞ Identify the key problem areas and suggestions for improving the effectiveness.

In order to accomplish this task you should identify and select a hospital/health institution which has average performance. You may finalise the selection of institution/hospital in consultation with your academic counsellor at Programme Study Centre. After selecting the institution you may collect the relevant information through interviews, study of records and by direct observation.

UNIT 2 PATIENT'S SATISFACTION

Structure

2.0 OBJECTIVES

After going through this unit, you should be able to:

- describe the importance of patient's satisfaction;
- enumerate the methods to determine the patient's satisfaction level;
- carry out the patient's satisfaction survey; and
- ensure that your patients in the hospital are satisfied and shall come back to you on a later occasion.

2.1 INTRODUCTION

In this unit you will get an outline about the assessment of patient's satisfaction in a hospital set up. You will learn about the importance of patient's satisfaction. You will also learn about the personnel responsible for patient's satisfaction and the ingredients of patient's satisfaction.

During the course of your working in the hospital you must have had some idea about satisfying your customers/patients. In this unit you will learn about the importance of patient's satisfaction in the modern age of quality assurance and total quality management. The number of repeat customer is very important in evaluating the reputation of the hospital. Advertisement by the word of mouth is also another tool very prevalent in the hospital industry. You will learn about the personnel responsible for patient's satisfaction and the ingredients of patient's satisfaction. You will also learn about various tools and techniques to assess the patient's satisfaction level of your hospital. The sample questionnaire is also given at the end so as to make it convenient for you to carry out the survey in the selected hospital.

2.2 REVIEW OF SITUATION

The goal of any service organisation as you know is creation of satisfaction among the customers. Customers are of two kinds—external and internal. External customers are patients, physicians or consultants, insurance agents/payers, vendors etc. Internal customers are the staff/employees and volunteers. The satisfaction of both these groups is equally important and are reciprocal in nature. Moreover, the concept patient satisfaction is rapidly changing to **customer's delight** which means the patient not only is cured of his ailments during the hospital stay but also is pleased with the amenities provided to him by the hospital and its staff during the stay which he fondly remembers after being discharged and longs passionately to avail the services on some other occasion.

UNIT 2 PATIENT'S SATISFACTION

Structure

2.0 OBJECTIVES

After going through this unit, you should be able to:

- describe the importance of patient's satisfaction;
- enumerate the methods to determine the patient's satisfaction level;
- carry out the patient's satisfaction survey; and
- ensure that your patients in the hospital are satisfied and shall come back to you on a later occasion.

2.1 INTRODUCTION

In this unit you will get an outline about the assessment of patient's satisfaction in a hospital set up. You will learn about the importance of patient's satisfaction. You will also learn about the personnel responsible for patient's satisfaction and the ingredients of patient's satisfaction.

During the course of your working in the hospital you must have had some idea about satisfying your customers/patients. In this unit you will learn about the importance of patient's satisfaction in the modern age of quality assurance and total quality management. The number of repeat customer is very important in evaluating the reputation of the hospital. Advertisement by the word of mouth is also another tool very prevalent in the hospital industry. You will learn about the personnel responsible for patient's satisfaction and the ingredients of patient's satisfaction. You will also learn about various tools and techniques to assess the patient's satisfaction level of your hospital. The sample questionnaire is also given at the end so as to make it convenient for you to carry out the survey in the selected hospital.

2.2 REVIEW OF SITUATION

The goal of any service organisation as you know is creation of satisfaction among the customers. Customers are of two kinds—external and internal. External customers are patients, physicians or consultants, insurance agents/payers, vendors etc. Internal customers are the staff/employees and volunteers. The satisfaction of both these groups is equally important and are reciprocal in nature. Moreover, the concept patient satisfaction is rapidly changing to **customer's delight** which means the patient not only is cured of his ailments during the hospital stay but also is pleased with the amenities provided to him by the hospital and its staff during the stay which he fondly remembers after being discharged and longs passionately to avail the services on some other occasion.

Two important aspects determining the level of ratio fraction are expectations and perceptions. Expectations are before being inside the hospital and perceptions are after coming out of the hospital. The reputation of any health care delivery system organisation is the dominant factor in determining patients preferences which in turn depends on their perceptions of the institution. The perceptions are based largely by personal experiences, word of mouth publicity and information shared by a close relative or someone from that organisation. Studies have revealed that these three factors constitute almost seventy per cent of the consumer's awareness about the hospitals. Rest thirty per cent are influenced by other factors like paid advertising which in turn creates expectations. The factors affecting patient's satisfaction in terms of quality of care are:

Appropriateness: The degree to which the care/intervention provided is relevant to the patient's clinical need, given the current state of knowledge.

Availability: The degree to which the appropriate care/intervention is available to meet the needs of the patient served.

Continuity: The degree to which the care/intervention for the patient is coordinated among practitioners, between organisations, and across time.

Effectiveness: The degree to which the care/intervention is provided in the correct manner, given the current state of knowledge, in order to achieve the desired/projected outcome(s) for the patient.

Efficacy: The degree to which the care/intervention used for the patient has been shown to accomplish the desired/projected outcome(s).

Efficiency: The ratio of outcomes (results of care/intervention) for a patient to the resources used to deliver the care.

Respect and caring: The degree to which a patient, or designee is involved in his or her own care decisions, and that those providing the services do so with sensitivity and respect for his or her needs and expectations and individual differences.

Safety: The degree to which the risk of an intervention and the risk in the care environment are reduced for the patient and others, including the health care provider.

Timeliness: The degree to which the care/intervention is provided to the patient at the time it is most beneficial or necessary.

In the absence of the above mentioned factors, patients could feel ignored and uncared for during their course of the hospital stay naturally tend to be upset and legally aggressive leading most of the times to consumer suits in the present day.

Staff Satisfactions

Human resource as you know is the greatest asset of any hospital. It is very vital to ensure that they are productive, satisfied and thoroughly involved in their respective processes of the health care delivery team. The hospital can't satisfy the customer unless it satisfies the staff. The role of the hospital administrator is very important in creating an environment conducive to all groups and employees so that they bring out the best in themselves and in turn increase productivity i.e. better service which is quantifiable.

Patient's satisfaction is built upon following service points/units:

1) ***Front office or Reception***

- Mannerisms and courtesy extended to the patients and relatives.
- Detailed information regarding various functionaries, timings, tariff etc.

2) ***OPD and Emergency***

- Promptness of the staff i.e. Doctors, Nurses and other paramedical staff.

- Sense of concern towards patient.
- Carrying out various examination and tests effectively and efficiently.

3) *Indoor Services*

- Ambience of the room
- Quietness
- Sense of privacy
- General cleanliness
- Housekeeping
- Safety and security
- Food services
- Behaviour of staff towards patients
- Sign posts, parking etc.

4) *Billing and Payment System*

- Timeliness of billing
- Accuracy
- Flexibility in form of payment e.g. cash, cheque, credit card etc.

Health care providers could be categorised into the following three types based on the culture and service of the place:

Factors	Type I	Type II	Type III
Attitude	Bureaucratic	Polite	Empathetic
Noise Pollution	Very destructive	Noisy	Low and quiet
Privacy	None	Reasonable	Concerned towards privacy
Information	None	Information given only to questions	Well informed through brochures and guides
Ambience	Institutional ambience	Comfortable surroundings	Caring environment
Service time	Long wait	Moderate wait	Prompt service
CEO commitment	None towards services	Minimises complaints	Top priority towards service
Patients impact	**Dissatisfied**	**Reasonably Satisfied**	**Completely satisfied**

2.3 MATERIALS AND METHODS

The various materials and methods in assessing the level of patient's satisfaction in a hospital are:

1) **Self assessment** is to be done by you to take stock of the situation in terms of patient satisfaction. Sample enclosed at Annexure 1. One can also review the total number of complaints received in the last one year.

2) **Interviewing hospital staff and patients**: A good range of the hospital staff (all levels) should be interviewed to assess the awareness amongst themselves towards the concept of patient satisfaction. The patients could also be interviewed during their stay. In this situation absolute confidentiality is

supposed to be kept and they should be reassured that the study is for a specific purpose designed to improve the services of the hospital. In a big hospital the sample size should be at least 100, in smaller places it should be 50. A pilot study could be performed on a sample size of 10. The data can be processed, analysed, and the results can be represented both in figures and graphical form. (Sample enclosed at Annexure 2.)

3) **Exit Interview or Survey of patient satisfaction:** By far this is the best tool to assess the level of satisfaction in any hospital set up. The patient had come with certain expectations and has gone with certain perceptions in his mind. The views could be of the patient, a relative who shares his views or a friend who was also accompanying the patient in the hospital.

   This should be an ongoing process and should be sustained if the hospital is keen to build up good guest relation programme. The results could be analysed every quarterly in excel and Epi-info and results to be formulated both graphically and in figures.

   It is the responsibility of the top executive of the hospital to see that the satisfaction graph rises and goes beyond all boundaries into "DELIGHT" zone. Sample enclosed at Annexure 3.

2.4 ACTION PLAN

The concept of customer's satisfaction and delight should originate from the top management and the idea should percolate down to the lowest member in the organisation.

However, the first step is to take stock of the situation and evaluate the existing scenario of patient relationship.

After assessing the level a detailed programme needs to be planned in a phase wise but time bound manner. Both the internal and external customers should be focussed but in the first step the internal customers need to be sensitised to this important issue. Its importance in terms of finance, quality and competition should be explained to the staff.

In phase 2, interviews should be carried out amongst the various members of the staff as well as the patients.

The results of the interview to be processed and analysed and kept as a baseline guide for future comparison.

Thirdly the exit interview or survey of patient satisfaction to be carried out as described and the results to be analysed and compared with that of phase 2. However, this programme should be sustained and ongoing because there is no end to win over our customer.

2.5 LET US SUM UP

In this unit you have learnt about the various facets of patient/customer satisfaction. You have also gained an insight into the concept of patient satisfaction, its importance and the various factors influencing it. You have been provided with the samples for the interview and survey which will serve as a ready reckoner to execute the programme in your hospital.

2.6 ACTIVITIES

You are required to carry out a study on patient satisfaction in a selected hospital and submit your comments on the following:

- ☛ Study the patient relationship in a local hospital, as per Annexure 1.
- ☛ Carry out a pilot study in medical ward (10-15 patients) in a local hospital as per Annexure 2.
- ☛ Go through the following case study and write the answers to the questions. You may discuss your answers/observations with your academic counsellor at Programme Study Centre and also with your peer group.

CASE STUDY

A middle-aged lady, a follow up case of carcinoma breast $T_3N_2M_1$, presently admitted for chemotherapy in one of the room of your hospital.

On the second day her husband complained that the patient couldn't sleep the whole night as there were rats in the A/C duct and the false ceiling. They were making such a noise that it was impossible for the patient to sleep.

Moreover, the bearer brought dinner at 7.30 p.m. and left in the room. By the time the cycle of chemotherapy was over it was 9.30 p.m. When the patient wanted to have her dinner they found cockroaches all over the food tray. The patient couldn't have her dinner because it was already 10 p.m. and the kitchen was closed and so also the shops nearby.

- ☛ How could rats and cockroaches enter the room without anybody's notice?
- ☛ Is someone responsible/accountable for the fact to see whether the patient has had her food or not?
- ☛ What would you do in such a situation?

Evaluation of Patient Relationship Programme

Given below are a total of 24 points wherein you have to tick **Yes** or **No**. If the total number of Yes is >20 then the programme is excellent, if >15 it is good but if it is less than 12, then it certainly needs improvement.

Section A : The need for improved patient relationship

1. Patients rarely complain about staff behaviour. Yes/No
2. The hospital's atmosphere is generally seen on very friendly. Yes/No
3. Employees speak good about the hospital to outsiders. Yes/No
4. If visitors to the hospital are lost then guide them properly. Yes/No
5. Generally there is a spirit of teamwork and cooperation among the staff. Yes/No

Section B : Awareness amongst staff

1. Employees understand the importance of patient satisfaction in achieving the hospital's goal. Yes/No
2. Staff at all levels are aware of the hospital's financial position and the competitive market. Yes/No
3. Employees are generally aware of their importance in attracting patients. Yes/No
4. Administrators give importance to guest relations and patient satisfaction in the culture of the hospital. Yes/No
5. All publications of the hospital carry features on guest relation issues, events and accomplishments. Yes/No

Section C : Accountability of staff

1. For the staff we have given instructions, clear, written expectations in specific terms. Yes/No
2. We punish/terminate staff who fail to meet high guest relation standards. Yes/No
3. Our top administrators are courteous, friendly and have a caring attitude towards patients and visitors. Yes/No
4. Guest relations behaviour has a prominent place in our performance appraisal forms. Yes/No
5. The quality of behaviour towards hospital guests affects employees pay increase and promotions. Yes/No

Section D : System for improving employee skills

1. Our organisation offers training programme to upgrade the guest relation skills of our employees. Yes/No
2. Our hospital conducts jobs specific guest relation upgradation skill training programme for:

   Security Staff Yes/No

   Parking Staff Yes/No

   Receptionist Yes/No

   Nurses Yes/No

   Technicians Yes/No

   Billing Clerks Yes/No

   Supervisors Yes/No

3. We offer training in handling complaints and complaints are seen as another chance to satisfy customers. Yes/No

PART-A

Dear Sir/Madam,

Our hospital is conducting a study to assess your valued opinion about the hospitality services provided in the hospital so as to identify areas where there is a need for improvement.

Please feel free to express your opinion objectively. You could withhold your identity if you so desire. You are also welcome to offer suggestions for the overall improvement of the services for which we shall be grateful to you.

Thanking you,

.....

.....

PART-B

Personal Particulars

a) Name (optional) Sex Age

b) Date of admission Date of Discharge

c) Diagnosis

d) Occupation
(If unoccupied please mention the occupation of the person you are dependant upon)

e) Annual Income <1 Lakh 1-2 Lakhs
2-3 Lakhs >3 Lakhs

f) Residential address
(Please mention only the city/state)

g) Who is bearing your hospitalization expenses
Government Employer (private or corporate) Insurance company Self

h) Have you been hospitalized before Yes/No
If Yes, Name of the hospital
If possible Govt. Hospital/Private Hospital/Nursing Home

PART-C

1. The reason you sought admission in our hospital:
   a) The medical care, rooms and environment are excellent.
   b) Our hospital is cheaper and has good treatment and room facilities.
   c) I was referred by my organisation/employer.
2. How was the behaviour of the booking clerk/Registration clerk/Receptionist?
   a) Polite and hospitable
   b) Indifferent/callous
   c) Rude
3. Once you got the admission to the ward how were you received?
   a) My relations/attendants took me to the room allotted.

b) Some one was there to guide and take us to the room (Hospital attendant/ Social guide/Nurse) {please tick}

4. If you were received by the hospital staff, how was the behaviour?
Very courteous/Cordial/Indifferent/Callous {please tick}

5. How is the room allotted to you in terms of size, layout and outlook?
Excellent/Good/Satisfactory/Poor {please tick}

6. What do you feel about the furnishings/furniture of the room?
Excellent/Good/Satisfactory/Not satisfactory {please tick}

7. If not satisfied, what additional things you recommend in the room?

a) b) c) d)

8. Were you briefed adequately about the functioning of the hospital either verbally/ written instructions.
Yes / No {please tick}

9. What was your first impression of the room after entering?
Very impressive/Satisfactory/Good/Poor {please tick}

10. How frequently is the linen (bed sheets, pillow covers, towels, curtains) changed?
Daily/Alternate day/Twice a week/On demand {please tick}

11. What is the quality of linen?
Good/Satisfactory/Poor {please tick}

12. What is the quality of laundering of linen?
Good/Satisfactory/Poor {please tick}

13. Is the quantity of linen provided sufficient for you?
Yes/No {please tick}

14. Do you bring additional bedding/linen from home?
Yes/No {please tick}

15. How often is the room cleaned and dusted (including toilets)?
Twice a day/Once a day/Once in two days/Once a day and on demand {please tick}

16. Are disinfectants/chemicals being used for cleaning rooms/wash rooms?
Yes/Occasionally/Never {please tick}

17. Is the room provided with adequate dustbins (for room and toilet)
Yes/No {please tick}

18. Are the dustbins emptied daily.
Yes/No {please tick}

19. Do you bring food from home or take hospital food?
Home food/Hospital food {please tick}

20. Are you being served food by your choice?
Yes / No {please tick}

21. How is the food preparation?
Invariably tasty/Spicy and oily/Bland/Not palatable {please tick}

22. Are you satisfied with the food timings (bed tea, breakfast, lunch, tea, dinner)?
Yes/No {please tick}

23. What is the state of crockery/cutlery?
Satisfactory/Good/Poor {please tick}

24. How is the food served to you?
Impressive/Homely manner/Unprofessionally {please tick}

25. What do you feel about the security/safety of the rooms?
Adequate/Inadequate {please tick}

26. What do you feel about the maintenance work?
Good/Satisfactory/Not satisfactory {please tick}

27. Is there any seepage from the walls or water dripping?
Yes/No {please tick}

28. Are you satisfied with the Air conditioning?
Yes/No {please tick}

29. Do you feel the need for a telephone in your room?
Yes/No {please tick}

30. What do you feel about the service of TV/cable.
Good/Satisfactory/Unsatisfactory {please tick}

31. When does the Nurse visit you in the room?
Only to give medicines/As and when called for/Comes frequently of her own {please tick}

32. How are the medicines given to you?
Always by the Nurse/Sometimes by the Nurse/Most of the times by attendants {please tick}

33. How would you rate the behaviour of the Nurses/Attendants/Sweepers?
Very good/Satisfactory/Indifferent/Rude and Callous {please tick}

34. What is your overall view about the service provided in the wards?
Very good/Good/Satisfactory/Poor {please tick}

35. What do you feel about the charges of wards?
Over priced/Reasonable/Very low priced {please tick}

36. Which are the areas in the ward that need improvement according to you?
a) Interiors b) House keeping c) Mannerism of staff d) Food services
{please tick}

37. As compared to other hospitals how would you rate our hospital wards?
a) Superior b) Comparable c) Inferior {please tick}

38. Would you like to recommend our hospital wards to your friends/colleagues etc.
Yes/No/Don't know {please tick}

Dear former patient

Recently we were privileged to serve you as a patient of our hospital. We would appreciate your assistance in evaluating our services by taking a few minutes to express your thoughts regarding your stay in our hospital.

Thank you for helping us to continue to improve and thereby serve you and others more effectively.

Sincerely,

Administrator

(Please tick the correct answer)

Admitting/Registration

1.	Waiting time before admission processing.	Poor	Average	Good	Excellent
2.	Thoroughness in answering questions, explaining forms and procedure.	Poor	Average	Good	Excellent
3.	Courtesy and efficiency of admitting process.	Poor	Average	Good	Excellent

Room Accommodations

4.	Docter of your room	Poor	Average	Good	Excellent
5.	Cleanliness of your room	Poor	Average	Good	Excellent
6.	Temperature of your room	Poor	Average	Good	Excellent
7.	Quietness of your room	Poor	Average	Good	Excellent
8.	Telephone service	Poor	Average	Good	Excellent

Nursing Service

9.	Was your admission to your room handled in a courteous,efficient manner?	Poor	Average	Good	Excellent
10.	Were you made comfortable within your first few hours here?	Poor	Average	Good	Excellent
11.	Did the nursing staff give prompt attention to your needs and requests?	Poor	Average	Good	Excellent
12.	Did the nursing staff explain your hospital routine adequately ?	Poor	Average	Good	Excellent
13.	Were you taught how to care for yourself after leaving the hospital?	Poor	Average	Good	Excellent

Special Tests and Procedures

14.	Were tests explaind to you so that you were prepared for what was going to happen?	Poor	Average	Good	Excellent
15.	Was enough time allowed for you to ask questions?	Poor	Average	Good	Excellent

Nutrition/Dietary Services

16.	Attractiveness and taste of food	Poor	Average	Good	Excellent
	Hot food served hot	Poor	Average	Good	Excellent
	Cold food served cold	Poor	Average	Good	Excellent

17. Variety and selection of food items	Poor	Average	Good	Excellent
18. Receiving the food items ordered	Poor	Average	Good	Excellent
19. If you received nutritional information from a dietician was it useful and meaningful?	Poor	Average	Good	Excellent

Visitors

20. Helpfulness of the hospital staff and volunteers to your visitors.	Poor	Average	Good	Excellent
21. Convenience of the visiting hours for family and friends.	Poor	Average	Good	Excellent

Signs and Directions

22. Signs and directions outside the hospital	Poor	Average	Good	Excellent
23. Sign and directions inside the hospital	Poor	Average	Good	Excellent

Parking

24. Convenience of parking	Poor	Average	Good	Excellent
25. Directions to parking	Poor	Average	Good	Excellent

Patient Billing/Credit Department

26. If you talked with the billing/credit department, were you given a satisfactory explanation of charges and insurance coverage?	Poor	Average	Good	Excellent
27. How were you treated by the other staff members you come in contact with?				
a. Physician	Poor	Average	Good	Excellent
b. Admissions	Poor	Average	Good	Excellent
c. Emergency department	Poor	Average	Good	Excellent
d. Physical Therapy	Poor	Average	Good	Excellent
e. Laboratory	Poor	Average	Good	Excellent
f. Respiratory Care Deptt.	Poor	Average	Good	Excellent
g. Housekeeping	Poor	Average	Good	Excellent
h. X-ray	Poor	Average	Good	Excellent

BLOCK INTRODUCTION

In the first block of this course you will learn about four important clinical service areas of a hospital viz. Out Patient Department (OPD), Accident and Emergency Services Department, Operation Theatre and Intensive Care Unit (ICU).

This Block contains four units.

Unit 1 deals with Outpatient Services. In this unit you will learn about the planning, organization and management of Out Patient Department (OPD) of a Hospital.

Unit 2 deals with Accident and Emergency Scrvices. In this unit you will learn about various administrative aspects of this department including planning consideration, equipment requirements, staffing, and policies and procedures governing this department.

Unit 3 deals with another important service area of the hospital i.e. Operation Theatre. You will learn about planning, organization and management of an Operation Theatre including the concept of zoning.

Unit 4 deals with another vital area of a hospital i.e. Intensive Care Unit (ICU). This unit deals with definition, types, staffing, physical facilities, planning, designing, and equipment requirements of ICU. The unit also discusses policies and proccdurcs, co-ordination and control mechanisms with regard to ICU.

UNIT 1 OUTPATIENT SERVICES

Structure

1.0 OBJECTIVES

After going through this unit, you should be able to:

- enumerate the role and functions of outpatient services;
- list the types of outpatient services;
- describe the physical facilities, layout, equipment and staffing requirements in planning of outpatient services:
- describe the policies and procedures adopted in organising and managing outpatient scrviccs; and
- list the activities and describe a plan for monitoring and evaluation of outpatient services.

1.1 INTRODUCTION

In this unit, you will learn about the planning, organisation and management of outpatient serviccs as an integral part of hospital services. Outpatient services in hospitals have evolved in line with patients' needs demands and expectations from a limited service offering basic and minor clinical services to a highly evolved and organised service. Outpatient serviccs when functionally integrated with the inpatient services of the hospital lead to continuity of carc.

In this unit you will learn about the roles, Functions and types of outpatient scrviccs. You shall further learn how through planned development of physical facilities, equipment and manpower the outpatient services could be integrated with the inpatient care. In addition, it shall be possible for you to understand the principles of devising policies and procedures for effective delivery ol'outpatient services. Finally. you shall be able to learn principles of monitoring and evaluation of outpatient services.

1.2 BRIEF HISTORY

Sir George Clark has suggested that outpatient department as wc know today originated in mid seventeenth century when at Hotel Dieu in Paris, six physicians were detailed for regular sessions on Wednesday or Saturday advising the poor individually. This

introduced the idea of outpatient clinic. The modern OPD began to emerge in 1850 in USA from the framework of dispensaries.

Historically, the family doctor or general practitioner (G.P.) referring his patient for specialist opinion had three options — the patient's own home, the specialist's room or the Outpatient Department of the hospital. In the later, the specialist saw the poor offering free or near free diagnosis and treatment, in his rooms he saw those who could pay and in the patient's home he saw only the very sick or the very very rich. Thus, the main function of the Outpatient Department was as a source of charity diagnosis and perhaps care and medicaments. However, in the 20th century with the growing dependence of the consultative specialist on the work of others such as radiologists and pathologists, with the continued growth of specialisation and refined and complicated techniques, and with the use of expensive medical diagnostic equipment it became increasingly convenient and in many cases imperative for the specialist to make use of Outpatient Department for both charity and paying patients.

The continued growth of the outpatient services was also seen as a dangerous threat leading to the reduction of the workloads and incomes of non-hospital doctors, a situation which still exists where the G.P. operates on a fee-for-service basis.

Despite unease in some quarters, about the trend, the functions of the outpatients service have gradually widened. Much of the investigational and diagnostic or even the therapeutic work that formerly necessitated admission to a hospital can now be carried out in a well-equipped outpatient department, with a saving of expense and avoidance of the disruption of family life that hospitalisation causes.

Check Your Progress 1

1) Enlist three alternatives that a General Practioner had while referring his patient for specialist opinion.

   a) .....

   b) .....

   c) .....

2) Write down three developments in the 20th century which have led to the specialist making use of Outpatient Department for both the charity and paying patients.

   a) .....

   b) .....

   c) .....

1.3 FUNCTIONS AND TYPES

Outpatient Department as you know is a very important department of the hospital which is visited by large section of community. It is also the first point of contact between patients, their relatives and hospital and its staff. The care provided in the OPD and behaviour of the staff determines the image of hospital and is aptly referred to as 'shops window of the hospital'. In a properly managed OPD the stay of the patients can also be considerably reduced, and the cost of care to the patient, hospital and the government can be brought down.

1.3.1 Role and Functions

Outpatient Department is one of the department of the hospital which cares for the ambulatory patient who come for diagnosis, treatment and follow up.

You must have observed that the roles and functions of Outpatient Services have gradually widened over the years. Now, the role and functions of outpatient services include:

1) To provide for the community a major source of specialist diagnostic medical opinion where the knowledge skills and resources of the specialist are backed up by the resources of the hospital. These include not only the physical resources but also the presence of a wide range of other specialists which facilitates early referral when necessary and of supportive paramedical staff of the allied health professions.

2) To treat on ambulatory and domiciliary basis all cases which can be treated in the Outpatient Department (for example surgery for hernia and varicose veins).

3) To refer patients for admission to the hospital of those who need it.

4) To carry out after care and medical rehabilitation, when necessary, after discharge from hospital.

5) To promote health of the individuals under care in the Outpatient Department by means of health education.

6) To train medical students, house physicians and other professional staff such as nurses and technicians with valuable and diversified clinical experiences.

7) To compile, collate and analyse records of patients using outpatient services for epidemiological, social clinical research and for periodic assessment of clinical outcomes.

8) To carry out preventive and promotive services through provision of immunization, screening, antenatal, well-baby, counselling, family welfare clinics etc.

1.3.2 Types

Outpatient Services could be of two types:

i) Centralized Outpatient Services: In centralized outpatienl services all the outpatient care relating to all the specialities are provided in a compact area which includes all diagnostic and therapeutics facilities also being provided in the same unit. Polyclinic in various hospitals is based on this concept.

ii) Decentralized Outpatient Services: In decentralized outpatient service, the outpatient care is provided in the respective departments. The same holds true for diagnostic and therapeutic services also. The speciality clinics are usually based on this concept.

Use of one type of outpatient service in a particular hospital depends on the size variety and workload of the hospital. Generally larger the hospital more centralized the outpatient services are, This also leads to economy as well as higher patient satisfaction.

1.4 PLANNING CONSIDERATIONS

1.4.1 Physical Facilities and Layout

Location

The outpatient department should be conveniently located adjacent or in close proximity to vital adjacent services such as registration and medical records, admitting, emergency and social services. It should be near the main road and close to the main hospital entrance

but with sufficient space to provide for parking etc. and to prevent noise and dust pollution. It should be separate from inpatient wards and other departments but connected with them. It is preferable to have outpatient departments of all specialities in the same building so as to facilitate cross-references between various specialities.

Principles of Planning Layout

The following principles should be kept in view while planning layout of the outpatient services:

a) It should be ensured that patient flow moves in one direction, in logical sequence and there is no undue back traffic.

b) It should be able to share with the inpatient departments, all diagnostic facilities, such as x-ray, and pathology laboratory.

c) It should be amenable to expansion without serious dislocation of work.

Layout

Various designs or layouts can be used, such as:

1) The double loaded single corridor with rooms on each side of the corridor;

2) The double corridor for entry from the opposite sides of the room; and

3) The triple corridor which provides two rooms of examination treatment rooms on each side of a staff corridor.

Size

Bureau of Indian Standards has recommended the following space provisions lor various zones : 2 square metres per bed for entrance zone, 10 square metres per bed for the ambulatory zone, and 6 square metres per bed for diagnostic zone out of a total of 60 square metres per bed lor the total hospital arca.

Physical Facilities

The physical facilities may be considered under four groups:

a) Public Areas (Entrance Zone)

b) Clinical Areas (Ambulatory Zone and Diagnostic Zone)

c) Administrative Areas

d) Circulation Areas

You will now learn about each physical facility in some detail.

Public Areas

i) **Entrance:** It should be easily accessible, with wide door and have ramps and sleps.

ii) **Reception and Information: A** desk or a counter located within the public area for information and reception.

iii) **Registration and Records Area:** This area should be located near the entrance. Railings should bc provided for separate queues — new and old and male and female patients. A counter 300 cm high and with work surface 60 cm wide and with file drawers is necessary. One desk should bc provided for 20 palients per hours. Two sq. metres per bed should be provided for outpatient records.

iv) **Waiting Area:** Main waiting area should bc adjacent to Registration area and sub-waiting area should be provided in each clinical department. Waiting area is provided at the scale of 0.1 sq. metre per patient, with a minimum of 4 sq. metre The arca provided in sub-waiting areas adjacent to various consultation, diagnostic and therapy areas is 0.8 sq. metre per patient.

v) **Public Toilets and Washrooms:** For males and females at the scale of one for each 200 patients and visitors should he provided.

vi) **Snack** Bar: It should be located convenient to the main waiting area. It should be maintained in a hygienic manner.

Clinical Areas

An OPD includes Surgical, Dental, Ophthalmic, ENT, Obstetric and Gynaecological, Paediatric, Medical, Psychiatric, Dermatology and Venereology, Orthopaedic and

Emergency Departments. Depending upon the type of hospital there may be superspeciality clinics such as Cardiology, Neurology, Urology to mention a few only. In addition there arc ancillary facilities like treatment sections including minor operations, injection, dressing and dispensary and auxilliary services of pathology, blood bank and radiology. There is also a growing need for instituting health education programmes to educate the public in environmental hygiene, family welfare ctc.

General requirements for the above clinics are as follows:

a) **Sub-Waiting Area:** This area should not have more than one-third of the total number of patients visiting the clinic in a day.

b) **Consultation Room:** This room should provide for accommodation for a doctor's chair, table, patient's stool, follower's seat, wash basin, examination couch and equipment for examination. Area should be about 15-17 sq.mt. Each clinic should be able to handle 100 cases per day.

c) **Special Examination Room:** Certain departments will need separate room For special examinalions depending upon the type of equipment being used in the OPD.

Ancillary Facilities

i) **Injection Room;** It should have wailing area for about 10-20 patients at the rate of 06-0.8 sq. metre per patient. The area may vary from 12-40 sq. metre depending on the workload.

ii) **Treatment and dressing room:** About 12-16 sq.mt. shall be required for each treatment and dressing room.

iii) **Pharmacy:** The wailing area should be comfortable in the pharmacy as the patients are quite tired when they reach this place. The accommodalion should be sufficient Io contain about 5% of total clinical visits to the OPD in one session.

Pharmacy will require multiple dispensing windows, compounding counters with sink, drug storage cabinet and shelves, the details of which you will learn in Unit 4 of Block 3 of this course.

Auxilliary Facilities

i) **Laboratory:** It should be able to serve both inpatient and outpatients. A sample collecling station for urine, stool and blood specimens should bc provided separately in the OPD. It should have two (male and female) wash rooms and toilets (15 sq, metre) and a bleeding room (15-20 sq. metre) with two or more examination tables. You will learn more details of planning and organisation of laboratory services in Unit 1 of Block 3 of this course.

ii) **Radiology:** It should be able to serve both inpatients as well as outpatients, the details of which have been described in Unit 2 of Block 3 of this course.

iii) **Blood Bank:** This will include a reception-cum-waiting area, bleeding room, laboratory for grouping, recovery room, and a room for storage of blood and ancillaries like washing and sterilization room, office room and toilet facilities. The details of planning and organisation of Blood Bank Services of a hospital have been discussed in Unit **3** of Block 3 of this course.

iv) **Health Education Facility:** This should include an office for the health educator, conference and lecture room, and space all over the OPD for display of educational material. Minimum area required for this facility would be 15 sq. metre. Audio visual aids such as TV, Video player and health education cassettes should be made available in this area.

v) **Medical Social Service Facility:** This facility should be located in the OPD with suilable cubicle for each social worker/counsellor to provide privacy.

vi) **Screening Clinic:** This is specially required in a teaching/tertiary hospital. It should be located near the registration area. It should consist of one or more cubicles with examination table, stool, table and chair with 12 sq. metre for each cubicle. This reduces the workload on the speciality clinic and also increases quality of speciality services.

vii) Preventive and Promotive Health Facility: An office of size 15 sq. metrc is the minimum requirement for this facility. This Sacility provides advice on sanitation, control of communicable diseases, nutrition, home care, public health nursing. mental health, occupational hazards, immunization, family welfare counselling, well baby and well adult clinics in addition to morbidity studies.

Administrative Areas

a) Administrative Office: A room of 15 sq. metre for a hospital with 100 beds or more is required to function for housing administrator's office.

b) Business Office: The office for personnel section, requisitions, making reports etc. is required in OPD area in large and active OPD.

c) House Keeping: A janitor's closet for house keeping and cleansing materials is required with a size of 4 sq. metre.

d) Storage Facilities:

i) ***General Stores:*** It should be with the general stores area of the OPD.

ii) ***Drugs Stores:*** Pharmacy stores should be in the hospital drug stores in a central place.

iii) ***Linen Stores:*** Each floor of OPD area will require a closet with shelves, for storage of daily supplies of linen. An area of 2 sq. metre may be sufficient.

Circulation Areas

This includes corridors, stairs, lifts etc. This occupies about 30%of the total building area, elevators should be easily accessible specially for cardiac and obstetric patients. Corridors should be at least 1.8 metre wide. Security post should be provided at strategic ,locations. STD/ISD phone facility also should be made available.

1.4.2 Equipments

Equipments as related to the speciality examination should be available in the concerned room. Sufficient numbers of wheelchairs and stretchers in a conveniently accessible location should be made available. Each consultation-cum-examination room should have a work table, physicians desk, wall mounted cabinets, x-ray view box, revolving stools and chairs besides examination couch, wash basin, instrument trolley. All OPDs should have equipments Sor resuscitation of patient collapsing suddenly.

1.4.3 Staffing

Staffing levels for the outpatient services should be dependent on analysis of the objectives of the department and on the volume of the workload in each of its functional areas. There should be no separation of medical staff into inpatient and outpatient staff so as to ensure continuity of high quality care. The nursing staff consisting of registered nurses, ANMs and nursing or hospital aids in sufficient number should be provided in the OPD. Ancillary staff in OPD e.g. X-ray, Laboratory, EEG and ECG technicians also are required. The clerical staff carry out registration, patient's billing, cashiering, secretarial and medical record functions. In teaching hospitals, senior physicians have interns and residents assisting them in professional care of patients.

Many hospitals use volunteers in a variety of activities in the outpatient services.

The outpatient department will require an administrator in large hospitals for planning, organising, supervising, evaluating, co-ordinating and improving outpatient services.

Receptionists, who make the first contact with the staff are an important members of outpatient staff.

Check Your Progress **3**

I) Enumerate the three designs of outpatient service facility.

a) .....

b) .....

c) .....

2) Specify the area required for the following zones in a hospital as recommended by the Bureau of Indian Standards.

a) Entrance Zone : ..... sq. mt. per bed

b) Ambulatory Zone : ..... sq. mt. per bed

c) Diagnostic Zone : ..... sq. mt. per bed

3) List the Sour areas in the physical facilities in the outpatient services.

a) .....

b) .....

c) .....

d) .....

4) Write True and False :

a) Corridors in the outpatient area should be at least 7 ft. wide. (T/F)

b) Medical staff for outpatient and inpatient care should be separate. (T/F)

c) The outpatient department should have a full time administrator in a large hospital. (T/F)

d) There is no need to have sub-waiting area in each speciality clinic, X-ray. Laboratory, ECG, injection room when there is already a main waiting area available. (T/F)

1.5 ORGANISATION AND MANAGERIAL CONSIDERATIONS

1.5.1 Policy

The policy in the outpatient services should be to achieve continuity of high quality patient care with modern techniques and methods in order to have total patient satisfaction at all times with the willing co-operation of all the health care personnel working in the outpatient department as well as inpatient departments.

1.5.2 Procedures

There should be a manual of the procedures to be followed by all health care personnel working in the outpatient services. All the health care personnel should be trained and retrained in carrying out all or any procedure related to their work area. All the procedures carried out in the outpatient department should be carefully recorded and documented in a retrievable format so that the patient can be benefited in future as well as outcome of treatment could be scientifically evaluated.

It is better to implement appointment system to spread out the reporting time of patients. This can be either individual or block appointments. The block appointment system calls for a certain number of patients to be present at a given time so as to provide a sufficient pool of patients; thus the physician will at no time find himself idle and it limits the pool to the capacity of the waiting room.

Information graphics and signage system, name boards, pictorial representation of services provided, direction signs, colour coding of different service areas facilitate easy understanding of hospital procedures and routines by the patients.

1.5.3 Managerial Considerations

Public **Relations**

For many members of the community, the OPD will be their first point of contact with the hospital, Ideally, therefore, it should be something of a showpiece making evident from the first the warmth and humanity of the hospital, its respect for the patient and his dignity, its provision of the proper setting for good clinical care, and its good administration, Many of these things the patient can and will judge for himself and they

may influence unduly his future opinions of the hospital. All efforts must be made that the impression on the patient gets in the OPD is a favourable ones.

Overcrowding and Long Waiting Time

Many hospitals face the problem of overcrowding and long wailing time. Due to various reasons, patient after initial waiting for registration waits for consultations, diagnostics, treatment or even for collection of medicinces at pharmacy.

Adequate attention by all hospital administrations must be given to resolve this problem. A simple random study of waiting patterns since the arrival of patients through his final disposal and reasons thereof must bc carried out and bottlenecks removed. The queuing theory which has been dealt in Unit l of Block 4 of this course can be applied to resolve the problem.

OPD Timings

The timings should he decided to suit the local and organisational needs. General OPDs with basic specialities are usually conducted six days in a week may be from 0800 hr to 1300 hr or so. All registered patient must be seen irrespective of the timings fixed for OPDs. .Timings for ancilliary/supportive facilities must be kept at least one hour after the OPD timings so that no patient who has been seen in the OPD is denied the treatment, investigation or drugs. It also must be ensured by the administrator that the timings for OPD are rigidly followed. Increase in registration time, adequate number of doctors, separate queue for new or old cases may help in reducing waiting time in registration.

Screening clinics help in disposal of patients with minor illnesses thus leading to less crowding and waiting time in speciality clinics. Special clinics at different timings, specially during afternoon hours, e.g.,well-baby clinic, diabetes clinic, leprosy/TB, follow up, super speciality clinics etc. also prevent overcrowding. Increasing the duration of OPD services or operating evening OPD services can also prevent overcrowding. Synchronizing functioning of ancillary facilities with OPD workload such that the laboratory, radiology and pharmacy are open and adequately staffed during peak hours when patients referred from the OPD arrive for these services is a managerial technique to increase patient satisfaction. These departments should remain open for a longer duration as compared to OPD.

The patients records of indoor and outdoor services, investigations and treatment should be available in an easily retrievable form at each visit by the patient.

Management Structure

This may vary considerably among hospitals. In larger hospitals, the Medical Director or the Medical Superintendent may be directly incharge of outpatient department. He may have assistants in various units such as clinics, outpatient surgery etc. reporting to him. In smaller hospitals, there may be a co-ordinator to co-ordinate the work of various units of the department reporting to the Medical Director or the Medical Superintendent.

The nursing side of the OPD should be the responsibility of a well-qualified and experienced nurse whose primary function should be to see that the work, in the various clinics proceeds smoothly. She will direct the activities of the nurses and ancillary personnel who work permanently in the department.

Check Your Progress 4

1) Enumerate two types of appointment system for outpatient services.

   a) .....

   b) .....

2) List three methods of reducing overcrowding and waiting time in Outpatient Departments.

   a) .....

   b) .....

   c) .....

1.6 MONITORING AND EVALUATION

The quality of outpatient services need to be monitored and evaluated on an ongoing basis in order that areas requiring attention for improvement could be identified as well as results of efforts made for improvement of quality of patient care could be known. For this purpose, data need to be collected, compiled, collated, analyze and acted upon on a regular basis by a nodal officer in the hospital. The various data that is needed for such a process is as follows:

i) Volume

a) Clinic/department-wise statistics of new and repeat visits on monthly and yearly basis.

b) Percent changes in new and repeat visits over years in relation to availability of doctors and registration staff:

c) Fluctuation in visits by days of the week (or month)---average, high, low.

d) Determine adequacy and utilization of clinics from clinic schedules of preceding year to determine number of hours the clinic was in session. multiply number of session hours by number of rooms to arrive at number of scheduled hours, and divide this by number of patients seen or average service time to evaluate adequacy of rooms. Further, by estimating actual room hours scheduled and dividing by potential room hours, it is possible to determine the clinic efficiency rate.

ii) Utilization and Vital Statistics

The number of people who account for total annual visit volume determines utilization (average number of visits per person per year), This figure should be broken down by vital statistics of the population (age and sex). Such information helps in deciding staffing, programme planning etc.

iii) Visit Levels

New appointments---walk-in, scheduled, short follows-ups, annual physicals, well-baby, well-child check-up, immunization and complex treatments indicate whether utilization, staffing, distribution and amount of revenues need to be changed or kept at the same level.

iv) Cost and Revenues

The cost of each service should be matched with revenues from respective service. As far as possible, each service should be self-supporting, else cross-subsidy system be developed Direct patient care costs like salaries, cost of supplies consumed as well as indirect patient care costs like utilities, free-care should be calculated.

Check Your Progress 5

Answer in **True** or **False**:

i Monitoring and evaluation is a continuous process. (T/F)

b) Monitoring and evaluation of outpatient services is required to identify and punish errant health care persons. (T/F)

c) Cost of each service in the outpatient facility should be matched with revenues from respective services. (T/F)

d) Salaries and cost of supplies consumed are indirect patient care costs. (T/F)

1.7 LET US SUM UP

In this unit you have learnt that outpatient services are an important component of clinical services in a hospital. You have learnt the functions and types of outpatient services. You have also learnt how one can plan—physical facilities, equipment and staff—an effective outpatient department.

Further, you have learnt how problems of over-crowding, long waiting time, structural organisation and policies, procedures and public relations could be tackled. You have also learnt the methods of monitoring and evaluation of outpatient services. You have now come to know how patient satisfaction from outpatient services could be obtained.

1.8 KEY WORDS

Ambulatory Care : Outpatient care or services

Block Appointment : Calling for a certain number of patients to be present at a given time

Direct Patient Care Cost : Costs directly incurred or attributable to the patient care e.g., salaries, cost of supplies consumed

Indirect Patient Care Cost : Costs indirectly incurred or not directly attributable to the patient care e.g., free care costs, cost of utilities e.g., water, electricity etc.

Individual Appointment : Calling for a certain patient to be present at a given time

1.9 ANSWERS TO CHECK YOUR PROGRESS

Check Your Progress 1

1) a) The patient's own home,
   b) The specialist's room, and
   c) The outpatient department

2) a) Continued growth of specialization and refined and complicated techniques.
   b) The use of expensive medical diagnostic equipment.
   c) Growing dependence of the consultative specialist on the work of others such as radiologists and pathologists.

Check Your Progress 2

1) a) To provide specialist medical opinion.
   b) To treat all cases which can be treated on outpatient basis.
   c) To refer patients lor admission to the hospital.
   d) To carry out after care and medical rehabilitation.

UNIT 2 ACCIDENT AND EMERGENCY SERVICES

Structure

2.0 OBJECTIVES

After going through this unit, you should be able to:

- explain the role and importance of the Accident and Emergency services;
- describe the planning, staffing and functioning of Emergency services;
- enumerate the equipments required in this department; and
- identify appropriate measures for evaluating the services provided there.

2.1 INTRODUCTION

In the previous unit you have already learnt about Outpatients Services. In this unit you will learn about the salient features and functioning of the accident and emergency

services which constitute one of the most vital, important, and sensitive component of acute medical care services provided by the hospilal.

In many hospitals this department/unit is called "Casually" even though all over the world nomenclature has been changed. This service is usually provided non-stop round the clock, throughout the year, and it is an essential elcmcnt in contributing to the health of the community Smooth and streamlined functioning of the accident and emergency services goes a long way in projecting a good image of the hospital. So much so that these have in fact bccomc "miniature" hospitals within hospitals.

In this unit you will learn about the various administrative aspects of Accident and Emergency services (Casually Department) in hospitals. You will also learn about planning considerations, the equipment requirements, the staffing of the department; and policies and procedures governing this department.

2.2 ROLE AND FUNCTIONS

2.2.1 Definitions

"Medical Emergency" is defined as a situation when the patient requires urgent and high quality medical care lo prevent loss of life and limb and initiate action for the restoration of normal healthy life.

"Emergency" may also be defined as a condition determined clinically or considered (perceived) by the patient or his/her relatives (attendants) as requiring urgent medical services, failing which, it could result in loss of life or limb.

An "Accident" is defined as "an uncxpccted, unplanned occurence which may involve injury" or "an unpremeditated event resulting in recognisable damage".

2.2.2 Development and Scope

In the beginning of the twentieth century, every hospital had an "accident room" which was used for treatment of patients injured in accidents. By the 1960's, these rooms gradually evolved into "walk in" medical clinics, and even patients with medical problems started utilising them. In 1961, the Platt Committee (U.K.) recommended the name "Accident and Emergency Department" after which this discipline made rapid progress to gain status of a Lull fledged department in all developed countries.

In our country, the Central Council of Health in 1963 urged all state governments lo set up emergency medical services in all major cities and towns; which has subsequently been re-iterated by a number of committees till date. Howcvcr, despite some progress, this has not been given the necessary inputs lo develop it to the status of a department. The scope of accident and cmcrgcncy scrvices is gradually broadening and infact these are now becoming "mini hospitals" within hospitals.

2.2.3 Functions

As you have read earlier in this unit, you must be aware about the important functions of the accident and emergency services which are:

- to provide immediale and correct life saving medical care at all times and in all situations. Services should bc both effective and efficient as the patients are likely to deteriorate quickly.
- to be sensitive to the emotional needs of the patients and atlendants.
- to liaise with the courts and police in medico legal cases whenever requircd.

In addition some of the subsidiary functions arc:

- to provide ambulance scrvices for pre-hospital care and transportation of patients to and fro the hospital.
- to fulfil the role of information and communication centre, especially during disasters.
- education, training and research activities of medical staff.

However, you should understand that the accident and emergency services which can be provided by any hospital, depends upon the number of beds and the policy of the hospital.

In general, in our country, smaller hospitals run accident and emergency services (called as "Casualty") during non-outpatient deptt, hours, and share facilities with the OPD.

2.2.4 Type of Emergency Services

There are four types of emergency services:

i) Major Emergency Services

The depatment is provided with all its specialised facilities. Diagnostic and therepevetic coupled with speciality in different categories. Generally such services are provided in large, teaching and tertiary hospitals.

ii) Basic Emergency Services

This is available in hospital where all basic emergency facility available the centre is run by general duty medical officer round the clock. Specialists in respective field are available on call duty.

iii) Stand by Emergency Services

This type of emergency service is seen in PHC and Community Health Centre as first referral centre. These are run by trained nurses round the clock and Medical Officers are on call duty.

iv) Referral Emergency Services

In these centres only first aid is given and the patient then refer to the health centre/ hospital according to the severity and need of the case. This type of services are provided by AIIMS and other tertiary level hospitals.

2.2.5 Importance

The importance of this service lies in the fact, that out of all aspects of seeking health care, this is the most crucial and vital, as it is perceived by the patient and the attendants as an "emergency" which calls for urgent action. Therefore, not only is the patients life/limb at stake; but also the image and reputation of the hospital and the health care providers. From an administrative point of view, it is one of the most stressful and sensitive areas, which can trigger off serious chain reactions hampering the functioning of the hospital.

2.3 PLANNING CONSIDERATIONS

As with other areas of the hospital the basic principle of "Design follows Function" should be applied.

2.3.1 Location

The accident and emergency department should definitely be located on the ground floor, with direct access from the main road (near the hospital) with ample space for ambulance and parking. A covered porch with enough space for vehicles and the patients to alight at the entrance is also important. Proper sign posting should be there and it should be easily located.

Though it should be physically separate from other areas in the hospital; it should be readily accessible from wards, OT's, ICU's, Laboratories, Blood Bank, and mortuary.

2.3.2 Space Requirements and Patient Wards

The space required for the accident and emergency department depends upon:

- the number of patients attending in a day.
- the size and the type of hospital.
- the type of diagnostic and therapeutic facilities available.

Simply stated, a daily census of 100 patients in the accident and emergency services requires 1000 sq. metres area. To this another 50% i.e. 500 sq. metres should be added to prevent over crowding.

Patient loads generally show an upward trend in this department and are about 10-15% of total OPD patients. Hence, it is better to plan for over usage than under usage and be prepared for increased patient load.

2.3.3 Physical Facilities and Layout

In large hospitals, there is a need to have a separate independent department, because the dependent population is larger and concentrated, Space for future expansion must be

kept in mind while planning for accident and emergency services, rooms with good accessibility to palicnls and space for un-intcrruplcd patient flow should be of primary concern.

The entrance should be separate with enough space for movement of ambulances and other vehicles. Ramps lor wheelbound and steps wilh side rails for ambulant patients should be present along with a porch lo protect from natural elements. The door should be two-way swinging type for easy How of patients.

Inside the entrance a waiting hall/area should be provided with basic neccssitics (Telephone, Toilet, Drinking Waler elc.) for the attendants, which helps decongesting the main treatment area. MSW could also be located nearby the Emergency Department. It can also be used for "triage" purposes during disasters. The main lobby should also have facilities for reception and enquiry, and a trolley bay for trollies and wheel chairs.

The main acute treatment area should have the patient cubicles in full view of the nursing station; and should be partitioned from each other with curtains. This area includes the resuscitation cubicles, examination cubicles, paediatric cubicles with benches etc. There should also bc provision of revolving stools for ambulant patients. One room/ area should be separately earmarked lor observation patients who arc likely to remain in the hospital for few hours. Other rooms which are also essential stores, nurses/staff rest room, toilets and O.T. complex with recovery room, fracture treatment and plaster room, a room for infectious patients, Doctors and nurses duty room, staff room and clean and dirty utility room. Investigation facilities include radio diagnosis unit with dark room and a emergency laboratory. For medico legal cases a police room and a "brought in dead" room arc also required.

2.3.4 Architectural Design

It is important to remember the principle "design follows function" in planning of hospitals. The design should be such that there is minimum criss-crossing of patient traffic and privacy is maintained while treating. The room should be spacious, and the joining corridors at least 3 metres in width, Door ways should be so designed as to allow unhindered passage of trolleys. Floor should bc non-slippery and wall colours sliould be of light shades.

2.3.5 Communication

An effective communication system is a must in any accident and emergency department. Communication within the department and to other areas like ICU, support service areas, stores, blood bank, consultants arc essential for smooth functioning. Pagers should be provided to staff' on call for prompt response. Adequate number of telephones for the staff, telephone with only incoming calls and telephone for the patients/ relatives should bc provided in the department.

2.4 EQUIPMENT REQUIREMENTS

In the earlier section you learnt about the physical facilities which should be available in the Accident and Emergency Services. However, it is imperative that adequate number of properly working equipments must bc present thcrc, otherwise the doctors will not be able to render optimal care.

2.4.1 Essential Equipments

Broadly speaking the following essential equipments should be present in all patient care areas:

i) Centralised piped oxygen and suction supply.

ii) Airways, outlets and resuscitation bags.

iii) Wall mounted/portable manometer.

iv) Portable defibrillators and ECG.

v) Respiratory aids e.g. ambu bag, ventimask, nebuliser etc.

vi) Cardiac monitors and defibrillators.

vii) Special medications, intravenous equipments and fluids.

viii) Sufficient bandages, drugs and plasters.

ix) Utility table with emesis basin, kidney tray etc.

x) Slit lamp, loupe, ENT cxmination equipment.

xi) All equipments that will be required for O.T. and ICU.

xii) Adequate numbers of trollies and wheel chairs.

In addition to these equipments required for direct patient care, others like radiology equipments: x-ray machines, ultrasound machine, dark room, C.T. facility and investigation equipments in laboratory are also required.

2.4.2 *Equipment Maintenance* Issues

If wc consider the sensitiveness of the functioning of the Accident and Emergency Department; it will be obvious at once that proper maintenance of equipment in good working/order is a must, so as to avoid mishappenings. The main objectives of equipment maintenance are to:

- ensure reliability and readiness of equipment as far as possible;
- extend the useful life of equipment and decrease the down time; and
- ensure safety of operation and minimum wastage of resources.

All three levels of maintenance i.e. first level (day to day) by the operator; second level by in house staff; and third level by manufactures; bio-medical engineer or third party should be ensured. Preventive and breakdown maintenance must be done at regular intervals.

.....

.....

.....

.....

.....

.....

.....

.....

.....

.....

4) Indicate "True" or "False":

a) Accident and Emergency Department is also known as "Casualty". (T/F)

b) It should be located either on the ground or first floor. (T/F)

c) The patient load in Accident and Emergency Department is approx. 25% of OPD Ward. (T/F)

d) Entrance of the hospital and emergency should be the same. (T/F)

e) First level of maintenance should be done by the operator. (T/F)

2.5 STAFFING CONSIDERATIONS

It is important that the staff members posled in the Accident and Emergency Department be highly skilled and competent. Besides they should also be of even temperament, calm and oricntcd Io the functioning of the department at the beginning of their posting. Staffing will depend upon the following factors:

- Size and nature of hospital (including category of hospital),
- Work load of the department,
- Resources available.

As' proper co-ordinalion and good team work is a pre-rcquisile, it is essential that similar staffing pattern is maintained throughout the day. Continous training should be provided so as lo keep them up Io date.

2.5.1 Categories

The following category of staff arc considered essential to maintain the accident and emergency department:

i) **Medical** : Physician, surgeon, paediatrician, orthopaedic surgeon and anaesthetist (in addition, house officers, interns, post-graduate students) should also be posted. These may bc available full lime on call. A lull time faculty incharge should by posted in the Accident and Emergency Services of a large hospilal.

ii) **Nursing** : The nursing staff should bc competent, intelligent, qualified and flexible, should he able to initiate life saving measures on their own.

iii) **Para medical** : ECG technicians, O.T. assistants, operalion room attendants, laboratory technicians, radiographers etc.

iv) **Group 'D'** : Orderlies, sweepers, drivers.

2.6 POLICY AND PROCEDURES

2.6.1 Ambulance Services

Generally, ambulance services arc considered lo bc a part and parcel of the Accident and Emcrgcncy Department. An ambulance is defined as "a vehicle for emergency care which carries equipment and supplies for optimal emergency care at the scene and during the period of transportation Io afford maximum safety and comfort and avoid aggravation of his condition. You will learn in more details about transporlation of patients in Unit 2 of Block 2, Course 5.

It has been established through several studies that the speed of transfer of a patient from the site of accident/emergency to the advanced treating centre is of utmost importance in saving life, and minimizing mortality and morbidity. The golden hour concepts, if a patient has besl chance of survival and minimum disability if brought to a centre will be an honour. It should also be understood that the basic minimum life saving/support equipments like oxygen cylinder, ambubag, endotracheal tube and airways, foot operated suction machine, portable ventilator, defibrillator with monitor, immobilising splints, PSAG/MAST and emergency drugs and fluids should be available in the ambulance. The ambulance should also be provided with two way communication system to facilitate its reaching at the sile will not delay and obtaining necessary guidence in rendering the pre hospital case lo the patienl if required.

Keeping in view the vastness and considerable geographical variation in the terrain, motorability of roads, lransportation facilities can be considered under the two broad categories of urban areas and rural areas. The essence of planning ambulance services should definitely take these factors into consideration.

2.6.2 Registration and Records

It is mandatory on the part of the hospital to develop and implement a simple and accurate system of registration of all patients who report to attend the accident and emergency department. If resources permit, in the present day scenario, computerised registration is the most effective and efficient way of alloting a serial registration number to all patients attending the department. In case resources do not permit, the manual system of registration can also suffice. However, one thing that needs to be emphasised is that the process of registration should not come in the way of starting the treatment. This becomes especially important in medico legal cases where, there is a ruling of the Hon'ble Supreme Court in this regard about which you will learn in greater detail in a subsequent section.

Proper and meticulous record keeping is absolutely essential, especially in the light of the Consumer Protection Act, which has been described in detail in one of the later units. The emergency department records should be simple, user friendly and should contain following:

- demographic parameters — name, age, sex, address. registration No.
- date and time of arrival of the paticnt
- the chief complaints — duration
- examination fin dings
- base line investigation and their values
- diagnosis and management
- whether admitted/discharged/referred

These should be retained for a period of at least two years. In medico legal cases, one copy of the emergency patient record should be retained by the hospital and the details of the findings should bc entered in a medico legal register, for safc custody. The investigation reports including radiological test reports should also be filed and kept in safe custody. Thcsc medico legal records should bc retained permanently; hence should be in a safc custody.

2.6.3 Investigations and Management

In tlic present scenario, by and large all patients attending the accident and emergency department require some or the other investigations before any treatment can be initiated. Hence, it is necessary to have an emergency laboratory and radiology unit within or near the department, so that these can be carried out urgently whenever required. Other basic investigations like ECG and arterial blood gas are also required on a number of occasions. For every patient, the investigation ordered and the results obtained should be mentioned in the emergency records and a copy of the same should be retained in safe custody for all medico legal cases.

2.6.4 Admissions and Referrals

Proper treatment should be initiated promptly on the arrival of the paticnt and accurate records of all ,fluids, drugs and medicines given should be maintained in the records and the treatment register (maintained by nursing staff), All the consultations carried out by different specialists in the department should be recorded chronologically and case management done accordingly. During the pcriod of observation the vital parameters should be recorded along with the time of recording. Whenever consultants/seniors are consulted their impressions should also be recorded. If it is required, the patient must be admitted in the hospital, and a new indoor patient registration number issued, along with the bed number, ward and the unit/ department under which the patient is being admitted. In case of admission, the emergency record is also sent along with the patient, and it becomes a part of the indoor patient case sheet, which is generally retained in the medical records department of the hospital.

However, if the patient has to be referred to another hospital with better facilities, it should be ensured that the patient has been stabilized, and vital parameters are okay, before the patient is referred. If possible, one doctor should be deputed to accompany the patient to the referred hospital.

2.6.5 Medico Legal Issues

In most of the accident and emergency departments in our country. a large majority of the patients who attend are medico legal in nature. A medico legal case is one, where tlie attending doctor, after taking the history of the patient, and performing clinical examination, thinks that some investigation by tlie law enforcing agencies are essential, so as to fix responsibility regarding the case in accordance with the law of the land. It is purely the responsibility of the Casualty Medical Officer to decide as to when to label a case as medico legal.

It is important to note that doctors posted in Accident and Emergency Department of a government hospital are duty bound to register, examine and treat all medico legal cascs coming to tlie department. The records should mention and categorise the case as medico legal case and injury report should be prepared and documented in the medico legal case register and intimation should be sent to police officials. Treatment of the patient, should in all cascs take precedence over medico legal formalities.

1.7 MONITORING AND EVALUATION

In tlie earlier section we have discussed about the operation and functioning of the accident and emergency department. It is clear that this department is one of the most important factors in giving a positive or negative image to the hospital. Hence the functioning must he subject to regular scrutiny, in order to ensure that the most efficient and effective services are available to the community. A study of the utilisation of these services should include data on tlie number of visits, tlie avcragc length of visits, the seasonal variation in patient load. the seasonal disease correlations, variations in "peak" and "slack!' hours and treatment categories. The last variable would help in determining how many cascs treated are actual emergencies.

The concept of 'medical audit' or 'peer review" must be initiated in the accident and emergency department. Broadly, it involves the review ofthc medical records of patients attending the casualty: and ascertains the Sollowing:

- the completeness, adequacy and accuracy of records,
- the correctness and substantiation of the final diagnosis,
- the errors in diagnosis and management of patients, and
- tlie causes of complications and death (if any).

2.7.1 Review (Audit) Committee

It is essential that a review or audit committee is constituted by the appropriate and competent authority to carry out this work, as it is of a highly sensitive nature. Senior Consultants belonging to broad disciplines of medicine, surgery, orthopaedics and paediatrics should be members of this committee, along with the administration and medical record officer. This committee should meet at regular intervals and take necessary corrective measures by training the staff in order to overcome the hurdles in future. The reports of tlie committee should be kept confidential.

2.7.2 Grievance Redrcssal Systems

A system must be implemented for the redressal of grievances by the patients/attendants who attend the accident and emergency department. This is more so, especially in the light of increasing number of cases against medical professionals/hospitals under tlie Consumer Protection Act. Complaint boxes should be strategically located and every valid complaint should be enquired into and necessary corrective action initiated. A senior consultant/faculty member should be made incharge of this forum; and it is also advisable to have prominent citizens from other fields as members.

Check Your Progress 2

1) List the various categories of staff and factors on which staffing of Accident and Emergency Deptt. depends ?

.....

.....

.....

4) Indicate True or False:

a) Registration of medico legal case must be finished before starting treatment. (T/F)

b) A good ambulance service should have all essential life saving equipments. (T/F)

c) A judge should be the head of the grievance redressal committee. (T/F)

d) Medical audit refers to costing of the services in accident and emergency department. (T/F)

e) Patient should be stabilised before being referred to another hospital. (T/F)

2.8 LET US SUM UP

In this unit you have learnt about the changing role and importance of the Accident and Emergency Department in a hospital. Starting with the planning considerations for an Accident and Emergency Department, you have learnt that planning should be done for future patient loads. The emergency equipments have been explained along with the most vital maintenance issue which is imperative in this department. The various categories of staff and the factors affecting staff have been discussed.

Subsequently, you have learnt about the policies and procedures which have a direct bearing on the operational aspect of the department; followed by monitoring and evaluation of these services.

2.9 ANSWERS TO CHECK YOUR PROGRESS

Check Your Progress 1

1) The functions of Accident and Emergency Department are:

- to provide immediate and correct life saving medical care at all times and in all situations. Services should be both effective and efficienl as the patients are likely to deteriorate quickly.
- to be sensitive to the emotional needs of the patients and attendants.
- to liaise with the courts and police in medico legal cases whenever required.

2) The broad planning considerations are location, space requirement, patient loads, physical facilities and layout, architectural design and communication system.

3) The essential equipments which should be present are:

i) Centralised piped oxygen and suction supply.

ii) Airways, outlets and resuscitation bags.

iii) Wall mounted/portable manometer.

iv) Portable defibrillators and ECG.

v) Respiratory aids e.g. ambubag, ventimask, nebuliser etc.

vi) Cardiac monitors and defibrillators.

vii) Special medications, intravenous equipments and fluids.

viii) Sufficient bandages, drugs and plasters.

ix) Utility table with emesis basin, kidney tray etc.

x) Slit lamp, loupe, ENT examination equipment.

xi) All equipments that will be required for O.T. and ICU.

xii) Adequate numbers of trollies and wheel chairs.

4) a) True

b) False

c) False

d) False

e) True

Check Your Progress 2

1) The various categories of staff are medical, nursing, paramedical and group 'D'. The factors on which staffing depends are:

- Size and nature of hospital (including category of hospital),
- Wwk load of the department,
- Resources available.

2) The following information should be present in cmergcncy deptt. records:

- demographic parameters—name, age, sex, address, registration No.
- date and time of arrival of the patient
- the chief complaints — duration
- examination findings
- base line investigation and their values
- diagnosis and management
- whether admitted/discharged/referred to other hospital.

3) The members of the review committee should be senior consultants from the broad specialities of medicine, surgery, orthopaedics, paediatrics; the administrative and medical record officer.

4) a) False

b) True

c) False

d) False

e) True

Rowland and Rowland, *Hospital Management—A Guide lo Departments.*

VHAI, A Practical Guide to Hospital Planning and Management.

Mc Gibony, *Principles of Hospital Administration.*

UNIT 3 OPERATION THEATRE

Structure

3.0 OBJECTIVES*

After going through this unit, you should bc able to:

- describe the objectives of planning of an Operating Department;
- describe the concept of zoning and list the advantages of zoning of the operating department;
- list out various facilities provided in different zones of the operation theatre department;
- describe various methods of calculating the number of operating suites required;
- discuss the various elements to be considered while designing an operation theatre; and
- describe the policies and procedures involved in an operation theatre dcparlment.

3.1 INTRODUCTION

During the course of your undergraduate studies, or while working in medical care facilities, you must have seen and heard about the functioning of operation theatre. In the previous unit you have already learnt about Accident and Emergency Services where Operating Department is one of the important components. The activities carried out in this department can make or mar the reputation of the hospital. It is therefore imperative that detailed planning should be done on scientific basis while evolving the operating department in order to ensure effective functioning of this department.

In this unit you will also learn about the essential policy and procedures which are required to be laid down for strict adherence by all concerned.

3.2 TYPES OF OPERATIONS

The significance of classifying operations as major and minor operalions has been seriously questioned. Statistics based on this classification may not produce meaningful data. Surgical operations may instead be broadly classified as emergency and elective operations.

Emergency Operation is that which must be carried out as soon as possible after the diagnosis has been madc and the patient prepared for the operation in a proper way. Emergencies from outside include patients who are admitted as urgent cases. In the case of in-patients emergencies, in a case like a wound dchisccncc or post-operative intestinal obstruction, the decision to operate is made by the surgeon-in-charge of the patient.

Elective Operations, which arc the majority, are carried out some time after the diagnosis has been madc and when they suit best for the patient and the hospital.

Currently there are at least fifteen surgical specialities or subspecialities which requires Operation Theatre to be equipped with spccialised euipment. Some of the advances that had taken place in recent years are:

Microsurgery: Microsurgery may be defined as surgcry performed under magnification; some people confine to surgcry using the operating microscope, while other includes loupes and other ocular aids.

Microsurgery has proved its usefulness in otorhinolaryngology, ophthalmology, neurosurgery, particularly peripheral nerve surgery, vascular, plastic and hand surgery.

Cryosurgery: Cryosurgery is that type o l surgery which is based on use of liquid nitrogen at a very low temperature. Nitrogen is brought into contact through prop with diseased tissue which dies and sloughs away. In this the local pain is absent.

Laproscopic Surgery: Major surgical interventions are done with the help of laproscope. Its use requires minimal incision post operative care and stay in the hospital.

Bio-medical Laser: Light amplification by simulated emission of radiation is one of the ways to make the conventional scalpel obsolete. In this procedure therc is absence of physical contact and the cutting is without mechanical pressure which makes the operation non-traumatic. The risk of infection is also less.

Check Your Progress 1

Fill in the blanks:

a) Elective operations are carried out .....
.....

h) Cryosurgery is based on .....

c) In biomedical laser procedure there is absence of ..... and the cutting is without .....

3.3 PLANNING

3.3.1 Aims of Planning

The aims of planning of an operating department arc to:

- promote a high slandard of asepsis.
- ensure maximum standard of safety lor patient and staff from environmental, anaesthetic, radiological and post-operative hazards.,

- ensure optimum utilization of operation theatre and staff time.
- ensure optimum conditions of work for the surgical team.
- ensure comfortable treatment of patients.

allow more flexibility by use of the individual operating rooms.

3.3.2 Planning Criteria

In order to achieve the above objectives, it is imperative that the operating department be so designed that they meet the functional, professional and technological requirements. The planning criteria so developed are:

a) Functional Criteria

The activities to be carried out in different functional areas of the operating department are to be critically studied and analysed. The design of the operating room must follow the functional requirement of the operating department.

b) **Economic** or **Work** Flow Criteria

The flow of patients, supplies and staff in an operating department is to be conceived and preplanned. This will ensure optimization of relationship between various functional areas of the operating departments.

c) **Environmental** Criteria

The environmental aspects should also be considered for the safety and comfort ot'the patient and staff, The complexities of the functional and workflow criteria will create numerous problems while designing an operating department and formulating its operational policies.

After a thorough study and analysis of the above criteria, the design considerations must be identified, which will decide the operating policies for the organisation and management of the department.

Check Your Progress 2

1) The aim of the planning of operation departments are:

a) To promote high standard of .....

b) To ensure .....of Operation Theatre and staff time.

2) Enlist three planning criteria:

a) .....

b) .....

c) .....

3.4 DESIGN CONSIDERATIONS

Before designing an operation theatre department should try to understand the various Activities Involved in operating a patient. There are number of activities which are involved with the basic procedures and other activities like supporting procedures and administrative activities. These are as under:

a) Basic Activities Involved in the Act of Surgery:

- Reception and identification of patient
- Pre-operating supervision of patient
- Depilation of patient
- Transfer of patient to operation table
- Administration of anaesthesia
- Intubation
- Positioning
- Preparation of the operative area and surrounding skin
- Draping of patient

- The act of surgery, OPERATION, which may involve blood transfusion, parenteral fluid administration and x-ray examination.
- Wound sewn up and dressed
- Drapes removed and bagged
- Extubation
- Transfer of patients from operation table to trolley or bed and to the post anaesthetic recovery area.
- Post operative supervision of patient.

b) Supporting Proccdurcs:

- Staff changing to opcration room garments and shoes
- Putting on cap
- Masking
- Aseptic washing of hands
- Gowning
- Putting on gloves
- Putting on apron
- Laying out, checking and re-checking the number of instruments and dressing to be uscd during the operation.

c) Administrative Procedures:

- Preparation of operation lists, duty schedules
- Requisition of patient
- Notification to wards of time for patient transport to and fro the surgical department
- Distribution of messages
- Requisition of records, equipment and material
- Contacts with other departments, laboratories, workshops and suppliers
- Ascertain availability of essential doctors and supporting staff for cmcrgcncy assistance

d) Clerical Proccdurcs

- Preparation of operation records
- Preparation of operation rooms records
- Filing
- Statistical interpretation of operation room records.'

c) Housekeeping Procedures:

- Collection of uscd instruments
- Collection of uscd materials and soiled surgical instruments, dressings and underlays
- Cleaning of operation rooms and other areas in the surgical department
- Disposal or incineration of refuse.

f) Storekeeping and Repairs

3.4.1 Location

The location of operating suites is dictated by the number of suites to be provided. The operation theatre complex can be conveniently located at the ground floor as siting an other floors adds to design and communication problems. However the OTs are usually located on higher floors in a multistorey building to minimise the general traffic and better maintenance of asepsis. The operating department should bc easily accessible Io the Central Sterile Supply Department (CSSD)/Theatre Sterile Supply Unit (TSSU),

Emergency Department, Surgical Wards. It should be independent of general traffic and should have maximum protection from sun, heat, noise, dust and wind.

The location of the department should be decided on the following factors:

a) Quiet environment

b) Noise, Dust, Wind, Heat and Direct Sun light Problem

c) Cross Infection Problem

d) Solar Radiation

e) Easy access to ICU, X-ray, Laboratory, Blood Bank, CSSD, Emergency Ward and Surgical Department.

The unit also needs constant specialised services such as piped suction and medical gases, electric supply, heating, air-conditioning, ventilation and efficient lift services (if theatres are located on the upper floor in the multistorey building).

If possible Operalion Theatres should be given its own wing, an independent low building. This will help in expansion of Operation Theatre complex without disturbance to other departmenls of the hospital.

Operation Theatres require more height (approx. 4.2 metres) bccausc of air-conditioning requirement of a modern OT. It is therefore felt if there is only one multistorey building of a hospital then OT should be located on the top floor of the building because of ease of providing more height. Dedicated (AHU) Air Handling Unit for 100% fresh air for each OT for blow through system could bc sited on the terrace of the multistorey building above the Operating Room.

3.4.2 Size of the Operating Room

Minimum clear area for a general operating room is 40 sq. metres. Cardio-vascular, Neuso-surgery, Orthopeadic and other spccialised procedures which require additional equipment needs minimum clear area of about 60 sq.metres. An additional adjoining room to the main OT may be needed for heart lung machines for cardio vascular OT and equipment storage for large equipment, in other specialiscd operating rooms. In Orthopeadic surgery, space may be needed for splint and traction equipmenl. Surgical cystoscopy and other endro-urological process room will require minimum clear area of 35 sq. metres.

Endoscopic Suite will require following rooms:

- Procedure Room(s)—minimum area 20 sq.metres
- Instrument processing room
- Processing room for cleaning and disinfection
- De-contamination room
- Patient holding/Preparation/Recovery Area

3.4.3 Number of Operating Rooms

Therefore, for calculating number of operating rooms approximately 80 minules including the hygienic intervals between operation is required as a average length of time per operation. The number of operation theatre rcquired for a particular hospital can be worked out by studying in greater detail the following factors which are more or less quantifiable:

- Number and type of Surgeons
- Type of hospital
- Hospital policy and procedures
- Hospital bed complement

  Number and'nature af elective and emergency surgery anticipated
- Number and type of surgical patients
- Number of operations per day
- Expected average length of slay of surgical patients

- Expected turn over interval in operation theatre
- Size of an average OT list
- Estimated time for cleaning between operations
- Time allowed for staff breaks
- Amount of time operating suites can be equipped and staffed
- Amount of time reserved for emergency use
- Allowance for septic patients

However, the number of operating suites can be conveniently worked out in the following way also:

i) **Number of Operating Suites and Number of Operations Per Day**

The number of operating suites can be found out from the predicted number of operations per day. Macaulay, in his book *Hospital Planning Administration* has stated that the number of operations can be calculated by dividing the number of surgical beds by the ALS (Average Length of Stay) of surgical patients.

Therefore,

$$\text{No, of Operations per day} = \frac{\text{No, of Surgical Beds} \times \%\text{ of BOR} \times 365}{\text{ALS} \times 100 \times \text{Number of working days in that hospital}}$$

Note: BOR - Bed Occupancy Rate

ALS - Average Length of Stay

The number of operations which can be performed in each operating suite can be determined by studying past trends and by conducting work studies or by making use of available standard norms. American authorities calculate one operating suite for two or three operations per day, while European authorities recommend that a minimum of six operations should be performed per day in one operating suite.

ii) **Number of Operating Suites and Hospital Beds**

According to American pattern, one operating suite is required for every 25 surgical beds while European authorities recommend one operating suite for every 50 surgical beds. Rao Committee (1968) which was appointed by the Govt. of India in connection with studying the facilities available in Delhi Hospitals has recommended one operation theatre for every 50 surgical beds.

However, the Committee on Planned Projects (COPP-1964) has given tlie following guidelines regarding number of operating suites in a hospital:

No. of Operating Suites Required

	Indoor		OPD Including Emergency	
No. of Hospital Beds	**Minor**	**Major**	**Mnjor**	**Minor**
300	2	3	x	1
500	2	5	1	1
750	2	8	1	1
1000	2	10	1	1

In addition to these, superspecialities like CTVS, Paediatric Surgery should have additional operation facilities.

3.4.4 Grouping of Operation Theatres

The centralization of major operation suites in one area has got definite advantage over individual operating theatre distributed close to the various surgical wards. These advantages are:

- Maximum flexibility in use
- Easy expansion at times of future demands
- Simplifies theatre staffing and better training, centralization and standardisation of procedures improving efficiency

- economics in common facilities such as men, material, machines and minutes
- Easy and economical maintenance
- Improved cleaning and better sterilization
- Flexibility in allocation of operating suites to various specialities
- Minimizes infection and cross-infection
- Improves utilisation of operating suites
- Improves efficiency to staff
- Minimizes cancellation of operating schedules

Therefore, grouping of operation theatres will ensure easy management and control.

Size of well administered OT unit varies in different countries:

Germany : 6-8 Operation rooms

Sweden : 8-10 Operation Rooms

Norway : Not more than 12 Operation Rooms

However, it can, therefore, be safely presumed that if there are more than 10 operation rooms two or more separate OT department may be provided.

3.4.5 Zoning

It is universally agreed that operation is to be performed under the most aseptic conditions. To ensure this aseptic condition the operating department is divided into four distinct Zones: Protective Zone, Clean Zone, Sterile Zone and Disposal Zone.

These Zones are bacteriological zones of varying degrees of cleanliness. The bacteriological count diminishes from the outer to the inner zones. 100% sterility must he ensured in the sterile zone. The zoning of the operating department has got the following advantages:

- Minimises risk of hospital infection
- Minimises unproductive movement of staff, supplies and patients
- Increases efficiency of staff working in the operation suites
- Ensures smooth work flow
- Reduces hazards in the operating suites

  Ensures proper positioning of the equipment
- Ensures optimum utilization of the operating suits

a) Protective Zone

It usually provides facilities like:

i) Reception

ii) Waiting Room for patients relatives

iii) Changing Room

iv) Pre-anaesthesia Room

v) Store Room

vi) Autoclave/TSSU

vii) Trolley Bay

viii) Control area of electricity.

b) Clean **Zone**

It provides facilities such as:

i) Pre-Operating Room

ii) Recovery Room

iii) Theatre Work Room

iv) Plaster Room

v) X-ray unit with dark room

vi) Sisters Work Room

vii) Staff Work Room

viii) Anaesthesia Store.

c) Sterile **Zone**

This zone has facilities.like:

i) Operating Room

ii) Scrub Room

iii) Anaesthesia Room

iv) Instant instrument sterilization

v) Instrument Trolley area.

d) **Disposal Zone**

This zone provides facilities like:

i) Dirty wash up room

ii) Disposal Corridor

iii) Janitor's Closet.

Check Your Progress 3

i) .....

ii) .....

iii) .....

iv) .....

v) .....

vi) .....

vii) .....

2) Fill in the blanks:

a) Minimum clear area of general OT is .....

b) Minimum clear area of cardio-thoracic surgery OT is .....

3) Fill in the blanks:

Area of general OT is:

a) According to COPP 300 bedded hospital will require ..... major OT and ..... minor O1'.

b) Operation theatre department should not have more than ..... rooms.

3.4.6 Electrical

The administrators and the planner has to ensure the availability of electricity all the time in OT department. Any disruption of electricity is likely to bring lo a grinding hall and give a bad name lo the functioning of the department. It is therefore essential to provide fool proof system in the OT, so that stable electrical supply is available all the lime. Particularly when the surgical team is operating on a case or the patient is being resuscitated on ventilator or have been put on heart lung machine, power supply should never fail even for an instant.

Like human beings mechanical and electrical equipment can gel sick and may require repair and maintenance. However, patient sickness needing operation cannot wait for equipment lo be repaired. Therefore, planning has to be done in such a way that if one source gets disrupted then the electrical supply is available from the other sources.

While laying down the electrical cable and connecting it to distribution boards (DB) it should be ensured that OT electrical points are distributed between two or more DBs. This will ensure DBs repair and maintenance without effecting electric supply of the OT. DBs should be located in such a way that electrician can repair and maintain the same without getting into clean and sterile zone. Apart from the main electric supply OT is also connected with the stand-by generator and UPS which are discussed below.

Light

Light is the most important component of the Operation Theatre. It is with the help of light the surgeon is able to see the surface of the operation area and also the very depth of the wound where he performs procedures like culling and suturing.

The central field of operation luminance should be 2000-3000 candles per metres square. Wound surrounding area luminance ratio should be 2.5 : 1. The floor around surgical table should be 200-300 candles per metre square and walls 300-500 candle per metre square.

Reflectance (Glare): The instruments, clothes of operating room should be selected to avoid glare.

Colour Composition: These should be such so that anaesthetist will be able to see the colour changes of the patient skin. The operating light (special light/operation lamp) and the complimentary lighting, the colour scheme of the room and the textiles must be co-ordinated.

Operating Light: Before sclccting a operating light one should look into the following aspects. These arc as follows:

i) easy maintainability repair and maintenance

ii) intensity:

— 40000 lux at the place of incision.

— 80000 lux at the bottom of 13 cm deep and 5 cm wide incision (hut nowadays surgeon prefer intensity of 100000 lux)

iii) Fitting be directionally flexible

iv) Control accurate and quick

v) Once positioned it should be steady and should not move

vi) Shadowless

vii) Heat radiation small

viii) Maximum temperature of luminaries should be 58°C

ix) Mirror for Anaesthetist for seeing the surgical procedure be incorporated

x) Secondary or satellite light for some OT like cardio-thoracic surgery etc.

xi) OT lamp should not bc lower than 2 metre above the floor

xii) Camera for viewing the operation

xiii) Sterile handle for adjusting the lights etc.

xiv) Supply of accessories like bulbs Tor replacement.

Fiber **Optic** Operation Lamp

We have earlier mentioned about laproscopic surgery, in which fiber optic lamps are used. The light in a fiber optic operation lamp is transmitted through electrically powered flexible fibers. It is also called cold light because the tube docs not become hol. The optical fiber may be incorporated in instruments itself to bring the light to operating field,

General **Light:** General light luminance intcnsity may vary from 500 lux to 2000 lux. This will also depend upon the luminance intensity used lor the operating lamp/light.

Presently in the market different types of operating lights are available. Prismatic type of light is also available which does not give any shadow or obstructions to the site of operation. However, before going for this light one has to cater for extra blubs for emergency replacement as these lights have got one or more blubs. While installing this light one should also see the radius of its operation as the movement should preferably not interfere with other suspended eyuipments like pendant etc.

Power Outlet

Operation Theatres require electro-medical equipment for life support and for performing surgery. All these equipments are dependent on stable electricity. For using these. equipments power outlets at convenient location are needed. It is therefore essential that four power outlet (duplex type) is provided on every wall of the Operation Theatre. Near the Anaeslhetist location, six power outlets should be provided.

One of the outlet should be of heavy duly variety, so that equipment like X-ray, Laser, C-Arm could be plugged in. These outlet should be located at one metre above the floor level as the anaesthetic gases are heavy and settle near the floor. It is also advisable that all these outlet should he on UPS, so that at the time of emergencies any of the power outlet could be utiliscd. The outlet should bc flushed with the wall for easy maintainability. Power outlet should also be provided for the viewing box.

Stable Electrical Supply

Stable electrical supply is important for effective functioning of equipments. Voltage and frequency fluctuation is likcly to damage the electro medical equipment. Therefore, it is essential that stable voltage and frequency electrical current should be supplied in the OT. This could be achieved hy a UPS in the OT complex.

Standby Generator

Captive powcr is an important necessity for a hospital to meet the emergent situation of high dependency area like operation theatre and ICU of a hospital. One cannot takc a risk of carrying out an operation procedure in OT without power assurance. The captive power could bc provided by a standby generator which should be able to take the full load of operation theatre including its air-conditioning, The standby generator should be provided with Auto Main Failure Panel (AMFP), so that the generator comes up on load as soon as the main supply fails or get disrupted. The standby generator should be situated away from the OT complex to avoid noise and pollution.

Uninterrupted Power Supply (UPS)

Apart from provision stable electric supply, slandby generator, operation theatres rcquircs UPS. Nowadays many computcrised cquipmcnts are used in the OT where disruption of electricity is likely lo cause loss of data. It has also been observed that in best conditions standby generalor takes a few minutes before it gets activated and comes on load. Loss of vital timc is likcly to adversely effect the outcome of the operation. It is therefore essential that all plugs and lights in operalion room are put on the UPS.

The total load of the UPS apart from the light in operating room will depend upon the number of equipment present and used in that OT at the time of lights disruption. The electro-medical equipment load of an operating room is likely lo bc in the region of 6 KVA.

3.4.7 Airconditioning and Ventilation

To achieve the basic objective of promoting high standard of aspesis and proper environments of the OT departments high quality air-conditioning with proper ventilation system of positive pressure with different gradients is essential. With the passage of time OT air-conditioning has gone into major changes. Different types of operalions like Heart Transplant, Kidney Transplant, Operation on Central Nervous System lasting many hours requires environment where any type of infection occurring to operated patient has to be avoided at all costs. Tlicse surgeries require environment which is very conducive to patient staff and equipment apart from providing microbes free environrnenl. Environment required for different surgery differs. For example Paediatric surgeon may require more temperature as compare to other OT used for the adult patients. These can be achieved if the planner and air-conditioning consultants along with surgeons arc involved in advance.

Civil construction is the one which lasts over 50 years. Some of the hospitals at this time may not contemplate conducting major operation of a complicated nature, but after some time with improvement in technology and availability of trained staff they may like to perform these procedures. Such a situation may occur even in smaller hospitals or those in rural areas. Therefore, construction of OT should bc made in a way that it could be fitted with modern air-conditioning system at that time. Air' conditioning duct, laminar flow and high efficiency filter takes almost one metre space above the

false ceiling. It is therefore felt that clear height of 4.2 metres is needed in the OT. The location of the beam should be such as to permit provisioning of air-conditioning duct and also the return air-duct. Grill for return air-duct should be located 30 cm above the floor level.

The duct should not protrude in the operating room. Many types of air-flow are possible, but vertical laminar flow is preferred in OT as it provides maximum aseptic environment above the operation table because of its location.

Location of return air-duct is important. Number of return air-ducts will depend upon the total quantity of air which has to be exhausted. However, minimum of two return ducts should be provided in the OT located opposite to each other. Different types of positive pressure is used in the OT, operating room having the maximum so that air from outside does not enter and contaminate the operating room. It is therefore essential that, even when the OT is not in use also, positive pressure of the operating room is maintained. In the non-occupied mode, less air is kept in circulation to save energy and prolong life of the air filters.

It is recommended that air supply outlet be located on the ceiling with exhaust out-lets 30 cm above the floor. This provides a downward movement of clean air through the working zone to the contaminated floor area for exhaust.

Air-handling unit (AHU): Air handling unit is the place where the chilled water comes in contact with the air and cools it to the desired level. The treated air passes through different filters and than the clean air is discharged into the OT. In some OTs like Cardio-thoracic, Neuro Surgery, Kidney Transplant, Orthopaedic the surgeon prefers 100% fresh air of class 100 clean room application. In other OT, some re-circulated air is also accepted. *This* will *be an economical system.* While laying down the temperature and humidity of various operation theatres one has to consider the clinical requirement of the patients. In most instances a temprature of 22°C (± 2°C) and humidity levels of 55% (± 5°C) achieving the optimum environment.

3.4.8 Manifold Facilities

The following outlets for Oxygen, nitrous oxide, suction (vacuum) and medical air should be provided:

	Oxygen	Nitrous-oxide	Suction	Medical air
General Operating Room	2	2	4	2
Cystoscopy and Endoscopy Room	1	1	3	2
Anaesthesia Workstation	1	1		1
Post Operalive Room	1		1	1

3.4.9 Service Pendent

According to Oxford dictionary Pendent means "hanging". For ease of function and movement of surgeon team, it is felt that no wires should be lying on the floor around the operation table.. Therefore, certain hanging fixtures are added in the OT. These are called service pendents. Service pendents are ceiling mounted and provide manifold and electric outlet at convenient height for use. These can be made use of quickly by surgeon and anaesthetist. Three designs are available:

a) Fixed length service pendent

b) Telescopic service pendent are designed to give ideal working height in the downward position. When not in use, they can be raised above the ceiling.

c) Rotating type pendent can rotate in X-axis, but this is costly as compared to the ones mentioned above.

Oxygen, Nitrous-oxide, compressed air and vacuum outlet are provided in the pendent. Electrical sockets which are on UPS are also provided in the pendent. The pendent with manifold facilities is located near the anaesthetist end of the Operation Table.

In some operating rooms, two pendents are provided one at the head end of the table (having manifold and electrical outlets) and other at the foot end of the table. They are located diagonally opposite to each other. The pendent should be located 45 cm from end of the table and 45 cm away from the table. Pendent fitting should be 1.9 metres above the floor level.

3.4.10 Structured Cabling

Hospital nowadays requires reliable network for faster access to information. The first step towards the adaptability, flexibility and logitivity of network is important and this can be providcd by structured cabling.

Tele-medicine has become one of the most important aspects of medical management. It may happen that with the help of tele-medicine surgeons of tomorrow at some remote location may bc able to carry out complicated procedures in the Operation Theatre with live advice from the expert who is a long distance away from the patient. Computer voice, telephone, TV and Video is going to be an important feature of Operation Theatre.

Therefore structured cabling for present and future use has become a necessity and should be planned well in advance. In India various firms arc available in the market who lake up the task of planning, designing and executing a network by structured cable. One cable can carry out lhc functions like computer, telephone, music etc.

Camera: It is not necessary to provide a view gallery in the Operation Theatre and thereby lose a space. Nowadays camera is fitted on to the Operating Lamps itself and it transmits picture of the operation for live demonstration in conference room situated elsewhere.

Check Your Progress-4

Fill in the blanks:

a) Nowadays for operating light surgeon prefers intensity of .....

b) ..... duplex outlets are provided on every wall of the OT.

c) Grill for return air-duct should be located ..... above the ground floor level.

d) It is recommended that air supply outlet be located on the .....

e) The following outlet of suction ....., Oxygen....., Medical air ..... should be provided for general operating room.

f) Pendent fitting should be ..... above the floor.

g) Camera in OT is fitted in ....

3.4.11 Plumbing/Sanitary Installation

Plumbing and sanitary installation planning is an important aspect of OT design. It should be ensured that sewage shaft should not pass through the operating room. If it passes through any other area, there must he no opening provided. The entire shaft passing through this area must have impervious lining lo seal contamination. Plumbing fixtures and lines above the operating room should be avoided because of leakage and contaminations. In change room area of the department toilets are provided arid also the facility of shower.

These facilities should be of hospital standard. These are attached with the change room made for doctors, female staff and other staff. The height of the wash room and the sink should be 91.5 cm to 96.50 cm.

Scrub station: Scrub station is provided near the entry room of the OT. One scrub station per Operating Room should be providcd, The working height ol' scrub station is 96 cm with water source 10 cm higher. In scrub station if possible gowning area should also be provided. A scrub station and gowning area with three scrub-up places require about 11 sq. metre space. This is usually providcd for one operalion room. However, it can be shared by two operation rooms, if located adjacent to each other.

To prevent splashing between scrub-up wash basin, screen/wire glass/non-breakable glass may be provided. Elbow operated/foot operated handles are provided in the scrub station, so that the surgeon can keep his hands free and clean. Howevcr, it is better lo have photo electric cell operated wash basin, so that there is no body contact. This arrangement is most hygienic.

Nowadays ready to use scrub stations are available in the market lor installations. Washing of the OT may be carried out. Necessary provision should be made to drain the waler from OT department.

3.4.12 Fire Fighting

Fire detection system should be available in the operation theatre complex and it should be connected to central control room so as to give adequate warning. Fire fighting appliances and equipment should be suitably designed for different areas of the operation theatre and it should be properly maintained. Its locations and use must be known to the staff working in the operation theatre department.

3.4.13 Design and Finishes

Floors and Walls: Floor and walls should be hard, robust, impervious, jointless, non-absorbent, washable and de-contaminated. All corners and joint should be curved. Viewing cabinet switches, plugs, door and window frames is flush with the wall surface to make cleaning routine easier.

Although anaesthetic gases like ether are not being used but still it is preferred to have a conductive flooring in the operation theatre. Linoleum PVC conductive flooring is also available.

Ceiling: Ceiling should contain minimum number of fissures, open joints or crevices that minimize retention of dirt. Height of the ceiling should permit location of operating lights and pendant. Minimum height of 2.9 to 3.05 metres is needed for fixing operating light conveniently.

Clean Room: A clean room is a enclosed space implying environmental control over atmospheric contamination, temperature, humidity and pressure. The cleanliness of the space is controlled by laminar air-flow through high efficiency particulate air (HEPA) filters.

HEPA Filter is high efficiency filter used in clean room, they remove particles from the air. A particle is counted if *it* is larger than 0.5 microns. A micron as you know is one millionth of a metre which is one thousandth of a mm (001 mm). Clean rooms have different class. It could be class 10 room, Class-100 rooms etc. (A class 10 room will contain less than 10 particles per cubic foot.) In operation theatre class 100 clean room is acceptable. These rooms are provided with mylar fine guard ceiling with a vertical laminar flow and HEPA filter. This will be able to provide class 100 clean room

Doors: Main door to the operating room should be of 1.5 metre clear width with 2 leafs. Door should be protected up to the height of 1.25 inetre with Rubber, PVC or Stainless steel. Sound insulation of door should be perfect. Kick plate should be sound absorbent. Post operative room door should be minimum of 1.45 meter in width.

In the operation theatre a staff person dressed in sterilized garment needs a minimum door opening of 90 cm (door between scrub room/gowning area and operating room).

Height of the Door: The minimum clear height of door opening should not be less than 2.13 metres (7 feet).

3.4.14 Equipments

a) Operation Table: The main item of the operation room is the Operation Table. One table per operation room is needed. If mobile tables are used reserve table may be needed and this will depend on the frequency of operation. All operation tables should be provided with a convenient insertion of x-ray cassettes.

b) Microscope: For micro-surgery, a microscope with remote control is used. Nowadays stereo-scopic colour video microscope is being used. Equipment wherever. possible should be of wall hang type or could be even hung from the ceiling.

c) Mobile Equipment: Other mobile equipment used in OT are:

   i) Anaesthetic apparatus

   ii) Anaesthetic table

   iii) X-ray equipment

   iv) Diathermy equipment

   v) Electrical suction apparatus

   vi) Pulse monitor

vii) Ventilator

viii) Monitor-cum-defibrillator

ix) Heart lung machine

x) Other devices for physiological and isotope investigations.

All surfaces of castor wheels of equipment should be easily accessible for cleaning and decontamination. No piece of equipment which stand on floor should have a height exceeding 1.8. metres.

3.4.15 Staffing

For routine general surgery operative team size will vary between 4 and 7 persons. The operative team consists of:

i) Surgeon

ii) Anaesthetist

iii) Assistant to help the surgeon with ligatures, retractors

iv) Scrub nurse to pass instruments to the surgeon

v) Circulating nurse

vi) Anaesthetist nurse

There may be up to four assistants to help the operative team. These are:

i) Radiographer

ii) Technicians

iii) Sterilising staff

iv) Disposal staff

However, for Cardio-vascular surgery OT total of approximately 20 persons may be involved.

Check **Your Progress 5**

Fill in the blanks in the space provided:

a) Floor and wall of OT should be .....
.....

b) Conductive flooring should be provided in .....

c) Height of ceiling in OT should be .....

d) Main door of OT should bc ..... width

e) Operation table should have provision of inserting .....

f) Staffing in routine general surgery will vary between .....

3.5 POLICY AND PROCEDURES

3.5.1 Operating Schedule

The time lost between cases in a given operating theatre may amount to as much as 15-30 minutes depending upon the hospital, its personnel, the number of surgical instruments available and discipline and control prevailing in the theatre. It is important to ensure that there is no wastage of operating time of the surgical team nor there is any over-crowding of the operation list resulting in postponement of operations.

3.5.2 Administration of OT

Time saving technique depends considerably on operating room discipline. A well run OT requires an untiring and energetic theatre matron, a dedicated and disciplined Chief Surgeon, an anaesthetist who is keen on high standard of efficiency and a trained and well motivated para medical staff, If instruments are ready in advance of the appointed time, the assistants arc in the room, gowned and gloved and the anaesthetisl helps to coordinate the presurgical details before entry of the operating surgeon the duration of occupancy of that room by a particular patient will be decreased considerably.

3.5.3 Punctuality

Punctuality by cvcryhody concerned with thc operating schcdulc is important. The first case of the day should begin promptly when scheduled i.e. operation at 0800 hrs. should mean "knife" at that time instead of the patient being wheeled in. All delay should be investigated and discipline enforced with suitable penalties and motivation.

3.5.4 Theatre Staff

The chief surgeon should take personal interest in the training of theatre staff. Each member of the team including the junior-most ORA and the safai karamchari should be put through progressive training to bring them to a high pitch of efficiency so that they carry out their duties more or less by reflex action or "mechanically".

3.5.5 Operating List

The operation list should be made judiciously and time of operalion indicated against each. Efforts should be made to ensure that the cases are not postponed barring unforeseen and exceptional circumslances. Rigidity of "working hours" should not normally be allowed to come in the way of completing the list for the day. Other reasons for postponing operations such as non-availability of theatre linen. Lack of sufficient instruments and inadequate prcparalion of palients should be reduced to the minimum by suitable administrative measures.

3.5.6 Outpatient Cases

It is a common practice to see outpatients requiring minor surgical procedures such as special dressing, change of plaster, injection of piles, incision of a whitlow and so on, reporting to the OT early in the morning and being disposed off late in the afternoon at the end of day's operating schedule. This should be avoided at all cosls. Following approach is suggested:

a) Awareness on the part of all concerned that the above practice is highly demoralizing to the palients and all efforts should be made to plan and organise prompt attenlion for OPD cases.

b) Where there is one Surgeon in a hospital such cases should be dealt wilh either on OPD days in the afternoon or on the following day in the morning using the minor OT.

c) Where more than one surgeon/trainee in surgery are available the OPD surgery should be listed separately for the day and a surgeon detailed for the same. If necessary one of the medical officers can be trained to give routine anaesthesia1 carry out minor surgery.

d) Patients should bc called by appointment at the appropriate time when they are expected to be dealt wilh.

3.5.7 Transportation of Patients

Transportation of patients from and to the ward should be organised by the anaesthetist at a suitable time depending upon the time of operation. For this purpose adequate start should be made available permanently to the OT.

3.5.8 Maintenance of OT and Aseptic Standard

i) Time should be given for normal maintenance of OT. One day in a week should be earmarked for maintenance.

ii) Swabs should be taken from various area of the OT to check the growth of bacteria if any, particularly in the air-conditioning duct.

iii) Air-conditioning of OT should be checked thoroughly including effectiveness of its filters.

iv) Filter should be properly maintained and if it requires replacement, local agencies should be identified where filters like HEPA fillers are readily available.

v) In the OT gauges for checking, humidity and temperature should be available along with controls, so that operating staff can control the same from inside the OT.

vi) Operating lamp bulb is also likely to gel iused. Therefore some spare bulbs should be kept in stock in Operation Theatre department.

vii) Manifold facilities in the OT like Oxygen, suction, compressed air and nitrous oxide arc important. Adequate pressure should be maintained all the time. Therefore, location of manifold facilities plant room vis-a-vis location of operation room assumes significance.

viii) Operaling stall having infection should not bc permitted in the operating department.

ix) Disinfection/sterilisation of mobile equipment and operation table should bc ensured. Post operative infection rate, anaesthetic death rate should be documented and constantly rcvicwed.

x) Electro medical equipment/mechanical equipment, cvcn if we take all precautions, can fail and some time does not work, when it is most needed. It is therefore suggested that OT having only one life saving equipment should know the location of the same type of equipment in other OT which can be utilised at the time of need.

Check Your Progress 4

.....

.....

.....

.....

2) Describe in brief the procedure for outpatient cases reporting to OT.

.....

.....

.....

.....

3.6 LET US SUM UP

In this unit you have learnt that the eminence of a hospital is determined by the performance of the OT complex. This is where the real action lies. It is here a clean aseptic environment is provided where a surgeon performs operative procedures wilh the objective of curing the illness of patients.

You have also learnt about the necessity of proper planning of the operation theatre department and elements of planning. It is, therefore, essential that the operation theatre department is planned properly. Location, grouping, size are important elements. Aseptic environment can bc cnsurcd if proper zoning is carried out and the best possible air-condilioning facilities with good control on ventilation system, temperature and humidity as per particular OT requirement and air pressure are provided. Asepsis standards ol' the OT shoulti be thoroughly checked by carrying out swab tests and bacteriological examination to check its sterility.

Further you have lcarnt that stable electricity is an imporlant element. While operating a case, the surgeon has to look at the site of incision and also look into the depth of the wound to operate there on. For this purpose operating lights have to be selected carefully to fulfil all the criteria.

Towards the end you have learnt about various policy and procedures, issues/ consideration.

You learnt that planning and creation of facilities is important, but it is necessary that it is staffed, equipped and organised properly. The policy and procedures should be laid down and adhered to. Any lapses in this is likely to adversely effect its functioning and spoil the image of the hospital,

3.7 ANSWERS TO CHECK YOUR PROGRESS

Check Your Progress 1

a) after the diagnosis is made and at time suitable for both doctors and patients.

b) Neuro surgeon and Vascular surgeon.

c) physical contact, mechanical pressure.

2) a) 40 sq. metre.

b) 60 sq. metre.

3) a) 3, 3

b) 10

Check Your Progress 4

a) 100000 lux

b) Four

c) 30 cm

d) ceiling

e) 4, 2, 2

f) 1.9 metre

g) operating light.

Check Your Progress 5

a) Hard, Robust, impervious, jointless, non-absorbent, Washable and decontaminated.

b) operating room floor.

c) 2.9 to 3.05 metres.

d) 1.5 metres width with 2 leafs

e) X-ray cassettes.

f) between 4 and 7 persons.

Check Your Progress 6

1) Operating list is made for each operating room/surgical team. This should he made properly and time noted against each case and it should be seen that patient in the list should be operated upon even when surgical team has to work for extra time. All administrative measures should be taken so that essential instruments, linen and staff are available for carrying out the operalion listed in the operating list.

2) These cases should be called by appointment. If there is only one surgeon, OPD cases should be operated on the OPD days itself. If there are number of surgeons then one surgeon should be earmarked to attend these cases. Outpatient cases should not bc made to wait from morning to evening. This has a demoralising effect on patient and their relatives.

UNIT 4 INTENSIVE CARE UNIT

Structure

4.0 OBJECTIVES

After going through this unit, you should be able to:

- define Intensive Care Unit area;
  select appropriate patients for ICU;
- describe the types of Intensive Care Units;
- assess the requirement of staff and equipment for Intensive Care Units;
- help lay down admission and discharge procedures; and
- help measure the quality of care and take steps for improvement.

4.1 INTRODUCTION

You have already learnt about three of the important Clinical Services in a Hospital. In this unit beginning from the definition and Development of Intensive Care Unit you will

learn about classification of patients for the purposes of intensive care unit. You will also learn about different types and the requirement of the staff and equipment for the Intensive Care Unit. In addition to learning about the admission and discharge procedures you will also learn about the assessment of quality of care and the steps necessary for improving the same. In the end you will learn briefly about the concept of cost effectiveness in Intensive Care Services.

4.2 DEFINITION

An Intensive Care Unit (ICU) is a specific area of the hospital where sophisticated monitoring, titrated life support, specific therapy and specialized nursing, can best provided for potentially salvageable, critically ill patients with life threatening illness or injury. IT IS A PLACE AND NOT A FORM OF TREATMENT

The ICU's were developed to concentrate three critical components—theseriously sick patients, highly skilled staff with the knowledge and experience to treat the patients and use equipments for better results at reduced costs.

4.2.1 Selection of Appropriate Patient

One of the objective of ICU is to decide which type of patient should be treated.

The selection of patient appropriate for Intensive Care not only depends upon medical and organisational factors but also on financial, legal, ethical, moral and societal values. Life would have been much simpler if we believed that we could characterize patients as too well, too sick and just right for intensive care.

In this connection following simple classification can be used a) Patients expected to survive; b) patients potentially recoverable (a good chance of recovery); c) patients having uncertain prognosis; d) not likely to survive whatever is done; and e) patients in which death is apparently imminent. In view of public expectations of what medicine can achieve, intensive care should be provided for the first two of these categories. However the classification system fails to recognize that these distinctions are not always possible and not necessarily desirable.

la fact to choose appropriate patient one must broaden the admission guidelines and include not only the Loo siclc patients but also those who may be too well for intensive care requiring only monitoring to prevent occurrence of serious complications.

4.2.2 Generic Goals

A qualitative basis for categorizing patients is required depending on generic goals of intensive care. The categories, which generally apply to all speciality ICU patients besides distinguishing surgical ICU patients from routine post-operative surgical patients have been identified. The three categories are:

a) monitoring/observation;

b) extensive nursing requirements; and

c) constant patient care.

Patients are considered appropriate candidates for ICU admission for just monitoring and observation even if they are physiologically stable. This is for early detection and rapid response to serious complications.

4.2.3 Distributive Justice

Intensive Care Units encompass the total number of patients who could be considered eligible for care, given the number of available beds. ICU beds are expensive and any hospital cannot afford to maintain excess of beds with available staffing to accommodate emergency admissions. Emergency admissions are predictable although not the timing. If all the existing care has been allocated, some decision will have to be made to distribute resources so that no patient is deprived of necessary care, In terms of ethical principle of distributive justice the principle usually followed is first come, first served in which the care is apportioned to appropriate candidate seeking admission; and these continue to receive care until there outcome is detennined. I-Iowever, it is inappropriate to devote limited ICU resources to a patient whose prognosis has resolved to one of vegetative state In routine wards intensive monitoring and observation was never easy or effective as the nurse patient ratio is usually 12 : 1 or 18 : 1 in night shift in regular wards in our hospitals. This means that a nurse has less than 30 minutes/shift available for individual

patients after excluding time for their administrative functions. This is so bccausc patient needing intensive monitoring and observation are looked after in ICU. However special areas intermediate care areas arc developed.

The third category of patients requiring constant physical care are physiologically unstable and require constant reaction to changes and implementing validating and redefining therapy. These patients conform to image of ICU because clcmcnts of high technology, rapid and efficient activity, crisis exists with dramatic success. There is no problem for selection of these patients for admission to ICU.

4.2.4 Immediate Objectives: Societal Patient Values

The immediate objectives for our patient's, society and ourselves are preservation of life and alleviation of sufferings which are derived from the sanctity and quality of life. ICU epitomises challenges of high tech medicine. The crisis in ICU care is mainly bccause of societal values that every problem has a solution, often technical one, and the expectations are to do everything possible, which ultimately raises the cost of ICU carc.

The objectives of improved utilization of ICU resources and better locus for care of dying patients are attainable today. Therefore diminishing unnecessary activity will decrease complications and have salutary effects. If we have more time for thinking, assessing and decision making and to be with patients and families rather than frantically ordering, reacting and intervening we will decrease our sense of failure and fulfil important goal of caring.

4.3 TYPES OF INTENSIVE CARE UNIT AND STAFFING PATTERN

Intensive care as you know is a method of organising medicine and nursing so that expertise and sophisticated equipments are concentrated whcrc they are most needed and efficiently utilized. However, the dcvclopmcnt of ICU's has suffered from overemphasis on gadgets and spatial designs and under emphasis on personnel.

4.3.1 Classification on Type of Patient Admitted

Intensive care units can be classified into following depending on type of patients admitted:

1) ICTU : Intensive Care and Therapy Unit
2) CICU : Coronary Intensive Care Unit
3) PICU : Pulmonary Intensive Care Unit
4) BICU : Burns Intensive Care Unit
5) OICU : Obstetric Intensive Care Unit
6) NICU : Neonatal Intensive Care Unit
7) ANCU : Acute Nursing Care Unit
8) MSICU : Medical and Surgical Intensive Care Unit

4.3.2 Classification on Organisational Structure

All the above Intensive Care Units can be of three types:

a) **Open** Unit: All attending physicians may admit and care for patients. However, Triage decision falls on director of ICU when there is bed or staff shortage.

h) **Semi Closed** Unit: The Directors ol' ICU and/or associates must review and approve all admissions. However they should take into care the approprialeness of care and staffing level. All final decisions are of administrators.

c) Closed Unit: The Directors and/or associates are responsible for all admissions and discharges. Once the patient is admitted, the unit team looks after in collaboration with admitting team for efficient patient care.

4.3.3 Staff Requirements

a) Medical Staff

ICU must have a Director/Incharge of ICU in the best interest of palienls. The referring unit consullant or surgeon cannot be constantly available and neither he nor his staff is l'ully experienced with specific problems of ICU patients, which are quite different from those in general wards. In UK and USA most ICU's are in administrative charge of one or more consullant anaesthcsiologists with variable amount of clinical autonomy. Besides his clinical duties, the incharge of ICU has other responsibilities viz.

i) is spokesman for unit in administrative matlers
ii) provides continuity of clinical care
iii) .organises leaching and supervision of junior staff who require detailed instructions, not only regarding palient care but also for use of unfamiliar equipment.
iv) is responsible for purchasing and servicing of ICU, cquipments.
v) should initiate research and be recognized as an authority.
vi) should review all treatment regimen with staff.

It is esscnlial that Director of ICU should be rcspccted by colleagues not only for his clinical and administrative abilities, but also for his tact. The sharing of responsibilities especially for care of patients always creates problems with disastrous results. It is therefore mandatory to define the terms of reference. In particular he/she must never appear to steal either his colleague's professional status or the palients.

In any case the outline of patients treatment is agreed in consultalion with parent unit. However staff of unit should have right to initiate carry out other treatments which may be necessary when emergency arises.

b) **Senior Registrar in ICU**

One senior resident (Post MD) will always be on duly. The shift duties of senior and junior staff is 12 hourly. The scnior resident has the right to initiate and carry out emergency treatment which may be necessary without permission. Nowcvcr later consultant must be informed.

c) **Junior Resident in ICU**

One doctor in training (during post graduation) will bc on duly in unit day and night. The duty roster will overlap so as to allow for proper handing over of responsibility. The duty would include keeping patients records while in ICU and preparing case summaries which will accompany the patients to his parent ward.

d) **Nursing Staff**

Continuous skilled medical and nursing carc is essential. It can be provided only on the basis of one nurse per patient at all times together with incharge nurscs. For a general ICU with a mean 75% bed occupancy, it can be achieved by five trained nurscs per bed together with appropriate number of sister or charge nurses for day and night duties. The nurse: patient ratio, which is acceptable on ICU is as follows:

Nurse : Patient Rutio:

1:1/1:2 during day time

1:2/1:3 during night

2-2.5 stall : 1 in a 6-8 beded ICU

1-1.5: in a 12 beded ICU

4 : 2 nurse/Bed including allowances for holidays and occasional absence arc required for constant patient care.

However for paediatric ICU it should not be less than 1:2 every time.

There should be inscrvice basic training programme in ICU for nurscs, and it takes about 2 months for a qualified nurse to become confident and compliant. As many student nurses as possible should spend fixed period (3 weeks) in unit to gain experience as it is from these sources nurses can be recruited at times of need. ICU nurscs are vulnerable to emotional and physical strain and therefore their postings should not be for more than one year. However, where the establishment is adequate and the nursing staff arc selected properly, trained and supported, this is not the case.

e) **Other Staffing Requirement**

In addition to nursing and medical staff requirement every ICU requires professional and non-professional assistance. The physiotherapists (including both physical therapist and respiration therapist) is an integral part of staffing of ICU. **A** Radiographer and Instrument technician is required. In USA the responsibility for establishing, maintaining and monitoring controlled ventilation is taken over by respiratory therapists. They arc also responsible for blood gas analysis. The amount of paper work done should bc reduced to minimum by clerical and secretarial assistant. It is difficult to overestimate need to maintain high standard of cleanliness.

f) **Intensive Care Unit Staff Requirements (8 Beds)**

Direct Requirements for Provision of Constant Medical Care

4	Sisters/charge Nurses
32	Trained Nurses
6	Nurses in Training
4	SHO/Registrar (on rotation)
1	Consultant
4	Domestic staff
2	Ward Administrator
1	Secretary
1	Peon
1	Director of ICU

2 Physiotherapist

3 Radiographers

1 Biochemistry Technician

1 Blood Bank Technician

1 Bacteriological Technician

Engineers, plumbers be together with optimum medical and surgical specialists (Expertise) are required.

These are ideal requirements and many departments may have to be satisfied with a less comprehensive standard.

4.4 PHYSICAL FACILITIES, PLANNING AND DESIGNING

The ICU requires special space and equipmenl considerations for effective staff function. Not every hospital can provide all types of critical care. It is a service faculty for its own hospital and its clientele, size and design is dictated by needs. Some hospital may have small combined unit, other may have separate, sophisticated units for highly specialized treatment. The following standards are for the more common types of critical care services which shall be appropriate to needs defined in functional programme for efficient, safe and effective patient care. The important problem of ICU is unpredictability of demand and occupancy. Underuse can never be avoided entirely in a service departmenl, but it can be minimized by careful planning.

4.4.1 Location

The ICU should be located close lo operation theaters and recovery rooms. Il should offer convenient access from emergency respiratory therapy, surgery and other essential departments. It shall be arranged to eliminale the need for through traffic. The movement areas should he large and freely accessible and corridor should be more than

2.5 metre wide. If elevator transport is used for transporting critical patients the size of cab, mechanism and controls should be carefully planned.

4.4.2 Levels of Provision

In the UK one ICU bed for every 100 acute beds in hospital is recommended. In USA and other countries up to four times this proportion may be provided. In UK units of 4-8 beds arc rule. In Germany 5% of total number of beds are for ICU. ICU of less than 4 beds and less than 200 cases annually with average occupancy of less than 75% is uneconomical. It implies that on 8 bedded ICU should admit about 500 cases per year with similar proportion in other sized units.

2% of the total hospital beds in ICU will generally meet the requirement.

However for Paediatrics ICU 6%of all beds or 8% of average hospital pacdiatric census.

4.4.3 Spatial Requirements

There is an average overall spatial need of 50 metre square per bed. The entrance should bc like an anteroom with a place for gowning and a separate emergency entrance for patients.

a) Patient's Space

If it is a new construction each patient's spacc (whether separate rooms, cubicles or multiple bed spacc) should have a minimum 15 sq. feet of clear floor area and minimum headwall width of 1.2 feet per bed exclusive of anteroom, vestibule toilet room, lockers and/or alcoves. A staff assistance system should he provided on most accessible side of bed which must annunciate at nurse station with back up from another staffed area from where assistance can be called. If private rooms or cubicles arc provided view panel to corridor are required and should have drapes or curtains which may be closed. Each patient bed area spacc should have space at each bcdsidc lor visitors, and provision for visual privacy. There must be a minimum 8 feet between beds for both paediatric and adults units. Patients bed should have visual access other than skylights, to outside environment. Therefore there should be at least one outside window in each patients bed area. The distance from patient bed to outside window should not exceed 50 feet.

Nursing Calling *System:* There should be two way voice communication provided which must include provisions for an emergency code resuscitation alarm to summon assistance from outside ICU.

Hand Washing Fixtures: These must be located convenient to nursing station and patient bed areas. It is recommended that there should be at least one hand washing fixture lor every three beds and should be located near entrance to patient room. Moreover these should be sized to minimize splashing water on to floor.

b) **Patient's Services**

The following are essential:

Pipeline oxygen and suction outlets.

Medical quality compressed air and Entonox.

- 12 electrical sockets.
- Outlets for transmission of biological data to central nursing station.

Medical gases and suction devices.

- Mobile partitions/Bed divider system.

c) **Nursing Station**

This area must have space for counters, storage and may include centers Sor receplion and communication, The patients in ICU needs to be visually observed at all times. The central station should geographically be so located that:

it allows for complete visual control of all patient bed

it is designed to maximize efficiency in traffic pattern

- the patients should be so oriented so that they can see nurse but cannot see othe patients.

Lighting: The ICU should be well illuminated with non-reflecting paint works and other surfaces.

d) **Medication and Nourishing Areas**

In ICU provision should be thcrc for 24 hours slorage and distribution of routine drugs and emergency medication. The area should contain a work counter, cabinets (for storage of supplies) sink with hot and cold water supply, refrigerator for Pharmaceuticals and should have a minimum 50 sq. feet area.

e) **Isolation Rooms**

Thesc must have minimum 14 sq. meter area plus space for Ante room, minimum 20 sq. feet Io accommodate washing, gowning and storage. The electrical, medical gas, heating and air conditioning shall support need for patient and ICU team member. The following additional service space should also be available within ICU and may be shared by more than one ICU, provided direct access is available.

a) Securable cabinet compartment for personal effects of personnel in ICU.

b) Clean supply room: IT it is used for preparing patient care ilems it must have work counter hand washing fixture and storagc facility for clean sterile supply material.

c) Clean lines storage.

d) Soiled work room/holding room: These must be separate from clean work room and should have separate access door, clinical sink, lavatory (or hand washing fixture) for both cold and hot mixing formulas.

e) Nourishment station: It should have sink, work counter, refrigerator, storage cabinets and equipment for hot and cold nourishment between scheduled meals.

f) An X-ray viewing facility

g) Equipment slorage room appropriate room shall be provided for storage of large items of equipment necessary for patients.

h) 24 hours laboratory, radiology and pharmacy services should be available.

The following should be provided and may be located outside ICU if convenienlly accessible:

- Visitors wailing room wilh convenient access lo telephones and toilets. One wailing room may serve several critical care units.

  Adequate office space adjacent to ICU for medical personnel which should bc large enough to permit consulting with mcmbcrs of ICU team and visitors.

- Staff lounges and toilets with telephones, intercom and emergency code alarm connection wilh provision person for storage of coats. It should have space for comfortable seating and preparation and consumption of snacks and hcveragcs.

- A special procedure room if required by functional programme.

- Sleeping and personal care accommodations for staff on 24 hr. on call work schedule.

- Multipurpose rooms for staff, patient and patient families for conferences, reports , education training session elc.

  A house keeping room containing service sink for floor receptor and provisions for slorage of supplies and house keeping equipment.

  Storage space for stretchers and wheel chairs in a strategies location without restricting normal traffic.

4.4.4 Intensive Coronary Care Unit

The coronary patients have special needs. They are fully aware of their surroundings but still requires immediate and intensive care. In addition to above requirements, the following standards apply to all. Each patient must have separate room for acoustic and visual privacy. Each patient must have access to a toilet in room. Portable comrnodcs if used the provision must he made for theirs storage, servicing, and odour control, Each unit must have equipment for continuous monitoring with visual display at paiients bedside and at nurse station. Monitors should be located for permitting easy viewing.

4.4.5 Combined Medical and Surgical Intensive Care

It medical surgical and cardiac intensive care services are combined in one intensive care then at least 50% of beds must be located in private roomed cubicles.

4.4.6 Paediatric Intensive Care Unit

The children have unique physical and psychological needs. Every hospital cannot have a separate paediatric ICU's and therefore a sale transport system is required to safely transfer these patients to appropriate hospitals. However, the paediatric ICU may be an open ward plan and one isolation room for every 6 ward beds is essential. In addition to general standards mentioned the paediatric ICU must include:

- Space at each bed side and separate space for visiting parents.
- Provision for formula preparation.
- Separate cabinets for toys and games for use by patients.
- Space allowance for paediatric beds and cribs equal to those of adults.
- Examination and treatment room, which should have minimum 120 square feet floor area and must have a hand washing fixture, storage facility and a desk, counter or shell space for writing.

4.5 EQUIPMENT REQUIREMENT

Intcnsivc Care Unit is a centre for physiological measurements, nursing procedures and therapeutic maneuvers including temporary replacement of functions of one or more organs. Therefore, there is heavy demand in terms of equipments. The type of equipment required are:

4.5.1 Monitoring Equipment

It is essential to have equipment for continuous monitoring of heart rate, e.g., blood pressures, temperature etc. with visual display for each palient at bed side and at nursing station. Non-invasive system should always be used if data provided are reliable. It is essential Io measure blood gases frequently and acute and it is essential to monitor oxygen saturation continuously by pulse oximetry. It is now possible to measure cardiac output non-invasivcly but the cost of such investigations including radionuclide imaging of heart limits their use in any but the most specialized units.

4.5.2 Therapeutic Equipment

Majority of patients in ICU receive artificial ventilation necessitating use of ventilation. The choice of ventilator depends upon the illness the patient may be suffering from in addition Io their age and size and financial resources available.

For diagnostic and therapeutic purpose a fiberoptic bronchoscope is required. The need for other therapeutic devices is dictated by functional programme of ICU's, haemodialysis, haemofitralion, plasmaphaeresis and haemoperfusion which is used in ICU require skilled staff and support service for safe application.

Check Your Progress 4

1) Enlist the important considerations to be kept in mind for purchase of ICU equipments.

.....

.....

.....

.....

2) What are the different equipments required in ICU?

.....

.....

.....

.....

4.6 POLICY AND PROCEDURES

ICU is place with high tension environment due to random appearance of catastrophic events or unpredictable clinical crises. Crises commonly reflect acute cardio-respiratory and oxygen transport problems. It is also apparent that initial success may not be sustained and death may occur in ICU or even after discharge. Therefore, standard policy and procedures to be followed based on evaluation of long term outcome, and they must form a part of process of starting therapy even in cases characterized as crises. The protocol should be unambiguous for smooth running of ICU's.

4.6.1 Admission Procedure

The type of patients suitable for admission to ICU's are:

- Patients with multiple injuries'or after major operations who require continuous observation, monitoring or support of vital functions.
- Patients requiring support of airway and/or artificial ventilation of lung.
- Patient requiring support to maintain cardiovascular integrity including those in haenzorrhagic shock.

  Patients requiring control of toxemia of metabolic or infective origin (including pneumonia).
- Patients who are donor or recipient of transplant.

Once the patients are admitted to the ICU the following policy is recommended:

a) Patients admitted to ICU will remain the clinical responsibility of consultant/unit under whom they are admitted.

b) A bed is kept in appropriate ward to await their return.

c) No patients are directly admitted to ICU. However, patients coming directly from casualty/transfer from other hospitals are first shown admitted under a special unit in ward and then shifted to ICU.

d) Admission to ICU shall normally be by recomn~endationof ICU consultant.

e) Admission will be made to ICU only if bed is available or alternative arrangement for speciatised care in intermediate care area will be done.

f) The consultant incharage of ICU will be responsible for maintaining continuity of care and for initiating treatment decided upon at morning rounds after consulting with physician under whom patient is admitted.

g) The senior resident may initiate such treatment as indicated in emergency by alteration in patients condition. However, consultant must be informed about it.

4.6.2 Day to Day Care and Discharge Procedures

- Liaision with the parent unit is essential for proper treatment of patients in ICU.

- Daily ICU rounds shall be held in morning at 9-11 AM along with doctors of parenl unit undcr whom patient is admitted. The main decision regarding treatment are taken in these rounds.
- The treatment instituted to palients is written by the senior resident posted in ICU.
- The decision of discharge of patients is taken in consultation with the consultant of the parent unil under whom the patient was admilted. A simple criteria can he followed:

  a) Patients who have recovered and are stable can be discharged.

  b) Patients in whom immediate threat is alleviated but requires close observation can either be discharged lo wards or in intermediate carc areas, depending on need for ICU bed.

  c) Patients in whom immediate threat is alleviated but expected to die shortly, are observed in ICU depending on bed required for other patients with rccoverablc illness.

  d) Patients in whom death is agreed to be imminent even if intensive care is continued again kept in ICU depending on availability of resources.

1.6.3 Quality Assessment and Improvement in ICU

The importance of quality assessment and its effects on bedside practice in intensive care unit is not always obvious. Every unit must develop plan for monitoring and evaluation, quality of carc, by whatever definition.

The physicians view of quality of trauma cases is in terms of readiness of OT, availability of ICU intensive care nurse and team protocol followed towards successful outcome. The patient's perception of quality is in terms of convenience, a caring staff, availability of services without undue wait and how he reels at the end of it.

The Administrators may consider cost and length of patients slay as primary factors in assessing the procedures quality.

The **Regulator/Controller** may look at all **of** above.

The ten steps plan for monitoring and evaluation is as follows:

- Assign responsibility

  Who is responsible-physician, incharge ICU/staff ?
- Delineate scope of key function

  What do one looks at?
- Identify important aspects of care

  What activities have highest priority'?
- How to know what you are doing is right

  Set indicalors
- When one knows that there is need for improvement

  Get triggers for evaluation.
- What actually needs improvement

  Probably methodology (data collection and aggregation).
- Do not know why it needs improvement

  Process of evaluation.
- Know why

  Then action after evaluation and feed back.
- How much successful

  Improvement is measured.
- Then what

  Lastly documentation and communication.

4.6.4 Aspects of Care

The monitoring and evaluation depends on aspects of care being provided in the ICU and the indicators and triggers to evaluate each procedure is developed. The different aspects of care provided in ICU include:

- Mortality
- Morbidity
- Appropriateness of admission
- Medication errors
- Timelines of discharge
- Assessment of physician response time
- Performance of tracheostomy care
- Management of ventilator support patients
- Performance of hazardous procedures (Arterial Blood gases sampling)
- Monitoring effects of medication ordered and administered
- Assessment of standard orders compared with actual practice
- Evaluation of patients satisfaction
- Evaluation of staff complaints and satisfaction
- Evaluation of nutritional needs
- Evaluation of patient care incidents
- Assessment of appropriate use of intravenous lines
- Assessment of equipment failure
- Development of CPR protocol

4.7 COST EFFECTIVENESS

On the other hand it is furthermore difficult to assess benefits. The important question is "Is society getting improved quality for our increasing expenditure in terms of number of lives saved, longevity and quality of life?" There are better places to invest the resources. The most popular representation of this trade off is the equation.

More money spent on prenatal care results in less money spent on neonatal ICU care.

There is often a disagreement about what constitutes benefit. It is only occasionally that it can be said with certainty that it this patient was not admitted to ICU he would have died. The benefit of survival depends on longevity and quality of life. Several attempts have been made to categorise the severity of illness, quantify treatment and predict outcome. The best known are:

- Injury severity score

  APACHE system (Acute Physiology and Chronic Health Evaluation)

- Engehardt and Ries ICU Entitlement index

The doctors are asked to be guardians of society's resources and gatekeepers of technology. Wc are implored to be efficient in our use of resources. Costs which are esclating at a rate that exceeds the growth of the economy are the driving force for cost containment. The benefit of intensive care is usually expressed as cost related to predicted remaining life span for the survivor.

4.8 COORDINATION AND CONTROL

The ICU senior residents should bc considered as central figure, with whom mosl other team members comes into contacl for patient information. He carries the responsibility of communicating patients status to others. Although the consultants on both the surgical and ICU team have ultimate legal responsibility for patients, the interaction between the ICU senior residents and senior residents of surgical team is the level on which many decisions reflecting changes in management occurs. They are also responsible for recognising which decision needs confirmation by their respective consultants and then to give feedback in those instance.

The consulting services are just consultants but they may be brought into patients management at the request of either the ICU or surgical team. Moreover they should also dictate the day to-day management of patient including admission and discharge.

The nurses in ICU are vital not only for nursing care of patients but also for keeping ICU consultants. Senior residents abreast of patients condition. The same holds true for the respiratory therapists and senior residents in terms of goals for respiratory management.

The junior members (residents) of both surgical and ICU team are important even though they are given least responsibility as far as patient management decisions is concerned. They are in the early stages of their careers and training and it is often their frequent innocent questioning which many times leads the senior to change perspective on patient care.

4.9 LET US SUM UP

In this unit you have learnt that though ICU is an expensive and polentially disruptive development in modern medical care, it can also be a valuable facilities with high tech. medicine supporting aspirations of patients, society and specialists. You have also learnt that it provides a safe, atraumatic and humane environment for those critically ill patient!, who need this-service in the hospital. It is also an area which provides invaluable teaching experience for all grades of nursing, medical and paramedical personnel. If used effectively and efficiently it may elucidate obscure problems endangering lives of sick patients. In addition you have also learnt about physical facilities, staffing pattern and coordination and control besides method of quality assessment and appropriateness of care. The relationships among cost, quality and liability are assessed and a favourable balance of improvement achieved.

4.10 ANSWERS TO CHECK YOUR PROGRESS

Check Your Progress 1

1) The ICU's were developed to concentrate three critical components—the sickest patients, the highly skilled staff with the knowledge and experience to treat the patients, and use equipments for better results at reduced costs.

2) In view of public expectations of what medicine can achieve, Intensive care should be provided for patients a) expected to survive, b) potentially recoverable (good chance).

3) The three categories of patients who require Intensive Care are those requiring a) monitoring/observation, b) extensive nursing requirements, and c) constant patient care.

4) In terms of ethical principle of distributive justice the principle usually followed is 'First come, First served in which the care is apportioned to appropriate candidate seeking admission; and these continue to receive care until there outcome is determined.

5) The third category of patients as per disributive justice requiring constant physical care are physiologically unstable and rcquirc constant reaction to changes and implementing validating and redefining therapy. These patients conform to image of ICU because elements of high technology, rapid and efficient activity, crisis exists with dramatic success.

Check Your Progress 2

1) Intensive care units can be classified into following types depending on type of patients admilted:

a) ICTU : Intensive Care and Therapy Unit
b) CICU : Coronary Intensive Care Unit
c) PCCU : Pulmonary Inlensivc Care Unit
d) BICU : Burn Intensive Care Unit
e) OICU : Obstetric Intensive Care Unit
f) NICU : Neonatal Intensive Care Unit
g) ANCU : Acute Nursing Care Unit
h) MSICU : Medical and Surgical Intensive Care Unit

Intensive care units organisationally are of three types:

a) Open unit
b) Semiclosed unit
c) Closed unit

2) The nurse : patient ratio, which is acceptable on ICU is as follows:

Nurse : Patient ratio

1:1/1:2 during day time

1:2/1:3 during night

2-2.5 staff : 1 in 6-8 bedded ICU

1-1.5 staff : in 12 bedded ICU

4:2 Nurse/Bed including allowances for holidays and occasional absence are required for constant patient care.

3) Direct requirements of staff for provision of constant medical care:

4 Sisters/charge Nurses
32 Trained Nurse
6 Nurse in Training
4 SHO/Registrar (on rotation)
1 Consultant
4 Domestic Staff
2 Ward Administrator
1 Sccrclary
1 Peon
1 Director of ICU

4) Besides his clinical duties, the incharge of ICU has other responsibilities viz.

a) is spokesman for unit in administrative matters.
b) provides continuity of clinical care.
c) Organises tcuching and supervision of junior staff who require detailed instructions, not only regarding patient care but also for use of unfamiliar equipment.
d) is responsible for purchasing & servicing of ICU equipments.
e) should initiate research and should be recognized as an authority.
f) should review all treatment regimen with staff.

Check Your **Progress 3**

1) The ICU should be located close to operation theaters and recovery rooms. It should offer convenient access from emergency respiratory therapy, surgery and other essential departments.

2) If elevator transport is used for transporting critical patients the size of cab, mechanism and controls should be carefully planned.

3) a) 4/100 acute beds.

b) 1/100 acute beds.

c) 5% of total acute beds.

4) ICU of less than 4 beds and less than 200 cases annually with average occupancy of less than 75% is uneconomical.

5) If it is a new construction each patients space (whether separate rooms. cubicles or multiple bed space) should have a minimum 150 sq. feet of clear floor area and minimum headwall width of 12 feet per bed exclusive of anteroom, vestibule toilet room, lockers and/or alcoves. A staff assistance system should be provided on most accessible side of bed which must annunciate at nurse station with back up from another staffed area from whcrc assistance can he called. If private rooms or cubicles are provided view panel to corridor arc required and should have drapes or curtains which may be closed. Each patient bed area space should have space at each bedside for visitors, and provision foi visual privacy. There must be a minimum 8 feet between beds for both paediatric and adults units. Patients bed should have visual access other than skylights, to outside environment. Therefore, thére should bc at least one outside window in each patients bed area. The distance from patient bed to outside window should not in exceed 50 feet.

6) The Nursing station should geographically be so located that:

- it allows for complete visual control of all patient bed
- it is designed to maximize efficiency in traffic pattern.
- the patients should be so oriented that they can see nurse but cannot see other patients.

7) The following patient's scrviccs are essential:

- Pipeline oxygen and suction outlets.
- Medical quality compressed air and Entonox.
- 12 electrical sockets.
- Outlets for transmission of biological data to central nursing station.
- Medical gases and suction devices.
- Mobile partitions/Bed divider system.

8) In addition lo general standards the pacdiatric ICU must include:

- Space at each bed side and separate space for visiting parents.
- Provision Tor formula preparation.
- Separate cabinets for toys and games for use by patients.
- Space allowance for pacdiatric beds and cribs equal lo those of adults.

Examination and treatment room, which should have minimum 120 square feet floor area and must have a hand washing fixture, storage facility and a desk, counter or shelf space for writing.

Check Your Progress 4

1) The three most important considerations which must be considered before purchasing or assessing the equipments are simplicity, reliablility and standardization. In addition mechanical and electrical safety must also be construed lo prevent potential hazards.

2) There is heavy demand in terms of equipments. With the high technology medicine practiced in ICU, there is no apparent limit to ingenuity of modern scientific equipments, bolh for monitoring and therapeutic purpose.

Check Your Progress 5

1) The different aspects of care provided in ICU include:

- Mortality
- Morbidity
- Appropriateness of admission
- Medication errors
- Timeliness of discharge
- Assessment of physician response time
- Performance of tracheostomy care
- Management of ventilator support patients
- Performance of hazardous procedures (Arterial Blood gases sampling)
- Monitoring effects of medication ordered and administered
- Assessment of standard orders compared with actual practice
- Evaluation of patients satisfaction
- Evaluation of staff complaints and satisfaction
- Evaluation of nutritional needs
- Evaluation of patient care incidents
- Assessment of appropriate use of intravenous lines
- Assessment of equipment failure
- Development of CPR protocol

2) The ten steps for monitoring and evaluation are:

- Assign responsibility

Who is responsible physician, incharage ICU, staff?

- Delineate scope of key function

What do one looks at?

- Identify important aspects of care

What activities have highest priority?

- How to know what you are doing is right

Set indicators

- When one knows that there is need for improvement

Get trigger.; for evaluation

- What actually needs improvement

Probably methodology (data collection and aggregation)

- Do nut know why it needs improvement

Process of evaluation

- Know why

Then action after evaluation and feed back

- How much successful

Improvement is measured

- Then what

Lastly documentation and communication

Check Your Progress 6

1) The immediate cost of intensive care unit is considerable, but it is very difficult to quantitate. It is around 15-20% of total hospital budget. The basic ICU cost must include cost of building services, staff salaries, initial and replacement costs of capital equipments, drugs, disposable items and therapeutic materials along with the costs of investigative services. If the amount is divided by number of patient days in unit it appears that one ICU day costs at least three times that of an acute bed in general ward. It is said that **Total costs = Volume of services x Unit costs.**

2) The important question is 'Is society getting improved quality for our increasing expenditure in terms of number of lives saved, longevity and quality of life?' There is often a disagreement about what constitutes benefit. It is only occasionally that it can be said with certainty that it this patient was not admitted to ICU he would have died. The benefit of survival depends on longevity and quality of life.

3) The benefit of intensive care is usually expressed as cost related to predicted remaining life span for the survivor.

Check Your Progress 7

1) The consultants on both the surgical/medical and ICU team have ultimate legal responsibility for patients.

2) The consultants of ICU team after discussing with the consultant of parent team under whom the patient is admitted should dictate the day-to-day management of patient including admission and discharge.

UNIT 1 INPATIENT SERVICES

Structure

1.0 OBJECTIVES

After going through this unit, you should be able to:

- enumerate the roles and functions of inpatient services;
- describe the various types of wards;
- discuss the various steps in planning inpatient services;
- describe the various equipment and staffing requirements in inpatient services; and
- discuss the various methods of monitoring and evaluation of inpatient services.

1.1 INTRODUCTION

You will appreciate that non-critical patients who require investigations, diagnosis and treatment are also admitted in the hospital. Therefore, it becomes imperative to plan and organise inpatient services on a scientific basis, In this unit, you will learn about these aspects. To begin with, the roles and functions of inpatient services have been described. Thereafter, you will learn about various planning considerations including physical layout and staffing of inpatient services. Subsequently, you will learn about the various managerial issues including policies and procedures. Towards the end, you will learn about the methods to monitor and evaluate the inpatient services.

1.2 FUNCTIONS

In hospital based health care delivery system, inpatient services or ward area is the mosl important and largest single component of the hospital, forming approximately 35-50% of whole hospital complex.

The prime objective of inpatient areas is to provide accoinmodation for patients at the point in an illness when dependence on others is at its highest. Because of this, they are, with the emergency department the only areas in continuous day and night operation for patient related activities. The inpatient care area, ward or nursing unit would thus include a nursing station, the beds it serves and the necessary ancillary and auxiliary accommodation needed for patients care.

Inpatient services are under constant pressure of increasing demand and its capital and operational cost is also very high, which effects directly on the hospital and national budget. It is, therefore, essential for all hospital administrators to be fully aware of cost intensive nature and assert on effective planning and efficient utilisation of inpatient services.

Every inpatient nursing unit should be designed in such a way that it can be built and operated at the lowest possible cost and at the same lime, it can achicvc the functional goals of the unit which are as follows:

1) To provide the highest possible quality of medical and nursing carc for the patients.
2) To provide necessary equipment, essential drugs and all other stores required for patient carc in an organised rnanner in the ward.
3) To furnish most desirable environment substituting as temporary home for the patients designed to accommodate all their basic needs (eating, sleeping, toilet activities, diversional matters).
4) To provide facilities to meet the needs of the visitors and attendants.
5) To provide highest degree of job satisfaction for the nursing and medical staff and to render opportunity for training and research.

Check Your Progress 1

Fill in the blanks:

1) Prime objective of inpatient areas is to provide.....for patients.
2) Inpatient services are under constant pressure of.....demand and its capital and operational cost is also very.....
3) Functional goal of inpatient care is to providc the highest possible .... of medical and nursing care for the patient.
4) Functional goal of inpatient services is also to provide highest degree of .... for the nursing and medical staff.

1.3 PLANNING AND ORGANISING INPATIENT UNIT

The planning and designing of an inpatient care unit is a very vital step in hospital planning. Following factors should be considered broadly when planning is being done:

a) Policy of the hospital
b) Physical facilities: Location and area, Size, Shape/Design, Ancillary accommodation, Water, Electricity supplies and air-conditioning, Auxiliary accommodation
c) Staffing

1.3.1 Policy of the Hospital

The policy of hospital is very important for, designing inpatient carc area, it should bc considered whether the hospital will be a general with all facilities grouped into or it be

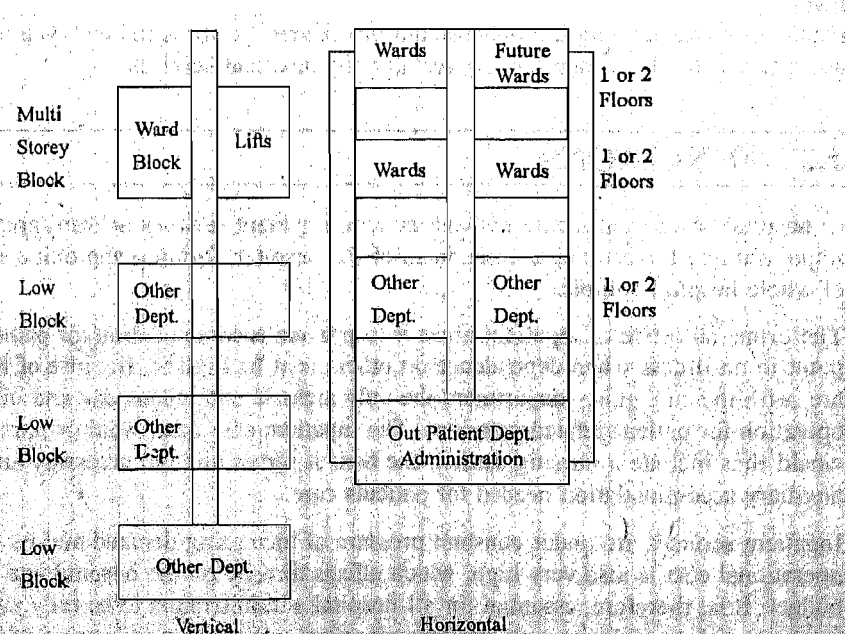

Fig. 1.1: Arrangement of Wards for Vertical and Horizontal Circulation

a super speciality or specific hospital, e.g., Neuro-Sciences Centre, Maternity & Child Centre, Psychiatric Hospital, elc. Bed strength of hospital influences on planning and designing of hospital structure. A hospital with less than 200 beds is generally planned as horizontal where it saves lot of time in internal movement than in vertical (multistorey complex). The upper limit for horizontal planning (maximum ground plus one floor) is considered up to 300 bedded hospital. However, all hospitals planning of 300 and more beds require the inpatient care area planning on vertical expansion which is cost effective and convenient for patient movement.

1.3.2 Physical Facilities

Location and Area

The inpatient area should be located away from main roads and from OPD area, to avoid disturbance and potential source of cross infection. Howcvcr, the inpatient area should be approachable from supportive services (Imaging, Laboratory, Blood Bank, CSSD, etc.) and a good intramural transportation should be planned for effective and efficient movement of patient and staff within the hospital.

Inpatient area covers approximately 35-50% of total hospital area. The arca per bed within the ward is 70-90 sq. It (about 7 sq. m.) but in acute obstetrics ward and orthopaedics wards it is 100-120 sq. It whereas ICU the area requirement is 120-150 sq. ft. per bed. Single bed rooms should have a minimum size of 125 sq. ft. Space left between two rows of beds is 5 It. Dislance between 2 beds is 3½ to 4 ft. Clearance between bed head and wall should be 1 ft and between side of the bed and wall about 2 ft. Standard dimension of hospital bed is 6'6"× 3'×3" and so the minimum width of 20 for dormitory type ward is optimum.

Size

The size of ward or nursing unit varies in different hospitals. Units of 20-90 beds are known to have been made. The nursing unit should not bc very small nor very large. There are various factors which have a bearing on the optimum size of a unit:

1) Type of Patients: In the wards where critical types of patient are kept, the intensity of work is high like rccovcry room, ICU, CCU, acute ward, burns wards, these should be of a smaller size. A chronic disease ward can have even more than 50 beds like tuberculosis ward, psychiatric ward.

2) Requirement of Staff: It has been observed that in the ward, maximum activities take place between 8 A.M. to 12.00 noon, fewer during the rest of the day and least at night. In a very small unit, the requirement of staff in the night shift will be the same as in average size unit, so the night nurse will not be gainfully employed unless the unit is of 30 to 50 beds.

3) Position of the Heud Nurse and the Ward Clerk: The head nurse and the ward clerk carry a lot of administrative responsibilities and clerical workload on their shoulders leaving the staff nurses to devote their mosl of the time to bed side nursing. The abscncc of a proper hcnd nurse leads to lack of leadership and guidance. The presence of an administrative nurse in the unit helps in improving patient care, inter departmental relationships and materials management in the ward. However, if the unit is very small, appointment of a properly trained head nurse and a clerical assistant is not justified. So the modern trend is in favour of a unit of 30-35 beds.

Shape/Design

The primary objective of a ward design is to facilitate the nurse to hear and see everything that happens in the ward and to react accordingly with maximum efficiency and minimum physical and emotional strcsa Many changes in designing a ward have been made and accepted during last 3-4 decades.

1) Open Ward: The rectangular pavilion type of ward was first constructed in 1770 by a Frenchmen. About 80 years later Florence Nightingale adopted this design and it is still known after her name. This ward consisted of patients beds in two rows at right angles to the longitudinal walls with bath rooms and WC facilities at one end and nursing station, doctors room and other facilities at the other end. It was usual to house 30-35 patients in such wards and the length of the ward was not less than 96 feet. This type of ward continued till 1925. Subsequently nurses

table was shifted to centre as the nurse had to walk long distance to attend to the patients. The bath rooms and WC facilities were also shifted in the centre in the form of an annexe. Still later this nurses table was replaced by a proper nursing station consisting a few cubicles to house the various service facilities. A treatment room and an isolation room were also added, In tropical countries wide verandahs are placed on either side of the ward to protect it from direct sun light.

Advantages of an open ward are:

- Nurses have ample visibility and direct observation of patients at all times
- Cross ventilation is maintained
- Natural light is available
- It is economical to construct and maintain

Disadvantages of an open ward are:

- Noise and lack of privacy
- Danger of cross infections
- Constant glare to the patients
- A critical ill patient if placed closer to the nurses desk as it requires maximum attention would thus lie in the centre of greatcsl traffic density

2) **Rig's** Ward: The first major development over above-mentioned defects appeared in Rigs hospital, Denmark and thus came the name Rig's ward. In this design the ward unit is divided into small compartments or cubicles separated for each other by low partitions, each cubicle having 1, 2, 4 or 6 beds arranged parallel to the longitudinal walls. Although the Rig's pattern does not suffer for disadvantages of open wards, it has its own problems, some of these are:

- Cominunication between the nurse and the patient becomes more difficult.
- The patients are deprived of direct observation by the nurse.
- Wards become longer, consequently the nurse has to walk more.
- More number of nurses are required.
- Costly to build and maintain.

In our country however it may not be practicable to have the entire ward on the Rig's pattern with single or double'bed rooms due to shortage of finances and nursing personnel. In a report on General Hospitals the Committee on Plan Projects (Buildings Projects Team) of the Planning Commission (COPP) have recoinmended that in our conditions maxiinurn of two single bed ,rooms in every Ward of 20-30 beds should be provided to accommodate such patients whose condition require special nursing and treatment. Two more single rooms may however be added as "Paying Ward" wherever required. The rest of the ward may be divided into compartments of 4-6 beds.

First two can be overcome by artificial devices like call bells, signal lights, two way speakers and close circuit television. In order to remedy next two, several modifications in different shapes have been adopted like T, Y, X, circular or semicircular shape and single or double corridor type.

Anciliary Accommodation

1) **Nursing Station:** This is the nerve centre of the ward unit and should be so located that the nurses can keep watch over as many patients as possible and the distance to the farthest patient should not be too much. In the Rig's pattern the acute patients are housed on either side of the nursing station with provision of large glass windows for direct observation. The nursing station should be 20'×20' and have the following essential components:

   a) Sister's room with attached bath and WC. This room should have cupboard for medicines and dangerous drugs.

   b) A large work table or counter in the open space outside the sister's room with stools here the staff nurse can carry out their work.

   c) A built-in drug cupboard to hold daily use medicines, stationary forms etc.

2) **Treatment Room:** A treatment room is required for each nursing unit for physical examination, dressing and certain procedures which cannot be carried out conveniently at the bed side of the patient. The room should be equipped with an

examination table, spot light, cabinets and a dressing trolley. Hand washing facilities should be provided inside the treatment room.

3) Clean Utility Room: This room 100-200 sq. ft is used for clean storage, e.g., intravenous sets and solutions, CSSD articles, packing dressing drugs and clean work like setting up a trolley or a trealment tray for minor procedure and so on. This is sometimes combined with treatment room.

4) Ward Kitchen/Pantry: The major function of the ward kitchen is temporary storage and distribution of meals and the preparalion of beverages. The kitchen should be equipped with facilities for hot water, refrigerator, hot case and facilities for storage of crockery and cutlery. This room should have a large sink with a drain board for washing various articles.

5) Day Room: Patients these days are encouraged to move about at the earliest. A place congenial for sitting and relaxing is provided in the ward unit with comfortable chairs and reading malerial. This place can also be used as dining place and for meeling visitors. A common day room can bc provided for two adjacent wards.

6) Stores: A small store room for keeping linen and bulk supply of cleaning material is also provided. Attached lo the slores, a space may be provided for patients lockers where they can keep their personal articles.

7) Dirty Utility Room: A dirty utility or sluice room is provided in each ward for cleaning bed pans, urinals, sputum, mugs and for slorage of slool and urine specimens. It should be fitted with bed pans washer and sink. Large stainless board is provided for slorage of specimens.

8) Bath and Toilets: Bath rooms and toilets are to be provided in adequate proporlion as per scales given below:

a)	Urinal	—	One for 16 beds
b)	WC	—	One for 8 beds
c)	Bath	—	One for 12 beds
d)	Wash hand Basin	—	One for 10 beds

The above scales are exclusive of WC, bath and wash hand basins provided for single and double bedded rooms and staff toilets provided on floor basis.

9) Janitor's Room: A janitor's room is provided in each ward for keeping mops, brooms, cleaning material and buckels. It should have a large sink for cleaning buckels and other equipment and adequate supply of hot and cold water.

Water and Electricity Supplies

Adequate round the clock water supply should be available for ward areas, approximately 300 litre of water is required per bed.

Light points for ward and anciliary accommodation should be carefully designed, There should not be any glare from the lights, alternative source of sunlight should be planned. There should be one industry switch for portable X-ray and one each of 15 amp, and 5 amp. in each cubicle (1, 2, 4, 6) for any contingency.

Auxiliary Accommodation

1) Duty Room for Doctors: There should be arrangements for doctors duty room where doctors can work during the day and rest during the night duty period. It should be equipped with a bed, chair and a table and attached toilet.

2) Seminar Room: One seminar room for each floor or block for teaching purposes should be provided if the hospital can afford. All the clinical teaching can be conducted in this room without disturbing rest of the patients,

3) Attendant Room: A small area on each floor for 2 or 3 nursing units is needed as a retiring room for the visitors and attendants of the patients, Lockers should be provided, so that personal articles of the attendants can be kept safe.

4) Side Room Laboratory: A ward laboratory where routine types of tests can be done is optional for each floor or block which can serve two, three or four nursing units on a hospital Boor.

5) **Locker Room for Staff:** A room with lockers should be provided for the staff who do not reside in the hospital campus for their changing and keeping their belongings safe.

6) **Wheel Chair/Trolley Bay:** A suitable area is needed for parking wheel chairs and trollies in the nursing unit.

Check Your Progress 2

State True or False:

1) The upper limit for horizontal planning is considered up to 500 bedded hospital. (T/F)

2) The inpatient area should be located near main roads and **OPD** area. (T/F)

3) The inpatient area covers approximately 35-50% of the total hospital area. (T/F)

4) Single bed rooms should have a minimum size of 125 sq. feet. (T/F)

5) One bath room is required for every 12 beds. (T/F)

1.3.3 Staffing

An appropriate planning of staffing for hospital inpatient care area should be done well in time, so that user staff is recruited and trained before the ward unit is completed. The general staffing norms for ward are suggested in Table 1.1,

Table 1.1: Staffing Norms for Medical Personnel for General Hospital

Sl. No.	Speciality	Bed Strength					Suggested Norms
		30-50	100	200	300	500	
1)	General Medicine	1	1	2	2	3	One physician up to 100 beds thereafter 1 for 50 additional beds
2)	General Surgery	1	1	2	2	3	One surgeon up to 100 beds and thereafter 1 for 50 additional beds
3)	Gynae. & Obst.	1	1	2	2	3	One Gynae. & Obst. up to 100 beds and thereafter 1 for 40 additional beds
4)	Paediatrics	1	1	2	2	3	One up to 100 beds and thereafter 1 additional for each 150 beds
5)	Anaesthesia	1	2	3	4	5	
6)	Dentistry	1	1	2	2	3	
7)	Radio-diagnosis	–	1	1	2	3	One up to 200 beds and one additional for each 150 beds
8)	Pathology	–	1	2	2	3	
9)	Orthopaedics	–	1	1	2	3	
10)	Opthalmology	–	1	1	2	3	
11)	E.N.T.	–	–	1	2	3	
12)	Skin & S.T.D.	–	–	1	1	2	
13)	Psychiatry	–	–	1	1	1	One per hospital above 200 beds
14)	Chest Diseases & Tuberculosis	–	–	1	1	2	One per hospital above 200 beds and thereafter one addl. for each 200 beds
15)	Biochemistry	–	–	–	1	1	One per hospital above 200 beds
16)	Microbiology	–	–	–	1	1	One per hospital above 200 beds
17)	Forensic Medicine	–	–	–	–	1	One per hospital of 500 beds
18)	General Duty Medical Officer	4	8	12	20	32	One GDMO for 12-15 beds

The norms for nursing personnel should be studied in Unit 3 of this block.

Table 1.2: Norms for Class 'D' Employees

Sl. No.	No. of beds in the Hospital	No. of Class 'D' employees suggested	Suggested Norms
1.	30-50	15-25	1 class 'D' per two beds;
2.	100	50	- do -
3.	200	100	- do -
4.	300	150	- do -
5.	500 and above	250	- do -

1.4 POLICY AND PROCEDURES

Policy: Every hospital has a definite hospital policy, though the basic policy of the hospital is to provide adequalc patient care, with available resources. However, certain policies differ from hospital to hospital. Various policies govern the functioning of the hospilal. Various committees or sub-committees are fonncd to form tlie policies and check the implementation of these policies. Various policies are drug policy, antibiotic policy, condemnation policy, procurement policy and other policies concerning the welfare of the patients.

Procedures: Knowing the policies of the hospital, various procedures are followed in providing inpatient care, Whcrcver the patient requires admission, it is given through out-patient department or casualty/emergency services. Once the patient is admitted, he has to make an Admission Card at the Central Registration Counter on admission. His/ her admission is recorded by a nurse. All tlie records of inpatient are written day to day. All the drugs given to tlie patient are entered and investigations performed are recorded, If any operative procedure is performed than an operation note is kept in the records along with anaesthesia record.

At the time of discharge, a discharge card is writtcn and given to the patient. The case paper along with all the records is kept in the Medical Records Department. In the event of death of the patient, a deatli summary is written and kept for tlie records, while a death report is given to the patient's relatives.

1.5 MANAGERIAL ISSUES

Day to day management of inpatient services is normally at two levels. At the medical level, implementation of the liospital policies is usually the responsibility of either the Doctors in-charge of the unit or tlie Medical Superintendent, But the specialists in-charge may leave much of the minutial of management to the sister-in-charge. It may also fall to her during the hours wlien the medical staff are not present. In such situations tlie principle of unity of command seems to have disappeared and there may well be a possibility of conflict arising with the sister-in-charge and from the Chief Nursing Officer. Clearly such problems can be anticipated and mutually satisfactory procedures and policies established to obviate them.

Another important issue in management of inpatient care services is the relationship with other departments. Because of the specialised and distinctive nature of the departments in the inpatient services, and the close contact with the medical staff, the senior nursing staff may come to regard themselves as being somewhat apart from the rest of the Department of Nursing, Valuable as espirit de corps is, the administrator may view this type of development with well foundcd suspicion.

Apart from the relationships with normal service departments of the hospital situations of conflict can arise. For example, in the obstetric ward, in the teaching of dietary information to expectant mothers for their pregnancy and for the care of their infants, confusion may arise as to the respective roles of the medical, nursing and dietary staff. By defining function and roles, the administrator can shape the management structure to avoid problems. The department of social work may also be involved with the work of the obstetric unit, dealing with some of the social problems of single mothers, adoptions and work related to problem families.

Management of inpatient services is defined as the optimum utilisation of the ward resources to produce maximum out put, namely, care and comfort of the patient. It is a specialised function performed by a group of doctors, nurses and other para-medical staff.

Ward Management

The objectives of inpatient services can be classified by the time spent and the tangibility of the objective. Patient care, treatment and early discharge will be short temi tangible objectives, while speciality treatment, personnel training and advancement will be long term objectives.

In case of intangible, short term will be patient comfort and rehabilitation, while long term will be image of efficient and effective speciality treatment centre. This should be in good co-ordination as the ward uses other resources from the hospital in addition to ward resources. Success of the ward depends on a number of intangible resources in addition to the ward infrastructure.

Main role in ward management is performed by the nursing unit. This nursing unit that forms the system in the ward ensures their proper implementation and performs its evaluation towards the care and comforts of the patients with full supervision. A nursing unit should be so designed that it can operate at minimum cost and can at the same time also achieve the functional goals of the ward. The person in-charge of a nursing care in the ward is called ward-sister or sister-in-charge.

The functions of ward-sister are:

- Good nursing care of the patient
- Carrying out instruction given by the doctor about medical care
- Supervise, guide and control the staff under her
- Proper orientation of the ward staff
- Evaluation of ward staff on a regular basis through systematic methods
- Proper management of ward with house keeping

Strategic Munagcmcnt

Wards need a strategic management. Nursing unit of the ward is responsible for giving strategic direction to a ward. Person in-charge of the ward should have over all perspective of the resources, constraints, objectives and plans of the hospital. There should be a definite image of the ward and the speciality treatment aimed for. The capacity, requirement of the personnel, medical and para-medical equipment should be determined. The standards of quality care of the patients must be set. There should be proper training of the ward personnel and should establish an evaluation system by patients to draw management's attention in areas where required.

Operational Management

Strategic management gives an anchor and direction, while operational management works towards this strategy. The objectives should be to provide comforts and good care to the patients, as a short term, while long term objective should be improvement and establishment of a system in the functioning of the ward.

1.6 MONITORING AND EVALUATION

Monitoring

Ward management is monitored by various methods. Nursing is a dynamic, therapeutic and educative process in meeting the health needs.

Various activities undertaken by the nurses are:

i) **Patient care:** providing adequate care to the patient.

ii) **Administration:** related to the direct process through which the unit functions.

iii) **Education:** it forms a part of the education programme for nursing students and other class of workers.

iv) **House keeping:** involves in maintenance of clean, safe and comfortable environment.

v) **Clerical:** involving maintenance of records and reports and giving routine information.

vi) **Maintenance of supplies and equipment:** involves replacement of equipment used and maintenance of supplies for carrying out unit activities.

vii) **Off-station: the** activities which take nurses away from the unit but have definite relationship to the patient or the unit.

Patient care is one of the important productive activities, which includes comfort, nutrition, needs, special care of the patient. It also includes preparing patient for procedures and follow up there after, carrying technical procedures, assisting technical procedures, health teaching, supporlive care, recording and collection, examination of specimens. By the effective control, nursing unit should be able to maintain discipline in the ward.

Ward-laboratory and Ward-pharmacy are attached to a ward. The management of this two important components increases the work. Investigations of the ward are done in the ward laboratory, while drugs distribution is done in the ward pharmacy.

House keeping gives first good impression about environment lo the patient. The person responsible for the function, should have knowledge of the activities concerned.

Efficient and effective monitoring of all the above activities will result in the better patient care in a hospital.

Evaluation

By quality of the inpatient care is meant by the degree of excellence of medical attention offered to the patients by a hospital. This quality will depend upon the efficiency of the hospital which in turn is influenced by many factors. In order to measure the quality standards should be available against which one product can be compared with another. The practice of medicine today has become very complex and multi-dimensional. It is provided by numerous categories of health personnel utilising a variety of equipment and is spread over a large physical area of activity, The administrator is responsible for monitoring this whole organisation of a wide spectrum of men and material into a functional effective machine. The product of this machine is the "service" or "medical care" provided by a hospital.

This product being tangible and depends on so many individually and collectively, does not lend itself to easily definable standards or to simple units of measurement. No rough and ready standards are available, which can be universally applied to directly measure the quality of hospital care. The evaluation of such care is, therefore, done indirectly by first examining the quality and adequacy of the factors and factors which contribute towards better patient care and secondly by analysing the medical care process of individual patients from the medical records maintained by the hospital, The latter method of judging the quality of medical care from medical records is called Medical Audit.

Factors Influencing Inpatient Care

i) **General:** There are a number of factors which contribute or influence the quality of hospital care. The presence or absence of these factors'or the extent to which a particular hospital tries to achieve better standards with regards to these factors will indirectly reflect the quality of hospital care.

ii) **Hospital staff:** Hospital care is provided by hospital staff. Their efficiency and proficiency will effect the patient care.

iii) **Education and training:** Continued education and in-service training of entire hospital staff will contribute to a large extent to better patient care.

iv) **Physical facilities and equipment:** Adequate space, good design and layout, clean and pleasant environment and availability of adequate equipment contributes greatly towards effective discharge of hospital functions, there by better hospital care.

v) **Clinical and service facilitics:** Availability of adequate and appropriate clinical facilities to take care of all type of clinical problems will improve the quality of medical care.

vi) **Effective** use **of beds:** Effective use of beds is a factor as well as a measure of the quality of care.

vii) **Quantum of work:** Load of work on a particular hospital affects the quality of carc and serves as an index for arrangement of rcsourccs.

viii) **Administration:** Proper administration and management of a hospital by trained and experienced administrators can contribute a lot towards improvement of quality of hospital carc.

Medical Audit

Medical audit is defined as the evaluation of medical care in retrospective through analysing of clinical rccords. The object of medical audit is to ultimately improve patient carc.

The evaluation of patient in-service or ward management is based on the performance, evaluation of the ward pcrsonncl. The Medical Supcrintcndent should provide with a detail mechanism of performance evaluation for efficiently achieving the ward objectives. Such evaluation procedures should bc performed with discharged patients. This will help in finding the deficiency and lack of services by the personnel and to improve in the near future.

Besides evaluation by the patient is very important. The assessment to be given by the patient should **be** based on nursing care, medical and investigative care of the patient, doctor-patient relationship, house keeping and any suggestion to improve the facilities and care with the rcsourccs.

1.7 LET US SUM UP

In this unit you have studied organisation, planning and management of inpatient services in a hospital. You have studied the functions of inpatient services. You have also learnt how physical facilities like location, size, shape and design, ancillary and auxiliary accommodation, and water supply could be organised in the inpatient services. You have also studied how medical and para-medical staff requirements could be planned for various sizes and levels of hospitals. You have also been able to know how the inpatient services should be managed in addition to policy and procedures involved in management. You have also studied the methods to monitor and evaluate the process of inpatient services.

UNIT 2 NURSING SERVICES ORGANISATION AND ADMINISTRATION

Structure

2.0 OBJECTIVES

After studying this unit, you will be able to:

- define the role of Nursing in the health care delivery system;
- identify the need for organisation, the staffing pattern and the duties connected with each appointment;
- identify the components of Administration i.e. Planning, Organising, Implementing and Evaluation, applicable to the nursing services; and
- effectively utilise the resources, facilities and services.

2.1 INTRODUCTION

In this unit you will learn about the brief history of nursing services, its role and functions, and the attrributes of a nurse, staffing and the duties involved.

A WHO Expert Committee on Nursing defines the Nursing Service as that part of the total health organisation which aims to satisfy the nursing needs of the community. The major objectives of the nursing services is to provide:

- the nursing care required for the prevention of disease and the promotion of health;
- the nursing care required in the interest of his mental and physical comfort, by reason of the disease from which he is suffering.

You are aware that nursing is only one part of the total care of the patient, and nursing activities must be co-ordinated with those carried out by other personnels, such as, doctor, social workers, technicians etc.

In this unit you will learn the role of nursing services, the skills and attributes of a nurse required for nursing care services and nursing activities. You will also learn the

importance and the place of nursing service in a health care organisation. For your guidance the job description of various appointments have been incorporated in this unit.

2.2 DEVELOPMENT OF NURSING AS A PROFESSION

The traditions in nursing stem from several sources. The earliest historical references to organised nursing services are based upon the work of the religious orders—heroic bands of sisters who dedicated their lives to personal and devoted service. Another source of nursing tradition has been the military influence.

Tribute must be paid to Florence Nightingale, pioneer in modem nursing and modern hospital administration. Some of her works, such as Notes on Nursing written in 1859, are as pertinent till day as at the time they were written. She was responsible for laying down the standards and started a school of nursing in 1860 in London. The advent of two world wars gave impetus to training of more nurses, and various schools were opened in all parts of the world. Indian history has many references to nursing. Lord Buddha in 500 B.C. created monasteries and hospitals and with that he established an order of nuns presumably for nursing in the hospitals. During the period 600 B.C. to 200 A.D., nursing had an important part in treatment of the sick, although the references are to males as nurses. A number of ancient Hindu medical treatises contain account of hospitals and of "attendants" (nurses). They give details of attributes of a good nurse. Notable among these are Charaka Samhita, Ashtanga Hridaya and the writing of Sushrata. Emperor Asoka built many hospitals and employed nurses. As per their writings, the nurses of those days should be proficient in cooking, in caring for bed patients and in other nursing procedures. Perhaps nursing schools existed even in those days.

Organised training for nurses in India can be said to have started in 1854 with the opening of a school for midwives at Madras. Soon schools for nurses training were opened in Calcutta (1859) and in Madras (1871). To cater for the demands of the Army during World War, Lady Reading Health School was opened in Delhi in 1918 to train nurses. Training of male nurses was also started during the early period of this century. In succeeding years, nursing schools were opened all over the country in collaboration with government and private hospitals. These schools generally followed the system which was in use in western countries at that time.

The next logical step in the development of nursing was the formation of trained Nurses Association in 1908 and passing of Nurses Registration Act in Madras in 1926. Soon various provinces except Assam formed Provincial Nursing Councils by 1939. Following Bhore Committee's recommendations in 1946, the Indian Nursing Council was formed in 1949 with the object of standardizing the training of nurses in India, and co-ordinating the efforts of various state councils so that there is an uniform policy for the whole country.

The need for a post basic training to improve the standards of nursing and also to prepare nurses for higher responsibilities requiring administrative skill was felt and a school was opened for that purpose in Delhi in 1943. This was later upgraded to a college. Similar colleges were opened in Madras and Vellore. In these institutions nurses are trained as tutors and as administrators. At present there are many colleges giving post basic training

2.3 ROLE OF NURSING SERVICE

One of the classic definitions of nursing, as formulated by Virginia Henderson (1966) delineates the unique function of the nurse as follows:

To assist the individual, sick or well, in the performance of those activities contributing to health or its recovery (or to peaceful death) that he would perform unaided if he had the necessary strength, will or knowledge. And to do this in such a way as to help him gain independence as rapidly as possible.

Professional nursing is changing and adapting to meet changing health needs and expectations. One such adaptation can be noted in the expanded role of the nurse. The nurse who functions in an expanded role provides direct care to patients through either

2.3 ROLE OF NURSING SERVICE

One of the classic definitions of nursing, as formulated by Virginia Henderson (1966) delineates the unique function of the nurse as follows:

To assist the individual, sick or well, in the performance of those activities contributing to health or its recovery (or to peaceful death) that he would perform unaided if he had the necessary strength, will or knowledge. And to do this in such a way as to help him gain independence as rapidly as possible.

Professional nursing is changing and adapting to meet changing health needs and expectations. One such adaptation can be noted in the expanded role of the nurse. The nurse who functions in an expanded role provides direct care to patients through either

independent practice, team or interdependent practice, or practice within a health care agency or with a physician. Specialisation had evolved within the expanded roles of nursing. Fundamental areas of functioning include practice, teaching, leadership and research.

However although each role carries specific responsibilities various aspects of each role interrelate with one another and are found in all nursing positions. Accomplishment of each of these roles is designed to meet the immediate and future health care and nursing needs of the patients who are the recipients of nursing care.

For your better comprehension the roles are briefly enumerated below:

2.3.1 General Role

- Round the clock nursing services
- Monitoring and coordinating nursing care
- Assisting other professionals in implementing their plans of care.

2.3.2 Specific Role

- Assess the patient care needs
- Plan and provide nursing care interventions
- Prevent complications and promote improvement in the patients comfort and well being
- Alert other care professionals to the patients condition
- Documentation.

2.3.3 Bole of Nurse Executive

- Participating with the organisation leaders in designing and providing patient care and services by allocating sufficient number of qualified nursing staff to care for the patients
- Ensuring continuous and tiinely availability of nursing services to patients
- Developing, presenting and managing the nursing services portion of budget
- Implementing the findings of current research into policies and procedures governing the provision of nursing care
- Measuring, assessing, and improving patient outcomes achieved through developing and implementing nursing standards of patient care and nursing standards of practice
- Organise continuing education programmes
- Assigning responsibility to individual or groups of nursing staff to take action to improve the nursing services performance.

The nurse executive has the authority and responsibility for establishing standards of nursing practice, and nursing policies and procedures and to coordinate and control the nursing service/care activities, through continuing education programmes and research.

2.4 FUNCTIONS, TASKS AND ACTIVITIES

Functions here broadly imply planning, leadership, co-ordination and control over all responsibilities as regards the provision of nursing care, in terms of quality, quantity, efficiency and effectiveness. The nursing care service functions are being described below.

2.4.1 Functions of Nursing Care Services

The functions involved in nursing care services include:

- The actual provision of nursing care services (all aspects) and treatment.
- The organisation and administration of nursing services.
- Education and practice.
- Quality control.
- Supervision.
- Provision for financial resources, and procuring materials and supplies, and for maintenance.
- The establishment of a communication system for nursing personnel, other health workers, patients, health authorities, government authorities and the public.
- Instruction in nursing and related subjects for students in formal programmes of education for the health services.
- Counselling for health personnel, patients and the public.
- The establishment of a system for the collection of essential information, research and studies concerning all aspects of nursing.
- The formulation of policies, standards and goals for nursing service, education and practice.

Operation of Nursing Care Services

In preparing for operation of the above functions for nursing care services, function must be clearly defined in terms of administrative process involved in the performance. For example in order to perform the function of quality control by means of supervision of nurses, you will need to define the objective of such supervision and to indicate the course of action to be taken (i.e. by whom, when, where and how the activities and tasks are to be carried out), the manner in which each action may be coordinated with other functions including those of other departments, and the manner in which supervision may be evaluated.

2.4.2 Nursing Activities

You must be remembering that functions are a group of activities with a common purpose. In operationalisation of the identified functions, therefore, you as administrator must define the activities involved in the performance of various functions for which nursing is responsible, in collaboration with planners of other components of health services.

It is particularly important for nurses to take initiative in this. If quality control by means of supervision is once again used as an example of a function the activities that will be involved include:

- The planning and coordination of programme of supervision and consultation to meet staff needs.
- The planning of education and training programmes including in-service training.
- The professional supervision of nursing personnel individually or in groups.
- Counselling in the field of professional development and the development of suitable areas for clinical practice and community health experience.

Following are other examples of activities involved in nursing care functions:

- Family health counselling and teaching.
- Assistance with medical treatment or physical examination on patients.

- Referral of individuals and families to the source of care.
- Follow up nursing care.
- Specialised nursing care.
- Rehabilitation and preparation of data relating to nursing needs and resources.

Because of the total health care concept and a multi disciplinary approach to the care of individuals, families and communities, it is difficult to define the scope of activities of each profession represented in the health team.

In some situations the activities of doctors and nurses and social workers will overlap. For example taking history of a patient may be performed by doctors, nurses and social workers etc.

2.4.3 Nursing Tasks

Any activity can be divided into units of work or tasks that can be further subdivided into a series of small steps — the kinds of skills involved in each task by defining the steps to be taken, the equipment to be used and the environment in which the task will be performed, and other relevant information being taken into account.

— In this way tasks can be classified in an order ranging from the simplest to the most complex.

This classification will help nurses to determine the category and grade of nursing personnel required for each task. Decisions in this respect will again depend on the availability, cost and effectiveness of each category of nursing personnel under consideration.

Nursing tasks include:

a) Those performed on the patient e.g. taking blood pressure, temperature and pulse.

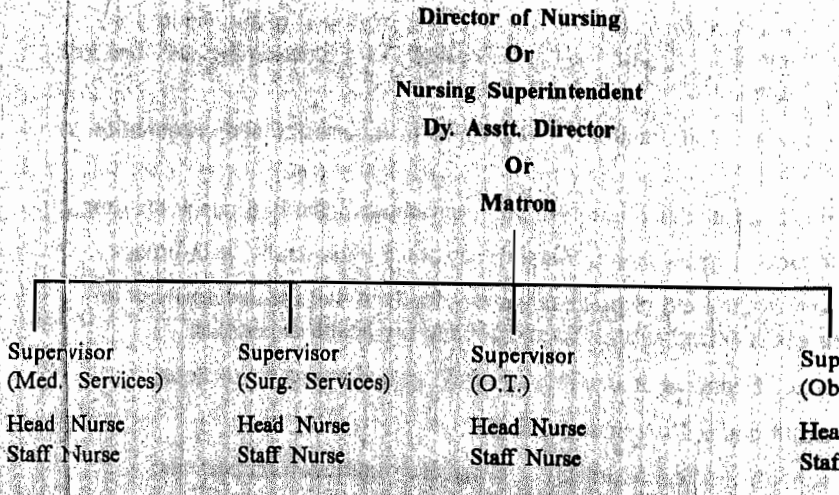
b) Those performed in the presence of the patient, e.g., observing his physical condition and behaviour, listening and talking to him and determining his needs.

c) All other tasks having a bearing on the care and welfare of patient, but not performed in his presence, e.g., preparing his medication, carrying out tests and establishing a plan of care.

2.5 ORGANISATION

You have already learnt that administration makes its greatest contribution in second managerial function i.e. organising. Planning paves the way for organising so that staff can accomplish the plans with efficiency and effectiveness. You also know that organising involves establishing a formal structure that provides the grouping and coordination of resources to accomplish objectives, establish policies and procedures, and determine position, qualifications and descriptions. Organising involves developing an intentional structure of roles for effective performance. Organising requires a network of decision and communication system for coordinating efforts towards a common goal.

The organisation of the nursing services of a general hospital may be drawn as under:



It will be seen from above that the work of the various nursing units in a service is coordinated by a supervisor and the general coordination is effected by the nursing superintendent through her deputy. In case of a teaching hospital, there may be a chief instructor who may be functioning under the Nursing Superintendent or independently with same status, depending on the size of the school.

The appointment of one person as supervisor of a service is followed mostly in advanced countries, with a view to relieving the nursing staff from a lot of administrative duties. In USA the trend is to appoint unit managers for each nursing unit, so that the sister-in-charge of the unit is free to concentrate on purely nursing duties. These unit managers look after the administration of the units and their work in turn is coordinated by service supervisors.

The idea of appointing supervisor for each service has not taken root in our country, possibly due to paucity of funds and shortage of nurses. In some of the Delhi Hospitals, there is a system of appointing supervisors in the rank of Assistant Matrons. The question of appointing floor supervisors is receiving consideration.

2.6 JOB DESCRIPTION OF NURSING SUPERINTENDENT AND DEPUTY NURSING SUPERINTENDENT

2.6.1 Nursing Superintendents

Qualifications

Master in Nursing (with any speciality) with 6 years experience of which 3 years in administration.

or

Post Basic B.Sc. Nursing with 3 years experience in any position.

or

Basic B.Sc. Nursing with 10 years total professional experience.

or

R.N., R.M. with Diploma in Hospital Administration preferable with 10 years experience in administration.

Line of Authority

The Nursing Superintendent is responsible to the Medical Superintendent. The Deputy Nursing Superintendent (in hospitals with less than 150 beds) is responsible to the Medical Superintendent. In hospitals where the post of Nursing Superintendent exists, the Deputy Nursing Superintendent will be responsible to the Nursing Superintendent.

Duties and Responsibilities

In hospital where posts of Nursing Superintendent and Deputy Nursing Superintendent both are available the two share the following duties and responsibilities. Where no post of Nursing Superintendent is in existence, the Deputy Nursing Superintendent shall carry out the duties and responsibilities along with the Asst. Nursing Superintendent.

The main thrust of the duty of the Nursing Superintendent and Deputy Nursing Superintendent is the smooth management of the Nursing Services in the hospital at all times and every time.

She/he shall be responsible for:

1) Planning and Organising Services in Hospital:
   - a) Preparing a philosophy and objectives for the nursing department in accordance with those of the hospital.
   - b) To see that all service areas are managed as per their needs.
   - c) Utilising specially trained nurses in that particular area only, i.e., psychiatry, paediatrics.
   - d) Planning and putting up of proposals to the authorities for increase of staff in different categories so as to fulfil the INC recommendations.
   - e) Co-operating with the authorities during emergencies in setting up special nursing squads, wards or any other machinery as required.
   - f) Preparing an organisational chart showing channels of communications.
2) General Administration:
   - a) Framing Personnel policies, keeping within the framework of government rules and regulations.
   - b) Interpreting and implementing policies of the Governing Body, the hospital and the Indian Nursing Council.
   - c) Carrying out correspondence with the hospital with nurses and others.
   - d) Attending to the correspondence from outside agencies and individuals.
   - e) Submitting proposals for special equipment required for Nursing Services giving specification.
   - f) Conducting rounds of Ward and Departments.
   - g) Preparing job descriptions where none are available and seeing that each staff member gets one.
   - h) Investigating complaints, preparing reports and taking disciplinary action or recommending the same.
   - i) Preparing annual statistics, and projecting manpower needs.
   - j) Handling grievances and solving problems frequently.
   - k) Holding Departmental meetings allowing free exchange of ideas and reviewing Ward staffing.
   - l) Guiding subordinates and delegating powers depending upon the person's ability to carry the responsibilities along with commensurate authority.
   - m) To see that ward procedure manual (Nursing Procedure) is maintained in all wards.

n) Sanctioning or recommending leave to Nursing personnel.

o) Maintaining individual and cumulative leave records of all Nursing staff.

p) Writing reports — confidential reports of Nursing staff, annual report of the Nursing department, depicting achievements, future plans of expansion — incidented report whenever required — any other report that may be required to be submitted.

q) Reading and analysing daily reports on hospital situation e.g. admission, discharges etc. in order to re-plan posting or submit reports to higher authority.

r) Making of a routine to have 6 monthly or yearly health checkup for all nurses and 6 weekly for those working in Tuberculosis department, to enable adjustment in duty schedule, if found necessary.

s) Taking an active interest in staff development through:

   i) Orientation programme for new staff.

   ii) In service education programme.

   iii) Encouraging and recommending interested nurses to get further training and higher education.

   iv) Performance: evaluation and guidance to those needing it.

   v) Experimenting with newer duty and staffing patterns.

3) Miscellaneous:

   a) Giving leadership to the Nursing department.

   b) Encouraging Nursing personnel to become members of the professional Association.

   c) Participating in meeting, workshop, seminars of local, State or National level and representing the profession.

   d) Providing counselling services to Nursing personnel.

   e) Carrying research or co-operating with others who may be doing it.

   f) Any other activity concerned with the profession.

2.6.2 Assistant Nursing Superintendents

Qualification

R.N.R.M./B.Sc. Nursing with 5 years experience as Ward Incharge

Line of Authority

The Assistant Nursing Superintendent is directly responsible to the Deputy Nursing Superintendent and the Nursing Superintendent. In hospitals where the Asstt. Nursing Superintendent is the only post, she/he becomes directly responsible to the Medical Superintendent.

Duties and Responsibilities

The main objective of the duties is to provide for good Nursing care to patients through proper Nursing services management.

a) In hospitals where she/he is working under the Deputy Nursing Superintendent and the Nursing Superintendent her/his work will be mainly to supervise wards and departments.

b) To help the ward incharge with solving problems.

c) To see that enough Nursing staff is available in all wards throughout the day.

d) To help newly appointed/promoted ward incharge to arrange duties, get indents and establish good inter personal relations with other Nursin staff, laboratory workers, physio-therapist, X-ray technicians, Doctors, linen keeper etc.

e) Arrange duty relation for Nursing personnel in consultation with the Deputy Nursing Superintendent.

f) Help Nursing Superintendent and Tutors with in-service education programmes.

g) Take rounds of the wards and departments and report anything requiring attention.

h) See that registers are maintained in each ward as required.

i) Check to see that treatment is carried out as prescribed.

j) Check day, evening and night report books.

k) Maintain the whole hospital statistics and submit the authorities whenever required.

l) Check duty assignment books in each ward as required.

m) Check drug cabinets and medicine cupboards occasionally.

n) Act as liaison between the hospital and public.

o) Perform any other duty assigned by the Nursing Superintendent.

In the hospital where there is only the Assistant Nursing Superintendent (Asstt. Matron) post, she shall carry the job description as listed under the title Nursing Superintendent.

2.6.3 Job Description of Ward-incharge (Sister)

Qualification

a) Registered Nurse, Registered Midwife, with 7 years experience as a staff Nurse.

or

b) Registered Nurse, Registered Midwife with Diploma in Ward Administration and 6 years experience as a staff Nurse.

c) B.Sc. Nursing (Basic or post Basic) with 5 years experience as a staff Nurse.

d) She/he must be registered with the State Nursing Council.

Ratio

- sister for every 25 beds for Medical-Surgical-Paediatric wards
- for each shift in ICU, CCU, Labour Room and Operation Theatre
- overall for OPD
- for Gynae. OPD

Casualty and Emergency	1 for each shift
Leave reserve	30%

Line of Authority

The ward incharge is directly responsible to:

a) The Departmental Supervisor or Floor Supervisor where such a post exists.

b) The Nursing Superintendent (Matron) where the above post do not exist.

Duties and Responsibilities

1) ***Administrative and Supervisory***

The ward incharge is responsible for the smooth running of the ward. This she can attain by:

a) Distributing ward duties to staff nurses, students and servants.

b) Making plans for recognization of ward and maintaining discipline.

c) Maintaining supplies.

d) Giving and receiving nursing reports of day and night duty nurses.

e) Writing report and orders.

f) Keeping custody of dangerous drugs and records of its administration.

g) Writing confidential report of Staff Nurses.

h) Reporting to the immediate authority any incident of importance relating to ward staff.

i) Maintaining good relations with all categories of hospital personnel.

j) Writing out the weekly duty schedule.

k) Reporting to the concerned authorities emergencies, accidents or deaths.

l) Maintaining a clear record of admissions and discharges of patients.

m) Supervising the general cleanliness of the ward and sanitory annexe.

n) Delegating to the other ward staff such work that she/he can do.

o) Supervising the laundry work.

p) Holding meetings with ward staff to work out difficulties.

2) *Nursing Care*

As the person incharge of the ward she/he is responsible for carrying out patient care with such devotion to help the hospital achieve its goal.

a) Total care of patient: she/he must know the patient's physical condition and any special nursing problems.

b) Seeing that the doctors orders are carried out.

c) She/he must not allow any nursing personnel to give I/V fluids, blood transfusion or take blood sample for investigation.

d) Seeing that the patients get good nursing care, and that the necessary observation and recording is done in each case.

e) Seeing that medications, dressings, nursing procedure, investigations and other treatment are carried out.

f) She/he must observe and report patients condition to doctors when they come on rounds.

g) She/he must prepare for ward rounds and accompany the head of the unit on rounds and bring to the doctor's attention any point of importance.

h) Seeing that the preparations for transportation of patients to Operation Theatre and other departments are done properly.

i) Varifying the patients coming from OPD of other departments for admission to that particular department only and that the papers of the patient are in order without which the patient should not be admitted.

j) She/he acts liaison between the hospital and the community.

3) **Teaching**

The ward incharge is also responsible for the eduational aspects — both for the Nursing students and ward staff.

He/she is responsible to see that:

a) The nursing students are helped in understanding the patients illness and type of care that is to be given. This can be done by having bed-side clinic, ward clinics or conferences.

b) The nursing students are taught the procedure they are required to perform. In case the student does not know the procedure the sister can herself teach or give the work to the senior students or the staff nurse. A student who does not know a procedure should not be left on her own. If something goes wrong the ward incharge will be responsible.

c) The procedure of patient care is carried out properly and all required articles, material are provided. It would help to have a procedure manual in each ward.

d) She co-operates with the tutors in teaching by assigning work to students according to their educational level (PTS, 1st year, 2nd year, 3rd year) by arranging clinical teaching, informing the nursing tutors about any patients admitted with special type of disease.

e) Practical work is supervised. Health talks are given as per schedules.

f) Students are taught how to handle sputum mugs, kidney trays, urinals, bed pans and soiled linen and dressings, they are also taught lifting and moving patients.

g) Plans and implements orientation programme for new staff.

h) He/she participates in in-service education programmes and encourage other nursing staff to do likewise.

i) She encourages staff nurses to take up higher studies.

j) Participates in research studies and cooperates with those nurses who may like to carry out research studies.

2.6.4 Job Description of Staff Nurse

Qualification

General Nursing and Midwifery (alternative courses for Male students) or the new general programme or Basic B.Sc. Nursing from a recognised university.

Ratio—Staff Nurses and Nursing Sister

	Department	Nursing Sister	Staff Nurse
1.	General Medical and Surgical Ward	1 for 25 beds	1 for 3 beds
2.	ICU, ICCU and other Special Wards	1 for each shift	1 for each bed per shift
3.	Labour Room	1 for each shift	4 for each shift
4.	O.T.	1 for each shift	3 per table per shift
5.	Obs. & Gynae	1 overall 1 for Gynae OPD	1 for each room of department
6.	Out-patient Department	1 for the OPD	Actual needs
7.	Paediatrics	1 each shift	1 for two beds
8.	Casualty and Emergency	1 for each shift	2-3 per shift depending on No./No. of Admissions
9.	Leave Reserve	30% in all categories Note: Norms vary from time to time	

Job Specification

The staff nurse is the second in nursing hierarchy in the ward, who works under the instructions of the ward-in-chief.

Her duties and responsibilities can be divided as under:

Administrative

a) Help the Ward Incharge to carry out her work.

b) Work in place of the Ward Incharge in his/her absence.

c) Maintain general cleanliness of the ward and the sanitary annexe.

d) Write the diet register and supervise distribution of diet. See that special diets are served and eaten by the patient.

e) Maintain poison/(scheduled) drugs registers.

f) Supervise medicine given by students or do it herself in case there are no students.

g) Supervise nursing care being given by nursing student.

h) Maintain emergency trays and other duty room trays, sterilizer, instruments in working conduction by getting indents from sister or getting repairs done in case of a break down.

i) Maintain good inter-personal relations with all other staff.

j) Maintain all procedure trays in readiness.

Nursing Care

a) Take over from previous duty nurse all new and serious patients, instruments, supplies, drugs, etc.

b) Make beds of serious patients and help students make beds, supplying necessary linen.

c) Administer injections/tablets or liquid medicines requiring care in giving e.g. oily medications.

d) Prepare patients for operations and see that he/she is sent to operation theatre with all necessary papers and medications.

e) Get patients clothes and bed linen changed as and when necessary.

f) Take rounds with doctors when called to list new orders and see they are carried out.

g) See that all investigation specimens are sent to the proper laboratory with forms.

h) Insist that the unit doctors prepare and sign the forms. Filling up the forms is not the duty of the staff nurse.

i) Keep I/V or Blood transfusion tray ready and help the doctor with the procedure.

A Staff Nurse is not allowed to give I/V infusions or Blood Transfusion.

j) Observe all patients conditions and report changes to ward incharge and/or the doctor.

k) Carry out nursing procedure for all serious patients. Help newly posted students, PTS students to carry out their nursing procedures.

l) Check on every new admission. Before admitting the patients all his papers must be in order. This is specially when a patient is transferred to your ward from another department.

m) Read case papers properly and carry out orders and see that they are carried out.

n) Give expert bed-side nursing care to serious patients.

o) Maintain case papers, investigation reports, etc. in the proper file or board. See that all reports get attached to the correct case paper, temperature charts and in take output charts or any special chart are maintained. Case papers should not be allowed to be handled by anyone except the doctor in-charge of the patient. This is specially for medico legal cases.

p) Write day and night orders and maintain ward statistics.

q) Talk to pre operative patients to reduce their tension and give them confidence.

r) Listen to patients problems and help to solve them through various means.

s) See that a discharged patient goes home with proper understanding of the follow up procedure and details of the diet and medication exercises etc.

t) Inform doctor in case of a patient dying during your duty time. All concerned records, reports must be completed and handed over to the next shift staff nurse.

u) In special areas carry out duties which required expert handling e.g.:

i) Labour Room	Difficult and abnormal deliveries. Premature baby care.
ii) Operation Theatre	Care of instruments and gloves. See to sterilization Trays and Trolleys.
iii) Mental Hospital	Prepare patient for ECT and assisting doctor with it. Care of mentally retarded (where such a Unit exists)
iv) ICCU	Total patients care, helping with ECG or any other investigative procedure.

Teaching

a) Instruct students in their work, and orient newly posted students.

b) Carry out health teaching for individual or group of patients.

c) Instruct students specially the newly appointed ones in the correct ways of handling bed pans, urinals, sputum cups, kidney trays, soiled dressings, bandages, binders, linen.

d) Provide for and demonstrate methods of dis-infection and cleaning.

2.7 STAFFING PATTERN

Staffing is the third managerial function. Having planned and organised, the manager must now staff to accomplish the goals of the organisation. Staffing involves the

selection of personnel and assignment systems and the determination of staffing schedules. There are many variables to be considered when planning for staffing. The more accurate the assessment, the higher the probability of containing costs while providing high quality care.

The nursing care of patients in hospital depends on the numbers and quality of nursing personnel on duty at all times of the day and night. The number of nurses required to man the nursing services in a hospital, depends on many factors, some of them are:

a) Number of beds in a hospital.

b) The type of hospital and the prevailing medical practice, including kinds of treatment and medications given, and tests and services required for the patients.

c) The design and layout of the hospital compact or spread out, and the type of physical facilities provided (single layout beds or multiple bed).

d) Pattern of assignment of nurses — based on functional method, case method or team method.

e) The type and the number of emergency cases coming into the hospital.

f) Available labour saving devices; automation, mechanization — centralization.

The staffing depends on the time spent by nurse on the patient. The work load to be undertaken in caring for patients may be considered from three points of view:

The quality of nursing, the characteristics of the patients and the schedule of nursing care.

Extensive research has been done to ascertain the average number of hours a patient needs nursing care in a hospital. It has been worked out that average number of bedside nursing hours required per patient in 24 hours is as under:

			Hours of Care
a)	Medical/Surgical and Mixed Ward	—	3.2
b)	Maternity Ward	—	2.3
c)	Neonatal Ward	—	5.5
d)	Children's Ward	—	4.3
e)	Communicable Diseases Ward	—	4.7
f)	Private Patients: i) Mixed	—	5.4
	ii) Maternity	—	6.5

Every hospital has to work out its own need based on the above factors. According to the recommendations of the Nursing Committee set up by Ministry of Health, Government of India (Shetty Committee), the ratio of nurses to patients in a hospital should be 1:3 in hospitals where nursing training is imparted. Other hospitals should have a rate of 1:5. These figures do not include teaching and administrative staff and staff for special departments which are to be provided in addition.

The Master Staffing Pattern

Making the Staffing Pattern for the nursing service of the whole hospital is relatively a simple task once the staffing patterns for each ward have been provided. The selection of categories and the number of personnel needed for each category are decisions made by the Director of nursing service, with the help of her assistants, Supervisors and head nurses.

The development of Master Staffing Pattern based upon a study of the needs of patients and availability of personnel should result in a sound, realistic, reasonable and understandable plan. Studies in some general hospital, however, indicate that the effective ratio for their particular need is one professional nurse to two auxiliary nurses.

Shortage and Turnover

Shortage of nurse is an old problem existing the world over. This is partly due to the rapid expansion of medical care programmes and the general lack of understanding on the part of the public about the duties and responsibilities of the nurses.

Connected with shortage is the problem of turnover of nurses. By turnover is meant the replacement of trained nurse due to her resigning or getting out of service. In a survey

conducted in Chaster Hospital (USA) over a period of 4 years it was found that 55.8% of resignations were due to personal reasons like change of town, domestic reasons and so on; and 44.2% due to factors related to the job. It is here in the later group that the hospital can reduce the turn over by using better man management techniques. Some of the major reasons related to job are given below:

a) Lack of Job Satisfaction

b) Inadequate Supervision

c) Maladjustment with Fellow Employees

d) Poor Personnel Policies

e) Other Job Opportunities, Incentives, Promotion etc.

2.8 LET US SUM UP

In this unit you have learnt that the nursing services play a very crucial role in the health care delivery system. The role of nursing service towards patients and the community has similar responsibilities as the medical service, and the need for close co-ordination between the doctor and the nurse and the other health workers is essential to maintain quality of care and patient satisfaction.

You have also learnt about the duties and responsibilities attached to the nursing staff and their vital role in the organisation to achieve the objective of patient care. Shortage of Nursing is an old problem existing world over. Nevertheless, there is a need to reduce the turn over by appropriate use of management techniques and improvement in the working environment.

1) a) Nursing Superintendent to Medical Superintendent
   b) Dy. Nursing Superintendent (DNS) to Medical Superintendent in hospitals less than 150 beds. DNS to Nursing Superintendent where the later post exists.

2) a) 1:25 beds for general wards
   b) 1 for each shift for ICU, CCU, Labour Room, OT, Casualty & Emergency
   c) 1 overall for OPD; 1 for Gynae. OPD
   d) 30% leave reserve

3) a) Number of beds, type and clinical services available
   b) Design and layout of hospital
   c) Pattern of assignment of nurses
   d) Patient load-type and number of emergency cases
   e) Labour saving devices available.

4) a) Personal reasons — change of place, domestic
   b) Job related — such as:
   Lack of job satisfaction
   Lack of supervision
   Maladjustment with staff, work culture
   Poor personnel policies
   Lack of incentives, opportunities, promotions.

UNIT 3 WARD MANAGEMENT AND NURSING CARE

Structure

3.0 OBJECTIVES

After studying this unit, you will be able to:

- explain the concept of Ward Management and Nursing Care;
- define the nursing needs of patients;
- enumerate the nursing service of department and organisation of units;
- list the nursing care methods;
- describe the management of ward personnel, patient and attendant; and
- describe nursing records and nursing audit.

3.1 INTRODUCTION

In the preceding unit, you have learnt nursing services and organisation. In this unit you will learn about ward management and nursing care. You shall learn the concept of ward management. You shall also learn the nursing needs of patients, how wards/units are organised and managed. You shall also learn various nursing care methods. It shall also be possible to learn how to manage patients and attendants, how to perform functions of coordination and counselling. You shall also study nursing records and nursing audit.

3.2 CONCEPT OF WARD MANAGEMENT AND NURSING CARE

The nursing care was considered as an art and vocation. Now ward management and nursing care is considered a scientific profession which is an important part of total hospital management and it is very much demanded for the care providing at the level of high technological areas of the health care organisation such as Operation Theatre and ICU. The nursing care required for the prevention of disease and promotion of health, it also required a) In the interest of the physical and mental comfort of the patient b) By reason of the disease from which the person is suffering. As nursing is only one part of the total health care of the patient, the nursing activities must be

- describe the management of ward personnel, patient and attendant; and
- describe nursing records and nursing audit,

3.1 INTRODUCTION

In the preceding unit, you have learnt nursing services and organisation. In this unit you will learn about ward management and nursing care. You shall learn the concept of ward management. You shall also learn the nursing needs of patients, how wardslunits are organised and managed. You shall also learn various nursing care methods. It shall also be possible to learn how to manage patients and attendants, how to perform functions of coordination and counselling. You shall also study nursing records and nursing audil.

3.2 CONCEPT OF WARD MANAGEMENT AND NURSING CARE

The nursing care was considered as an art and vocation. Now ward management and nursing care is considered a scientific profession which is an important part of total hospital management and it is very much demanded for the care providing at the level of high technological areas of the health care organisation such as Operation Theatre and ICU. The nursing care required for the prevention of disease and promotion of health, it also required a) In the interest of the physical and mental comfort of the patient b) By reason of the disease from which the person is suffering. As nursing is only one part of the total health care of the patient, the nursing activities must be

coordinated with those carried on by workers such as doctor, social worker and others. A distinction is sometimes made between the terms nursing care and nursing services. Nursing care refers to the care of patient with specific regard to nursing, while the term nursing service/ward management refers to the coordinating responsibility of the nurse who in addition to giving nursing care also works with the members of allied disciplines. In recent years, increased emphasis has been given lo the administration/ ward management in nursing services as a result of increased scope of activities related to hospital services other than the true nursing, e.g., supervision of food, care and distribution of linen and compilation of reports and maintenance of patient records. With the ever increasing dimension of medical sciences quantitatively and qualitatively, nursing care is becoming more and more complex with its management services and the services provided for the patient care scienlifically based on needs of the patients/ community,

Florence Nightingale, the pioneer in modern nursing and modern hospital administration is the first nurse executive to start the concept of modern nursing care/ intensive nursing care (ICU care). She also recognized medical administration a tool for improving medical care in civilian hospitals. She was responsible for laying down nursing standards and started a school of nursing in 1860 for providing the training to the nurses. The Indian history has also had many advents. Lord Buddha in 500 B.C. created monasteries and hospitals where running by deploying the monks for nursing the sick patients. Emperor Ashoka built many hospitals and employed nurses for the care of the sick. During this time there were no special training for the nurses but they were selected on the basis of the fact that they should be good in cooking and taking care of the patients and experts in various nursing procedures.

Definition of Nursing Cnre

WHO expert committee on define the nursing as "the conscious practice of human relationships. It is clear that nurses must keep alert to observe the needs of their patients as individual human beings."

Nursing as per the WHO definition is the part of total health organisation which lo satisfy the nursing needs of the community, organisation of nursing service is a complex process which helps the institution to stand on its own.

Nursing care is defined as the care of the patient with the specific regard to nursing.

3.3 NURSING NEEDS OF PATIENT

The plan for the care of a patient in the hospital begins with the plan made by the physician for medical care. The plan for nursing care begins when the patient is admitted to the ward. An analysis of the nursing needs of the patient necessarily includes consideration of the plan for medical care, and the facilities for patient care provided by the hospital.

The patient being the central figure, his needs are paramount:

a) First need is an accurate assessment of his illness in as short a time as possible with least disturbance to him.

b) The second need is the appropriate and effective action in accordance with the assessment of his condition.

c) The third need is to provide him the maximum degree of comfort and happiness by way of pleasant surrounding and service by people attending on him.

d) The fourth need is to prepare him for return to the society completely cured or with such supportive therapy as needed.

3.4 NURSING SERVICE DEPARTMENT/UNIT

The nursing services must be under the direction of competent leader i.e., Chief Nursing Officer/Director of Nursing Service/Nursing Superintendent who is responsible to the hospital administration for the programme and activities of the nursing care of the patient. The Chief Nursing Officer/Nursing Director/Nursing Superintendent has dual role of responsibility. In addition to nursing administrative responsibility to the hospital

administration she has the role of coordinating professional activities of nursing staff with those of medical staff. She has also the responsibility of entire nursing service as well as the patient care services. In the ward/unit the ward incharge/Sr. incharge ANS is the key person.

In the hospitals, nursing care is broadly classified into general wards, speciality wards and intensive care units, casually or emergency unit, ambulatory care unit and operation theatres unit. In general wards one can ensure sufficient nursing care by segregating patients according to the categories (according lo the sickness of the patients).

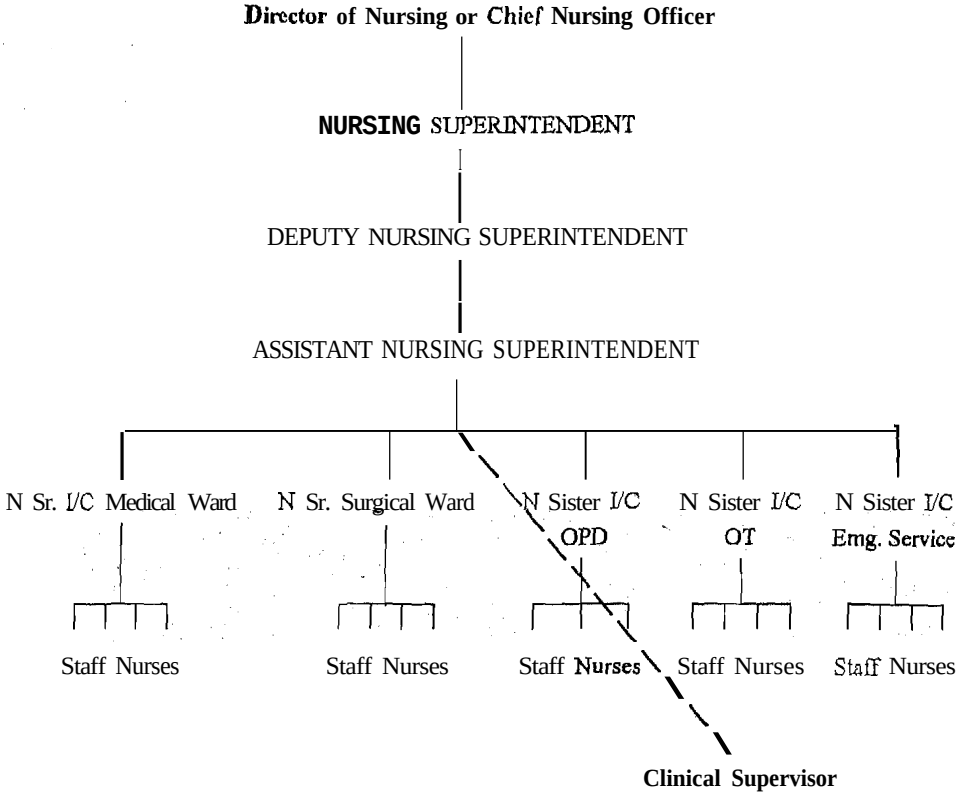
3.5 ORGANISATION AND MANAGEMENT OF UNITS

There are two accepted types of organisation in the nursing services, which run parallel to each other. They are the Line and Functional Organisation about which you have learnt in the earlier unit.

You will recall that in the Line organisation the Director of Nursing or Chief Nursing Officer or the Nursing Superintendent is responsible for the selection/recruitment, appointment, training and deployment of nurses in various areas. The post of Chief Nursing Officer (CNO) was created in 1992 and filled by all central govenunent hospitals as well as undertaking e.g. All India Institute of Medical Sciences, New Delhi. There are other nursing administrators like Nursing Superintendent, Deputy Nursing Superintendent and Assistant Nursing Superintendent who have direct control over the nurses activities. In the functional organisations the nurse takes the instructions from the physicians so far as the medical care of the patient is concerned. The physician, however is not authorized to act or take the action against the nursing personnel for the nursing activities. If a nurse does not perform her duties, she should refer the matter to the nursing in-charge whose responsibility is to deal with such' matters. The physician, however is not authorized to act in the line organizational manner. Effective coordination and cooperation is ensured for the proper functioning of dual activities. Normally there is no conflict but controversy exists whether the nurse should be counted

as an assistant to the physician or from her background knowledge and training she should plan nursing care independently within the framework of the physicians policy. More and more emphasis is laid on the coordinating member of the team, coordinating the orders of the physician and the work of the other services to achieve efficient patient care based on the above lines, the organisation of the nursing service of a general hospital may be drawn as under: (In this Diagram both the Line and Functional/Staff authority has been showned.



It could be seen that the work of the various nursing units/wards in a service is coordinated by a supervisor (Ward Sister, Assistant Nursing Superintendent, Deputy Nursing Superintendent) and the general coordination is affected by the Nursing Superintendent/Chief Nursing Officer through her deputy. In case of a teaching hospital there may be an inservice education coordinator or instructor who may be functioning. under the Nursing Superintendent/Chief Nursing Officer or independently with same status depending on the policy of the hospital and the size of the school/nursing college. The appointment of one person as supervisor of a service is followed mostly in advanced countries, with a view to relieving the nursing staff from a lot of administrative duties. In USA the trend is to appoint unit managers for each nursing unit, in England the trend is to appoint a clinical manager for each unit, in India in All India Institute of Medical Sciences there is an Assistant Nursing Superintendent posted in each ward, so that the sister in-charge of the unit is free to concentrate on purely nursing duties. These unit managers look after the administration of the units and their work in turn is coordinated by service supervisors.

The idea of appointing supervisor for each service has not taken root in our country except in AIIMS, New Delhi, possibly due to paucity of funds and shortage of nursing personnel. In some of the Delhi hospitals there is a system of appointing floor supervisors in the rank of Assistant Nursing Superintendent (assistant matron). In Safdurjung Hospital and Ram Manohar Lohiya Hospital, New Delhi the question of appointing floor supervisors is receiving consideration.

Objective of Nursing in the Ward/Unit

While providing nursing care in the ward/unit a nurse must always be able to:

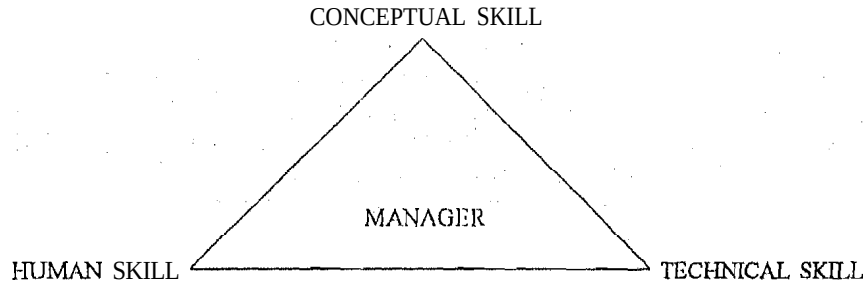
1) Maximum comfort and happiness to the patient by way of pleasant surroundings.
2) Qualitative/Comprehensive care to the patient.
3) Care based on the patients need.

4) Accurate assessment of illness.
5) Adequate material resources at all the times.
6) Health cducntion to the patient and attendants.
7) Managerial skills as and when required,
8) Privacy at all levels.

Management in the Ward

Management defined in a simple language is to get the work done in a systematic way for accomplishment of defined objectives based on management of Man, Money and Materials. Management gives us the clue to how Io get best possible services and how to make the ward administration successful and fruitful. It is also said that management is a process by which a cooperative group directs action towards common goals.

Ward management is facilitated by the development of systematic procedures for dealing with the details of ward administration by adoption of a system of day-to-day tasks. While managing a ward/unit the manager has lo apply various managerial skills which differ as per the level of the management. These can be shown diagrammatically as under.



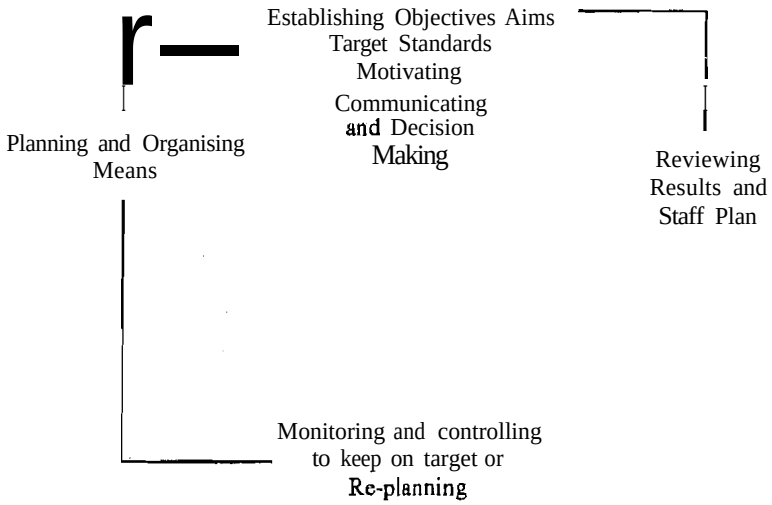
A diagram of the application of managerial process has been drawn in the next page to its application as per the level of nurse managers.

For an effective management, a Nurse Manager must apply the managerial skills.

Though the above mentioned skills are needed in all levels of nursing management, to provide the effective nursing care to the patient by a nurse manager in the ward/unit, but the use of them vary as per the level of the managerial role of the nursing personnel, according to their category.

At the top level, the nurse manager, the Chief Nursing Officer/Nursing Superintendent has to apply the conceptual skill for planning the nursing service, nursing man power, and to make the decisions of various aspects of nursing. It is the top level of nursing where the Nurse manager has lo play the role in planning, policy making, liasoning, co-ordinating, and controlling for these the conceptual skill is needed. In the middle level the nurse manager, the Deputy Nursing Superintendent/Assistant Nursing Superintendent has to apply the human skill as well as the conceptual skill to manage his/her unit effectively. As she/he has to keep coordination with various departments for the day-to-day management of the unit and has to plan the nursing care as well as to take some decisions to solve various problems at her own level. Being a middle level manager the nurse manager has to ploy a crucial role in the midline supervision by liasoning, and co-ordinating with the various departments for smoothening of work and strive professional growth. For this she/he needs to apply the human skill as well as the conceptual skill. Besides this the middle level nurse manager has lo apply the technical skill also.

At the base level of the management the ward sisters and the staff nurses are responsible to provide the total/comprehensive care to the patients of their respective unit. For this they have to apply the technical skills mainly though they have also to apply the human skill to manage the patient care services effectively. The base level/core level nurse manager is responsible for direct and total patient care.



The nurse manager has to apply the whole management process while managing the ward/unit and to follow these main four steps mentioned above for an effective management of her/his ward. These steps are to be followed in a cycling way as they are related to each other. In every step the monitoring, controlling, and the reviewing must be done to get an effective result and to avoid/minimise the errors which may be cost effective as well as time effective also. Special care should be taken in the step of planning which is a crucial and most important step of whole management process.

.....

Management of Nursing Personnel

The nursing care of patient in hospital fully depends upon the number and the quality of nursing personnel on duty at all times of the day and night.

The following factors should be considered before planning the nursing manpower.

1) Number of beds in a hospital.
2) The type of hospital and the available services.
3) The design and the lay-out of the hospital.
4) Available/pattern of arrangement of nurses.
5) The type and number of emergency cases coming to the hospital per day.

Staffing Norms

For planning of nursing manpower wc have to follow some norms.

The nursing norms are recommended by various committees, such as; the Nursing Man Power Committee, the High-power Committee, Dr. Bajaj Committee, and the Staff Inspection Committee, Trained Nurses Association of India, and Indian Nursing Council (1985). (For details See Unit 2 of this Block.)

All the above committees and the staff inspection unit recommended the norms for optimum nurse-patient ratio. Such as 1:3 for Non Teaching Hospital and 1:5 for the Teaching Hospital. The Staff Inspection Unit (S.I.U.) is the Unit which has recommended the nursing norms in the year 1991-92. As per this S.I.U. norms the present nurse-patient ratio is based and practiced in all central government hospitals.

Most of the hospital today is following the S.I.U. norms. In this the post of the Nursing Sisters and the Staff Nurses have been clubbed together and the work of the ward sister is remained same as staff nurse even after promotion. The Assistant Nursing Superintendent and the Deputy Nursing Superintendent have to do the duty of one category below of their rank. There will be:

- One nursing sister for 3.6 staff nurses (30% nursing sister) has been fixed by the Government in settlement with the Delhi Nurses Union (DNU) in 1990.
- One ANS (Assistant Nursing Superintendent) for every 4.5 Nursing Sisters.
- The ANS will perform duty in shift as done by the present Nursing sisters.
- One DNS for 7.5 ANS.
- The DNS will perform the duty of the Assistant Nursing Superintendent.
- One Nursing Superintendent for 200 beds in the Hospital.
- One Chief Nursing Officer for 50Q to 750 beds.

There should be 45% posts added for the area of 365 days working including 10% leave reserve (maternity leave, earned leave, and days off as nurses are entitled for 8 days off per month and 3 National Holidays per year when doing 3 shift duties).

The Nurse-patient Ratio as per the S.I.U. Norms

General Ward	—	1:6
Special Ward	—	1:4
Nursery		1:2
Labour Room	—	1:1 per table
I.C.U.	—	1:1 (Nothing mentioned about the shifts)
O.T. Major	—	1:2 per table
O.T. Minor	—	1:1 per table
Casualty		1:35
Burn	—	1:2
O.P.D.	—	1:40

The Nurse-patient Ratio as per the norms of *TNAI* (Trained Nurses Association of India) and INC (The Indian Nursing Council, 1985)

The norms are based on Hospital Beds.

1)	Chief Nursing Officer	1 per 500 beds
2)	Nursing Superintendent	1 per 400 beds or above
3)	D.N.S.	1 per 300 beds and 1 additional for every 200 beds
4)	A.N.S.	1 for 100-150 beds or 3-4 wards
5)	Ward Sister	1 for 25-30 beds or one ward. 30% leave reserve
6)	Staff Nurse	1 for 3 beds in Teaching Hospital in general wards and 1 for 5 beds in Non-teaching Hospital +30% Leave reserve

7) Extra Nursing Staff to be provided for departmental research function.

8) For OPD and Emergency 1 staff nurse for 100 patients (1:100) + 30% leave reserve

9) For Intensive Care Unit (I.C.U.) 1:1 or (1:3 for each shift) +30% leave reserve.

10) It is suggested that for 250 beded hospital there should be One Infection Control Nurse (ICN).

For specialised departments, such as Operation Theatre, Labour Room, etc. 1:25 +30% leave reserve.

Norms are not based on Nursing Hours or Patient's Needs here.

Following is another set of norms in practice based on the nature of illness of patients. These norms will be helpful to you in implementing progressive patients care concept in your hospital.

Nursing Hours Required

Nature of Illness	Direct Nursing Hours Required	Nurse-Patient Ratio	Remarks
Critically ill patient needing intensive care	8-10 hours	1:1	
Moderately ill patients needing intermediate care	3-5 hours	1:3 1:5	(Teaching hours) (Non-teaching hours)
Mildly ill patients needing self care (Ambulatory)	1-2 hours	1:6 1:10	(Teaching hours) (Non-teaching hours)
Chronically ill patients requiring skilled prolonged medical and nursing care	30 minutes to 1 hour	1:12 1:18	(Teaching hours) (Non-teaching hours)

Source: Academy of Hospital Administration, *Diploma in Hospital and Health Management Course Paper II*, 11th edition, 2000.

.....

2) Match the following:

S.I.U. recommendation of Nurse-patient ratio is:

	A	B
i)	I.C.U.	a) 1:1
ii)	General Ward	b) 1:4
iii)	Special Ward	c) 1:6
iv)	O.T. major	d) 1:2
v)	Casually	c) 1:1
vi)	O.T. Minor	1) 1:35

3) Indicate True and False:

a) For ICU Nurse-patic111ratio is 1:1 recommended by S.I.U. (T/F)

b) The S.I.U. Norms were recommended in the year 1991-92. (T/F)

c) The INC recommended Nurse-patient ratio in 1985. (T/F)

d) The norms of the staff nurses should be 1:5 in teaching hospitals. (T/F)

e) For every 200 beds one additional DNS to be posted as per TNAI and INC norms. (T/F)

3.6 NURSING CARE METHODS

There are many incthods that may be applied for providing the care to the patient in the ward, but mainly three methods which should be practiced for an effective ward management. There are three Nursing Care methods used for the assignment of nursing work.

The tasks of the ward are carried out mainly by these three accepted patterns of Assignments/methods which depend on the training, experiences and the rules of a particular hospital/institution.

1) Functional Method
2) Case Method
3) Team Method

Organisation of ward work and assignment of staff need careful.consideration.

I) Functional Method

In this method the tasks are divided among the staff e.g. in a ward one sister (nurse) is made responsible for giving injections, another sister takes care of oral medications and the third sister does all the other works for the patients. In this a nurse is assigned to specific function in the ward as mentioned above, giving injection, oral medicines, taking vital signs of the patients, doing any other work of the patient etc. This method is also called efficiency method.

Following are the advantages of this method:

a) It helps to improve the efficiency of care provider (Nurse).

b) More work can be accomplished in a given period of time, so it is very useful method during evening and night shifts.

c) Less interruption and less confusion is there.

d) It helps in developing the skill when the activity is repeated often.

Following are the disadvantages of this method:

a) There is no satisfaction to the nurses.

b) Nursing activity becomes monotonous when the same activity is repeated again and again leading to less interest in the activity,

c) No individualized nursing care is possible, so patients also do not get satisfied and they do not know whom to approach in case of any problem far clarification.

d) More confusion is there in the patient to attend many people (nurses) in a day.

e) Less accountability of the work by the staff can lead conflict with the supervisor.

2) Patient/Case Method

In this assignment a nurse is expected to give complete nursing care to one patient. Each nurse is assigned to one or two cases and she is fully responsible for total care of those patients. A nurse is providing general nursing measures, treatment and medications, taking temperature, pulse, respiration, serving nourishment to lier patients also giving health education. If she goes off for lunch that time she has to hand-over the patient to another nurse for the time being. She is responsible to giving complete hand-over to her next shift partner about her patients before going off from duty.

The advantages of this method are:

a) More individualized care is possible.

b) Opportunity of nursing education is superior.

c) Satisfactions to the nurse are getting increased.

d) Satisfaction of the patient is also of a higher grade and there is less confusion.

Disadvarilages of this method are:

a) More workers (Nurscs) are required for the patient care.

b) Less work is done in a given period of time,

c) This method does not improve the efficiency of the workers (Nurses).

d) The method is not good for developing the nursing skills,

3) The Team Method

It is a new method of assignment/patient care. In this method the nursing staffs are divided into Teams, each of which is led by an experienced Nurse. There is one experienced professional nurse, who is being designated as a team leader. This leader assigns duties to other nursing staff members of her team for giving care to a group of patients. The work is done under the direct supervision and guidance of the leader. The team leader is fully responsible to the ward sister/ward in-charge (A.N.S.).

The advantages of this method are:

a) Better patient care is provided to the patients assigned to the team.

b) It helps the leader to assume the responsibility and to organise the work efficiently and independently.

c) There is better ward management and better planning of patient care.

d) Job satisfaction is there among the nursing personnel.

e) All the members learn to work in a team spirit.

Disadvantages of this method are:

a) More nurses are required than the functional method.

b) The team cannot function unless there is a stable team leader,

c) It can be successful only if everyone concerned is interested and determined to make it work efficiently,

3.7 MANAGEMENT OF PATIENT AND ATTENDANTS

It is the legal responsibility of the nursing administrator/ward incharge to provide and ensure quality care to the patients. The administrator/ward incharge should instruct his/her employees to be very cordial and sympathetic with the patients and their attendants besides providing the quality care to the patient, he or she is also responsible for the welfare of the patients as well as the attendants. It is to be ensured that nothing is provided or done which is harmful for the patient and attendants, as any casual remark by the employee can hurt the patient and attendants and may lead to conflict.

Management of Personnel

Management of personnel is not an easy job. The nursing administrator/ward incharge has to create a working environment providing facilities and services within the reach of all categories of staff. He/she has to motivate the subordinates to achieve the organisation goals. Other duties of the nursing administrator are conflict resolution, maintenance of industrial harmony and well-coordinated activities, staff counselling etc.

3.7.1 Coordinating

Coordinating is the integrating process in an orderly pattern of group efforts in any enterprises towards the accomplishment of a common objective, To ensure the harmonious and smooth working of an organisation with a number of its divisions, departments or units, the activities in all areas are required to be pulled together, unified and blended so as to give them a common purpose. Coordination must have time, quantity, and direction dimensions. It is a mutually arranged effort of the requisite quality and quantity, arranged at the proper time through deliberate executive action. Coordination should not be confused with cooperation. Coordination is one of the most important managerial function. The ward incharge/nurse administrator has to coordinate or work with his/her subordinates to achieve a common goal. The Chief of the nursing services has to coordinate with the chiefs of the other departments to ensure the smooth functioning of the hospital. Good coordination among the different departments help in achieving the organisational goal i.e. good patient care.

3.7.2 Counselling

Counselling in general is defined as advising and guiding. It is the process of helping a person to solve his problem by himself. Counselling is also defined as a conversation between two people for the purpose of solving the problem or as an interview conducted for the same purpose. Counselling is the heart of guidance. It is the main element in guidance, regardless of the field of nursing service or others. Guidance is impossible without it. The main purpose of counselling is to develop self-reliance of the counsellor, chief of the nursing services and its staff members at the supervisory level should learn the art of counselling. The counselling skills are acquired by practice and experience. The term counselling is used in three senses:

a) **To describe a helping relationship**

This refers to the core qualities of the counsellor and includes empathetic understanding, respect for the client and genuineness.

b) **As a set of activities and methods**

These activities and methods include empathetic relationship with clients and theoretical approaches such as psycho-analytical, behavioural and rational-emotive.

c) **As a special area for providing services**

The differences between psychological therapies and counselling lies in the type of clients. In counselling the focus is on the clients in non-medical settings who are less disturbed than those who are receiving psychological therapy in the hospital.

Factors Necessary for a Counselling Programme

1) Gathering the data about the counsellee.
2) Conferring with others concerning the counsellee.
3) Assessing the employees potentialities, attitude, stamina, etc. for a given position.
4) Building an index to helpful information.
5) Consulting sources of information, gathering facts and determining the type of counselling required or best suited.
6) Follow-up and evaluation of results.
7) Organisation of cumulative records to determine not only immediate but also the long term progress of the counsellee.
8) Writing up case records of counselling in regard to certain problems to serve as guide in similar issues. Records can be used for research purpose also.

Types of Counselling

Counselling may assume one of the several forms:

1) **Directive counselling:** In this type of counselling, counsellor collects the information about the aptitude, interest, motives and other characteristics that facilitate or inhibit adjustment. It is mainly diagnostic or conventional counselling. The counsellor establishes rapport with his/her client, investigates his/her problems and help the client to solve these problems.

2) **Non-directive counselling:** It is client oriented. In this the counsellor talks less but listens more. The counsellor is not interested in historical background of the counselling. The counsellor assumes the passive role. He/she maintains an attitude of interest and avoids expression of shock, discomfort etc. that may cause psychological blocking in the counsellee.

3) **Electic counselling:** It is the combination of directive counselling and non-directive counselling. The following steps are taken in this as under:

   a) Put counsellee at ease.
   b) Cultivate self-understanding.
   c) Demonstrate interest and listen sympathetically.
   d) Be personal in manner but impersonal in interest of workers etc.

   There are occassions when counselling needs to be forceful, when the counsellor needs to make decisions and when the insight and acceptance of counsellee is minimal. For example in emergency situation when the client possessed of very rigid mind set.

4) **Group counselling:** In this the counsellor is counselling a group of counsellees at a given time. All the process of counselling is also being done with the group and the same decision by the counsellor is being taken for the group.

Role and Function of the Counsellor has been termed as the three C's:

1) Counselling 2) Consulting 3) Co-ordinating

Generic Role of Counsellor

1) Counsellor as a Counsellor
2) Counsellor as a Consultant
3) Counsellor as a Manager
4) Primary Prevention Agent

There are some basic counselling skills like attending, observing, active-listening, summarising, reflecting, questioning, silence, independence, and concreting etc.

While using above-mentioned counselling skills, Nursing administrator/Manager can get source of the administrative problems solved. Good counselling helps the counsellee to develop the insight, also helps in establishing new goals. There is a growth of confidence and ability to take the decision, once the client develops ability to take self decision, no more help by the counsellor is given. The relationship betwen the counsellor and counsellee should break gradually. Too early breaking will give more emotional trauma to the counsellee.

3.7.3 Nursing Records

Nursing record is defined as the record of events pertaining to patients, maintained by a nursing personnel, it is the responsibility of the ward sister to maintain the records correctly. They should be complete in all aspects. The records have got a medico-legal value, they should be preserved carefully, the nursing personnel do keep non-medical records like stocks ledgers, breakage book, drug ledger, ward maintenance register etc. It is the ward sister's duty to ensure that the records are accurate and uptodate. The ward incharge should help the staff in maintaining adequate and useful records. Routine record review may be done by the ward incharge periodically or when common errors are committed by the staff repeatedly. The records may be scanned in a given order first the admission and discharge records of the patients, then the records of the treatment rendered to the patients, and the procedures done in details. The staff may be encouraged to check their own records to improve their accuracy and the completeness.

A routine may be established for the scanning of each new record. The records may be scanned again at the time of closing or before final filing.

Purpose of Records

- Provide data for programme planning and evaluation;
- Tools of communication between the health workers, the family and other development of personnel;
- Record indicates plan for the future.

It provides baseline data to estimate the long term changes related to the services. It provides an opportunity for evaluating the services. It helps in the research for improvement in the ward management and nursing care.

Types of Records:

1) **Cumulative Records:** This is the record which is bound to be time saving. It is also helpful to review the total history of an individual (patient) to evaluate the progress.

2) **Family Records:** All records which relate to the members of the family should be placed in a single folder. This gives the picture of the total situation, and helps to give effective economic services to the family, as a whole.

Filing of Records

Records could be arranged alphabetically, numerically, geographically, and with index cards in a systematic way. It is important at all levels.

Characteristics of the Good Records

The records should be complete and accurate, it should also be legible. There should be mentioned the type of services rendered to the patients in details and written clearly.

Advantages of Keeping the Records

Records are the properties of the hospital and the patients. The advantages of keeping the records are:

1) The records speak on the behalf of the personnel in his/her absence.
2) It protects the hospital employees from baseless allegations.
3) It helps to keep the hospital staff away from the Consumer Protection Act (C.P.A.).
4) It is beneficial for the staff as well as the patients for future reference.
5) It helps in research to the medical and the nursing students.

3.7.4 Nursing Audit

Nursing audit is a new adventure in the nursing services which plays a crucial role in this modern nursing era. It may be a good start of improvement of nursing services by implementing nursing audit in India, though it has already been started in Western countries and found very useful.

Nursing audit is defined as periodic evaluation of nursing service. Some of the indices to base on the evaluation are the qualification and the practical skills of the nursing personnel, turnover of the patients and their satisfaction. Correctness and the promptness of the execution of doctors, dietician, pharmacy, sanitation and the cleanliness of the ward. The nursing audit was first time discussed by the R.N. Peterfisher, in 1953, at an Institute for nursing service administration in New Orbans. Seven years later, Sister Helen Louise Deeken published a guide for nursing service audit. A periodical review of the nursing care by nursing professional is now become an actuality. Monthly meetings are held to audit a random selection of charts on patients discharged during the preceding month. Now it is a felt need of every hospital administrator to implement the nursing audit as well as the medical audit for obtaining the best result of the services provided to the patients by the hospital.

There can be mainly two types of nursing audit — Retrospective and Introspective. The audit can be done during the patient's stay in the hospital or after the discharge from the hospital, depending upon the policy of the Institution. Nursing Audit helps in evaluation of nursing service. A periodical evaluation is necessary.

3.8 LET US SUM UP

Ward Management and Nursing Care as well as the Nursing Service is the part of total health organisation that helps the institution to stand on its own. The nurse works with the members of allied disciplines in supplying a comprehensive programme of health care. Nursing services developed to a profession with the work of Florence Nightingale. She let down the nursing standards and started a school of nursing in 1960. Nursing services are always to be under the direction of a competent leader, i.e., Chief Nursing Officer who is responsible for the entire nursing services. Nursing service is broadly classified into general ward nursing, speciality ward nursing, intensive care unit, casualty, O.T., and ambulatory care unit nursing. There are two types of organisations in nursing service i.e., line and functional. In the nursing service various norms and methods are practiced. Every method has its own merits and demerits. The important aspects of ward management are Management of Patient and Attendants, Coordinating, Counselling, Keeping of Nursing Records and Nursing Audit. So, good quality patient care is only possible in the hospital through good ward management and good nursing administration.

3.9 KEY WORDS

Felt Need : This is a need experienced by individuals, which they are prepared to acknowledge, and for which they may be able to demand services.

Florence Nightingale : The Lady With the Lamp; the Founder of Modern Nursing.

High Power Committee	:	Committee constituted with nursing and other experts which submitted report on various nursing aspects in 1989.
I.N.C.	:	Indian Nursing Council. A professional Body for Nurses.
Management	:	Function of an enterprise which concerns itself with the direction and control of the various activities to attain the organisational objectives.
T.N.A.I.	:	Trained Nurses Association of India, Founded in 1908. The National body of nursing practitioners at various levels.

3.10 ANSWERS TO CHECK YOUR PROGRESS

Check Your Progress 1

1)
- Accurate assessment of illness of patient
- Appropriate and effective action
- Provision of maximum degree of comfort and happiness
- Preparation for return to society

2) She was the first nurse executive to start the concept of modern nursing care/ intensive nursing care. She also laid down the nursing standards and started a nursing school in 1860.

3) The conscious practice of human relationships.

4) a) Florence Nightingale
   b) Lord Buddha
   c) Ashoka

Check Your Progress 2

1) Line and functional organisation

2)

Check Your Progress 4

1) Functional method

Case method

Team method

2) **Functional Method:** The tasks are assigned to each nurse according to the specific function in the ward.

Case Method: A nurse is assigned to a one patient.

Team Method: Nursing staffs are divided into teams, with one acting as the team leader, looking after nursing care to a group of patients.

3) Functional method.

4) **Advantages:** More individualized care is possible and opportunity of nursing education is superior.

Disadvantages: More nurses are required for patient care and less work is done in a given period of time.

Check Your Progress 5

1) It is a process of helping a person to solve his problem by himself through advising and guiding.

2) Directive counselling, Non-directive counselling electic counselling, Group counselling.

3) Gathering the data about the counsellor; conferring with others concerning the counsellee assessing the employee's potentialities, attitude, stamina etc. for a given position; building an index to helpful information.

4) It is a combination of directive and non-directive counselling. It is most useful in emergency situations where counselling needs to be forceful. In such situations the counsellor needs to take quick decisions and when the insight and acceptance of the counsellee is minimal.

Check Your Progress 6

1) To provide data for programme planning and evaluation, as a tool of communication between the health workers, the family and other personnel and baseline data to estimate long term changes related to the services .

2) i) Records speak on the behaviour of the personnel in his/her absence

ii) Records protect the hospital employees from baseless allegations

iii) Records are beneficial for the staff as well as the patients for future reference

iv) Records help in research to the medical and nursing students

3) Records should be arranged alphabetically, numerically, geographically, and with index cards in a systematic way.

4) It helps in evaluation of nursing services with a view to improve the services on a continuous basis.

UNIT 4 PHYSICAL MEDICINE AND REHABILITATION

Structure

4.0 OBJECTIVES

After going through this unit, you should be able to:

- define the tenns Disability and Rehabilitation;
- discuss the role of PMR in total health care and the various rehabilitation approaches;
- describe planning and organisation of PMR services;
- discuss physical layout, staff and equipment requirements for developing and organising a PMR department; and
- understand the laws related to disabilities and their significance.

4.1 INTRODUCTION

In this unit you will learn about a comparatively newer speciality of Medicine called Physical Medicine and Rehabilitation (PMR), and its role in the delivery of total health care as defined in our National Health Policy.

During the course of your graduation studies you must have learnt various aspects of family medicine. At that time, and, even till today the component of Physical Medicine and Rehabilitation is not included in the medical curriculum at graduation level. In this unit, you will know about Physical Medicine and Rehabilitation and its components, the process of rehabilitation of a person who becomes disabled due to either congenital or acquired causes. You will also learn about magnitude of the disability problem, levels of disability prevention and why it is important to prevent disability and rehabilitate persons with disabilities. You will also briefly learn the different rehabilitation approaches, and the planning and organisational aspects. The purpose of this unit is essentially to impart you knowledge on the subject of PMR, and its importance in the total health care.

4.2 BRIEF HISTORY OF PMR SERVICES

The history of Physical Medicine and Rehabilitation is as old as the mankind. There is mention in our ancient literature of treatment of disease and disability by use of hot and

cold water, application of mud, use of various types of leaves from plants and trees, in the form of poultice etc. There is mention of use of artificial leg and artificial eye in "Atharva Veda". During the regime of King Chandragupta Maurya, people with disabilities like the dwarfs, hunched-backed used to be employed in his court to vocationally rehabilitate them. During the regime of King Ashoka, a number of non-profit organisations were started to help people with disabilities, King Harsha also employed disabled persons in his court. The Mughal regime and the Rajput administration also encouraged employability of disabled persons. The Western Civilisation gave a serious blow to these measures, and disabled persons started resorting to beggary and crime. Thereafter, revival of rehabilitation services was due to the selfless and devoted efforts of philanthropist and non-profit organisations, and the credit for this goes to personalities like Mrs. Fatima Ismail, Mrs. Kamla Nimbkar, and a number of other devoted personalities, who made efforts to sustain the rehabilitation services in India. It needs to be rnenlioned that whatever efforts were made to provide the rehabilitation services at that time, were not based on sound scientific principles, and, the services were not well organiscd and were patchy. With the development of modern medicine, Physical Medicine and Rehabilitation did not get its due importance, as more importance was laid to curative medicine. Now, with the passage of time, its importance is being realised, and, Physical Medicine and Rehabilitation is finding its place in modern medicine. It is now a growing speciality based on sound scientific principles. There is ever increasing awareness in the medical fraternity and people at large about its role, and its demand is increasing day by day.

In the last one and a half decades, awareness has increased greatly and several significant landinarks attained in the disability sector both at the international and national levels.

United Nations General Assembly declared the year 1981 as the International Year of the Disabled Persons (IYDP), and called upon the member nations to start rehabilitation programme for the persons with disabilities in their countries.

Following this, the period 1983-92 was proclaimed by the General Assembly as the UN Decade for Disabled Persons. The major outcome of the Decade was the emergence of a global movement recognising the importance of integration of people with disabilities in the society through a world programme of Action, The Economic and Social Commission for Asia and the Pacific (ESCAP), at its 48th session in April 1992 declared the period 1993 to 2002 as the Asian and Pacific Decade of Disabled Persons. The Proclamation on the "Full Participation and Equality" of People with Disabilities was adopted. The primary focus of ESCAP decade action is expansion of opportunities for the full participation of the people wit11 disabilities (PWD) in the society and their equality in the process of development.

At the country level, the nodal ministry to provide rehabilitation services to the disabled persons is the Ministry of Social Justice and Empowerment. It has developed National Institutes in each area of disability, which are engaged in providing services, training of manpower, development of educational material and research activities. Their names are mentioned in the following pages. Some institutes have regional centers in different parts of the country.

The Ministry of Health and Family Welfare is taking care of the medical rehabilitation componenl. The Ministry of Health and Family Welfare, in its 5th Conference of Central Council of Health and Family Welfare in 1997 passed the following resolutions:

- The council noted that there are a number of on going National Health Programmes run by the Health sector, which bas a direct bearing on prevention of disability. They are:

  i) National Leprosy Eradication Programme

  ii) Blindness Control Programme

  iii) Iodine Deficiency Disorders Control Programme

  iv) National Mental Health Programme

  v) National AIDS Control Programme

  vi) Universal Immunization Programme including the Child Survival and Safe Motherhood (CSSM) Programme

These programmes may be further strengthened and attention be given towards preventive and rehabilitative aspects.

- The council recommended that state/UT governments may consider establishment of centers for rehabilitation in the district hospitals and further added that the existing health infrastructure be utilised and further strengthened to incorporate the various aspects of prevention and rehabilitation of various disabilities.
- The council felt that there is need for development of trained manpower base to tackle the problem at the periphery within the community and for transfer of technology to grass root level. To achieve this States and UT's should fully utilise the opportunity for training of PHC doctors and paramedical personnel to reorient them to the various aspects of Rehabilitation with the help of training institutions under the Ministry of Welfare as well as Ministry of Health and Family Welfare as a collaborative effort.
- The council recommended strengthening of research on causation and prevalence of disability within the cominunily.
- The council resolved that Medical Council of India recommendations of starting Physical Medicine and Rehabilitation Department in every Medical College should be strictly implemented which would enable doctors and paramedical to be trained in PMR, who in turn can act as trainers for middle level and grass root level workers.

Presently, there are National Institutes of Rehabilitation under the Ministry of Health and Family Welfare and Ministry of Social Justice and Empowerment. These are:

a) Apex Instilutes under Ministry of Health and Family Welfare are:
   i) All India Institute of Physical Medicine and Rehabilitation, Mumbai (AIIPMR)
   ii) All India Institute of Medical Sciences, New Delhi (AIIMS) which is also collaborating center for Community Based Rehabilitation (CBR)
   iii) All India Institute of Speech and Hearing, Mysore (AIISH)
   iv) National Institute of Mental Health & Neuro Sciences (NIMHANS), Bangalore
   v) Deparlment of Rehabilitation, Safdarjung Hospital, New Delhi

b) Apex Institutes under Ministry of Social Justice and Empowerment are:
   i) National Institute for Visually Handicapped (NIVH), Dehradun
   ii) Ali Yavar Jang National Institute for Hearing Handicap, (AYJNIHH) Mumbai.
   iii) National Institute for Mentally Handicapped (NIMH), Secunderabad.
   iv) Institute of Physically Handicapped (IPH), New Delhi
   v) National Institute for Rehabilitation Training & Research (NIRTAR), Cuttack.
   vi) National Institute for Orthopaedically Handicapped (NIOH), Calcutta

Besides these, there is an Artificial Limb Manufacturing Corporation of India (ALIMCO), at Kanpur, UP which is engaged in mass manufacture of assistive devices for people with disabilities to assist their ambulation and improve their functional level. In addition to this a large number of non-governmental organisations (NGOs) are providing need based services especially in the area of education, training and therapeutic interventions.

Under the Ministry of Labour, there are 17 Vocational Rehabilitation Centers in the country where facilities of training for gainful employment are available, 40 special employment exchanges for people with disabilities exist; who register them for various categories of jobs.

In spite of all this progress, the rehabilitation services reach approximately to 2% of disabled population and that too concentrated to the urban areas mainly. With the result majority of rural disabled are still deprived of rehabilitation services.

4.3 DISABILITY AND REHABILITATION

The conventional medical view of disease is as follows:

Causes — Pathology — Manifestation

In chronic progressive or irreversible disorders, the sequence is

Disease — Impairment — Disability — Handicap

In order to understand the above terms, let us take the example of a person who has met with a traffic accident and has lost his one leg below *the* knee (Impairment).

The loss of one leg by this person will result in decreased mobility, like walking, running, going to place of work etc. (Functional limitation).

In addition to the physical loss of the limb, the person also suffers from psychological setback, social segregation, and it can also lead to loss of his earning capacity (Disability).

In addition to *the* consequences of the disability upon the disabled person himself, the family, the society, and the Nation as a whole also has to face the consequences of the disability. The family has to directly face the burden of supporting the disabled person physically, socially and mentally. The society has to cope up with the increased demands and the country as a whole has to spend on the care and maintenance of the disabled person, and decreased productivity because of the disability resulting in low G.N.P. (Gross National Product).

Definitions of the terms concerned with the disability process are as follows:

Impairment

An impairment is a permanent or transitory anatomical, physiological or psychological loss or abnormality, e.g., a missing limb, paralysis after polio, mental retardation etc.

Functional Limitation

Impairment may cause functional limitations which are partial or total inabilities to perform those activities necessary for motor, sensory or mental functions within the range and manner of which a human being is normally capable, e.g., walking, seeing, speaking, hearing etc.

Disability

It is defined as an existing difficulty in performing one or more activities, which in accordance with the subject's age, sex and normative social role are generally accepted as essential basic components of daily living.

There are many components that interact with each other in disability process:

1) The patient

2) The environment

The patient has two components — disease and psychological response.

The environment also has two components — social and vocational. Disease factors are reciprocally influenced by psychological factors. On the other hand social factors are mutually influenced by vocational factors. That means that the patient and the environment mutually influence each other resulting in a disability.

Recently, WHO has proposed revision of these definitions (ICIDH-2betadraft-unpublished).

These are as follows:

Impairment

An impairment is a loss or abnormality of body structure or of a physiological or psychological function.

Activity Limitation

Activity is the nature and extent of functioning at the level of the person. Activities may be limited in nature, duration and quality.

Participation Restriction

Participation is the nature and extent of a person's involvement in life situation in relationslup to impairments, activities, health conditions and contextual factors. Participation may be restricted in nature, duration and quality.

Various Approaches to Prevent Disability

The old dictum "prevention is better than cure" still holds good in the modern day world. Prevention is usually defined at three levels — primary, secondary and tertiary prevention.

Primary Prevention

Primary prevention can bc defined as "action taken prior to the onset of the disease", which removes the possibility that a disease will occur. Primary prevention may be accomplished by measures designed to promote general health and well being and quality of life of the people or by specific protective measures. It includes the concept of "positive health", a concept that encourages achievement and maintenance of an "acceptable level of health" that will enable every individual to lead a socially and economically productive life. It concerns an individual's attitude towards life and health and the initiative he takes about the positive and responsible measures for himself, his family and the community.

Common examples of primary preventive measures are:

- Proper antenatal, natal and postnatal care, to prevent child born with disability,
- Avoid consanguineous marriages.
- Prevention of accidents.
- Proper immunisation to prevent diseases like polio.

Secondary Prevention

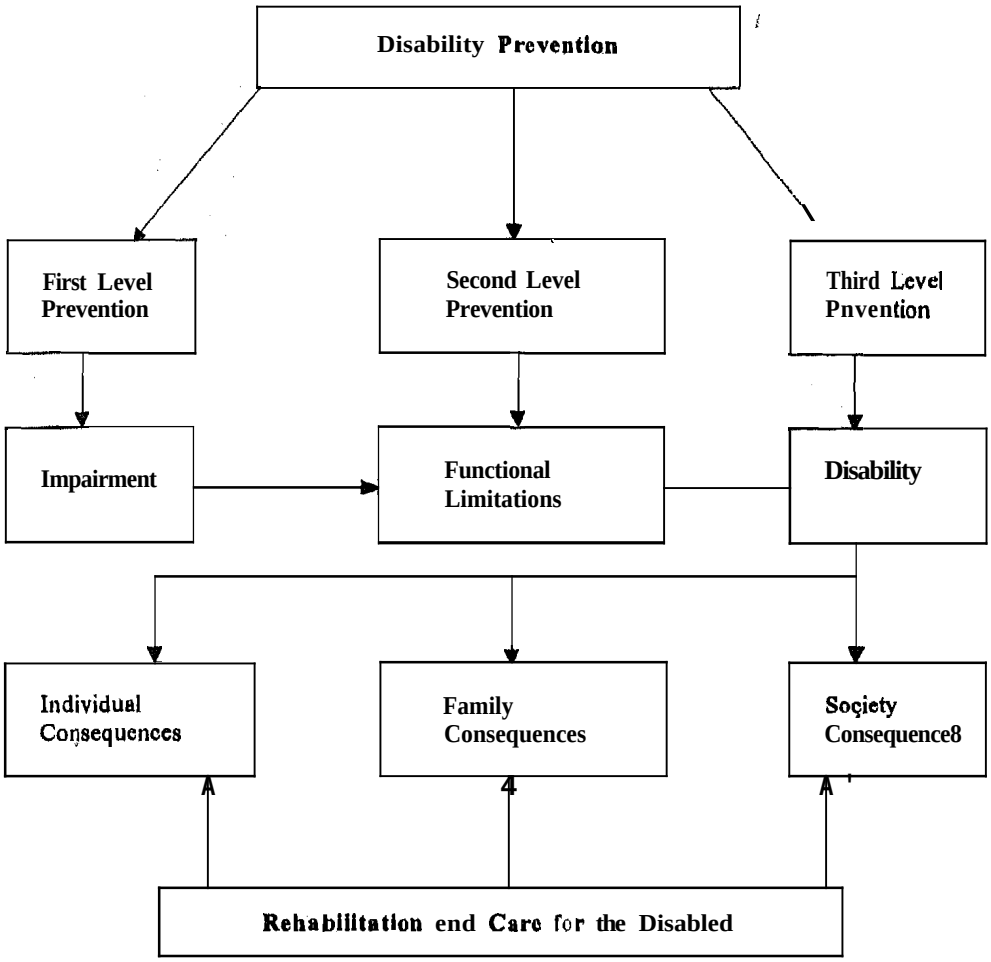
It can be defined as "action which halts the progress of the disease at its incipient stage", and prevent complications. The specific interventions are "early diagnosis and adequate treatment". It is largely the domain of the clinical medicine.

Tertiary Prevention

When the disease process has advanced beyond its early stage, it is still possible to accomplish prevention by tertiary prevention. It signifies intervention in the late pathogenesis phase.

Tertiary prevention can be defined as all measures available to reduce or limit impairments and disabilities and minimise suffering caused by existing disability. The tertiary phase of prevention is also called rehabilitation, wluch includes physical, psychosocial and vocational measures taken to restore the patient back to normal or near to normal condition.

The following flow chart depicts the various levels of disability prevention.



Rehabilitation

Rehabilitation has been defined as the "combined and coordinated use of medical, social, educational and vocational measures for training and retraining the individual to the highest possible level of functional abilily". It includes all measures aimed at reducing the impact of disabling conditions and at enabling the disabled to achieve social integration. Social integration has been defined as the active participation of the disabled person in the mainstream of community life. Rehabilitation medicine has emerged in recent years as a medical speciality. It involves discipline such as physical therapy, occupational therapy, audiology and speech therapy, psychosocial work, prosthetics and orthotics, education, vocational guidance and placement.

By medical rehabilitation we mean restoration of function.

Vocational rehabilitation means restoration of the capacity to earn livelihood.

Social rehabilitation means restoration of family and social relationships.

Psychological rehabilitation means restoration of personal dignity and confidence of the disabled person.

Rehabilitation measures include:

1) Training to increase independence in self care.
2) Educational and vocational measures aimed at achieving economic independence.
3) Social measures to ensure full integration and acceptance in community.

Independence in Self Care

Training and teaching of patients, or family members and neighbours etc.

Independence self care calls for independence in:

1) Activities related to daily life such as dressing, eating, drinking, washing, personal hygiene etc. by giving:
   - Training activities.
   - Provision of simple technical aids (at lirnes).
2) Mobility, sitting, standing, walking etc. They require the provision of shoes, crutches. ctc.
3) Physical environmental changes suited to the kind of functional limitation.

Economic **Independence**

It includes:

- Educational training
- Vocational training
- Employment opportunities

Social Intergration

It means bringing out attitudinal changes in the community at large by ratifying their misbelief and misconceptions about disability and ensuring social inlegration. It requires education of people at large through mass media and community leaders.

   iii) Disability

2) Define disability?

   .....

   .....

3) What is psychological rehabilitation?

   .....

   .....

4.4 DISABILITY: TYPES, MAGNITUDE AND CAUSES

Broadly, the disabilities can be grouped into the following groups:

1) Locomotor disability i.e. Disability of moving.
2) Visual disability i.e. Disability of seeing.
3) Hearing and speech disability i.e. Disability of hearing and speaking.
4) Mental retardation i.e. Low I.Q.

The people with Disabilities Act has also included the following as disabilities:

1) Low vision
2) Leprosy cured
3) Mental illness

However, there are certain anomalies in this grouping. Pulmonary conditions like chronic obstructive pulmonary diseases (COPD), cardiac conditions like Myocardial

Infarction, Thalassemia, Loss of kidney, though cause permanent impairment are not included as disabling conditions.

As regards the magnitude of the problem, estimates of the number of disabled vary a great deal depending upon certain factors such as the definitions used, the source of information, the methodology of the survey, the extent of use of scientific observation methods in identifying and measuring the degree of disability and so on.

According to one estimate, the population with disability in India is approximately over 90 million (based on 10% prevalence of disability) of which 12 million are blind, 28.5 million are with low vision, 12 million are with speech and hearing defects, 6 million are orthopaedically handicapped, 24 million mentally retarded, 7.5 million persons with leprosy related handicaps.

A comprehensive country wide sample survey of persons with disabilities was undertaken by the National Sample Survey Organisation (NSSO) in 1981. This survey indicated that 1.8% of the total population of the country has physical or sensory disabilities.

No survey of inentally retarded persons was done at that time. Another survey was conducted by the NSSO in 1931. The suivey indicated that 1.9% of the population of the country have physical or sensory disabilities which include locoinotor, visual, speech and hearing disabilities.

Almost all the disability prevalence studies undertaken in India have been based on questionnaires. The appropriate survey of the prevalence of disability must be based not on questionnaire only, but on examination and observation of each household member. Therefore, it appears that the findings of survey conducted in India are an under estimate of the inagnitude of the problem in the country.

Furthermore, whatever the magnitude of the disability may bc, there are trends to indicate that there is anticipated rise in the number of people with disabilities, and also, the spectrum of the causation of disability is changing. As we are able to control the communicable diseases like polio, leprosy, etc., the prevalence of disability due to these causes is on the decrease. On the other hand with the ever increasing population, worsening of food situation and consequently increase in nuinbcr of cases of malnutrition, the prevalence of disability is on the rise. Similarly, with the change in the age composition, wherein there is more elderly population, work related and age related disability is on the rise. The overall scenario reveals that we are going to have more people with disabilities than henceforth. Therefore, there is a need for laying more emphasis on their rehabilitation.

Medical Causes of Disabilities

1) ***Congenital Disorders***

a) Genetic : Genetic defect

b) Non-genetic : Include consequences of disease or functional disturbances affecting the foetus during pregnancy or delivery.

a) **Genetic**

- a Mental retardation
- a Hearing impairment
- Speech disturbance
- Visual impairment
- Genito urlnary malformations
- CHD
- Malformations of digestive systems

b) **Non-genetic Disorders**

Perinatal disability, low birth weight

i) **Malnutrition, severe anaemia during pregnancy.**

ii) **Disease during pregnancy**

— **Communicable disease: Rubella**

- Syphillis
- Tetanus
- Drug Use

iii) Complications during delivery owing to low quality midwifery

- Birth trauma
- Brain damage
- Respiratory or circulatory disturbance

2) *Communicable Diseases*

Common

- Poliomyelitis
- TB
- Leprosy
- Trachoma

Others

- Meningitis
- Encephalitis
- Herpes
- Osteomyelitis
- Veneral disease
- Septic arthritis
- Chronic eye infections
- Otitis media
- *AIDS*

3) *Noncommunicable Somatic Diseases*

- Back disorders
- Paralysis
- Arthrosis
- Rh. Arthritis
- Heart Conditions
- CVA
- Pulmonary Dysfunctions
- Epilepsy
- Vision impairments
- Hearing impairments
- Diabetes
- Cancer

4) ***Functional Psychiatric Disorders***

- Psychotic : Schizophrenia
- Non-psychotic : Phobic states

5) ***Alcoholism and Drug Abuse***

6) ***Trauma and Injuries***

- Traffic accidents : rail, road, air, sea
- Work accidents : industrial, agricultural
- Home accidents
- Other sources
  - Recreation and sports
  - War and civil unrest

- Natural catastrophies
- Earthquake
- Floods
- Cyclones

7) *Malnutrition*

- Protein calorie
- Vitamin Xerophthalmia
- Nutritional anaemia

8) *Other Causes*

- Exposure to toxic substances in air, water, food.
- Unsuccessful suicidal attempts
- Crime : inflicting bodily injury, psychological disturbance
- Iatrogenic disturbance

Coinmon Causes of Disability

Visual	:	Cataract Trachoma Trauma Congenital Vit. A Deficiency
Hearing	:	Congenital nerve deafness Chronic Otitis media Noise pollution
Speech	:	Congenital Brain damage
Locomotor	:	Poliomyelitis Amputation Cerebral Palsy Accidents
Mental	:	Congenital Cerebral Palsy Cretinism

4.5 PROBLEMS RELATED TO DISABILITIES

The various problems encountered by persons with disabilities are:

- **Physical**
- **Psychosocial**

- Educational
- Vocational

Physical/Medical Rehabilitation

Persons with disabilities often suffer from the following physical problems:

- Motor weakness/paralysis
- Spasticity
- Sensory loss
- Pressure sores
- Deformities and Contractures
- Loss of limb or part
- Urinary and faecal incontinencelretention
- Pain

There may also be hearing, speech, visual, mental retardation or higher function problems either in isolation or combination of them.

Due to the above physical problems, there are subsequent functional limitations in the performance of activities oi daily living (ADL). For example:

- Transferring from one place to another
- Mobility, ambulation and transportation
- Self care activities like toileting, bathing, grooming etc.
- Social and leisure activities
- Work place activities

For the physical restoration and achieving maximum function and independence, rehabilitation interventions are called for. These are:

- Appropriate exercise therapy for maintaining the range of motion of the joints, regaining or improving the muscle power in the weak muscles and strengthening of normal muscles.
- Restoring the function of the affected extremity by appropriate training, including gait training.
- Provision of external appliances, splint or caliper if required.
- Relief of pain by means of physical modalities like heat, cold, electricity etc.
- Bladder/bowel training to achieve continence.
- Training in the activities of daily living in order to restore the various lost functions like transfers, self-care etc. It may require the use of self help devices, if indicated.
- Education of the patient to maintain the physical status so achieved preventing any coinplications.

Artificial limbs (prostheses); splints/calipers (orthoses), walking aids like crutches, sticks, canes, walker or wheel chair may be prescribed depending upon the physical status of the patient. These are to be fabricated or made available to him and patient trained in their use.

Patients with physical disabilities cannot afford to negotiate narrow entrances and lanes, elevated platforms, cemented or wooden doorsteps and stairs. To facilitate their unimpeded mobility, it is necessary to provide special ramps, remodeling of entrances, widening of doors, construction of slopes instead of stairs; creation of flat plain floors without raised platforms or barriers. These modifications are required not only at the place of residence of patient, but also in the public places visited by the disabled persons. This type of barrier free environment will improve their mobility and consequently provide more opportunities in life by limiting their handicap.

Psycho-social Rehabilitation

Indeed, the process of rehabilitation is never complete unless the psycho-social aspects are duly taken care of. Psychological, social and economic rehabilitation of patients with

disabilities is intimately interrelated. Together, they provide the crowning glory to the entire success story of a patient's ultimate rehabilitation. The attending doctor is the fulcrum of such efforts. The key to success is the right attitude of the doctor and other members of the team. The doctor must extend his horizons beyond the diagnosis and treatment of the patients. They benefit from such treatment only when it is conceived and planned from the outset with the effect on the patients working capacity and his home life in mind, The likely residual disabilities, their effect on his work/occupation and the need for retraining must be assessed with the most compassionate attitude.

Illness and injury always induce some anxiety in the patient and relatives, and the response to incapacity depends on the patient's personality, education, and social and economic situation. Motivation may be dcscribcd as the expression of the patient's personality when striving to overcome adversity, and thus, it is also an expression of his response to rehabilitation. Evaluation of the premorbid personality and adequate assessment of the social, educational and economic circumstances are as important in rehabilitation as a realistic delineation of the prognosis and likely functional handicap. It is within this area that the art of medicine is as important as the science for the methodology available for the quantitative assessment of personality and motivation of the disabled person is not readily achieved and not generally acceptable and simply applied techniques have been described. Disabilities undoubtedly bring about reactive dcprcssion. Severe disability limiting social activities and contacts will clearly be accompanied by personality changes. The psychological trauma of amputation is obvious and the appropriate preparation of patients for ablative surgery is being increasingly introduced.

Specific psychological problems of patients with disabilities include — depression, anxiety, feeling of insecurity, loneliness, behavioural disorders, affective disorders, personality disorders, suicidal tcndcncies, dependence, low self esteem, irritability, impaired psychomotor coordination, malingering and hysteria.

Although patients with disabilities undergo a variety of personality changes in response to their disabilities, no specific personality types have been identified which may be more prone to physical handicaps or an impaired response to it.

There is no gain saying the fact that economic independence is the single most important measure contributing to a sound psycllological and social restoration of the disabled. It goes a long way in ameliorating the specific problems of insecurity, dependence, anxiety, depression, social isolation, low self-esteem and emotional disorders.

The clinician, besides his role in the diagnosis and cure of patients has to carry out the sacred duly of explaining and reassuring his disabled patient about his disabilities, their effect on his work and its possible solutions. This may not necessarily require the services of a specialised rehabilitation unit or an expert psychiatrist. A little change in the attitude of the treating doctor can easily accomplish this supposedly difficult task. A genuine interest in the patient's welfare is the key to success in this hallowed work.

Educational Rehabilitation

The disability may hinder the educational process of the disabled child. Attempts should be made so that the education process continues without any hindrance, in spite of certain difficulties that might come in the way. Normally, a child with a physical disability can pursue his education in a normal school. At the most, he may require ***some assistance*** in overcoming the physical bamers as far as children with other disabilities like visual, hearing, speech and mental retardation or a combination of above, they need admission in special schools for their education. Most of such special schools are run by NGOs with assistance from Stale and Central governments. The greatest disadvantage of being in special school is that the children live in secluded and sheltered environment, which turns out to be a disadvantage later on in their social adjustment. In order to take care of this problem, a scheme of Integrated Education of the Disabled Children (IEDC) was initiated by the Government of India to provide educational opportunities for the disabled children in normal schools. The scope of this scheme includes pre-school training for the disabled children, counselling for the parents, special training in speech and language for the hearing impaired children, orientation and mobility training for the visually impaired children, daily living and communication skills training for children with other disabilities, and training in home management.

Vocational Rehabilitation

Whatever the stage of economic development of country, none of its citizens (above all, the disabled people) can be left out of the planning for the care and improvement of conditions for them, certainly not in a welfare state.

While even the able-bodied are handicapped in doing one thing or the other, the disabled have certain obvious limitations. Those limitations however, do not warrant their being labeled as 'Vocationally' handicapped, With increased emphasis on the utilization of all man-power and the obvious need to offer opportunity to everyone to utilize his capacities, the productive potential of the disabled has to be developed to enable them to find their places in national economy.

Despite tremendous progress in rehabilitation medicine and a marked change in our attitude towards the rehabilitation of the people with disabilities, much headway has not been made in their placement. Most of them are unaware of their productive potential and available opportunities. Many take to begging or lead a forsaken life of hopeless gloom. The disabled and his family certainly deserve a caring sympathetic and positive attitude from the attending doctor and other medical personnel. Above all, the doctor must express a genuine interest in the overall well being of his disabled patienfs, including their financial well being. They benefit to the fullest extent from treatment only when that treatment is conceived and planned from the outset with the effect on the patient's working capacity and his home life in mind.

Vocational rehabilitation is the process of exploiting the avenues for gainful occupation of a disabled individual.

The clinician's responsibility is not restricted simply to the diagnosis and care of the patient. There is a further responsibility of assessing the patient's capacity and recommending the appropriate rehabilitation and training for any patient likely to be left with some locomotor disability. These patients will need assessment of

1) What work can be done;
2) Whether new employment is necessary and, if so, whether retraining is indicated;
3) What assistance is needed at home;
4) Whether the expected earning will be enough for sustenance;
5) What other Govt./Agencies aids and facilities are available.

The team approach to such problems is mandatory and many involved are the medical social worker, vocational advisor, employment officer, occupational therapist, NGOs etc. besides the doctor.

In India, Vocational Rehabilitation centers, working under the Ministry of Labour, Directorate General of Employment and Training,are entrusted with the work of vocational assessment, training and placement of the disabled.

4.6 GOALS AND OBJECTIVES

The main goal of rehabilitation is the restoration of the physical, social, psychological and vocational potentials of the disabled person to the maximum extent possible, so that he can function in as normal way as possible.

The three main objectives in rehabilitation are:

i) prevention of disability, if possible

ii) maximum reduction or elimination of the disability

iii) training the disabled person with residual abilities to achieve independent living.

4.7 REHABILITATION APPROACHES

There are three major strategies for carrying out rehabilitation programmes:

1) Community Based Rehabilitation (CBR)

2) Institution Based Rehabilitation (IBR)

3) Out Reach Programmes

1) Community Based Rehabilitation (CBR) is a strategy within tlie community for the development of the rehabilitation services, equalization of opportunities, and social integration of people with disabilities. CBR is implemented through the combined efforts of disabled people themselves, their families and communities and the appropriate health, education, vocational and social services.

2) Institution Based Rehabilitation (IBR) takes place in institutions. People with disabilities attend the rehabilitation institution in order to undergo training under the direction of staff in the institution. Institutions also serve as referral centers to a CBR programme,

3) Out Reach Programme for rehabilitation is one in which the professionals in the rehabilitation field provide services lo people with disabilities, who visit the community, or the homes of people with disabilities. Advice is given on how to improve in specific activities such as self-care, moving around or communication. The out reach services could either form an extension of the institution to the neighbouring area or by organising camps in the neighbouring area from time to time.

4.8 PHYSICAL LAYOUT, STAFFING AND EQUIPMENT

In order to provide PMR services, these have to be developed at all the three tiers of health care i.e. PHC, District and State/Medical College Hospital level.

The manpower, space and equipment requirements at the tertiary level i.e. State level/ Medical College Hospital level are enumerated below:

At the tertiary level each Medical College Hospital should have a Department of Physical Medicine and Rehabilitation as recommended by the Medical Council of India.

a) **Manpower**

1) New

— Director Professor (PMR): 1

- Associate Professor (PMR): 2
- Assistant Professor (PMR): 2
- Senior Resident (PMR): 4
- Junior Resident (PG students): 4
- Junior Resident (house surgeon): 10
- Senior Physiotherapist: 2
- Physiotherapist: 10
- Senior Occupational Therapist: 2
- Occupational Therapist: 10
- Audiologist and Speech Therapist: 2
- Multi Rehabilitation Worker: 10
- Sr. Medical Social Officer: 1
- Medico Social Worker: 1
- Psychologist: 1
- Vocational Counsellor: 1
- Workshop Manager: 1
- Sr. Prosthetist and Orthotist: 2
- Prosthetist and Orthotist: 4
- Prosthetic and Orthotic Technician: 12
- Teacher: 2
- Craft Instructor: 2
- Technicians in various trades: 4
- Administrative Officer: 1
- Head Clerk: 1
- Accounts Clerk: 1
- Stenographer: 2
- Typist: 2
- Personal Assistant: 2
- U.D.C.: 2
- L.D.C.: 4
- Nurses: 2
- Nursing Orderly: 10

Safaiwala: 6

- Driver: 2
- Peon: 2

The above requirement of the manpower is ideal to establish a PMR Department in a Medical College Hospital. The Department shall deal with the patients suffering from various types of impairments. It will also cater to the referrals receiving and group 'D' staff shall be required for the wards.

2) **Existing Manpower**

The existing manpower of the hospital viz. doctors of other departments, nurses and the other auxiliary staff can be provided orientation training in PMR in order to impart them basic idea about the activities and the usefulness of the PMR services in the total health care of the patients visiting the hospital.

b) **Infrastructure and Space Requirement**

A full-fledged PMR Department shall require space for the following sections:

- Medical Section and OPD Services
- Physiotherapy Services
- Occupational Therapy Services
- Hearing and Speech Therapy Services
- Medico Social Services

- Psychological and Vocational Services
- Prosthetic and Orthotic Services
- Indoor Services
- Operation Theatre Services
- Administrative Block
- Public Utility Services
- Wheel Chair and Trolley Services
- Waiting Space
- Dharamsliala for Attendants

While planning the building for a PMR Department, the following things have to be borne in mind, because the department has to primarily have disabled persons as its clients, most of whom shall be walking with the use of aids and appliances or wheel chair bound or geriatric age group.

Therefore, the department area sliould be barrier free with wide door, smooth flooring which is non-slippery. Ramps if required may be provided of the appropriate dimensions. Preferably the building should be single storied, and if the same is not possible because of constraints of land area and vertical expansion is must, there should be provisions of lifts with wide doors with back-up generator facility. There should also be a climbing ramp instead of stairs in addition to the lifts. The doors may be electrically operated, so that the patient does not have to maneuver them himself.

In general hospital setting, it is preferable that a 75 bedded rehabilitation unit is made available, for admitting people with disabilities for medical rehabilitation intervention. Physical layout of a PMR department is enclosed to have a general idea about the location of its various sections.

c) Equipment

The department sliould be equipped with following types of equipment:

- Diagnostic equipment
- Therapeutic equipment
- Surgical equipment

In the diagnostic equipment there should be electro neuro muscular diagnostic equipment and urodynamics equipment.

It is presumed that the other radio diagnostic facilities, clinical laboratory facilities and other diagnostics facilities shall be available in the main Medical College Hospital. In the therapeutic equipment, there should be equipment for Electrotherapy, Hydrotherapy, and Gymnasium. For occupational therapy activities, sensory perceptual training and training in activities of daily living, there sliould be appropriate equipment available.

For the prosthetic and orthotic workshop, tliere should be equipment for measurement, fabrication and manufacturing of aids and appliances and the materials and supplies required for their manufacturing. Similarly, for psychological testing there should be appropriate tools available for assessment and in the vocational training section, there should be availability of equipment for the various vocational training activities. For hearing and speech section, there should be a fully equipped hearing and speech assessment laboratory and therapy room.

The other essential office equipment and materials like computer, typewriters, furniture etc. will also form part of the overall equipment. A vehicle will be required for home visiting of people with disabilities.

.....

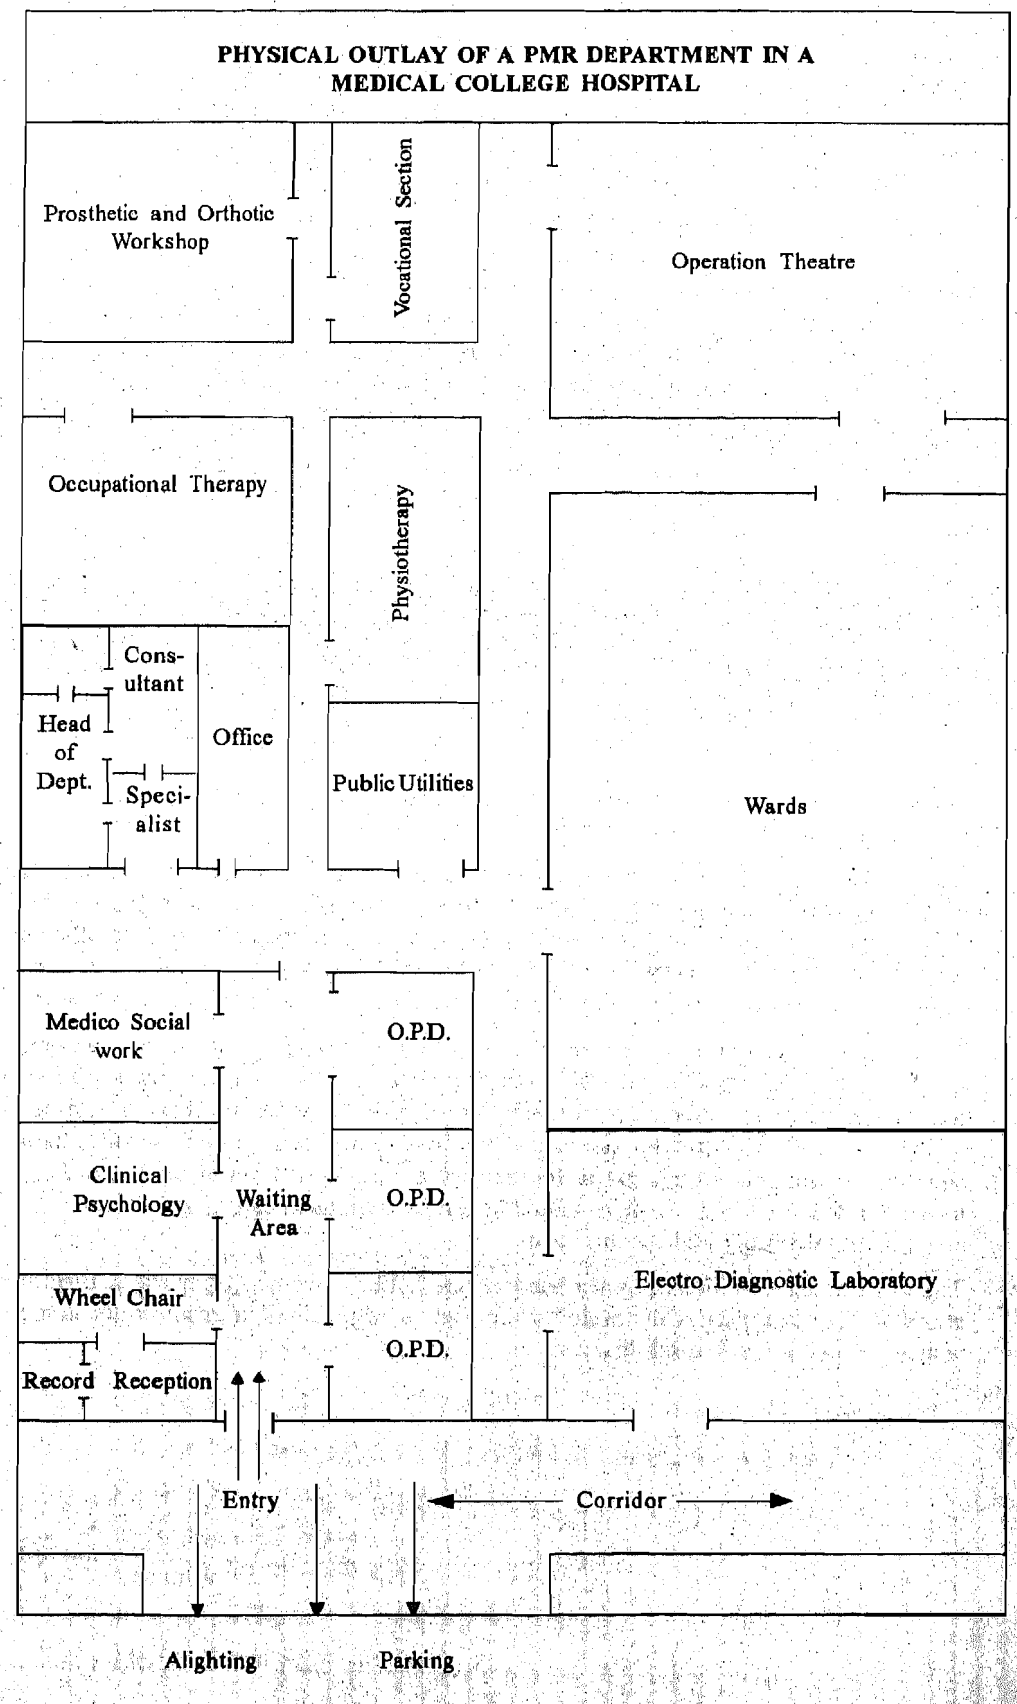
2) Discuss the paramedical manpower requirements of a PMR Department.

.....

.....

.....

.....



4.9 POLICY AND PROCEDURES

As enumerated in Section 4.5 a person with disability encounters psycho-social, educational and vocational problems in addition to the physical problems. In order to rehabilitate him, a comprehensive team approach is essential. A comprehensive rehabilitation team approach envisages rehabilitation management of person with disability to train and to re-train him to the maximum extent possible in terms of physical, psycho-social, educational, and vocational functions by a team of personnel, which include doctors (Physiatrist), physiotherapist, occupational therapist, medical social worker, psychologist, vocational counsellor, speech therapist, special educator and prosthetist and orthotist.

Such comprehensive rehabilitation management services can only be accomplished in a hospital setting where a separate rehabilitation department exists.

Thus, it is essential that each medical college hospital or a major services hospital should liave an independent Department of Physical Medicine and Rehabilitation, which can, in addition to providing the services, also act as a teaching centre for human resource development in physical medicine and rehabilitation. At the same time, it has to bc considered that such departments can only serve limited number of persons with disabilities either as out-patient or while patients are admitted in other specialities and required services of rehabilitation department. Alsa through such department in a hospital setting, it is mainly the medical rcliabilitation component i.e. physical restoration which can be accomplished. For meeting educational and vocational needs person with disability has to be referred to the appropriate institution.

Further, considering the magnitude of 'the problem of the disability, a large number of persons with disabilities cannot come to the hospital for availing the rehabilitation services due to variety of reasons, neither the hospital based department can cater to a very long case load. As such, either the hospital based rehabilitation department has to make provision for extending the services to the nearby community, or community based rehabilitation services have to be organised in order to provide for larger coverage as been mentioned in Section 4.7.

The function of a physical medicine and rehabilitation department in a hospital setting consists of medical measures, in the form of diagnosis and treatment of'neuro-muscular and musculo-skeletal problems. The patients either report directly in the department or may be referred by other'specialily doctors, if they feel that the patient will be benefited by rehabilitation services; As mentioned earlier it'can be both for outdoor as well as indoor patients. In the Department of Physical Medicine and Rehabilitation, the Rehabilitation Specialist examines and'diagnoses the condition and prescribe the treatment which is usually in the form of therapy or provision of certain aid and appliances. In certain cases, need may arise for rehabilitative surgery e.g. correction of a contracture or deformity, or revision of a bad stump in order to achieve better fitting of the artificial appliances. The Physiotherapist works with the aim of physical restoration of the patients in the form of improvement of power in the weak muscle, improving the range of motion of a joint and application of various modalities to relieve the pain. Occupational Therapist works with the aim of training the patient through a range of activities in order to achieve maximum independence and make him as functional as possible, so that he can carry out his day to day activities with as much independence as possible, thus minimizing dependence on the family member or the community. The Prosthetist and Orthotist measures, fabricates and manufactures the artificial appliances as prescribed by the Rehabilitation Specialist. Thereafter, the patient has to be trained to use it to achieve the desired function like ambulation, feeding, writing etc. The speech therapist works with the aim of assessing the speech defects and providing for any aid, if indicated, and to give speech therapy to improve communication. The psychologist evaluates the intelligence and any psychological disorders like depression, anxiety etc. which may be associated with the physical disability and provides the required counselling as and when indicated. The medico-social worker act as a liason person between the treating team and the patient, as she/he acts as a friend and philosopher of the patient, gains his full confidence and assists the rehabilitation process. The medico-social worker also evaluates the economic and social problems encountered by the patients and tries to resolve them to the best of his/her potential.

For patients who are admitted to the various wards, and who need rehabilitation services, a referral system is required to be developed so as to attend to their needs

either on the bed side or by bringing the patient to the rehabilitation department depending upon the disability of the patient and the acuteness of the problem. A close liasoning has to be developed with the various other specialities in order to provide the maximum benefit to the persons with disabilities.

In some hospitals, where independent department of physical medicine and rehabilitation do not exists but there is a nucleus of physiotherapy and/or occupational therapy, ideally such nucleus has to be upgraded to a full-fledged department of physical medicine and rehabilitation, but till such time the therapy can be prescribed by the treating specialist which in turn can be executed by the therapist.

Ideally speaking, each major hospital/medical college/teaching hospital should have a physical medicine and rehabilitation department and rehabilitation centres at district level, with the community based rehabilitation services at the grass root level, and there should be two way linkages at all the three levels. Only then, we can hope to provide rehabilitation services to all the persons with disabilities.

4.10 MANAGERIAL ISSUES

Rehabilitation is a team work, where in the skills of the rehabilitation team consisting of the physiatrist, physical therapist, occupational therapist, nurse, medical social worker, prosthetist and orthotist, speech therapist, vocational counsellor, psychologist etc. are integrated as a single force to assist the persons with disabilities in reaching the maximum of their physical, emotional, social and vocational potentials. As a matter of fact, good team work is the key to successful rehabilitation.

One of the most important managerial issues, therefore, is that the multi disciplinary team should work effectively, and for this purpose, effective leadership is needed. The appointment of a leader helps to clarify the aims of team work. The team leader has to assume responsibility for the coordination of the team activities, without which the team will lack cohesion and sense of common purpose,

The leader ensures that there are adequate opportunities to discuss issues relating to team work and tries to encourage all team members to participate.

The leader has to assume responsibility for developing and maintaining a 'unit culture'. The leader of the team should not be 'autocratic'. The leader should actually clarify for all members of the team where independent action is to be encouraged, where joint decisions are to be made, and in the event of differing views, unify the team behind a common decision. In a team work situation, it is important that every one tries to understand what individuals are suggesting rather than opinions being dismissed out right. There should be a genuine interest expressed in each other's views. A team should exhibit a balance between agreements and disagreements. This balance is called cohesion and this hinges on the team's ability to accommodate disagreement, which is necessary before roles, tasks and goals can be clarified. Someone has rightly said that 'Teams are Built, Not born'. And, the one way to build good teams is by finding solutions to various issues that come in way to effective team functioning.

The second important managerial issue is the management of machinery and equipment. A PMR Department, in addition to the multi disciplinary team approach, has to depend

heavily on the various diagnostic and therapeutic equipment and machines in order to provide patient services.

An effective planned approach towards purchase of new equipment and most importantly the maintenance of the equipment in functioning order through annual maintenance contracts (AMC), so that the idling time of the machine or equipment is kept to the minimum possible. It will help in providing uninterrupted patient services.

The third managerial issue is the material management because a variety of materials have to be stocked in a PMR Department, specially for the fabrication and manufacture of artificial limbs and appliances for the people with disabilities. An uninterrupted supply of good quality materials will ensure proper and timely delivery of aids and appliances to the people with disabilities for their rehabilitation.

The fourth managerial issue is the record keeping. The clients visiting a PMR Department usually suffer from chronic problems and visit the department frequently to avail the various facilities like physical treatment, counselling, certification, repair of aids and appliances etc. Therefore, effective and systematic record keeping is essential for smooth functioning of the department.

Check Your Progress 8

411 LAWS RELATED TO DISABILITIES

Article 41 of the Constitution, which is one of the Directive Principles of State Policy, reads, 'Right to work, to education and to public assistance in certain cases—Thestate shall within the limits of its economic capacity and development, make effective provision for securing the right to work, to education and to public assistance in cases of unemployment, old age, sickness and disablement and in other cases of undeserved want, Here again, the right to public assistance in cases of disablement, subject to the economic capacity of the State has been recognised. There has, however, been a sea-change in the attitude and perception of the society regarding the disabled over the years. The disabled who, were classed along with unemployables and were made entitled to public assistance in the Constitution, have now been favoured with job reservation in State sector and all round promotion of rehabilitation to government providing grants, setting up of institutions and infrastructure etc. This significant change needs to be reflected through suitable amendments.

First Central Act

The first Central legislation enacted by the Government of India is the Rehabilitation Council of India Act, 1992. This Act provides for the constitution of the Rehabilitation Council of India for regulating the training of rehabilitation professionals, and the maintenance of a Central Rehabilitation Register and for matters connected therewith or incidental thereto. The Act provides statutory basis to the Rehabilitation Council, which was set up earlier, in 1986, as a registered society. The Council is expected to undertake the functions of recognition and derecognition of qualifications granted and training courses run by institutions/universities and of registering rehabilitation professionals who possess the recognised rehabilitation qualification. Practice by persons not

possessing recognised professional qualification has been made illegal and punishable under this Act. The Act thus, aims at ensuring quality of rehabilitation services. The Act is modeled on the pattern of Medical Council of India Act and like the medical discipline, rehabilitation, too has acquired the status of a discipline, in which education and training is to be regulated in order to ensure quality.

Persons with Disabilities (Equal Opportunities, Protection of Rights and Full Participation) Act, 1995

In the year 1995, a Bill entitled "Persons with Disabilities (Equal Opportunities, Protection of Rights and Full Participation) Act, 1995" was passed by the Parliament which was made into a law in 1996. The purpose of the Bill is to fix responsibilities on the Central and State Governments to the extent their resources permit, to provide services, create facilities and give support to people with disabilities in order to enable them to have equal opportunities in participating as productive and contributing citizens of the country to their fullest extent. It fixes its responsibilities on the governments (Central and State) to ensure that disabilities do not prevent individual citizens of this country from living a dignified life and making full contribution by each in accordance with his/her ability. This Act provides a framework within which specific demands can be made by the disabled persons in order to ensure that the Government honors the promises made in this Act.

It is hoped that the Act will enable the fellow citizens with disabilities to become equal partners in Nation building and valuable contributors to socio-economic development of the country. The Government has from time to time announced concessions and facilities for the people with disabilities to facilitate their lives, such as concession in travel by rail, road and air, incoine-tax rebate, priority in house allotment, reservation of jobs in governinent sector, age relaxation in jobs, scholarship to students, conferring National awards to outstanding disabled employees in government and those who are self einployed, best employer of disabled, best individual working for disabled welfare, best institution for disabled welfare, placement officer of disabled, and National technology award for welfare of the disabled. Besides these there is a Scheme of assistance (ADIP, 1981) for disabled persons for purchase and fitting of aids and appliances.

.....

2) Write a brief nolc on RCI ACT, 1992.

.....

.....

4.12 LET US SUM UP

In this unit you have learnt some basic concepts about disability prevention and rehabilitation and, the discipline of Physical Medicine and Rehabilitation, and the growing need of this discipline, keeping in view the increasing incidence and changing spectrum of disabling conditions.

You have also learnt about the problems related to disabilities and their solutions. Keeping in view the gigantic problem of disability, the various rehabilitation approaches have been explained, of which, the community-based rehabilitation (CBR) deserves special mention. As through this approach approximately 70% of the problems can be handled at the community level itself. The integration of CBR into the country's existing health care delivery system is perhaps the crying need of the time, so that universal coverage can be provided to the disabled masses.

While mentioning this, the role of the State/Medical college level PMR Department cannot be undermined, as without them, there cannot be generation of more manpower which is so much required, and availability of referral services, which these centers provide.

UNIT 1 LABORATORY SERVICES

Structure

1.0 OBJECTIVES

After going through this unit, you should be able to:

- list the roles und functions of laboratory:
- describe the types and functional components of a laboratory service;
- discuss the planning concepts in organisation of laboratory services;
- describe the policies and procedures concerned with laboratory services: and
- identify the key managerial issues in planning and organisation of laboratory services.

1.1 INTRODUCTION

In this unit you will learn about definition, types and characteristics of laboratory services and also about planning consideration, physical facilities and layout, You will also learn

about the use of equipment for various types of laboratories and staff requirement, need for training and research requirements. Further you will learn about the maintenance of minimum standards of lnboratory quality assessment and various programmes of the country. Towards the end you will learn about the application of sound principles for personnel management, efficient and cost effective operation of a clinical laboratory with timely, effective delivery of medical laboratory services to clinicians and patients.

1.2 ROLE AND FUNCTIONS OF LABORATORIES

The laboratory as you know exists for the sole purpose of providing diagnostic and management information for the physicians to aid in the patient care, The ultimate goal of laboratory is to attend to the ailing patients, carry out the investigations asked and prompt issue of accurate results for favour of diagnosis and treatment.

The clinician uses the laboratory to get assistance in diagnosis and management of the patient. Infact, a test requisition is a request for consultative services which sets in motion a vnst array of activities to generate a laboratory report. Usefulness of the data in making clinical judgements depends upon prompt, accurate reporting of the result. Each procedure to generate a result consists of series of steps, or processes. An adequate understanding of each process enables the laboratorian to achieve more nearly optimal conditions and, consequently, to improve the accuracy and precision of each measurement. Collection, handling and processing the specimen prior to analysis must receive prime consideration. Validity of data obtained on the specimen itself is highly dependent upon the excellence of laboratory technique, including proper manipulation of equipment, use of reagents of specified purity.

1.3 TYPES AND FUNCTIONAL COMPONENTS OF LABORATORIES (LABORATORY MEDICINE)

Having learnt the definition and functions of laboratory, now you will learn the functional components and types of laboratories.

1.3.1 Functional Components

The Functional components of a clinical laboratory are:

i) Histopathology
ii) Clinical Pathology
iii) Microbiology
iv) Haematology
v) Biochemistry
vi) Research laboratories

There are further subdivisions of each of the above components related to sub or super

specialisation. However, these are not enumerated here. Only the functional laboratories in routine day to day diagnostic work are summarised.

i) Histopathology

Laboratory performing organ, tissues, cell examination for the diagnosis of various types of abnormalities/diseases is called as Histopathology Laboratory. Examinations of tissues/organs are from living/dead body, in the form of either surgical specimen; biopsy or autopsy.

ii) Clinical Pathology

This is the branch of pathology in which all body fluids such as blood, urine, sputum, stool, pleural, peritoneal fluid are examined for physical, chemical, bacteriological and microscopic examination for normal or abnormal contents.

iii) Microbiology

This is the science which deals with study of microbes such as bacteria, viruses, parasites etc. The study involves the identification, morphological and cultural studies, serology and sensitivity of organisms responsible for causing the disease or commonly found as commensals.

iv) Haematology

Branch of laborntory Medicine in which the study of blood and blood components is done for detection of various abnormalities in normal and ill health.

v) Chemical Pathology (Biochemistry)

Science which determines and measures various chemical substances in normal and abnormal amounts produced during disease process. The study includes examination of various groups of clinical substances, hormones, enzymes, isoenzyme, vitamin and metabolites etc.

vi) Clinical Research Laboratories

Are those laboratories which deal with research related to patient care system or services, research related to development of techniques, methods and applications, therapeutic trials of drugs, reagents, kits, equipment development and animal experimentations. Research nnd development is an integral part of patient care services and such laboratories are designed for research and academic purpose.

1.3.2 Types of Laboratories

Most of the hospital laboratories function as:

i) OPD Services

ii) Ward Services

iii) Emergency Services

i) OPD Services

OPD Laboratories are basically Central laboratories in a large hospital which caters to the need of out patient department during OPD hours.

ii) **Ward** Services

Ideally each ward is attached with functioning laboratory catering to needs of the ward for routine investigations. However, some ward laboratories are attached to respective specialities (Block system) i.e. Surgical; Medical; Paediatric; Orthopaedics; Obstetrics and Gynaecology etc. The investigations other than bed side/routine tests are referred to central ward laboratories of specific departments between 9-10 AM to 4-5 PM, normal duty hours of hospital.

iii) Emergency Services

These can be 24 hours (round the clock) services or restricted emergency services,

a) ***Round the Clock Services***

Majority of hospitals having 100 bed capacity and above should give round the clock emergency services. Each Emergency Service includes 3 shifts of duties (24 hours).

b) *Restricted Emergency Services*

These types of emergency laboratory services are restricted to one or two shifts excluding public holidays and national holidays.

These services are restricted to augment manpower in particular specific organisation and depends on structural and functional requirements of hospital.

Check Your Progress 2

Name the functional components of the Clinical Laboratory.

.....

.....

.....

1.4 CONCEPTS OF PLANNING ORGANISATION

The efficient operation of clinical laboratory and effective delivery of medical laboratory services to clinicians and their patients require a complex interaction of expertise in medical, scientific and technical areas, of resources in the form of personnel, laboratory and data processing equipment supplies and facilities, and of skill in organisation, management and communication. Awareness of accreditation standards and Governmental regulations of laboratory practice should be known to I-Iead of laboratory services and he must ensure quality laboratory performances.

The steps in systemic approach to the orgnnisation and management is to establish general goals and specific objectives, To maxirnise the effectiveness and efficiency of operations. the functioning laboratory must have the following:

a) Adequate facilities (including Lab, wash rooms, store, reagent preparation rooms, staff common library. toilets, conference room etc.)
b) Approprinte Equipments
c) Standurd Reagents/Chemicals regular supply
d) Adequate number of qualified staff.

1.4.1 Physical Facilities and Layout

Physical facilities for laboratory function and its complete layout depends upon the structure, culture and environment of organisation. Specific design considerations include:

1) The concern of size in planning a laboratory is always a major question. Factors for consideration in dotermining space requirements include the scope of procedures to be performed, intended operationnl approach for performing procedures, and the anticipated size of the laboratory depnrtment.
   a) **Square Footage:** Depending on design of the laboratory, the net square footage in the modern laboratory varies approximately 65-90% of gross square footage.
   b) **Scope of Services:** Depends upon type of hospital and facilities to serve e.g. teaching hospital, research hospital etc. Adequnte scope for future expansion must be kept.
   c) **Mechanical Services:** Proper planning for mechanical services essential specially civil and electrical work of PWD (CPWD), provision of safety devices etc.
   d) **Operational Approach:** The amount of space required in laboratory somewhat depends upon how tests are being performed, the space requirement gradually reduced with use of automation computerised technology. The interior design to be suitably modified with consultation and coordination of architect engineer and Laboratory Manager.
   e) **Laboratory Information System:** Provision of communication between laboratory with ward/OPD and treating physician be maintained.

f) **Laboratory Safety:** Various safety measures for staff and property etc. as against fire, biological toxic waste, radioactive material, following the universal precaution etc. be made adequately.

2) Functional Consideration in Laboratory Design

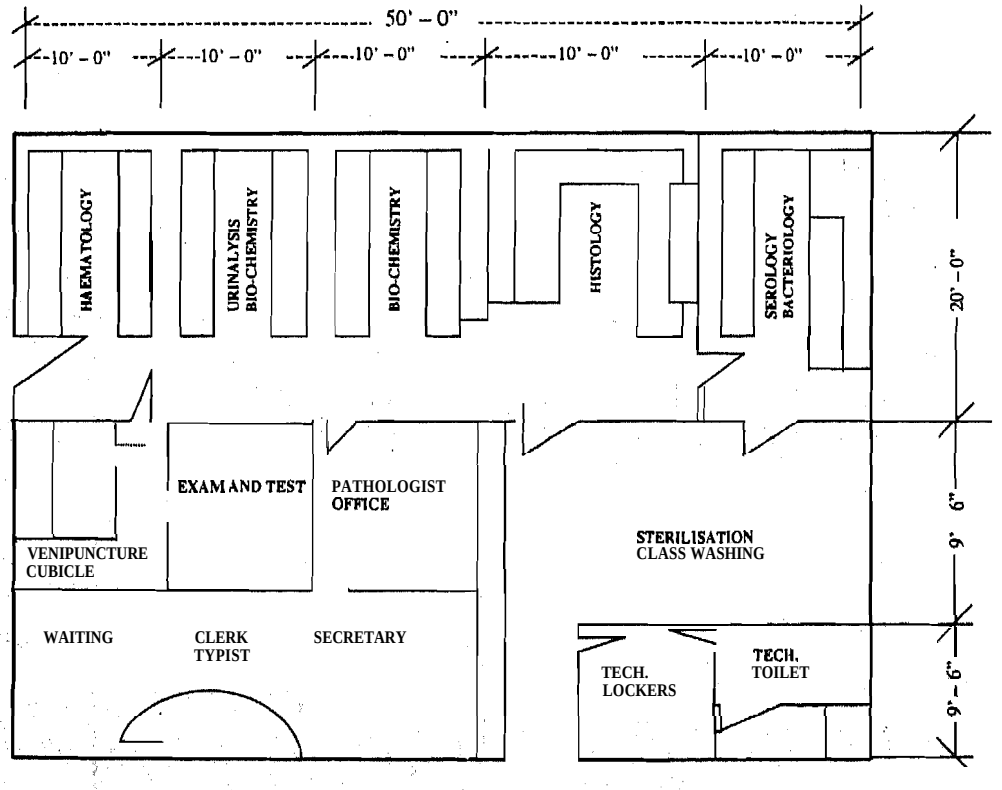
Considering recent trends and advanced technology, changes from traditional laboratory set up to be made in relation to clinical problems, disease orientation nnd functional efficiency. Various sub-units of laboratory medicine viz. Clinical Chemistry, Clinical Pathology, Microbiology, Histopathology, Haematology etc. have different functional set up of orientation. The organisational approach must have its value in future along with alternative functional approaches being considered.

Pathologist having the opportunity to design a new laboratory or make major renovation in older laboratory, should,think in functional terms about the laboratory operations and their facility needs.

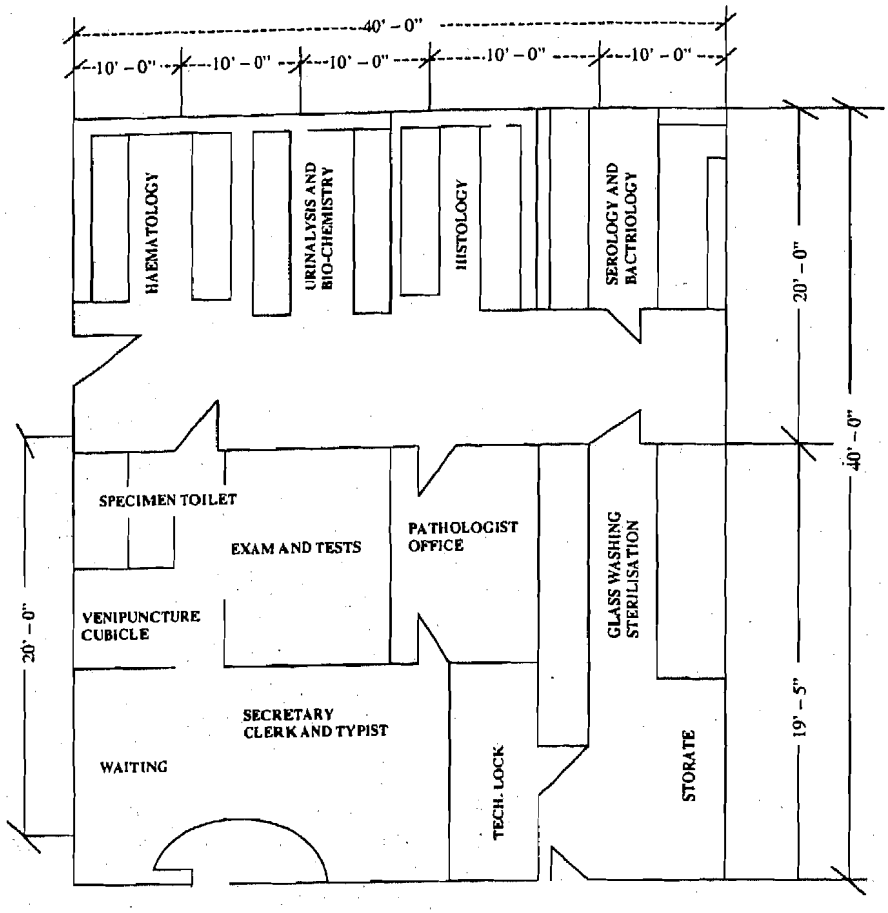
Traditionally laboratories have been organised without due regard to the functional requirement. The whole concept of a laboratory has changed during the last decade. Unfortunately there has been a lot of proliferation of laboratories which are sub-standard and with no knowledge of quality control. The only way to curb such practices is to start good laboratories and provide facilities at reasonable costs, by qualified pathologists. Today, a planned laboratory can be started with a budget of one lakh rupees. The basic needs to start a laboratory can be worked out on the basis of a survey made which will give the probable sample turnover.

The accommodation initially, should be reasonably good to start the common tests that are in demand and should be properly planned so that it will be functional and convenient.

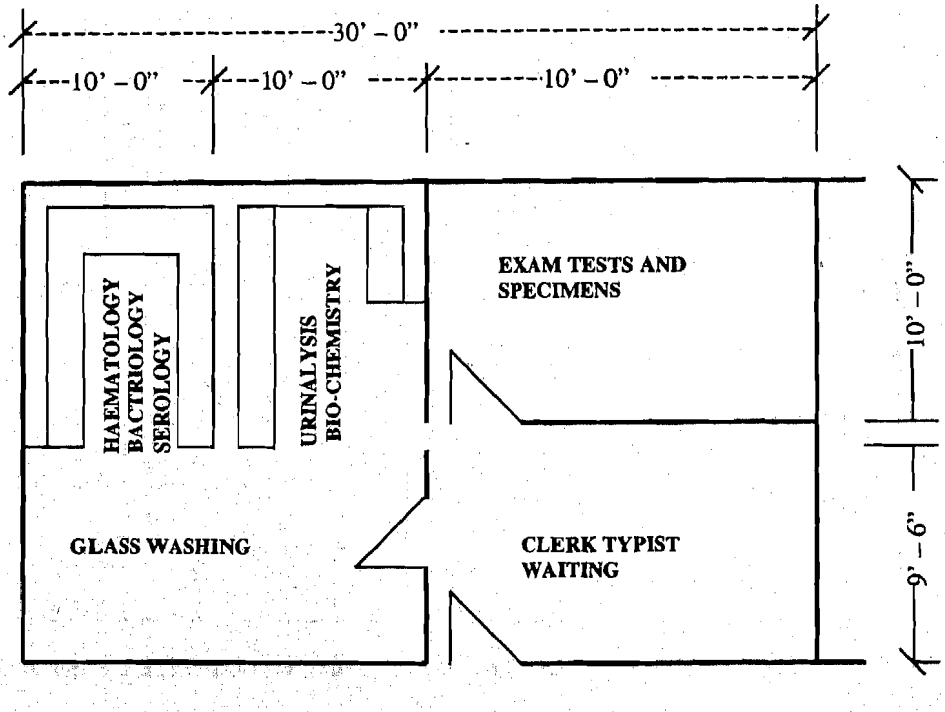
A few samples of plan (Plan **A,** Plan B, Plan C) are given below which are scientifically developed. Depending upon the area available, these plans may be applied suitably.



PLAN – A (70,000-1,20,000) TESTS ANNUALLY FOR AVERAGE SIZE OF 150-200 BEDS



PLAN– **B (40,000-75,000)** TESTS ANNUALLY FOR AVERAGE **SIZE** OF **100-150** BEDS



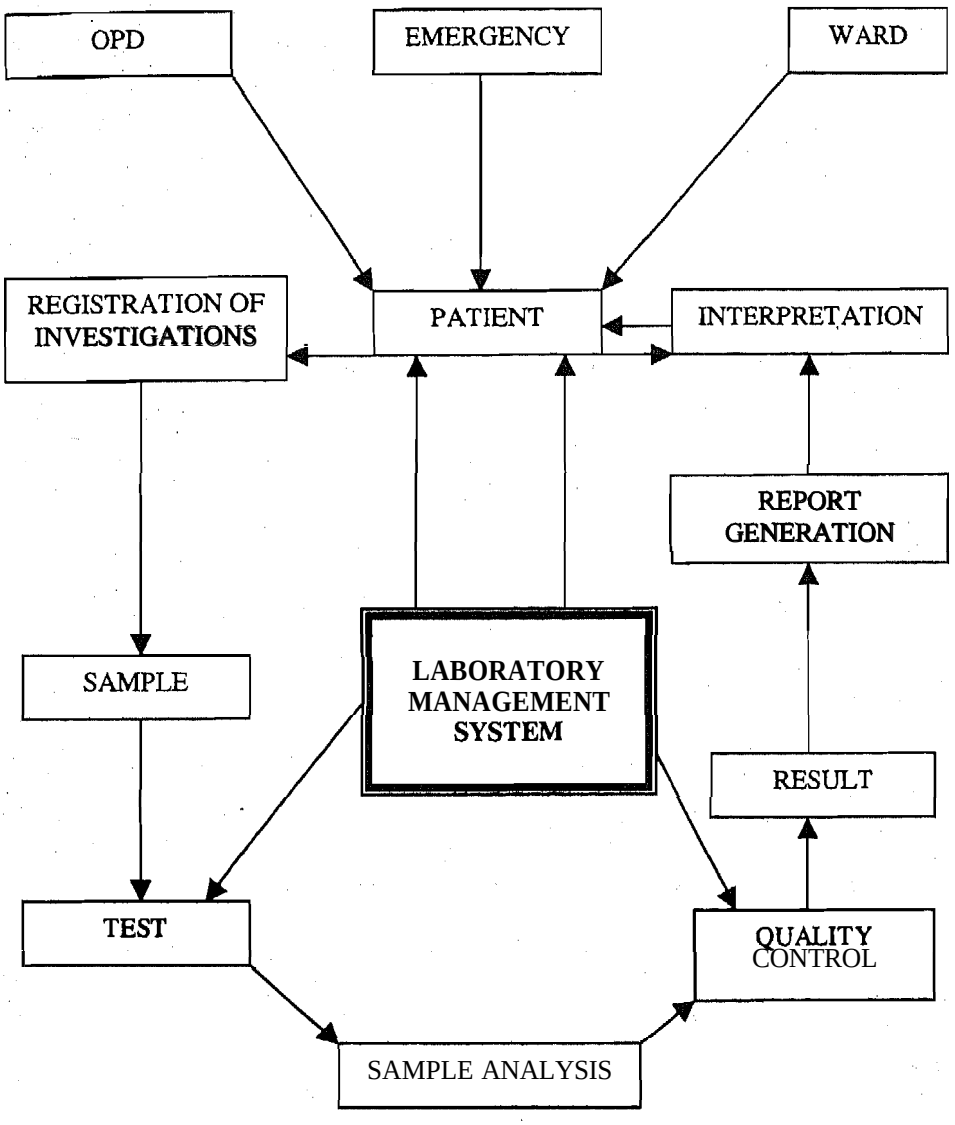
PLAN – C (20,000-30,000) TESTS ANNUALLY FOR LESS THAN 100 BEDS

3) Spatial Considerations in Laboratory Design

Spatial relationships within the institution are important. It is critical that location of the laboratories be studied in relationship to the other hospital services, traffic, supporting services, and users. Emergency laboratory system should be readily accessible to emergency, surgical, medical, orthopaedic, gynaecology etc. wards, ICU, ICCU and casualty.

Organisation in the clinical laboratory refers to both structure and process whereas structure exemplifies stated relationship or framework and process deals with interaction.

The following is the flow diagram in Laboratory function system:



Three key elements of organisation are:

A) ***The clinical laboratory:*** as a work place

B) ***Staff***: who performs the test

C) *The* task: to be performed (Investigations and Reporting)

A) The Clinical Laboratory

The first important object is:

i) **Traffic flow planning:** The intra laboratory traffic is separated from out side traffic. Adequate provisions should be made for ambulatory patients and blood bank donors where ever applicable. Usually blood bank has separate building in majority of, hospitals with provisions of independent functioning unit.

ii) Specimen and Data flow: The authentic schematic layout to be available with Head of Department for strict compliance.

iii) Process and Storage: Pre-analytical process and storage of specimen/material to be done with each laboratory or to be done centrally if organised.

iv) Emergency Sample: Provision of emergency samples to be arranged.

v) LIS: The laboratory information system to develop according to available resources.

B) Staff Requirement

There use to be a relation between number of tests and staff requirement, given in old text books, Now due to development of automation in clinical, chemical pathology and all branches of laboratory medicine the conventional techniques are being replaced by automated techniques. Hence it is difficult to calculate the number of test performed by an individual per day and relate it to day to day activities. A time study format has been developed by Rappoport in 1975 in which standard time of each investigation (job activity) to be calculated and related to time availability of working technical personnel on day to day basis to evaluated per day investigations.

The following formulae are used to determine average investigation/day/technical staff.

Standard time = Total basic time x Time allowance

i) Total basic time = Total average basic time of job element
Basic time = Average observed time x Rating

ii) Time allowance = Contingency allowance (5% of the total basic time) x Relaxation time (12% of the basic time)

Parameters

i) Element/job description steps (which should also include job elements other than investigation steps)

ii) Observation 5-10 times

iii) Total observed time in each step

iv) Average observed time of one test

v) Rating of individual as 100% by an average working

Total laboratory functioning job activities from reception of sample, registration, solution preparation etc., processing, reporting entry, indexing, despatch, laboratory waste disposals etc. are considered in job element per day.

Day functioning technical staff = 6½ hour of duty (36 hours per week)

Observed work/day/technical staff when both automation/conventional techniques are shared in mixed type of spectrum of investigations } =60-70 tests/day

1.4.2 Equipment/Reagents and Facilities

While planning equipments, reagents and other facilities for laboratories following need to be considered:

a) Basic instruments and equipment should be made available. All vital equipment to be in duplicate or alternative arrangement for its applicability to be provided.

The following instruments are basic equipments for all types of routine investigations:

i) Colorimeter/photoelectric colorimeter
ii) Centrifuge
iii) Water bath

iv) Microscope – Mono occular/Binoccular
v) Hot air oven
vi) Autoclave
vii) Incubator
viii) Ph-Meter
ix) Automated Biochemistry analyser
x) Automated Haernatology analyser
xi) ELISA – Reader
xii) ELISA – Washer
xiii) Microtome
xiv) Wax melting bath
xv) Hot plate

The requirement of specialised functions of laboratory depends upon the type of speciality developed in organisation. The spectrum of investigations and number increases accordingly. The advances in laboratory medicine is tremendous, more sophisticated, technology equipments are being added day by day. The need to acquire depends upon:

i) Type of hospital/organisation and structure of the institute

ii) Daily attendance of patients either from out patients/inpatients with available speciality are important factors in deciding procurement of high sophisticated automated equipment. The cost effectiveness to be evaluated as per standard parameters. The choice of high technology equipment to be related to number of test performed per day and spectrum of test needed to be performed on day to day basis, The specification of equipment for procurement is a very vital parameter in decision of choice of equipment and procurement. The head of Deptt. and hospital/institute procurement authorities should discuss at length the use coefficient, the need and justification before placing order.

b) Purchase and product specification should be viewed justifying the need of the equipment and the use of instrument in relation to number of investigations and spectrum of investigations.

c) Type of automation and availability facilities which are essential pre-requisite for installation of equipment.

d) After sales service, availability of reagents as open system, warranty and availability of spares till life of instruments and possibility of upgradation of instrument in due course of time.

e) Every person working in a laboratory should be thoroughly familiar with storage specifications, irrespective of chemicals, reagent or instruments, A constant check is maintained on expiration dates. Chemicals and reagents after the expiration dates should be disposed without delay to prevent impending hazards.

f) Apart from basic amenities like water, electric supply the measures should be taken for condemnation and disposal of all items as per inventory.

g) Laboratory wastes and its disposal is an essential element of focus to all laboratories for early and immediate compliance,

h) Basic record cards or register should be maintained as per laid down guidelines issued from time to time from the organisation of the structure. Computerised inventory system if available should be encouraged for constant use.

1.4.3 Research and Training

Research

Research is an integral part of laboratory system. Various research projects pertaining to hospital's functioning, equipment development; technology upgradation; disease incidences; treatment progress and all matters in relation to diagnosis and monitoring of patient are part of the system management.

Training

Training of technical personnel either in service or who intend to join service or engaged in practice of technology should undertake complete, prescribed, identified, recognised course of stipulated period before rendering any type of service in the field of laboratory medicine. Continuing Medical Education (CME) programme for technical people should be made compulsory if not mandatory. Participation in training programmes, workshops, seminars are to be encouraged amongst all working technical personnel from time to time.

Orientation

Early introduction to laboratory staff of the new employee contributes to the development of an effective inter personal relationship, which is necessary to build teamwork. An orientation programme is one of the most over looked management tools. Apart from institutional orientation, each laboratory should have a defined programme of orientation for all new employees to make them aware of policies, SOP (Standard Operative Procedures) and standard performance are expected in laboratory environment and culture. Orientation serves to correct potential misunderstanding that are so often present with new employees and establish channel of communication between management and the new employee. During orientation, rules and regulatory demands regarding quality assurance, universal precautions, hazardous waste, the right to know etc., are clearly defined and expectations well presented.

1.5 POLICIES AND PROCEDURES

The provisions of quality laboratory services with efficient reporting, interpretive diagnosis depends on the application of sound principles for personnel management. Efficient and cost effective operation of a clinical laboratory with timely, effective delivery of services requires a complex balance of expertise in medical, technical and scientific activities.

1.5.1 Laboratory Administration

There are four basic elements of laboratory administration:

1) **Objectives:** Goals and purposes consistent with high quality and cost effective delivery of laboratory services.

2) Guiding People: Leading and directing in such a manner that professionals feel sense of responsibility, achievement and appreciation of work performed.

3) Resources: Proper utilization of physical resources such as instrumentation, desk top computers, space, Laboratory Information Service (LIS) etc.

4) Organisation: The dynamic organisational unit where labour policy, procedure and operations are managed in a reasonable cost effective, safe and productive manner.

1.5.2 Quality Control and Assessment, Accreditation and Total Quality Management (TQM)

Quality Control and Assessment

Quality Control and Assessment is the process to ensure a test from being done wrongly. The primary aim of Quality Control and Assessment is to see that the very purpose for which a test is performed is not defeated due to unreliability of the result. Quality assessment of all process of testing sample, analysis pattern, check of reporting and result with precision and accuracy has to be done. The following are techniques of Quality Control:

i) ***Internal Q.C. (Intra Laboratory Q.C.)***

- Performed by individual laboratory at their own level.
- Forms the basis of day to day work of quality assurance.

ii) ***External*** Q.C.

- Performed by many laboratories at the same time monitored by one.
- Periodic monitoring for the performance of the laboratories.

Accreditation

Laboratory accreditation is a procedure by which an authoritative body gives formal recognition of technical competence (including qunlity system management) of testing and or calibration for a laboratory to carry out specific tests. This is based third party assessment against set standards.

Accreditation is considered to be the essential first step toward mutual acceptance of test results and test certificates. An increasing number of health care organisations now require that diagnostic laboratories meet national standards for accreditation. The laboratory accreditation is a means to improve customer confidence in the calibration and testing reports issued by the laboratories so that all interested parties shall accept the reports with confidence.

Total Quality Management (TQM)

This is one of the most promising managerial innovations introduced within the health sector within the last several decades. TQM increases the efficiency and effectiveness of health care services.

The following factors are to be considered:

- Top Management Leadership
- Creation of an organisational frame work for quality improvement in hospitals
- Transformation of hospital work culture
- Customer focus
- Process focus
- Employee education and training
- Learning by practice and teaching
- Bench marking

- Quality measurement and statistical reports at every level
- Recognition and reward
- Management integration

1.5.3 Leadership and Motivation

It is the integral part of laboratory management system. Studies have been conducted to know the effects on productivity and concluded that the administrative process of management includes planning, decision-making, organising, directing and controlling. This process completed with management inputs (financial, physical, and human) has a direct effect on outputs (cost benefit, performance, products and behaviour).

1.5.4 Personnel Management

Personnel policies, procedures and records are vital to the efficient and cost effective operation of any laboratory. In addition, policies and procedures are necessary to meet accreditation and regulatory requirements. In fact, a proper staffing and effective scheduling have more impact than any other management tool in establishing quality laboratory service and cost reduction.

1.5.5 Personnel Policies

With regard to personnel policies following must be taken care of:

i) Qualified persons should be recruited.
ii) A good rapport should be maintained between person-in-charge and the working staff.
iii) Basic needs and comforts should be provided.
iv) The person is given the job description.
v) Duty allotment schedule among the staff should be carefully prepared.
vi) Opportunities should be provided for betterment of skills and position.

1.5.6 Job Description and Staffing

Staff pattern depends upon member and spectrum of investigations in clinical laboratory, Scheduling and staffing are important management responsibilities that must be reviewed and revised as often as necessary to maintain efficient and cost effective services,

Job description is a summary of all important and significant facts about a particular job, Duties and responsibilities of working technical personnel to be clearly defined and illustrated and should be confined to gazette notification of recruitment rules approved by Department of Personnel in Government Organisation. For other organisations it is between employee and employer with clear understanding and written document contract mutually agreed upon. Finally, although job descriptions are essential management tools for staffing process, they also sense as both training and evaluation guides for establishing employee incentive,

The basic job description as you know should include a job title, duties, qualification, job relationship, and necessary work aids. (Conventional techniques and Automation.) Day and hours to be worked out as per existing norms laid down by institutions/respective Government.

1.5.7 Recruitment, Policies and Procedures

Recruitment policies differ according to organisation structure. However it is advised to follow strictly the Recruitment Rules of the designated post and appointment to be done strictly under rules of the institution/Government by competent authorities to avoid legal complications. Adhoc appointments for vacent position whenever filled up to be regularised within limited period.

It is recommended that prior to interview process a list of establish criteria and interview question based on job description, be prepared, qualitative criteria be made to ensure that

all candidates are compared equitably and the laboratory is generally able to recruit quality personnel.

1.6 INFORMATION MANAGEMENT

Laboratory management is a complex process involving quality control, work flow allocation etc. Information system within the laborntory and inter laboratory are order of magnitude, more complex than the communications with outside world.

Day by day, there is addition to technology information nnd transaction to users. Data transfer at much higher rate is in common use. A properly selected and installed laboratory information system, can provide valunble benefit in improved laboratory operation and higher quality patient care.

The following are benefits of laboratory information system:

- Reduces errors such as mix up specimen, calculation errors, transaction errors etc.
- Improved staff productivity.
- Rapid availability of results and improved tum around time.
- Transformation of reports to patient.
- Improved patient reports legibility; duplicate reports, interpretive diagnosis, graphics etc.
- Improved management information.
- Quality assurance data record maintenance.

1.7 MANAGERIAL ISSUES

Laboratory as you know exists for the sole purpose of providing diagnostic and management information for the beating medical official, to aid in the care of patient. During the past few years there has been a considerable increase in the clinical demand for laboratory investigations both in number and spectrum of tests.

The following managerial issues are essential to consider:

1) In recent years, there has been an alarming increase in the error of judgement, errors of omissions'and commissions on the part of technical staff, Pathologist/Microbiologist, Biochemists and other working laboratory staff in processing and reporting the wide spectrum of routine and sophisticated investigations.

2) Advances in early diagnosis, quick reporting, use of high sophisticated microprocessor based instruments, microtechniques are in practice without adequate quality control. Maintenance programme methods "that identify and minimize sources of variation in test system are. therefore, essential.

3) For a good laboratory, appropriate planning, procurement and controlling of resources will ensure efficient, quality operation in performances. Personnel policies, procedures and records are vital to the efficient and cost effective operation of any laboratory. In addition policy protocols and procedures are necessary to meet accreditation and regulatory requirements.

4) Proper staffing and effective scheduling have more impact than any other management tool in establishing good quality and cost effective laboratory services.

1.7.1 Problems of Management

The following are the problems which are major issues in day to day practice of laboratory medicine:

i) Lack of technical knowledge amongst working personnel
ii) Non-availability of uptodate modern technology.
iii) Lack of resources.
iv) Inability to maintain an adequate staff.
v) Frequent rush orders for reports and work load beyond capacity.
vi) Low morale among the working laboratory staff.
vii) Irregular supply and increase lead time of material supply from stores and purchase of substandard material.
viii) Lack of recognition of dignity of work.
ix) Lack of job satisfaction.
x) Lack of work attitude, sincerity and devotion to work.
xi) Indifferent personnel behaviour
xii) Communication gap between officers and subordinate staff
xiii) Lack of Quality Control and standardisation of procedures; absence of protocols, SOP and manuals.
xiv) Paucity of in service training programmes; CME and lack of technology transfer.
xv) Lack of norms of technical staff.
xvi) Lack of promotional avenues and revision of cadre at par with similar services.
xvii) Lack of laboratory information system.
xviii) Absence of rationalisation of reporting pattern.
xix) Absence of integrated approach of patient care system for laboratory management.
xx) Different kinds of malpractices.
xxi) Lack of medical audit.

1.7.2 Laboratory Hazards

Now you will learn about some of the laboratory hazards. Today a laboratory personnel is exposed to various kind of infectious material which are of great risk to life. All can not be described here and is beyond the scope of this unit. The following are some of the dangers to a laboratory worker:

i) Handling of infectious material.
ii) Handling of broken glassware.
iii) Accidental spill over of corrosive reagents.
iv) Swallowing of corrosive material such as concentrated sulfuric acid, Hydrochloric acid, sodium hydroxide; Trichloro acetic acid etc.
v) Inhalation innoculation, swallowing of infectious material — bacteria; viruses (HbsAg, HIV etc.)
vi) Inhalation of poisonous fumes.
vii) Potential hazards in the form of inflammable chemicals and gas leakages.

1.7.3 Safety Precautions in the Laboratory

The infection as you know can occur through ingestion, inhalation, injections or aerosols. In laboratory acquired infections the route could be any of the above. Bio-safety in a laboratory is very essential and basically depends on three components:

a) Basic standard of laboratory design, operation and equipment.
b) Selection and use of essential bio-safety equipment.
c) Safe laboratory procedures.

1.7.4 Laboratory Waste Management

Laboratory waste can be classified into following main categories:

i) General waste
ii) Pathological waste
iii) Radioactive waste
iv) Chemical waste
v) Infectious and potentially infectious waste
vi) Sharps.

The management of laboratory waste involves following steps:

i) Collection and segregation at storage site
ii) Storage and pretreatment (disinfection)
iii) Transportation
iv) Disposal

The above steps could be applied to hazardous and non-hazardous waste. The bio-medical waste handling rules are tabulated in Table 1.1 and various methods of the disposal of blood and laboratory material are tabulated in Table 1.2.

Table 1.1: "Bio-Medical Wastes (Management and Handling) Rules, 1995"

Colour of Containers	Types of Wastes
Yellow	Clinical waste for incineration only
Yellow with black stripes	Clinical waste which is suitable for landfill disposal
Light blue or transparent with Light blue lettering	Wastes for autoclaving or equivalent treatment before final disposal
Red	Human anatomical wastes
Black	Normal household waste

Table 1.2: Disposal of Blood and Laboratory Material

Hyperchlorite detergent solution	0.5-1.0 per cent solution of hypochlorite dissolved in 0.5% anionic or non-ionic detergent is the best general purpose disinfectant if contact is maintained for atleast 30 minutes.
Sterilisation	Autoclaving for 60 min. 121^{0}C (68.5 cm Hg) is the method of choice.
Incineration	Materials may be disposed of by burning in incinerator.
Disinfection of glassware	All reusable glassware must be disinfected by treating with Hypochlorite detergent before cleaning.
Spills on the table tops/sinks	Remove the spills with swabs soaked in hypochlorite solution immediately.

For your guidance minimum and more practical, easily achievable safe laboratory rules are listed here:

i) Avoid mouth pipetting as far as possible.

ii) Avoid enting, drinking, smoking and storing eatables in the laboratory.

iii) Decontaminate the working area atleast once a day and more frequently after the spillage of potentially infective material.

iv) Wash hands with soap and water after handling the infectious material.

v) Wear laboratory gowns/coats in the laboratory and these should not be taken outside the working area.

vi) Use gloves for all those procedures that may involve accidental direct contact with blood or infectious material.

vii) Decontaminate all liquid or solid waste materials as per the guidelines issued by Environment Ministry and Directorate of Health Services for proper directed disposal.

viii) Use of gloves for all those procedures that may involve accidental direct contact with blood or infectious materials.

ix) Perform all technical procedures in a way that minimizes the aerosol formation.

X) Provide adequate training to staff in laboratory safety procedures.

xi) As far as possible, actively immunize the workers against the diseases, the materials of which they are handling.

xii) Employ medically fit staff only to work in clinical laboratories and staff to be subjected for regular health check up at least twice a year.

xiii) Provide ample space and illumination for safe conduction of laboratory procedures.

xiv) Ensure constant and adequate water supply for immediate washing and cleaning of glasswares and premises for adequate safety from infectious materials.

1.8 CONTROL AND EVALUATION

Perfection in the management of laboratory issues are essential. Every problem has its own solution and control. Quality control and assessment is integral part of management. Maintenance of services, material supply, equipment maintenance, personnel management are components of evaluation in the procedures. A quality report and consumer satisfaction is final goal of evaluation programme.

1.9 LET US SUM UP

In this unit you have learnt that laboratory and laboratory services play an important role in patient care services and also the types and functions of laboratory; the physical facilities required for laboratory existence. You have also learnt the important'concepts of planning policy and procedure, information management in laboratory. Further you have learnt various problems in management of laboratory system, quality control, assessment and total quality management. The importance of trained qualified staff, laboratory accreditation, performance appraisal and methods of evaluation has also been emphasized in this unit.

1 . 1 ANSWERS TO CHECK YOUR PROGRESS

Check Your Progress 1

1) Laboratory is a place of work for testing patients sample for results in favour of diagnosis and treatment.

2)
- To provide diagnostic management information to treating physician.
- To generate results of samples for investigations.
- To report samples with accuracy, precision and reliability.

Check Your Progress 2

- Histopathology
- Clinical Pathology
- Microbiology
- Haematology
- Biochemistry
- Research Laboratory

Check Your Progress 3

1) Adequate space provision, regular supply of water, electricity reagents, chemicals, **kits** etc. and appropriate instruments, glasswares for use.

2) A) The clinical laboratory: as a work place.

B) Staff: who performs the test

C) The task: to be performed

3) Adequate functioning space of work for staff, space for wash room, store items, **toilets,** reagent, preparation rooms etc.

Check Your Progress 4

1) There are four basic elements of laboratory administration:
a) Objectives
b) Guiding people
C) Resources
d) Organisation

2) Accreditation is a procedure by which an authoritative body gives formal recognition of technical competence (including the quality system management) of testing and or calibration laboratory to carry out specific test.

The advantages of accreditation are:

a) It maintains standard and quality which creates confidence of customer and laboratory manager.

b) Mutual acceptance of reports between laboratory and the user.

C) Accredited laboratory is accepted in inter laboratory net work system.

3) This is the most promising managerial innovation which increases the efficiency and effectiveness of health care session. The following important factors are considered in quality management:

a) Top management leadership

b) Customer and process

c) Learning by practice and teaching

d) Quality measurement and statistical reports at every level

e) Recognition and reward.

4) Leadership and motivation are prime important factors in planning management without which productivity is negligible.

Check Your Progress 5

1) Information management is essential component and high order of magnitude complex communication system within and outside laboratories of the country and world. It reduces errors, mix-up specimen, calculation errors etc., improves staff productivity, quality assurance and interpretive diagnosis for the patients.

2) The following are the important managerial issues which require more attention in laboratory management:

a) Quality control and management

b) Technological updates

c) Human Resources

d) Staffing pattern and promotional avenues

e) Automation

f) Total Quality Management (TQM)

4) The following problems which affect the laboratory report are:

a) Unqualified staff functioning

b) Inadequate input and processing unit functioning

c) Lack of resources

d) Absence of Quality Control

e) Lack of work attitude, sincerity and devotion of work.

The above problems are definitely solved if the authorities concerned provide the above and the laboratory workers attitudes are changed and they work with sincerity and devotion.

Check Your Progress 6

1) a) Hospital acquired (nosocomial) infections

b) Hepatitis B infection

c) HIV infection

2) a) Proper discard of laboratory waste as per the guidelines issued by Directorate General of Health Services and Ministry from time to time.

b) Personal precautions such as washing of hands with soap and water before and after for any sample handling in laboratory; use of gloves; use of Hypochlorite solutions for discard etc. Wear Laboratory gown/coats in laboratory.

3) Bio-safety of the laboratory is dependent on the following components:

a) Basic standards of laboratory design. operation and equipment

b) Selection and use of essential bio-safety equipment

c) Safe laboratory procedures.

UNIT 2 RADIO DIAGNOSIS AND IMAGING SERVICES

Structure

2.0 OBJECTIVES

After going through this unit, you should be able to:

- enumerate various radio diagnostic and imaging modalities;
- discuss planning premises to establish nny modality;
- evolve organisation details; and
- develop policies to ensure effective and efficient output, including detail maintenance schedule.

2.1 INTRODUCTION

The Radio Diagnosis and Imaging Services as you know are one of the most important diagnostic armament with any medical practitioner. With increasing complexities of disease profile, there is increasing need to improve diagnostic approach (early and precise) and therapeutic modalities to achieve best patient care. The metamorphosis in medical technology, with application of bio-physics and computer sciences, have made available the newer modalities in the field of Radiology and Imaging Services. You wil! also appreciate that these changes have made these services more and more informative, dynamic and accessible. However, with advancement, the service has also become more expensive and at times un-affordable and hence it is very essential to manage these activities very effectively and efficiently.

In terms of financial effect radiology services consume major chunk of financial resources. For consideration of financial management it is experienced that the budget provision is to be kept for both recurrent budget and capital investment.

The following components should be given due regards for better planning and management of these services:

- Erection of physical facilities;
- Planning, procurement and maintenance of equipment;
- Appointment and training of human resource;
- Scheduling (work planning or utilisation of services); and
- Utilisation of financial resource.

In this unit, you would learn in details about planning and management of Radio diagnostic and Imaging Services.

2.2 TYPES OF SERVICES

Conventionally radiology services are linked with x-rays. However ever changing need for more and more information and introduction of newer technology has definitely revolutionalised these services to a great extent. The radiology is linked to images of human body, and these images can be achieved either by transmission or by emission from a source.

Transmission is a technique where there is a source which emits rays and which are picked up after reflection from body part and taken on plate or on screen (films) and studied by competent professional. The modalities under this group are : X-rays, CT Scan, Ultrasound.

Emission is a technique which involves giving a dose of radioisotopes or radionuclides to the patient, which are picked up by target organs or cells and emitted gamma rays are recorded by gamma or scintillation camera.

2.2.1 X-rays

X-ray is oldest radio diagnostic tool. The principle is transmission of rays from a source to the specified part of body and images are taken on films. It still remains main modality and number of x-rays performed has been on increase, but total percentage has been declining with the advent of newer modalities.

2.2.2 Ultrasound and Colour Doppler

It is no longer a newer modality but its role has been ever increasing since its introduction, because of continuous improvement in results by introducing improved version transducer, machines and also expertise. This modality is also increasingly accepted, because of lack of significant biological hazards associated with this modality and easy accessibility.

2.2.3 Computer Assisted Tomography

With introduction of CAT Scan, which is considered as most significant advancement in the x-ray field, as this modality has astonishing clarity details of morphology, previously seen only at necropsy or anatomy atlases. Although conventional roentgenography is valuable in evaluating tissues with large differential densities, it cannot clearly distinguish most soft tissue structures, and display overlapping superimposed shadows of the area under investigation, but CT images has overcome this limitation and provides sensitive, well demarcated and detail images. The CT scanning plays vital role in CNS (Brain and Spine) diseases or injuries to decide treatment plan particularly in emergency situations.

2.2.4 Magnetic Resonance Imaging (MRI)

This non-invasive modality has further facilitated diagnostic approach by providing even clearer images of human body without any biological burden. The concept is, a magnetic field is created over part of body being evaluated by a strong magnet which results in emission of RF (Radio Frequency) signals by hydrogen nuclei of tissues after they have been perturbed by RF pulses in presence of strong magnetic field. The RF signal so emitted has characteristics called *relaxation time*: T1 relaxation time (longitudinal

magnetization) and T2 transverse magnetization. These properties are variable among tissues and are the predominate factors responsible for tissue characteristics and images. The modality helps in obtaining both structural (anatomy) and functional (physiology) aspect of tissues studied. The contrast study further helps in getting more details. It is extremely useful in not only in CNS disorders but also for other systems e.g. cardiology, gastrointestinal.

2.2.5 Positron Emission Tomography (PET)

Its more dynamic modality which helps in studies of physiology of human body e.g. isotopes of short half life can be utilized by PET scanner in obtaining information regarding fundamental metabolic process. The equipment also needs a cyclotron to complete the study. The PET is based upon three dimensional restructure of brain section using positron emitting radionuclides. By utilization of a number of individual radionuclides and radiolabeled moieties, it provides an opportunity to measure quantitatively: regional cerebral blood flow, blood volume, oxygen metabolism, glucose transport and metabolism, neurotransmitter metabolism and it permits neurotransmitter localization. Though this is a highly selective modality in imaging field but not,available for routine use as on date.

2.2.6 Mammography

An x-ray based modality commonly used to detect breast diseases. The role of this technique has assumed great importance particularly in screening the breast cancer, incidence of this cancer is very high in Indian population.

2.2.7 Nuclear Imaging

The nuclear medicine is the speciality in which radioactive tracer (Radionuclides) are applied to medical situations. In broader sense, the nuclear medicine speciality should be part of diagnostic imaging team. As such the Nuclear Medicine expert should be part of diagnostic imaging team. However, this practice is not commonly seen in our country. The nuclear medicine studies include all radionuclides use in medicine. These studies can be *Invivo* i.e. studies requiring injection of radionuclicles into patient involving absorption, excretion and haematology uptake and imaging studies, such as renal scan, liver scan, bone scan, thyroid scan, thallium scan for myocardial perfusion and others. The vitro studies which do not require any injection to patient and use of radionuclide is done in laboratory setting, such as thyroid hormone assay by radio immune assay method. Internationally the nuclear medicine services have not a uniform organisation position more so in our country. As these are complete independent units, but at places some of the activity is spread to x-ray diagnostic unit, radiotherapy, clinical chemistry. Techniques in use are Single Photon Emission Computed Tomography (SPECT) and Gamma Camera.

2.2.8 Single Photon Emission Computed Tomography (SPECT)

This is widely available and less expensive system of obtaining images of gamma-emitting radionuclide molecules in the body those can also cross blood brain barrier. For example isopropyl amphetamine (IMP) and other radionuclides have been used to demonstrate abnormalities in epilepsy, Alzheimer's disease and in Parkinson's disease. However present SPECT technology is relatively non-quantitative and insensitive in demonstrating changes and its spatial resolution is considerably less than that of PET. Most of nuclear medicine centres have SPECT installed along with Gamma Camera.

2.2.9 Futuristic Scenario

The development of radiology and imaging services revolves around acquisition, manipulation, storage, retrieval and analysis of images. Keeping these concepts in mind the future of these services largely depends upon technology advancement in bio physics and its application on human systems. Cardiac MRI is recent modality being used to evaluate coronary vessels non invasively. There are many modalities in pipe line to be introduced in practice e.g. PET (Positron Emission Tomography); NMRS (Nuclear Magnetic Resonance Spectroscopy) — which offers the potential of assessing brain function at metabolic and molecular levels.

23 PLANNING AND ORGANISING RADIO DIAGNOSIS AND IMAGING SERVICES

The basic question for planning an activity is 'WHAT' and 'FOR **WHOM'** meaning here is that we are aware of the activity i.e. radio diagnosis and imaging services but for whom remains vague as these services can be rendered from a small diagnostic unit to tertiary care hospital, implications are well understood. Hence it is proposed to deal with planning of radio diagnosis and imaging services for 500 bedded teaching hospital. Keeping national scenario and present trend of the patients and doctors requirement in mind following equipment are proposed to be installed:

a)	X-ray Machines:	500 MA	: 2 Number
		200 MA	: 1 Number
		Portable 100 MA	: 2 Number
b)	Ultrasound		: 4 Number (One with Department of Gynae. & Obst.)
c)	Doppler		: 1 Number
d)	Mammography		: 1 Number
e)	CT Scanner		: 1 Number
f)	MRI Scan		: 1 Number
g)	Gamma Camera		: 1 Number
h)	SPECT		: 1 Number

2.3.1 Physical Facilities

Physical facilities is one of the important consideration in establishing any service, more so in radio diagnosis department as it is highly equipment based, which are very sensitive, specific, sophisticated, and costly. Hence needs in depth planning to match available resources to achieve maximum in terms of output, without compromising the quality. The points (planning premises) to be considered are discussed as under:

a) Expected Work Load

These services are increasingly in use, in arriving at early and correct diagnosis. Though it is difficult to forecast exact work load, as there are wide variation in various establishment and countries. An international statistics, according to CBA Puijlaert (International Symposium on the Planning of Radiology and Imaging Sciences, Lisbon, May, 1978— expansion of radio diagnosis services and diminishing work loads) the average work load of all modalities in various western countries are:

Italy	7000/Year/Radiologist
Sweden	6000-8000/Year/Radiologist
US	8000/Year/Radiologist
UK	15000/Year/Radiologist

Since we in India do not have any national statistics on average work load, the figures available indicate that there is tremendous work pressure on this facility. As a rough guide in a 500 bedded hospital with availability of above mention modalities the per working day work distribution will be as: Routine X-rays 100-120, Special X-rays 15-20, Ultrasound (All Category) 35-45, CT Scan 6-8, MRI 4-6, Mammography 3-4, Nuclear Imaging 4-6. Over and above there will be some emergencies from within hospital or from places where these facilities are not available. The work volume will be on rise in times to come and hence planning of services should be accommodative and flexible for future expansion.

b) Location

The department should be located in such a way that it is easily accessible to in patients, out patients and emergency patients. Ideally it should be at one end of establishment to avoid criss cross movement of personnel. Ground floor is most suitable to accommodate heavy machinaries and their scaffoldings. A high power or with appropriate wattage electricity connection should be made available, preferably direct from source with proper earthing.

c) Areas

There should be proper demarcation of work areas for each activity. Approximate space requirement is proposed on the basis of information available. However one has to be flexible and innovative to adjust with available resources both in terms of space and funds.

i) **Patient Waiting Area:** According to western datas approximately 80-85% patients are ambulatory and 15-20 are either on wheel chair or on stretcher, It has been estimated that 5-10% are paediatric group of patient. It is, therefore, experienced that large number of personnel i.e. patient and along with them not only attendant but relation and friend will nlso nccompnny, hence expected human load on this service will be enormous. Therefore, waiting area should be planned with utmost core. It is proposed to have a main waiting area with reception and registration counter and other facilities like lavatories (Rest Room) easily accessible to the patients and sub waiting area with each activity to accommodate changing cubicle, recovery room, contrast preparation room etc. As per western literature again space requirement is 1.3 sq. m per patient visit, if relative and friends are allowed to accompany as practice in our country the space requirement will also increase. The sitting arrangement should be adequate and appropriate, e.g. there is constant increase in number of elderly patient and they find very inconvenient to sit on low soft chair and hence they should be avoided.

ii) **Circulation Area;** The movement of patient, attendant, staff should be properly planned to avoid unnecessary criss cross movement and over crowding at any point or activity area, There should be parking area for stretchers nnd wheel chair. The corridors must be 2.8 m wide to avoid crowding.

iii) Technical Area: This is the prime area of the service and should be designed and planned with utmost care keeping technology advancement in mind. Activity wise space requirement is discussed below, however space utilization/allotment will primarily depend upon total available space and the layout plan of the department should also be considered along with overall plan of hospital.

iv) X-ray **Rooms:** The size of X-ray rooms will depend upon the capacity and type of equipment to be installed (Whether 500 MA or 200 MA, What are the fitments along with?). However general guidelines are:

v) Space: An X-ray room should approximately be 40 sq. m, with its long axis minimum of 6.7 m, depth not less than 5.8 m and height 3.3 m approximately. Door opening should be atleast 1.3 m wide and there should preferably be mazes between staff corridor and X-ray rooms to prevent radiation exposure. A lead glass window or screen is essential between X-ray machine and control panel to protect staff from radiation. In a 500 bedded hospital X-ray department distribution of radiology work with activity wise and accessories requirement are given as below as per western literature:

• General Radiography (47%) (Including Skeleton and Skull)	Bucky Table, Ceiling Mounted Tube, Vertical Bucky
• Chest Examination (31%)	Specialized Chest Unit or Vertical Bucky
• Radiology with Fluoroscopy (13%)	Tilting Fluoroscope with Image Intensifier and Bucky Ceiling Mounted X-ray Tube
• Urography, Tomography and Spine Exnmination (6%)	Bucky Table, Ceiling Mounted Tube, Pendulous Tube Stand, Tomography
• Angiography and Other Special Procedures (2%)	Bucky Table, Image Intensifier Film Changer etc.

These are recommendations, which help in development of plan and can/should be modified to match resources.

vi) Related Areas for X-ray Department: The film processing is an essential post exposure activity. Still at large number of centres the processing is done by conventional method that is in dark room by processing films through fixer, developer and than rinsing and drying manually. The approximate space requirement for dark room is 2 sq. m with single entry and of course black paint, with dim red light source. The auto processors are now made available, where exposed film is loaded and comes out dried after fully processed. With the introduction of auto processor units, the developing processes have become easy and space requirement has also decreased considerably.

vii) Ultrasound Unit: The central sonography unit should be located within the main radio diagnosis department and it should have direct access to patient without interfering with other work areas. The space requirement for single ultrasound unit room is approximately 25 sq m. Planning for supportive area like department reception, patient waiting, change room, toilets, radiologist office and record room should be done in coordination with main activity, to maintain smooth and effective work flow.

viii) C.T. Area: The CT room has to accommodate the CT Scanner, an anaesthesia Machine, Ventilator and other routine monitoring equipments and a patient bed. The CT room should have attached toilet facilities preferably. Beside main scan room the department should have reception, waiting area, change room, toilets, record room, and a recovery room which can be utilised for induction and should have piped gases with monitoring facilities. A complete CT unit will require approximately 110-120 sq m. of space.

ix) MRI **Centre**: The MRI Unit has to accommodate an MRI Room, where magnet is installed, the Gantry which has roof level scaffolding carrying all connecting wires (Electricity and Computer Connections), pipes for cooling the magnet and other necessary fitments. Besides main MR room other supportive area as Reception, Sub Waiting area, Change Room with locker facilities, Toilets, Radiologist Room, Departmental Conference room, Hileum storage and other supportive areas. The approximate space requirement is 125-130 sq m.

x) Mammography: Preferably located near CT or MR Unit so the support services can be common to save on space. The approximate space requirement for Mammography Unit is 15-20 sq m.

xi) Nuclear Imaging: This department is highly sensitive, as it has to accommodate *hot* lab, which houses active radio-nuclides which are potentially hazardous and needs extra care in receiving, storing and also in disposing. Beside common areas as in other activity i.e. reception, registration, waiting area—sub waiting, hot room, cold room, store, the main space is required for GAMMA CAMERA or SPECT and its accessories. Approximate recommended area is 110-120 sq m.

d) Supportive Areas

The department will need supportive areas beside technical area as mentioned above. These supportive areas are essential to maintain activities effectively, these are:

1) Consultant Rooms: Each consultant should be given separate chamber of approximately 10 sq m with basic fitments and furniture including a wash basin.

2) Conference Room: There should be a Departmental Conference Room, where adequate accommodation to be planned to hold not only Departmental Conferences but also Inter Departmental Academic activities at periodic intervals.

3) Library: The same can be accommodated in conference room depending upon physical layout. However the department must have a properly planned and maintained Library.

4) Store Room: An appropriate store should be planned for keeping all essential expandable items including equipment spares and unexposed x-ray films. There should also be place for store keeper.

5) Staff Room: Staff rest room with facilities for changing and lockers.

6) Record Room: A department record room must be planned, with present day trend, a central Computer with LAN facilities should be made available for easy entry and access.

e) Lay Out and Flow of Activity

There are many ways departmental activities can be organised depending upon availability of space and over hospital plan. Many Radiology departments have been designed around the concept of the Diminishing Rectangle. This approach positions Imaging activities (rooms) on the outer boundary of rectangle and utilizes boundary for technical support and radiologist work areas. The major benefit of this layout is the minimum interference or disruption that can occur when widely different task occurs in close proximity. This configuration allows patients requiring simple procedures to be separated from those requiring complex studies. However one shortcoming of this layout is that the monitoring of patients become more difficult as they are maintained on outer edge of rectangle.

The strategic placement of imaging rooms is generally based on the concept of minimising the movement of patients in the department. For example the most commonly used x-ray is for chest and is located near the entry and imaging rooms which serve low volume and require longer duration are located more centrally in the department.

f) Communication

An effective communication network both intra departmental and inter departmental and also with parallel organisation should be provided. In present days we should also plan for on line Internet and Web site facilities for keeping staff members abreast with the latest.

g) Equipment Installation

While at pladning stage of physical facilities it is important to consider the type, make and other essential installation requirements e.g. construction. electricity connection, scaffoldings, tubings, water outlets etc.

h) Heating Ventilation and **Air** Conditioning System **(HVAC)**

The Radio Diagnosis and Imaging Department of the day is very sophisticated and primarily based on computer technology and there is increasing demand on maintenance of room temperature. As in operating of these equipment quite a bit of heat is generated which needs to be properly ventilated or neutralised and optimum temperature is to be maintained to obtain maximum efficiency from equipment and staff both. Hence there is a need to plan a proper and effective air-conditioning system for the department.

i) Electricity **Source** and Back-up System

An in-depth calculation of electricity load with future expansion plan should be estimated and preferably a separate line from the direct source should be taken. An approximate requirement for the proposed department is 140 KW. Back up supply should of course be planned, It is recommended that beside emergency connection from main Hospital there should be a separate back-up source of the department. All essential equipments particularly computers should have **UPS** system.

j) Future Expansion

An exercise should be done at this stage to keep future expansion in mind and adequate measures must be taken to accommodate those changes at later date without disturbing existing set up.

2.3.2 Equipment Planning, Procurement and Installation

This aspect is well covered in units on Materials and Equipment **Management in course 2.** However it is essential to have detailed knowledge and understanding of this issue at this juncture., Planning for establishing the department, an indepth evaluation of equipment requirement with its-detail specification has to be understood. As these equipment are technically very advanced, sensitive, expansive and critical to patient care. There is ever increasing competition with fast ohanging technology and increasing vendor pressure.

Hence it is recommended that a high level committee comprising of Head radio diagnosis department, unit/activity Head, minimum two expert in the field from out side the Hospital, Senior Store Officer/Purchase Officer, two Senior staff members from other specinlities who will go into all details of equipment in question. An approach to this exercise is enumerated as under:

- Identify the Activity
- Select the Equipment
- Develop Specification
- Locate the Vendor/Vendors
- Prepare the Tendor Enquiry (which should be very elaborate i.e. all detailed specification of equipment and its accessories)
- Receiving and opening of Tendor Document
- Preparation of Comparative Statement
- Selecting the Supplier
- Preparation of Supply Order: This document should be very comprehensive including all specification and terms and condition about equipment, financial effect with payment schedule and spares, its installation and after sale services.
- Reception, Inspection and Installation: Before releasing final payment the committee should certify effective functional status of the equipment.

It is observed that equipment commissioning which is comprising of identifying, procurement and installation is complex process and many hurdles are encountered in this exercise. It is, therefore, felt that an approach as suggested above if followed in the letter and spirit than problems can be minimised. It is also important to mention about financial resources, as most of the decision will depend upon availability of funds and their control.

2.3.3 Equipment Maintenance

For ensuring credible, economical and continuous equipment maintenance an effective maintenance programme is essential, all the more in radio diagnosis services as it is totally equipment oriented department. Therefore, a comprehensive maintenance plan is an inescapable requirement. The maintenance can be classified as:

1) Plan Preventive Maintenance
2) Concurrent Maintenance
3) Breakdown Maintenance

1) Plan Preventive Maintenahce

Preventive maintenance is essential to prevent breakdown and disruption in services from all equipment and particularly for expensive machines, Beside on job checks and control by operator the preventive maintenance is achieved through after sale warranty and Annual Maintenance Contracts (AMC). The AMCs are awarded to the supplier, invariably as all sophisticated machines have some or other peculiarity which can only be hnndled by them, however there are other agencies also to take on such contract.

Warranty: The warranty clause is very essential for all new installation. All equipment should be under warranty as long as agreeable by supplier, normally this period is one year only and during this period complete responsibility is with company, including spares at no cost. The cost normally included in the initial cost only and hence buyer should hold minimum 10%of pnyment till warranty period is over. During warranty period staff training for both operation and maintenance must be emphasised.

Annual Maintenance Contract: This is the contract generally awarded to supplier or any other agency competent to handle the equipment on pre-determined terms and conditions. These conditions should include:

- Duration of contract,
- Periodicity of visits and check points of preventive maintenance to be supervised by the user.
- Spares—adequate fast moving (frequently needed) should be made available in house and other should be provided without undue delay.

  Financial effect with details of payment schedules.
- Breakdown time should be spelt out that is the number of breaks during contract period and maximum duration of a breakdown and it should not be more than accepted.
- Penalty clause—in the service contract a mutually agreed penalty clause should be spelt out to keep check on agency and also on operator.

2) Concurrent Maintenance

The department should have well written plan for each and every equipment particularly for life saving and expensive ones (not on AMC) for their in house concurrent maintenance by operator and hospital maintenance cell. Here it is worth mentioning a little about Hospital Maintenance Cell. This is a small inhouse organisation which is equipped with trained men power e.g. bio medical engineers, technicians and necessary infrastructure of tools.

3) Breakdown Maintenanoe

Even after detailed precaution one cannot avoid unwanted and untimely breakdowns resulting into crisis situations. There should be a departmental plan to deal with such situations effectively. In the department each unit (equipment) incharge should have knowledge of agencies, who can be contacted during such eventuality both in house or outside the hospital.

An effective maintenance plan will achieve:

- Reduction in Down Time
- Safety of Equipment and Men
- Credible and Cost effective services
- Increased life of Equipment

2.3.4 Staffing

The staffing is most difficult but very essential component of the organisation infrastructure as no machine can be useful without an operator. Hence the basic exercise of recruitment is must i.e. **job analysis, job description** and **job specification** meaning by identify the appointment and then describe its QR (Qualitative Requirement) for selection and then specify his job. This department is highly cost intense and the personnel's accountability has to be of very high order. The category of staff required are:

1) Radiologists: HOD (1), Sr. Consultant normally heading each unit (4-5), Jr. Consultant (8-10), Residents depending upon status of hospital.

2) Technicians: Sr. Technician and Inchnrge (1), Sr. Technicians (8-10), Jr. Technician (10-12), Nursing Personnel (2).

3) Others: Receptionist, Store Keeper, Scribes (both for record keeping and billing), Helpers (a multipurpose worker useful in assisting staff and patient). These personnel can be pooled in from main hospital resources. However it is recommended that there should be continuity in their duties to maintain smoothness in functioning. As regard qualification and experiences central (hospital) recruitment rules should be observed. The appointment of staff should also be done in phases to start with, meaning by depending upon work load to minirnise recurrent expenditure. The most important aspect of human resources is there is continuous training both on job as well as through structured programmes specially planned for each technical staff member. Besides their high order technical skill they should have or develop good human skill i.e. attitude and behoviour with patient, patient's relation and also with staff members.

Check Your Progress 4

What are pre requisites for recruitment?

.....

.....

.....

.....

.....

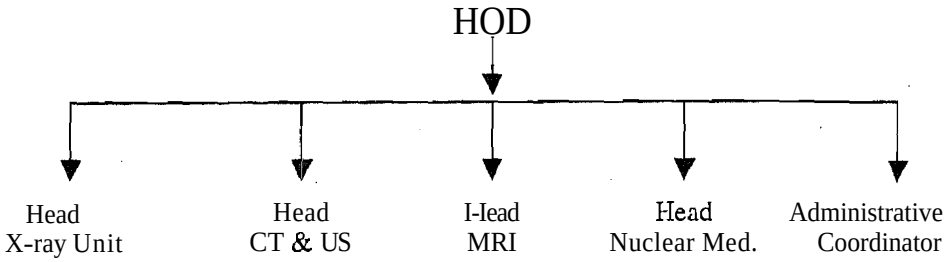
2.4 POLICIES AND PROCEDURES

In today's hightech world a top online computer system remains a show piece till a well developed software (programme) is developed and fed in, and hence it is very vital for systematic and effective functioning of a departmedt that detailed and workable policies and procedures are prepared. All major establishments have well documented SOPs (Standing Operational Procedures) e.g. Defence Services have such system which not only

facilitate smooth functioning, but ensure accountability of personnel responsible for various acts. It is, therefore, recommended to develop a detailed written programme of the department which should be periodically updated or reviewed and properly communicated to all concerned. An outline plan for department SOP is suggested as under:

1) **Organisation Structure:** giving details of chain of command i.e. distribution of staff with referance to their activity.

2)



The technical and supportive staff should be affiliated by name with the activities as mentioned above. Though continuity is helpful but in the interest of organisation a planned rotation of duties particularly among technical staff is advised. A detailed Job Specification of each member of staff should be written and communicated to them, periodically.

2) Working Hours: Working hours should be spelt out in coordination with other department.

3) Work Handling Capacity: Work handling capacity of each unit should be evaluated and documented. There should be policy where every unit's maximum functional capacity in terms of number of cases can be carried out in a day or shift is calculated on the basis of equipment capacity, staff availability and other variables. Once maximum handling capacity is known it is easy for management to plan patients appointment schedules and also assess the work output vis-a-vis resource input. It has been observed following a work study at few prestigious institutes that with application **of** concept of maximum handling capacity in any patient care area in general and ambulatory care including diagnostic services in particular has improved level of patient care and patient and staff satisfaction to a great extent.

4) Equipment Management Plan: The hospital should have a well spelt out plan for equipment planning, purchase, maintenance, and disposal. It has already been discussed in detail, however it is important to have detailed instructions written in department's SOP.

5) Staff Performance Appraisal Policy: No organisation can grow or prosper till its all members are satisfied to the desired level of satisfaction. Moreover it has been a known fact that morale of staff irrespective of his status directly effects organisation, environment and culture and in turn its output. Hence it is very essential that a well planned performance appraisal policy and system to implement same is written in SOP.

6) **Financial Management:** The crux of all issues are availability of finance and authority to spend it, There should be well prepared and communicated financial policies so there is no ambiguity about the authority and system to be followed. Head of Department should ensure timely and appropriate projection of funds requirement. Since the department is cost intense and huge amount (approximately 40%) out of total hospital budget will be required in procurement of new equipment, updating exhausting ones, maintenance and purchase of consumables beside staff salary, an effective financial control is inescapable.

7) **Radiation Safety Policy:** Safety measures against radiation should be taken with a lot of care and plan. The effects of radiation on human body can be classified as *somatic*, affecting irradiated person, or *genetic* affecting progeny. The safety of staff and patient while they are exposed to radiation during various diagnostic and therapeutic procedures depends upon safety measures taken while performing these activities and close monitoring by radiation dosimeters (Geiger Counter). Hence all staff members

who carry a risk of exposure to radiation should be provided with radiation monitoring dosimeter by name and should also be checked periodically for levels of exposure, to prevent any over exposure. The details of safety should be written and communicated. You will learn about this in detail in Unit 3 of this block.

8) Expansion **or/and** Upgradation Committee: To keep technology updated there is need to have a departmental committee to periodically review the needs of expanding the department in terms of Physical Facilities, Equipments, Staffing. The committee should submit their proposal with detailed justification for appraisal and approval of Hospital Management Board in which department representation will be there.

The basic objective to have a departmental SOP is to monitor the performance against pre determined guidelines and periodically assess the quality of services in terms of professional patient care and patient and staff satisfaction. It is also recommended to have an in house performance grading system with an objective of rectifying the shortfalls observed. This is a positive exercise and should be done with lot of care and commitment.

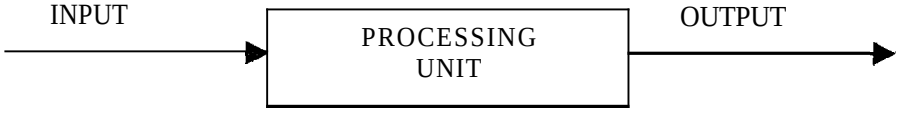
2.5 MANAGERIAL ISSUES

The management or managerial issues means application of management tools to ensure effective and efficient running or functioning of the department. To recapitulate and remember principles of management a commonly used letter is recommended i.e. POLICE, a concept of *guarding* to the manager. On expanding this letter a complete aspect of modern managerial tools is covered. Expansion of word 'police' is as under:

P : Planning
O : Organising
L : Leading
I : Integrating
C : Controlling
E : Evaluating.

Managerial issues of the radio diagnosis on day to day practices involves the common pathway of flow chart which are commonly seen in all diagnostic service:



Issues at Input

Registration: Reception.

i) Registration timing notification nnd exhibition in bilingual languages
ii) Any restriction in number of caseslday
iii) Selective directions for appointment cases.

Issues at Processing **Unit**

i) Personnel management issues
   - Lack of availability of qualified persons at equipment (machines)
   - Lack of desire to work in time/delayed function

ii) Lack of machineslnon-functioning unit informations

iii) Processing mistakes of numbering

iv) Mistakes of organ/part of exposures as desired.

Malpractices/Pilferages

i) X-ray films: at various levels—receipt/entry/disposals

ii) Developing solutions

iii) Cassettes etc.

Issues at Output

i) Reporting officer — misinterpretation of lesions

ii) Wrong reporting, mis-matched papers

The ultimate aim of any service is to achieve its desired objective with full satisfaction of consumer and provider. To arrive at this objective there is need to spell out all aims of the department in detail at very outset of department establishment and is to be reviewed periodically. Once we are aware of aims to achieve and resources available, than to match these the managerial approach through POLICE should be applied to get best out of situation. It is, therefore, felt that manager should be familiar with managerial approach and should not only use them but apply them very professionally.

26 LET US SUM UP

Changing trends and needs of health care delivery system has made medical practice more and more complex and demanding. The revolution in technology has not only brought improved and sophisticated diagnostic and therapeutic modalities in use, but has also made system mare transparent and accountable. The radio diagnosis and imaging is one of the most important branch of health care delivery system and plays very vitul role in urriving at correct and early diagnosis of disease profile. With introduction of newer modalities already and on going further advances in techniques and modalities, the planning and management of these services requires more and more emphasis, For establishing a department and/or single unit an in-depth study of all planning premises is an essential requirement, which means identifying servicelservices and knowing resources i.e. availability of physical facilities (land and/or building), human resources, equipment position nnd financial resource, Having planned and established a radio diagnostic and imaging centre. the functional plan should be developed and written as standing operative procedures (SOP), which should also be communicated to all concerned and updated periodically. A lot of emphasis should be given to equipment management, which not only deals with procurement but also with maintenance programme. The staff selection, positioning, satisfaction and their training is very important aspect to achieve desired results of the department or services. While dealing with humun resources, management should also plan for their professional growth and remunerations keeping pace with time and performance to avoid any staff dissatisfaction. It is desired that services should be dynamic, qualitative and cost effective and to achieve this objective an effective and aggressive management should be provided by applying principles of basic management.

2.7 ANSWERS TO CHECK YOUR PROGRESS

Check Your Progress 1

1) These are diagnostic modalities, where body or part of body is exposed to an environment resulting in formation of images either on screen or on plate, which are

stored and studied by competent professional and who gives opinion on the status (normal or abnormal) of the part under study. The techniques involved are either transmission i.e. there is source which transmits rays in to body or emission i.e. rays are emitted from a body part after it has been activated. The most conventional example is X-ray examination, other modalities are: ultrasound, CT scan, MRI scan, Mammography, PET, nuclear medicine studies and others.

2) The nuclear medicine is based on the concept of studying the distribution of radiopharmaceutical in the body with a scintillation or gamma camera. To elucidate further a desired radiopharmaceutical is given in the body and its distribution is observed over a period of time by/under gamma camera, these studies are called study in vivo. Commonly performed studies are: thyroid scan, renal scan, liver scan, bone scan, thallium scan for studying myocardium perfusion (a popular non-invasive technique to study coronary arteries). In vitro studies nre performed in laboratory setting using radionuclides.

Check Your Progress 2

1) For planning any activity following aspects are to be remembered/considered:

a) Identify service and its scope i.e. radio diagnosis and imaging services with what all modalities are going to be installed.

b) Select location and prepare lay out plan in discussion with users.

C) Develop design for construction bf new physical facilities or renovation of existing structure keeping prospective functions in mind (prepare architect brief).

d) Plan for equipment establishment i.e. identification of equipment, selection of vendor, preparation of supply order and reception, inspection, installation and commissioning. Also to be incorporated equipment maintenance schedule;

e) Planning, recruitment and training of staff.

f) Prepare policies and procedures for functioning.

2) Though space is a very vital parameter in terms of functioning and finance and hence should be planned very meticulously. It is again very difficult to give rigid guidelines as regard space. however an approximate modality wise requirement is given ns under, these specifications are suggested for technical nrea only where as requirement for other essential supportive is to be considered separately:

X-ray Room (one machine with accessories)	40 sq. m
Ultrasound unit	25 sq. m
CT scan	110-120 sq. m
MRI unit	125-130 sq. m
Mammography	15-20 sq. m

Check Your Progress 3

I) It is very vital step in the process of department functioning. Following points are to be considered while procuring any equipment:

a) Identify the activity

b) Select the equipment

c) Prepare specification

d) Locate vendor/vendors

e) Prepare supply order

f) Instructions for reception and opening of tender inquiry

g) Preparation of comparative statement

h) Selection of vendor by hospital/department purchase committee

i) Preparation of supply order (this document should be very exhaustive)

j) Detailed instructions for reception of equipment, opening of packages, installation and commissioning of equipment

2) An effective equipment maintenance plan is an inescapable requirement of any hospital/department. There are following types of plan:

a) Plan preventive maintenance (including annual maintenance contracts)
b) Concurrent maintenance plan
c) Breakdown maintenance plan

Importance of effective maintenance plan are:

a) Reduction in down time
b) Safety of equipment and men
c) Credible and cost effective services
d) Increased life span of equipment

Check **Your** Progress 4

As said that human resource is most important and live input of any organisation and hence its planning is very vital for organisation credibility and growth. The basic components are:

a) Job analysis : We should know what category personnel are required for the organisation.
b) Job description : Give details about qualification and experiences required for a particular post.
c) Job specification : Specify detail about individual job specification i.e. person's duty schedule, responsibilities and accountability.

Check Your Progress 5

No organisation/department can achieve its objective without systemic functional policies, hence its importance cannot be undermined. With well prepared and periodically revised standing operative procedures (SOPs), the achievements are:

a) A qualitative performance in terms of patient care i.e. creditable and timely results
b) Optimum utilisation of resource i.e. capacity utilisation of equipment and man power
c) Cost effectiveness of services i.e. effective control of financial resources
d) Highest level of patient and staff satisfaction

UNIT 3 RADIATION HAZARDS

Structure

3.0 OBJECTIVES

After going through this unit, you should be able to:

- enlist the biological effects of Radiation Hazards;

  describe the radiation protective and safety measures in designing of diagnostic x-ray, Magnetic Resonance Imaging, Nuclear Medicine Services;
- discuss various aspects requiring attention in planning of Radiation Therapy with particular reference to design and protection of personnel and materials; and
- describe the procedure for radio waste collection and disposal relating to Nuclear Medicine, Tele Therapy and Brachy Therapy.

3.1 INTRODUCTION

Radiation, as you know, is an energy emitted in the form of a beam of rays or waves, whereas hazards are risk involved to life, health or property due to poisonous nature or combustibility or other environmental causes of dangerous substance, here in mainly related to radiation.

This unit aims at making you aware of the problems associated with hospital diagnostic and therapeutic services involved in use of ionizing radiations, along with the problems in

planning of these services with particular emphasis on radiation hazards. It also highlights vital planning aspects and protective measures.

In this unit you will learn about the causes and safety measures for radiation hazards. You will also learn planning and designing aspects of various departments using radiation technology, though you may find too detailed description of these aspects but if due care is not taken during initial planning stage you cannot reduce the hazards later on.

3.2 BIOLOGICAL EFFECTS OF RADIATION HAZARDS

Radiation protection and safety in all imaging techniques are of great concern to safeguard radiation hazards. Radiation protection facilities and disposal of radioactive waste are of paramount importance in radio-therapy centres. Failure to observe the safeguard procedures invariably leads to harmful biological effects.

Radiation injuries can arise from various sources, viz. Gamma, Beta, Alpha and Neutrons. The effects of radiation depend on type of cells of body affected, dose and source of radiation to which individual is exposed. The effects can be acute and chromic.

Acute radiation effect is called as acute radiation syndrome (ARS). This is combination of syndromes occurring in stages during a period of hours to week after exposure, as injury to various organs is expressed. It occurs in three successive phases:

Prodromal		Appearing within a first few hours, lasting for a day or more.
Latent period	:	Lasting for days and weeks.
Manifest phase	:	Where recovery or death occurs within 6 weeks of exposure.

Chromic or Delayed Effects occur months to years after radiation exposure and include a variety of effects on almost all tissues and organs. Some of the possible delayed effects are:

a) Shortening of life span.

b) Cataract formation.

c) Chronic radio dermatitis.

d) Leukaemia.

e) Cancer.

f) Decreased fertility.

g) Genetic mutation.

h) Epilation (falling of hair).

3.3 DIAGNOSTIC IMAGING

In this section you will learn about diagnostic imaging which includes radiography, fluoroscopy, mammography, and other similar techniques. Radiography is a device of making pictorial records by means of x-ray on sensitised film, fluoroscopy is direct visualization through medium of x-ray, where as mammography is a screening technique for determining the presence of breast tumours. Most imaging requires radiation protection.

Diagnostic x-ray department usually consists of following sub-departments: inpatient, outpatient, emergency and special procedures departments as well as section for diagnostics in operation unit. The pattern of conducting of all x-ray examinations in one centralized department, although generally advocated, is by no means self evident at least in larger hospitals.

Diagnostic x-ray room should be multifunctional, the long axis of the room being not less than 6.7 m, the depth should not be less than 5.8 m and the working height of about 3.3 m could be recommended. In all x-ray rooms, astainless steel wash basin is needed because of microbial cross contamination and infection potential. Each x-ray room shall include a

shielded control alcove. This area shall be provided with a view window designed to provide full view of the examination table and the patient at all times, including full view of the patient when the table is in a tilt position or the chest x-ray is being utilized. For mammography machines with built in shielding for the operator. Mammography room should be designed to appeal to women.

X-ray room in which remote control is to be used, it is essential to have a lead glass window to protect the radiologist who is in line with x-ray table at floor level, so that the operator can see and communicate with the patient. The lower edge of the protective screen should be about 115 cm for use in the erect position.'The television monitor should be placed so that it can be easily seen through the lead glass window. Simultaneously the patient should be kept in view. The control panel should be close to the x-ray table so that the patient showing any signs of distress could be quickly reached. Door opening should be at least 130 cm wide. All artificial lighting in the screening room should be wall mounted. The ceiling has to be free from air ducts, pipes etc., and should be weight bearing in all directions for the installation of ceiling mounting equipments.

An examination room suites for general examinations including chest, abdomen, skull, extremities, spine and IVP; a suite for special procedures including cardiovascular, neurological and urological procedures, and suites for routine fluoroscopy, and for rapid chest examinations could be envisaged.

The x-ray film processing devices have until very recently been concentrated to dark rooms, which in a sense have been the central point of the department. The size of the darkroom depends on the number of staff working in it. Citrus fruit colour and pastel shades are suitable for the walls and ceiling of the dark room. Dark colour, above all black should be avoided. Ten air changes per hour are recommended.

Since automatic processors have largely taken over from manual systems, there have been changes in the dark room planning. Medical x-ray films can be cassette loaded, exposed, unloaded and processed entirely in daylight. About 90% of all x-ray examinations could be performed without access to a dark room. The automatic system reduces the physical workload of carrying the cassettes by the radiographer.

3.3.1 Radiation Protection and Safety

In general, the amount of radiation in a small basic radiological facility is so little that radiation protection is not a major problem. In larger set ups it assumes a greater proportion and requires urgent attention.

The recommendation for wall thickness for radiation protection which follow is based on a minimum x-ray room size. Calculate the desired thickness of material on the basis of total radiation exposure of 150 mA-minutes a week at 100 kv. The number of milli-Amperes used for each exposure multiplied by number of seconds provides the milli-Ampere-seconds (mA-s) for each exposure; the milli-Ampere-minutesper day can be calculated by multiplying the number of exposures per day by the average exposure used.

In basic radiology facility it is, therefore, permissible to utilize a wall thickness design figure of 1 mm of lead equivalent. This incorporates a sizeable safety factor and will be satisfactory until at least 30 patients are examined daily.

A standard poured concrete wall of about 8-12 cm thickness would be required to provide a lead equivalent of 1 mm. If cinder blocks or bricks are used, a thickness of about 12-15 cm will be required depending upon the density of the material actually used i.e., (thickness of concrete) x (2.35 gm/cm^3) = thickness x density (of similar material).

Within the x-ray room, there are two specific high-risk areas; the wall behind chest stand and the wall of the dark room. Provided the x-ray unit is properly positioned, the wall of the dark room will need no special protection if it is constructed of at least 10 cm of concrete. At no time should the main x-ray beam ever be pointed at the wall of the dark room, to prevent radiation fogging the stored films.

There are two ways to over come; increased protection as part of the chest x-ray cassette stand or increased protection on the wall itself behind the chest stand. For the farmer chest cassette holder must carry 2 mm of lead equivalent, whereas in the later way, an area, 2 m

in height and 1 m wide, centered immediately behind the chest stand must have the shielding of 2 mm of lead equivalent. This can be obtained by increasing the thickness of the concrete wall to 20 cm, It is worth remembering that simple plate glass of Icm thickness is equivalent to 1mm of lead and provides a very satisfactory radiation barrier.

It should be re-emphasised that these calculations provide for more of a margin of safety than is likely to be necessary in a basic radiological facility. However any change in room dimensions, a more powerful generator or a large increase in the number of patients will alter these requirements. Normal one brick wall thickness up to 250 mm is considered adequate.

The x-ray control (console) must be designed in such a way that the switch is an integral part of the unit and protection should be incorporated in the design of control panel. There should be a shield of 1 mm lead equivalent, at least 75 cm wide in front of the control panel and extending 50 cm on either side. It should be 2 m in height and should have a lead glass window with at least 1 mm lead equivalent (25 cm x 25 cm in size) situated in the central panel at eye level, so that operator can see clearly through it. Should there be a requirement for patient to be held then lead protective clothing must be worn.

Standard glass windows do not provide much radiation protection. However there is no radiation hazard provided people do not loiter within 1 m of the window of standard size of x-ray room. If patients wait outside the room, the window should be at least 1.5 m above the floor finish inside. Windows are desirable for both light and ventilation.

3.3.2 Radiation Safety Monitoring

It is internationally accepted practice that all personnel who work with ionizing radiation be continuously monitored to record the dosage received during their work. In diagnostic x-ray department, this is usually done by requiring each operator to wear while at work a small film badge of standard design. A written record must be kept for each wearer. Such a film badge service can only be organised and controlled on a central basis and report must be examined on monthly basis by a radiologist or radiation safety officer.

Other personal methods of protection include the routine use of radiation proof apron (lead equivalent 2.5 mm). These are usually double sided, and racks to support them should be provided in the x-ray room, preferably near the control panel. Protective gloves (lead equivalent 0.3 mm) must also be worn whenever a patient needs to be held by a nurse or aide who will be in the x-ray beam during the exposure.

3.3.3 Principles in the Layout of a Diagnostic X-ray Room

There are four basic principles in the layout of a diagnostic x-ray room:

i) The x-ray tube should never point towards the control unit.

ii) The x-ray tube should never point towards the dark room.

iii) The x-ray tube should never point towards any window or door, sometimes this is not avoidable, especially during a cross table control lateral view, but no one should be allowed to stand next to a door or window when these-films are being taken.

iv) The control should be as far away as possible from the x-ray table.

The main radiation danger in any x-ray room is scattered radiation, because with proper cones or collimators the primary beam will be controlled. Radiation decreases in proportion to the square of the distance, and distance is the most important single factor in radiation protection.

Radiation exposure to patients, staff and other personnel should be kept to the minimum required for performing the radiological procedure, metal cones and adjustable shutters (Collimators) are fastened to x-ray tubes to limit the size of the beam and to reduce scattered radiation. A further advantage of these devices is to increase the quality and confining them to the exact size and direction required, Collimators in major x-ray department incorporate multiple shutters and a light system coupled with mirrors which clearly defines the field size being used.

3.4 VIDEO IMAGING MODALITIES

Video imaging modalities (diagnostic imaging) in radiology department are those which do not involve direct or indirect exposure of radiographic films. In this section you will lean about these video imaging modalities which include Digital Radiography, Digital Subtrnction Angiography, Computed Tomography, Sonography (Ultrasound Scanning), Echocardiography, Thermography, Cnrdiac Catheterizetion Laboratory, Magnetic Resonance Imaging and Nuclear Medicine Scanning. All these result in a video image viewed on a television monitor from which hard copy must be made. These hard copies are useful as research tools and legal supportive documents.

Digital Radiography

In digital radiography, an x-ray image produced by an image intensifier is recorded digitally and stored in a computer memory, replacing the conventional x-ray film. An image intensifier is a device for greatly enhancing the faint fluorescence of an input phosphor screen in response to radiation, by electron release and capture, causing much brighter fluorescence of an output phosphor screen viewed by a TV camera. The resulting image is viewed on a TV monitor. Careless handling of fluorescent devices may lead to unnoticed overexposure.

Digital Subtraction Angiography

Digital Subtraction Angiography (DSA), previously known as Digital Vascular Imaging (DVI), is similar to digital radiography, but may be included as an "add-on" to fluoroscopic

imaging equipment as well as being built into digital radiographic equipment. DSA is very sensitive and can satisfactorily image considerably diluted contrast medium. The subtraction images can be viewed dynamically on a TV monitor as a continuous real time image showing the gradual appearance and disappearance of contrast medium in the blood vessels being studied, or as regularly upgraded static images at short time intervals. The optional images can then be frozen for production of hard copy.

Computed Tomography

Computed tomography (CT or computer assisted tomography CAT scanning) uses measurements of x-ray attenuation recorded by an array of detectors from a thin fan-beam of x-rays. The x-ray source and detector array rotate circumferentially around the patient. It is possible to construct simulated 3-D images of bones and blood vessels opacified with radiographic contrast medium. The latest generation of CT scanner use helical or spiral scanning instead of planar scanning of individual axial slices, resulting in decreased scanning time and allowing better dynamic imaging of blood vessels following contrast medium injection.

The CT unit has to accommodate the CT scanner (a large machine with a "doughnut hole" in the centre), anaesthesia machine, a ventilator, and routine monitoring equipment. The CT room tend to be cold, with the temperature under 21°C and control of patient temperature may become difficult. Piped anaesthesia gases and vacuum with connectors for anaesthesia machines should be provided. An appropriate electrical power source and piped oxygen connection for ventilators are also required.

Sonography (Ultrasound Scanning)

Ultrasound scanning uses a robe operating by the piezo electric effect to emit ultrasound of frequency 33-10 MHz into the patient and receive returning echoes from internal structures, producing a real time, grey scale image displaying the echo intensity as a 2-D image on a TV monitor. Doppler Ultrasound allows flow within vessels to be displayed. In duplex doppler the2-D image and doppler wave form are displayed simultaneously, allowing accurate placement of the sampling gate over the region of interest. Colour Flow Doppler assigns different colours (usually red and blue) to flow in different directions, so that adjacent arteries and veins are displayed in different colours superimposed on the monochrome ultrasound image.

In the field of cardiology and obstetrics, ultrasound is indispensable source of diagnosis. Sonography provides answers to some clinical questions without discomfort or great expense that otherwise demands hazardous invasive and costly investigations. Hot and cold water as well as suction and oxygen supply should be available. Sonography is relatively safer technique and no significant harmful effects have been documented because of its widespread use.

Echocardiography

Pulsed ultrasonic doppler techniques afford opportunities for making transcutaneous measurements on the cardiovascular system and to provide information, which other approaches cannot make available. For echocardiography room the door width should be 130 cm. There should be commonly grounded electrical outlets, a dimmer switch to adjust room lights and a washbasin. There is no radiation protection requirement.

Thermography

Thermography is an infra red scanning system for measuring changes in distribution of surface temperature and presentation of the temperature distribution and development. Warm areas may represent inflammatory or cancerous processes. Cool areas may signify inadequate blood supply. The temperature information from the infra red camera (with or without use of colour filters) which is normally displayed as a picture or an oscilloscope screen is particularly suitable for computerization. Thermograms could be assessed using a computer without loss of accuracy and without the necessity to use expensive personnel for examination and interpretation.

Thermography room requires a size of about 18 m^2 and a height of 2.5 m. The room should not be smaller than 3.5 × 3.5 m. Room should be maintained at a temperature of 21± 1°C and humidity of 50 per cent. The thermal environment must be controlled with great

accuracy. There should be no heat sources or draughts. No sunlight should enter the room and it is best if not even daylight comes in. Light should be provided by fluorescent tubes. There should be no glass or polished metal surface near the subject. The walls of the room should not have glossy paints.

Cardiac Catheterization Laboratory

Cardiac Catheterization Laboratory is vital to the diagnosis and treatment of coronary diseases. Cardiac catheterization is the insertion of a catheter (a long, narrow, flexible tube) through a blood vessel into the heart. It allows examination of the heart and coronary arteries. The procedure may be either diagnostic or therapeutic. Coronary angiography (injection of contrast media) is a diagnostic procedure that causes arteries to become visible or x-rays. Therapeutic procedures include the installation of pace makers and angioplasty (balloon catheter) which can clear an occlusion in the artery.

The cardiac cath lab (cardiology) is normally a separate suite located near surgery, but may be a part of imaging provided that the appropriate sterile environment is provided. The amount of radiation protection to be installed has to be certified by the physicist. A viewing area in addition to control room should be provided with a space for processing, individual counter top projection and film boxes (3.05 m in length) with illumination to provide light of the same colour value and intensity for appropriate comparison of several adjacent films. Other facilities needed are scrub up, soiled holding and contamination holding, storage space for portable equipment such as defibrillators, catheters and other supplies for use during clinical emergencies.'

3.4.1 Contrast Media

All the video imaging modalities (diagnostic imaging) described above have created their own demands for contrast media. The use of contrast media in computed tomography improves the visibility of anatomic structures and also provides important information on organ function and pathological changes in organ function. In digital subtraction angiography and conventional angiography, the use of contrast agents are essential. Administration of the contrast medium via a catheter allows the visualisation of greater vessels as well as the entire vascular periphery.

3.4.2 Laser Imaging

The laser imaging is a much more sophisticated method of converting an analog or digital signal from an imaging modality into hard copy. The electronic data of an image is converted into a digital signal from which a laser beam of corresponding intensity scans across a photographic film exposing it in proportion to the brightness of the image line by line, in exactly the same manner as the electron beam scans the phosphor screen of a TV monitor. This results in true reproduction without loss of contrast or resolution, free from distortion. The image can be electronically smoothed so that TV lines are not visible. The photographic film is designed with sensitivity to match the wave length of light output of the laser.

A laser (light amplification by stimulated emission of radiation) is an intense, parallel, coherent beam of light with fixed frequency and phase. The laser beam can be shaped with collimator lenses or deflected by mirrors. Laser imagers in clinical radiology use a helium-neon (HeNe) laser or a laser diode,

The helium-neon laser is a thermo-emitting valve, with a warm-up period of 15-20 minutes, emitting a red light of wave length 633 n m. The solid state laser diode has the practical advantage of no warm-up time, and is, therefore, only " O N while printing (about 8 seconds per film), emitting radiation in the infrared range of wave length 780-820 n m. It has a life span of 80,000-10,0000 hours where as helium-neon laser has a life span of 15,000-20,000 hours.

3.5 MAGNETIC RESONANCE IMAGING

Magnetic Resonance Imaging (MRI) as you know is a relatively new and potentially significant imaging modality in medicine. MRI uses the principles of nuclear magnetic

resonance (NMR) to produce cross sectional images without the use of ionising radiation. MRI technology is a synthesis of several technologies—RF technology, Computer technology, super conductive magnetic technology. The use of magnetic technology poses a unique challenge to the hospital planner.

The installation planning for a superconducting MRI system requires extreme care to assure that the magnetic field is protected from the influences of the surrounding environment and conversely, that the surrounding environment is undisturbed by the effects of the magnetic field.

The static magnetic field of the MRI system is 3-dimensional and, therefore, extends to the space above on the same level. Magnetic field strength which is measured in Tesla (I Tesla = 10000 Gauss where the earth's magnetic field is 0.7 Gauss) decreases as one moves away from the magnet. Two problems arise: First, ferromagnetic materials in the environment can distort the magnetic field of the system degrading image quality, spectroscopic studies would be impossible. Second, the magnetic field can interfere with the function of certain electrical/mechanical devices such as instruments with cathode ray scopes, pace makers and so on.

Ferro magnetic material in the vicinity of the magnet could be stationary, such as structural beams or moving objects, such as elevators, passing vehicles. The former can be foreseen and compensated by symmetrical magnet placement and use of shims. Compensations of field distortions encountered from moving objects is generally more difficult and often impossible. It is necessary in such cases to make actual physical measurements on site to determine the compensation required.

Another aspect of planning involves shielding the examination area against rndio frequency waves emanating from external transmitters. The materials used for making the RF shield are one of the three: Copper, Aluminium and Stainless Steel. It is important to have good contacts between the panels used or else RF leakage can take place. Hence long term stability of the joined parts is essential. Parts which are bolted may become loose or oxidation may break down the conductivity of panels resulting in either case of RF going through.

A crucial aspect of planning MRI systems in India is the availability of cryogens. In super conducting magnets, liquid Helium and liquid Nitrogen are used to maintain the temperature of the magnet at the super conductive temperature (approx. 4 K). It is necessary first to fill the magnet with liquid helium and later on to refill the magnet after the permissible drop in level of liquid helium in the mngnet is reached. Liquid nitrogen is replenished more often than liquid helium. A minimum stock of both cryogens must be maintained at site to prevent magnet shut down in case of delay in cryogen supply.

Provision must be made to adequately vent the evaporated helium and nitrogen. Liquid helium can be vented to a recovery system and subsequently sent for liquidification. Oxygen monitors should be installed to ensure that the oxygen level in the examination room is not depleted due to leakage of the inert gases. Apart from the normal boil off, there must be a provision to vent off the helium in the event of a quench.

3.5.1 Planning Constraints

In terms of architectural planning constraints, the epicentre of all activity is the examination room (magnet room) which houses the magnet. The magnet is enclosed in an RF cage. The room is surrounded by satellite spnces viz. the control room, the computer room, the technique room, the cryogen storage, dark room etc. The computer room projects out of the central circle. This is done to avoid the field strength I mT where storage devices (magnetic disks) are sensitive. At the same time this projection has to be away from the expected I mT field of the proposed small magnet. The dark room is to be outside the magnetic field.

When spectroscopy is provided, caution should be exercised in locating it in relation to the magnetic fringe fields. Magnetic shielding may be required to restrict the magnetic field plot. Radio frequency shielding is required to attenuate stray rndio frequencies.

Facility shall be provided with uninterrupted power supply and central air conditioning to maintain temperature of 21°C. Noise generated by equipment can be frightening and

irritating to patients; accoustic treatment is recommended for a successful MRI procedure room.

3.5.2 Preventive Measures Against Magnetic Field Hazards

Metal detectors are placed at the entrance to screen any ferrous objects on patients and medical personnel. Besides warning notices are placed at strategic points warning visitors with pace makers, metallic implants etc. from entering the magnetic field. The magnet is in one piece and the floor must be reinforced to take the load of the magnet weighing approx. 10 ton in case of 1.5 Tesla while at the same time avoiding use of steel reinforcement. In the magnetic room and surrounding areas, air conditioning ducts, soil pipes, electrical conduits are to be of non-ferrous materials.

3.6 NUCLEAR MEDICINE DEPARTMENT

Nuclear Medicine as you know is concerned with diagnostic and therapeutic uses of artificially produced radioisotopes. Nuclear medicine procedures are of two types:

a) In-vivo procedures in which radioisotopes are administered to patients, and

b) In-vitro procedures where radioactivity is added to the samples collected from the patient.

Again, in-vivo tests are classified into imaging procedures, and non-imaging procedures. An imaging procedure, which is more popularly known as scintigraphy, provides an image of the distribution of administered radioactivity in the organ or tissue of interest at any given time. Non-imaging procedures are aimed at measurements of gross radioactivity in the organ of interest at any particular time. Serial measurements provide a time activity curve.

With the availability of many short lived radioisotopes, nuclear medicine has now become an important medical speciality with wide applications in various branches of medical science. Some of the important applications of nuclear medicine are:

- Imaging of various organs such as thyroid, liver, brain, bone and kidney etc.
- Thyroid function studies
- Investigations of central nervous system
- Absorption studies in gastroenterology
- Nuclear haematology e.g. blood volume studies, iron kinetics, etc.
- Renal function studies
- Nuclear cardiology e.g. stress thallium and MUGA studies
- In-vitro studies like radio immuno assay (RIA) of various hormones

With the help of an on-line computer, coupled to a gamma camera, a variety of dynamic function studies can also be performed using appropriate radio pharmaceuticals. Therapeutic uses of radio-nuclides are mainly limited to treatment of thyrotoxicosis and thyroid cancer with I-131, polycythemia vera with P-32, intracavitary installation of radiocolloides for malignant ascites and effusions and radio isotope synovectomy for painful joints.

A nuclear medicine department caters to the need of all clinical departments, because of radiation hazard associated with the use of radionuclides, planning of the department should be done in such a way that there is no radiation exposure to non-radiation workers and the genera1 public, and also that workers handling radioisotopes receive minimum exposure.

Nuclear **Medicine Imaging**

Nuclear medicine imaging, or gamma camera/rectilinear scanner produces images from gamma rays emitted by radionuclide injected into the patient. The commonest radionuclide used is technetium 99-m (Tc 99-m) which is tailored to image different structures or physiology by chelating it with compounds to target specified organs or physiological functions. The emitted gamma rays are detected by a gamma camera consisting a large lead shielded crystal that gamma camera scintillates when a gamma ray enters it. Groups of photo multiplier tubes behind the crystal detect and localise the scintillations and a computer analyses the resulting electrical signals and reconstructs an image.

Positron Emission Tomography

Nuclear medicine includes Positron Emission Tomography (PET) which is not common to most facilities. Positron emission tomography scanning is generally used in experimental settings and requires space for a scanner and for a cyclotron. For both a hot (radioactive) lab and a cold (non-radioactive) lab may be required. Significant radiation protection may be required since the cyclotron may generate high radiation. Special ventilation systems together with monitors, sensors and alarm systems may be required to vent gases and chemicals. The HVAC system will require particular attention, highest pressures should be in coldest (radiation) areas.

The cyclotron is water cooled with deionized water. A heat exchanger and connection to a compressor or connection to chilled water may be required. A redundant plumbing system connected to a holding tank may be required to prevent accidental leakage of contaminated water into the regular plumbing system.

Radio Pharmacy

If radio pharmaceutical preparation is performed on site, an area adequate to house a radio pharmacy shall be provided with appropriate shielding. This area should include adequate space for storage of radionuclides, chemicals for preparation, dose calibrators and record keeping. Even for use of pre-prepared material space adequate for dose calibration, quality assurance and record keeping shall be provided.

3.6.1 Facility Planning

Planning of a nuclear medicine facility be approached cautiously, as it is a facility with interrelated areas that require both a high degree of integration and a high degree of isolation. In order to understand these simultaneous need for integration and isolation,

awareness of the procedures to be performed within the nuclear medicine laboratory is required.

The value of nuclear medicine as diagnostic tool is based upon the ability of certain organs and system of the body to absorb radioactive isotopes of certain elements, measured with various types of radiation detection equipment. Unlike Radiology and Radiotherapy, nuclear medicine does not involve the use of radiation emitting equipment. The only radioactive materials used in diagnostic areas are those that are administered to the patient.

The Nuclear Medicine department is divided into:

i) Hot areas, those in which radiation levels potentially could approach a dangerous intensity,

ii) Diagnostic areas, those areas where the patient and staff are exposed to low levels of radiation, and

iii) Patient Support areas, those areas in which no one should be exposed to any radiation.

Hot' Areas

Activities performed in hot area include receiving, holding and stirring, diluting, counting and issuing of radioisotopes. Where work with liquid isotopes is performed in open laboratory areas, floor and work surfaces should be made of non-porous materials in case of spillage. All work with isotopes in solid should be performed in a glove box or under a hood, so that if spillage occurs the technician will not inhale or ingest the solid particles or fumes. The handling of isotopes before and during dilution is the hottest procedure performed in the nuclear medicine department.

After dilution for use in diagnosis, the radioisotopes require storage and their radioactivity level needs to be counted. These procedures are carried out in an area free of direct contamination from handling and diluting areas. From storage area, isotopes are sent to diagnostic area for administration to patients.

Hot areas facilities thus include a radio pharmacy cum Tc99m generator room, radio isotope storage, decontamination room, and dose administration room.

Diagnostic Areas

The focal point of the nuclear medicine department is the diagnostic areas, where actual isotope procedures are performed on patients. The mbst common procedure involves use of scanners, counting units, scintillation camera and counters. Diagnostic areas must be located immediately adjacent to patient support areas. Direct access between hot and diagnostic areas provides a high level of functional integration.

Support Areas

Such as waiting and reception areas, for the convenience of the staff as well the patient's. Waiting areas for patients should be located off the major circulation corridor and should be marked as to be easily seen and recognised. Staff support facilities, such as lockers and lounges, should be located as close as possible to the employees work areas. Important aspect to keep in mind for planning is to provide toilets separately for radioactive and non-radioactive patients.

The only area of the nuclear medicine department that must be isolated is the hot area. Such isolation is required, first because levels of radiation within the hot area potentially dangerous to personnel and secondly to prevent high levels of background radiation from distorting readings in the diagnostic area.

3.6.2 Radiation Protection Aspects

Radiation protection is an important aspect to be taken care of in nuclear medicine department. Adequate number of radiation monitoring instruments should be procured for routine monitoring and survey. A portable contamination monitor with aural alarm is an essential instrument. In addition, beta gamma survey meter with measurement ranges from a few in mR/hr to a few R/hr is also required where large activities are handled. Persons

handling radioisotopes should wear personnel monitoring badges while working in nuclear medicine department.

For effective implementation of radiation safety in nuclear medicine department, following points are to be ensured:

a) All walls and doors of the radioisotope laboratory are to be painted with a good quality washable paint.

b) Minimum furniture should be used.

c) Top surfaces of work tables should have a smooth laminated finish.

d) Adequate number of lead containers and interlocking lead bricks should be procured for providing adequate shielding in storage and handling rooms.

e) Remote handling devices for different operations in the radioisotope laboratory should be procured.

f) Ventilated fume hoods for handling large.doses of 1-131 and for carrying out extraction of Tc-99m should be installed.

g) The drainage pipes of the radioisotope laboratory i.e. of sinks, washbasins, toilet etc., should be connected directly to the sewage system.

h) Ordinary wall thickness is sufficient, in general, for the diagnostic nuclear medicine laboratory. However, extra wall thickness may be required for rooms where patients administered with I-131 therapy doses are to be hospitalized.

3.6.3 Radioactive Waste Collection and Disposal

The radioisotopes used in nuclear medicine are mostly short lived, the half-life being in the range from a few hours to a few days. In India, at present Tc-99 m and I-131 are the two major radioisotopes that are used for nuclear medicine procedures in large quantities. Because of the short half-lives, the disposal of radioactive waste is done by the simple method of decay and disposal. When the quantity of radioactive waste is large, specific advice on disposal may be obtained from the Radiological Physics and Advisory Division (RPAD) earlier known as Division of Radiological Protection (DRP), Bhabha Atomic Research Centre (BARC),Trombay, Mumbai-85.

3.6.4 Procedure for Obtaining Clearance

For obtaining the necessary license to handle radioisotopes, the user has to get the design of the department cleared by RPAD, BARC. Proposed layout of the department, indicating the locations of each operation with radioactivity such as storage and handling, dose administration, counting etc. to RPAD, BARC. Approval will be accorded for construction of the department with due modification as deemed necessary.

Simultaneously, information regarding the radioisotopes intended for use, their activity and purpose of use should be furnished to RPAD, The names of nuclear medicine staff, their qualifications and experience should be intimated in the prescribed form available with RPAD, The nuclear medicine specialist attached to the department has to get a clearance from Nuclear Medicine Committee for human administration of rndio pharmaceuticals, After these requirements are fulfilled, RPAD will issue the necessary authorization/no objection certificate for supply of radioisotopes by Board of Radiation and Isotope Technology (BRIT), a unit of Department of Atomic Energy.

3.7 RADIATION THERAPY

Radiation therapy is a speciality in the field of oncology. Radio-therapy was started in India with the installation of first telecobalt unit in 1957. Recent reports of Bhaba Atomic Research Centre states that more than 60% of all cancer cases can be treated by radiation. The majority of the radio-therapy patients can be treated on out patient basis and also in limited radio-therapy facilities, Chemotherapy, which is exceptionally demanding in medical science both in the clinic and the laboratory, is given as an adjunct to radio-therapy or as a continuing treatment.

Radiation therapy can be divided into following categories:

Brachytherapy

Brachythernpy involving use of ionizing radiation is an important mode of treatment for cancers of specific sites. Isotopes like radium or the equivalent or radioactive cobalt cenium or iridium are used in the form of needles for implantation of tumours or in applicators to be placed against the tumour or inserted into a cavity containing a tumour. Because of the potential hazard involved in the use of ionizing radiations, it is essential that every brachytherapy facility complies with the various regulatory requirements as specified by the Radiation Protection Rules (1971) promulgated under the Atomic Energy Act (1962).

The medical institution while selecting and ordering a specific remote after loading brachytherapy unit must ensure from its supplier that the type approval/No objection certificate for the make and model of that unit has been issued by the competent authority i.e., Chairman, Atomic Energy Regulatory Board (AERB) from operational and radiation safety stand points. In case of sealed sources, it must be ensured from the supplier that the design of source encapsulation is also duly approved by AERB.

The radio isotope laboratory has for its solid sources a general service area where applicators and accessories are stored together with shielded containers and appliances for radioactive materials. A radio pharmaceutical room is needed to produce under aseptic conditions substances which are injected intravenously into the patient. Rooms for general in-vivo and in-vitro coupting are needed, where gamma cameras and rectilinear scanners are used. Additional rooms will be required for imaging equipment, A sub-waiting area will enable to separate patients who have received radio isotopes from other waiting patients. Where ever possible, rooms should have outside windows.

Mega Voltage Therapy (Teletherapy)

Teletherapy involving use of ionizing radiations of greater than one million volts. This includes cobalt 60 and a variety of accelerators using high energy x-rays. Most of the radiation therapy centres have more sophisticated accelerators which deliver radiation at 4 to 12 million volts. A few of the large centres have accelerators and betatrons which produce x-rays at 25 to 35 million volts.

In the linacs of linear accelerators, electrons are accelerated in a linear tube by high frequency power generators. Electrons are emitted from a gun, travel down the tube gaining energy all the way to hit a target and produce x-rays at the end of the tube or to be let out. The main advantages over the cobalt are the higher quantum energy of the radiation, better depth dose curves, better collimation and much higher radiation intensities of the x-rays. The maintenance of a linac is more complicated and costly than that of cobalt unit.

In the betatron, electrons are accelerated by induction and guided by magnetic fields. The betatron is basically a very simple and reliable, though expensive machine for producing very high-energy electrons. Unlike radiation from other common sources, the dose it delivers drops off very sharply after a certain depth and in general, a lower amount passes through the patient on the side away from the point at which the radiation enters. These advantages are countered to some extent by the fact that electron beam is not particularly well focused and radiation is scattered to tissues around the cancer.

According to Snelling a cobalt unit can treat 30 to 40 patients in a day of 7 hours and a linear accelerator treats 60 to 70 patients in the same duration. All machines should be replaced in 12 to 15 years.

Ortho Voltage Therapy

Ortho voltage therapy involving use of ionizing radiation with energies from 150 to 400 kilovolts. This equipment now stands replaced largely by megnvoltage units. It is used in the treatment of infiltrating surface malignnncies and often as a supplement to megavoltage therapy such as interoral and intervaginal treatment.

Superficial Therapy

Superficial therapy employing ionizing radiation with energies from 8 to 140 kilovolts. Relatively soft x-rays are used for non-infiltrating cancers such as skin cancers.

3.7.1 Facility Planning and Procedure

Functional facility planning of the department includes clinical examination section, treatment section and the radiation rooms.

The clinical examination section of radio therapeutic clinic includes a reception area including a registration room, examination and consultation rooms, medical staff and social workers rooms, waiting area including stretcher or trolleybays, storage, toilets and telephones.

The treatment section comprises the treatment planning room for time consuming dosimetric planning which requires access to a computer assisted tomography, simulator, mould room, medical officers and staff rooms, physicists, technicians, secretarial work rooms and record facilities, space for machinery including the power supply components and the control room.

A computer nssisted tomography coupled with computerized treatment planning and dosimetry offers a great potential for improving radiation therapy through accurate localization of tumour and critical normal structures within the host and by utilizing the tissue density and x-ray attenuation coefficients to increase the accuracy of close computations.

A simulator is an essential piece of equipment and mandatory for all teletherapy units. The accommodation will comprise the main simulator room and a control room, an x-ray

processing room and a clinical room for the preparation of the patient for minor surgical procedures.

A mould room suite is a key supporting facility. The prime function of this suite is to produce skills and applicators for tumour sites. Here patients impressions are taken, appliances constructed. A vacuum forming and injection-moulding bay is required as well as a store for materials. As the mould room uses inflammable materials, good ventilation is essential.

To reduce the hazard of transporting radioactive sources, the insertion of radioactive materials is undertaken in the operation room. A single operation room unit is needed. Extra space must be allowed for radiation protection equipment.

The treatment or radiation room needs about 45 cm^2 to 80 cm^2 depending upon the nature of teletherapy unit for its irradiation area. Various methods are used for providing access to the room. The most convenient is a door leading directly into the room. Such a door requires heavy shielding. A maze arrangement is generally the most economical, as shielding of the door can be greatly reduced, usually to less than 6 mm of lead, if it is exposed to multiple scattered radiation only. The required lead equivalence of the door will depend upon radiation energy, maze design, weekly work load and beam orientations.

The people outside the treatment room must be protected from accidental radiation. The walls of the treatment room likely to be hit by the direct radiation must be made of baryt concrete, the other walls may consist of normal concrete (refer to specifications at sub-section 2.6.4). In treatment room, there is a hazard due to high concentration of ozone and the oxide of Nitrogen. An air flow across the room to reduce rapidly the gas concentrations and about 12 air changes per hour should be provided. The machine control room or station needs not border on the treatment room. It should allow adequate space for the radiographers.

Govt. of India has designated Chairman, Atomic Energy Regulatory Board (AERB) as competent authority for implementation of radiation protection. Institutions intending to set up radiation therapy centre must seek clearance from RPSD. No construction work should be undertaken by the institution unless prior approval of RPSD of BARC for the specific layout of the installation has duly been obtained by the institution.

When the installation of the unit is completed as per specifications, the institution must immediately inform RPSD, so that pre commissioning radiological protection survey of the facilities could be carried out and necessary permission accorded for the commissioning of the installations.

For supply of source, the institution is required to place an order with the senior manager of technical sales operations, Board of Radiation and Isotope Technology (BRIT), Mumbai.

3.7.2 Radiation Protection Facilities

For storing Brachytherapy sources/applicators, the medical institution should ensure the availability of an appropriate lead protected storage safe. For movement of sources, an adequately shielded lead transport container must also be made available. To reduce the exposure to the personnel handling sealed sources, the institution should ensure the availability of an appropriate lead-bench which is essential for preparation of interstitial implants.

The institution concerned is responsible' for making necessary arrangements for the transportation of the decayed/damaged sources to Bhabha Atomic Research Centre for subsequent safe disposal. It is desirable to preserve the original packing and lead containers of the sources carefully so that they can be made use of for transporting the decayed sources, when necessary.

The decrease in output of a tele cobalt machine due to the decay of the cobalt source necessitates the replacement of the source once in 5-7 years. The source also requires replacement when the output of the machine falls below 50 rads per minute at treatment distance for meaning full radiation therapy. The institution is also responsible for the safe disposal of the decayed source in consultation with RPSD.

3.7.3 Radioactive Waste

Radioactive waste from tele-curie and brachy-curie treatment is in the kilocurie or 100 milli curie range with a half life of about five years. These preparations as well as cobalt-60 are regarded as no longer useable after a few years. These waste are not bulky but are highly active and need to be fully screened at all stages.

Waste from nuclear medicines and other applications are bulky but with a half-life of less than 14 days can be treated as inactive waste after 24 half life periods. Iodine 125, with a half-life of 60 days, need special storage. When providing facilities for storing of these wastes, the national regulations have to be observed.

3.7.4 Specifications for Tele Therapy and Brachy Therapy

Siting

The location of the Tele therapy and Brachy therapy installation should be so chosen that it is away from unconnected facilities and is close to the related facilities. These shall be planned at ground floor with requisite radiation protection shielding barrier walls and ceiling. Specific layout indicating appropriate wall and ceiling thickness should be worked out by the institution in consultation with Radiation Protection Services Division (RPSD) of Bhabha Atomic Research Centre (BARC) Trombay, Mumbai. The actual wall and ceiling thickness required will relate to the type and model of the Tele therapy unit, (telegamma unit relating maximum activity of the source and or an accelerator depending on maximum energy of the electron/photon beam) and will also depend on the nature of occupancies in the immediate surroundings and above the ceiling. Whereas in case of Brachy therapy, it will depend on the type and activity of sources, work load, nature of occupancies in the immediate surroundings and also above the ceiling and below the floor, if any. In the case of accelerators additional rooms for modulator, cooling etc. are required.

In case of Brachy therapy facility, it is desirable that the minor operation theatre is situated in close proximity to the treatment room/ward so as to facilitate easy transfer of patients. It is also to be noted that treatment room/ward should be exclusively used for brachy therapy patients only. U-traps or appropriate sieve arrangements should be provided in the toilet drain to ensure settling of any Brachy therapy source accidentally discharged into the toilet. Windows may be provided in the outerwalls of the wards facing open area above a height of at least 200 cm from the finished floor level inside.

Construction Material and Restraints

The construction material to be used for Tele therapy treatment room and for the treatment room/ward of Brachy therapy should be concrete of density 2.35 gm per cubic cm (gm/cc). However, where structural requirements so demand, RCC may be used. In case concrete of higher densities like haematite, baryt etc., are used the thickness may be reduced in inverse proportion to the ratio of their densities. Regarding feasibility of reduction in the physical thickness of some of the shielding barriers for getting more clearance to take the crates of Tele therapy unit into the room, reduction by a factor of 0.67 can be achieved by using haematite concrete of density 3.5 gm/cc instead of ordinary concrete of density 2.35 gm/cc. Alternatively steel in the form of sheets can be used as shielding material. Ten millimeter thick steel sheet will replace approximately 33 mm thick shielding barrier of ordinary concrete.

When two radiation installations are envisaged, they may preferably be located adjacent to each other so that one of the thick walls may be made common for both the installations. This will help in reduction of construction cost. In case there is no likelihood of occupancy above the Tele therapy room the primary barrier thickness for the ceiling may be provided from above. This will ensure that there will not be any construction above the ceiling in future and further the construction cost is also reduced.

It may be necessary for the installation of the Tele therapy unit that some portion of the wall or ceiling be constructed after bringing the crates carrying the unit into the treatment room. It may also be ensured from the supplier of the unit before, starting construction work that the maze planned for the treatment room is adequate for the movement of the various components of the unit with or without crates.

A ramp may be provided in close proximity to the tele therapy installation to facilitateeasy movement of the crates carrying the unit to tele therapy room. The ramp is also useful in future during source replacement operation, which is to be carried out once in every 5-7 years. The height and slope of the ramp should be so adjusted that the transport container can be unloaded with ease from the truck and transported into the Tele therapy room on a suitable trolley.

In certain instances, it is difficult to meet the shielding requirements of a Tele therapy installation due to structural and space constraints. This situation may arise when a:

- tele therapy unit is to be installed in an existing room,
  stationary telecobalt unit in an existing installation is to be replaced by a rotational telecobalt unit, or
- telecobalt unit is to be replaced by an accelerator.

This difficulty can be circumvened by installing a Tele therapy unit with a beam stopper. The beam stopper completely intercepts the primary beam and reduces its intensity approximately by a factor of 1000 and thereby decreases the shielding requirements for the primary barrier.

Viewing System

For observing the patient under treatment and the gantry movement from the control room, appropriate viewing system being an essential need must be provided. This can be achieved by providing either:

- Lead glass viewing window or
- Closed Circuit TV System (CCTV).

A viewing window of 4 cm lead equivalence should be installed. For this purpose an opening of 120 cm × 120 cm should be left untilled at the time of construction of wall in question at a height of atleast 135 cm from the finished floor level of the control room and a lateral distance of about 100 cm from the central line of the unit.

Alternative to lead glass viewing window, a CCTV system may be installed in the treatment room for observing patients under going treatment. The system should be supported by an additional camera and monitor should be available as standby or a back up mirror arrangement must'be available for viewing whenever CCTV system fails. In case of accelerator installations CCTV needs only be provided.

The mirror arrangement consists of installation of mirrors at appropriate locations inside the treatment room so that the image of the patient reflected in the mirrors is viewed through an observation panel fixed on the door of the treatment room. This observation panel may be of glass of size 20 X 20 cm located at a height of about 1.4 m from the floor.

Conduit

A conduit of 5 cm diameter should be provided in the wall to enable cables of radiation's measuring instruments to pass through from the control room to the treatment room. The conduit should be fixed in the specified wall at an angle between 20"-45" to the horizontal. The lower end of the conduit should be located in the treatment room at a height between 15-20 cm from the inside finished floor level.

Door Interlock

Door leading to the treatment room (Tele therapy/Brachy therapy) may be ordinary wooden door of width 150 cm for Tele therapy and 120 cm for Brachy therapy. This door should be so inter-linked to control panel by electrical interlocks that the unit cannot be operated upon when the door is open. A red warning light should be provided above the door and should be so inter-linked to the control panel that the light glows only when the unit is in operation,

Alr Conditioning

The treatment rooms (Tele therapy/Brachy therapy) should be air-conditioned. Central air conditioning or split type of air conditioning may be provided. In case of central air

conditioning, ducts should pass over the entrance door and along the ceiling over the maze for entry into treatment rooms. In case of split air conditioners, conduit of minimum diameters as required may be provided at a height of about 1.5 m from the floor of treatment room. Conduit for the passage of the air conditioning duct is to be provided in the specified wall at an angle to avoid direct scattered radiation passing through it. In the case of accelerator installations special ventillation arrangements are required for which RPSD should be consulted. It is desirable that control room should also be air-conditioned.

Electrical conduit requirement and any pit in the ground, load specification, conduit etc., particularly Tele therapy unit should be decided in consultation with the firm installing the unit, before commencement of the actual construction work.

3.8 LET US SUM UP

In this unit you have learnt about the Radiology Services involved in use of ionizing radiation requiring radiation protection and safety measures to safeguard occurrence of radiation hazards in health care institutions and hospitals.

Radiology department uses many different diagnostic-imaging modalities, radiograph to video imaging associated to use of contrast media. The process of Radiography, Fluoroscopy and Mammography involves mainly x-ray film exposures where in control of radiation is of prime importance. Other video imaging modalities of diagnostic imaging as radiology services not involving direct or indirect exposure of radiographic films include Digital radiography, Digital subtraction angiography, Computed tomography, Sonography, Echocardiography, Thermography, Magnetic resonance imaging and Nuclear medicine scanning.

Magnetic resonance imaging is considered by many to be the most revolutionary imaging technology of the 20th century. Advances in medical technology have reduced the area of magnetic field influence (the gauss field) surrounding the equipment to allow it to be more easily integrated.

Nuclear medicine department emitting radiation hazards associated with the use of radio nuclides require careful planning to ensure that there is no radiation exposure to non-

radiation workers and the public, staff handling radioisotopes are subjected to receive minimum exposure.

Cardiac catheterization laboratory employing ionizing radiation is vital to the diagnosis and treatment of coronary diseases. The procedure may be either diagnostic or therapeutic. Coronary angiography is a diagnostic procedure where as therapeutic procedure involves installation of pace makers and engioplasty.

Laser imaging is much more sophisticated technique of converting digital signals from an imaging modality into hard copy. It emits radiation in the infra red range requiring protective measure.

Radiation therapy is an important therapeutic technique for treatment of cancer. Brachy therapy and Tele therapy, which includes cobalt-60 and a variety of accelerators, are the vital units mainly involved in this therapeutic field.

Because of the potential hazard involved in the use of ionizing radiation, it is essential that every radio-therapy facility complies with various regulatory provisions as specified by the radiation services department, as envisaged under the Radiation Protection Rules (1971) promulgated under the Atomic Energy Act (1962). Government of India has designated Atomic Energy Regulatory Board as the competent authority for the implementation of radiation protection.

3.9 ANSWERS TO CHECK YOUR PROGRESS

Check Your Progress **1**

I) Radiation hazard in an x-ray room can be avoided through a provision of shielded control alcove with a view window designed to provide full view of patient and examination table.

2) • The wall behind chest stand

• The wall of dark room

are two specific high risk areas within an x-ray room.

3) All operators who work with ionizing radiation to wear small film badge to record the dosage received during their work, routine use of radiation proof apron (lead equivalent 2.5 mm) and protective gloves (lead equivalent 0.3 mm) are the radiation safety monitoring practices.

4) Some of the important effects are: a) Shortening of life span, b) cataract formation, c) chronic radio dermatitis, d) leukemia, e) cancer, f) decreased fertility, and g) genetic mutation.

Check Your Progress 2

1) MRI uses the principles of nuclear magnetic resonance (NMR) to produce images without use of ionizing radiation. Magnetic field of 1.0 Telsa is equivalent to 10000 Gauss whereas the earth's magnetic field is 0.7 Gauss.

2) Shielding of Radio frequency waves is achieved through an R F cage made of non-ferrous material such as copper, aluminium or stainless steel.

Check Your Progress **3**

1) The two types of nuclear medicine procedures are: In-vivo procedures in which radioisotopes are administered to patients, and In-vitro procedures where radioactivity is added to samples collected from the patient. Former involves radiation hazards.

2) There are three functional divisions of Nuclear Medicine Department. Hot areas, in which radiation levels potentially can reach dangerous intensity. Diagnostic areas,

3) Due to radiation hazard associated with the use of radio nuclides, medicine department should be in such a way that there is no radi non-radiation workers and general public, and also that radiation radio isotopes are subjected to minimum exposure.

4)
- DRP stands for Division of Radiological Protection.
- BRIT stands for Board of Radiation and Isotope Technology
- BARC stands for Bhabha Atomic Research Centre.

Check Your Progress 4

1) Mega voltage therapy or tele therapy units are in general use. Thi and variety of linear accelerators using high energy x-ray.

2) Cancers, Tumour

3) Radiation protection services division as envisaged under Radiati (1971) promulgated under the Atomic Energy Act (1962) is the re

4) Radiation hazards can be avoided through provision of radiation p barrier walls and ceiling, a maze, door interlock, viewing system a radiation measuring instruments.

UNIT 4 BLOOD TRANSFUSION SERVICES

Structure

4.0 OBJECTIVES

After going through this unit, you should be able to:

- identify the major nim of blood transfusion;

  provide information about the planning considerations including physical facilities and layout, equipment and staffing;

  decide category of blood bank appropriate to a hospital depending on its bed strength, specialised services, teaching and training facilities available;

  identify managerial issues involved; and
- describe the quality assurance and control measures.

4.1 INTRODUCTION

Blood transfusion is a broadly based discipline that overlaps and intersects many other medical, scientific and managerial fields, including haemntology, immunology, genetics, histocompatibility, cellular function and metabolism protein structure and function, cryobiology, disposable equipment, bioengineering, statistics, data-processing, public relations, logistics, and standardisation. Coordinated long-range planning is needed for the development and integration of such diverse activities, together with careful consideration of priorities and optimal use of resources. This is particularly important in developing countries where financial and other resources are very limited.

Accumulated information has revealed that Blood Transfusion Specialists, especially in developing countries, often need training in various aspects of management, such as planning the development of n national blood transfusion service, or expanding and improving the efficiency of an existing one, calculating the present and projected needs for blood, determining priorities in developing production of essential blood derivatives, and preparing budgets for the development or expansion of such services. Guidance is needed for the planning of the premises and staff training, for estimating the number of personnel required, and for preparing instructions (including principles and practice of quality assurance), regulations and job descriptions.

4.2 HISTORICAL DEVELOPMENT

In this unit you will learn in detail about various aspects of planning and management of Blood Transfusion services.

Resolution WHA28.72, adopted by the Twenty-eighth World Health assembly in 1975, requested the Director-General of the World I-Iealth Organisation (WHO) Io increase assistance to Member States in the development of national blood transfusion services. The blood transfusion service is a vital hut very often neglected part of the National Health Service, although blood and blood products have become indispensable in medical treatment during the past thirty years.

William Harvey ⓒ of blo.

1400's: During the time of Christopher Columbus at the end of 1400, Pope Innocent VIII, when he was old and ill, was given the blood of three young courtiers, probably by mouth. The illustrious patient died as did the three youth, who probably had lost too much of blood.

1616: William Harvey described circulation of blood.

1667: Jean Baptiste Denis, Physician to Louis XIV, transfused 9 oz. blood from carotid artery of a lamb into the vein of a young man successfully. Subsequently the transfusions failed and transfusions were prohibited except with the sanction of Faculty of Medicine in Paris. In 1668 the dangers of transfusing animal blood into man were recognised.

1678: An edict of French Parliament declared transfusion unlawful and similar decision in other countries followed.

1818: James Blundell, English obstetrician, gave first man to man transfusion, in a case of post partum haemorrhage. The patient recovered.

1899: Shattock noted agglutination, which he interpreted to be result of rheumatic fever. The pioneers in transfusion therapy faced not only the problems of an unpredictable outcome of each transfusion but also the problem of blood clotting and sepsis.

Landsteiner. 3 BG
A B O

1900: Landsteiner described 3 blood groups, which he called 1, 2 and 3. Karl Landsteiner, the father of modern immunohaematology, discovered the importance of blood groups and agglutinins, the so-called natural antibodies, which are responsible for transfusion reaction due to major blood group incompatibility. He subsequently called these as blood groups A, B and O.

Decastello & Sturli AB

1902: Decastello and Sturli, his pupils, discovered group AB.

1914-1916: Hustin in 1914. demonstrated the use of a mixture of sodium citrate and glucose as a satisfactory anticoagulant and blood preservative doing away with the practice of direct transfusion from donor to the recipient. The outbreak of World War I saw the large scale of anticoagulant stored blood to treat war casualties.

1937: On March 15, 1937 first blood bank in U.S. was opened at Cook County Hospital through the efforts of Dr. Bernard Fantus who conceived the term " Blood Bank".

1939: Levine and Stetson discovered Rh system and its role in hemolytic reactions. On the basis of Rh typing the human population was divided into Rh positive (85%) and Rh negative (15%) individuals.

1945: Coombs Mourant and Race introduced antiglobulin test based on a method described by Moraschi 1908.

World War II saw major advances in the organisation of regional transfusion centres, organisation of voluntary blood donors services, collection and preservation of blood and production of plasma, on a scale unknown earlier to meet the needs of the war time casualties.

Other blood groups were discovered during 1946 and 1951.

1964: Blumberg discovered Australia antigen.

1981: First case of AIDS was detected. This resulted in a radical turnabout in the transfusion medicine to review many of the established approaches. There were primarily two reasons for this change—the discovery of AIDS and major advances in technology.

Developments over the last three decades in the field of renal dialysis, cancer therapy, cardio-vascular surgery, transplantation surgery, treatment of hemophilia and related

disorders have put enormous burden on the blood transfusion services, not just for whole blood, but for products not available earlier, namely, blood components or blood selectively depleted of specific cellular components.

As a consequence three major changes have taken place in the blood traasfusion services throughout the globe.

1) Blood Donors

There has been increasing change in donors being accepted from professional donors to the voluntary donors. It is due to the increased awareness of the risk of transfusion transmitted diseases especially through that of the professional donors. Another important factor is the awareness that the blood of professional donors is under-haemoglobinised and, therefore, does not serve the real purpose.

The trend for **Autologous** Transfusion has opened a much better arena both from safety as also disease transmission.

2) Blood Transmitted Diseases

Blood is a double-edged weapon. On one hand whereas it is life saving, on the other it is endowed with the dangers of transmitting deadly diseases. Fortunately more and more awareness is coming into the public regarding this danger. The infections that may be transmitted through transfusion are Hepatitis B, Hepatitis non-A and non-B, HIV, CMV, Syphilis, Malaria, E.B. virus and HTLV infection.

The discovery of post transfusion Hepatitis in 1968 led to mandatory testing of blood for Hepatitis B antigen (HbsAg). This resulted in lowering the incidence of post-transfusion hepatitis. But it was found that many other organisms like non-A non-B hepatitis virus (called as Hepatitis C and D viruses), Cytomegalovirus (CMV), EB virus, were also responsible for post transfusion hepatitis, In addition to these the transmission of HIV I and II through transfusions resulted in overall changes brought about in blood banking. The role of blood in transmitting Treponema causing Syphilis and Plasmodium resulting in malaria too were highlighted. Hence it has been made mandatory that every donor must be tested for these. HTLV implicated in endemic T-cell leukemia are other viruses transmitted in blood that can cause serious and fatal diseases.

3) Introduction of Disposable Plastic Bags

In 1960 the changeover from glass bottles to plastic bags revolutionised the working of the blood banks. This helped in the use of the components to a much greater extent and also helped in better safety procedures. The introduction of disposable too helped in much safer transfusion procedures. The added advantages of the disposable are:

a) convenience in storage and transportation
b) no breakage
c) ease to transfuse
d) less risk of transfusion reactions
e) facilitates various blood components separation

With the availability of Apheresis procedures the scene in the blood banks has changed tremendously as one can now procure what is really needed.

4.3 ROLE AND FUNCTIONS

Blood Transfusion Services play a vital role in daily functioning of a hospital. The major functions of blood transfusion service are:

a) Recruitment of donors and maintenance of donor records.
b) Collection, storage and preservation of blood and blood components
c) Laboratory procedures
d) Teaching, training and research
e) Clinical/therapeutic functions

4.4 TYPES/CATEGORIES OF BLOOD BANKS

Based on consumption of blood and bed strength, blood banks have been divided into three categories:

Category I : Hospitals consuming 3-7 units of blood/Bed/Year
Bed strength 100-400
It includes District Hospitals, Corporation Hospitals, No Superspecialities, and Non-teaching

Category II : Hospitals consuming 8-15 units of blood/Bed/Year
Bed strength 400-1000
It includes State Medical Colleges, Specialised Hospital, and Teaching Hospital.

Category III : Hospitals consuming more than 16 units of blood/Bed/Year
Bed strength > 1000
It includes Apex Institutes, Metropolitan Medical College, and All Superspecialisation Teaching Hospitals.

Check Your Progress 1

1) Fill in the blanks.

a) William Harvey described the circulation of blood.

b) Blood group AB was discovered by Decastello and Sturli in the year 1902.

c) Blumberg ... discovered Australia Antigen in the year 1964

d) In the year 1981 first case of AIDS was detected.

2) Give True or False:

a) Malaria may be transmitted through blood transfusion. (True/False)
b) Introduction of disposable transfusion sets helped in transmission of diseases. (True/False)
c) Based on blood consumption and bed strength; blood banks can be divided in to four categories.@ (True/False)
d) There is more risk of transfusion transmitted diseases among professional donors as compared to voluntary donors. (True/False)

3) List the advantages of using disposable plastic bags.

- no breakage in storage + transportation
- convenience & ease of transfusion
- & risk of transfusion reactions
- facilitates old component seperation

4) List the major functions of blood transfusion service.

.....

.....

.....

.....

4.5 PLANNING CONSIDERATIONS

4.5.1 Physical Facilities and Layout

A blood transfusion centre can meet the demands made on it only if adequate premises are

available. It should preferably be located at the ground floor, close to the emergency and the operation theatres. The premises must be of suitable size, construction, and location to facilitate their proper operation, cleaning, and maintenance in accordance with accepted rules of hygiene. They must comply with the Requirements for Biological Substances No. 1 (Geneva Requirements for Manufacturing Establishments and Control Laboratories) and provide adequate space, lighting, and ventilation for the following activities:

- Medical examination of the individuals to determine their fitness as donors of blood and/or blood components
- Taking blood from donors with minimum risk of contamination or error
- Care of donors, including those who suffer adverse reactions
- Storage of whole blood and blood components pending completion of processing and testing
- Separate storage of whole blood and blood components after testing and before distribution
- Laboratory testing of blood and blood components; processing and distribution of whole blood and blood components in a manner that minimizes the risk of error
- Performance of all steps in apheresis procedures where applicable
- Labeling, packing and other additional operations
- Storage of equipment, reagents and disposable material
- Documentation and recording of data of the donor, the donated blood and, the recipient

Further in planning a transfusion centre, due consideration should be given to the following;

- Total amount of blood to be taken; and
- The level at which the centre will operate (national, regional or district), which will determine the different tasks requiring different premises, working conditions, equipment and personnel.

The centre must make special provisions for space if it is to:

- Have an outpatient department for activities such as sampling for antenatal serology or treating patients with haematological diseases;
- Produce sterile containers (bags), blood taking and giving sets and other sterile equipment;
- Produce blood grouping reagents.

General Considerations

Location and Space

The blood transfusion centre should be located where it provides easy access for donors and staff, and allows quick and safe transportation of blood and components to hospitals. The areas of the blood bank should be contiguous. The blood bank should have the following areas:

- Donor Recruitment area
- Bleeding complex
- Therapeutic area
- Laboratories
- Administrative and clerical offices
- Teaching Facilities

Donor Recruitment **Area!** Donor recruitment is extremely important for success of a blood bank. Recruiting voluntary donors requires techniques of mass contact, therefore, the donor recruitment area should be provided with:

- Adequate space for interaction with the'donor, It should be air conditioned and comfortable, so that any apprehensions in the mind of a donor are removed.
- Adequate facilities for maintaining and retrieving donor data as and when required.

- Printing facilities to provide required information to the donor should be available.
- The bleeding complex should have adequate space and facilities for a comfortable bleeding of the donor.

Hygienic Conditions: The best hygienic conditions must be ensured throughout the premises of a transfusion centre since there is a continuous movement of donors, staff, materials, and blood and blood samples.

Blood and blood components taken from the centre are used in hospitals, and external contamination of containers should, therefore, be avoided. All rooms must be easy to clean, with washable floors and walls.

The collection and disposal of waste must take place separately from the distribution of clean material, to avoid the spread of infection; provision for the expedient disposal of potentially infective materials by autoclaving and/or incineration must be made, There must be compliance with local by-laws in the disposal of these materials. It is particularly important that special arrangements be made for the disposal of blood samples and occasionally, of outdated blood: they Should not be directly discharged into the public sewerage system.

Air-conditioning is desirable for the greater comfort of donors and staff.

Moreover special conditions, including a supply of filtered air, or low temperature and humidity. may be required for some types of equipment and procedures.

Infrastructure within the Transfusion Centre

Following facilities need to be considered and taken care of while planning a blood transfusion centre.

Water Supply: The water supply should never be contaminated with any material potentially dangerous to health; it must be suitable for production of pyrogen-free water. Installation of filters is often necessary.

Electricity Supply: A reliable electrical supply is essential for lighting and for operation of equipment. A power failure to refrigerators may damage stored blood and blood components, and a transfusion centre must, therefore, have its own stand-by generators. The cost of damage caused by a power cut will almost certainly exceed the cost of the generator. Special attention should be paid to the possible need for a nonstandard electrical supply and for voltage stabilization, especially when considering the suitability of particular equipment.

Sewage: Sewage disposal must comply with the sanitary requirements of the local health authority. It should be noted that highly nitrogenous sewage has a high biochemical oxygen demand rating and should, therefore, never be discharged in an untreated condition.

Storage: Whole blood and blood components must be stored separately in a refrigerator, refrigerated room, or freezer, as appropriate, which is used only for this purpose. Refrigerated rooms are more economical for larger transfusion centres, where large quantities of blood and components must be accommodated,

Steam: If large-scale production of solutions is undertaken, there should be an adequate supply of steam for cleaning of equipment and operation of sterilizers. The steam itself should not cause or leave a contaminating deposit on the equipment or containers to be cleaned or sterilised.

Distilled Water: A supply of freshly distilled (and usually deionized) water should be available in every blood transfusion centre.

Gas, High-pressure Air Vacuum: Depending on the task undertaken by the transfusion centre, there may be a need for a gas supply, for high-pressure air and for vacuum facilities.

Communications: The transfusion centre requires telephones and/or telex facilities to maintain communications with hospitals and other transfusion centres, and to call in donors in special circumstances.

Factors Determining Adequate Floor Space

If a transfusion centre is not located within a hospital, the following supporting facilities must be provided:

- Sterilizing room
- Laundry
- Garage
- Store rooms
- Changing rooms, toilet facilities and canteen for staff of the centre
- Workshop for maintenance of the building and equipment

In the case of multistory buildings, the floors should have large loading capacity; where floor space is limited; weight distribution must be carefully considered.

The provision of a basement depends on the climatic conditions and the type of ground, and may prove impossible in tropical areas.

Standards for Space for Blood Bank

Depending upon the type of the Blood Bank the standards for space are as follows:

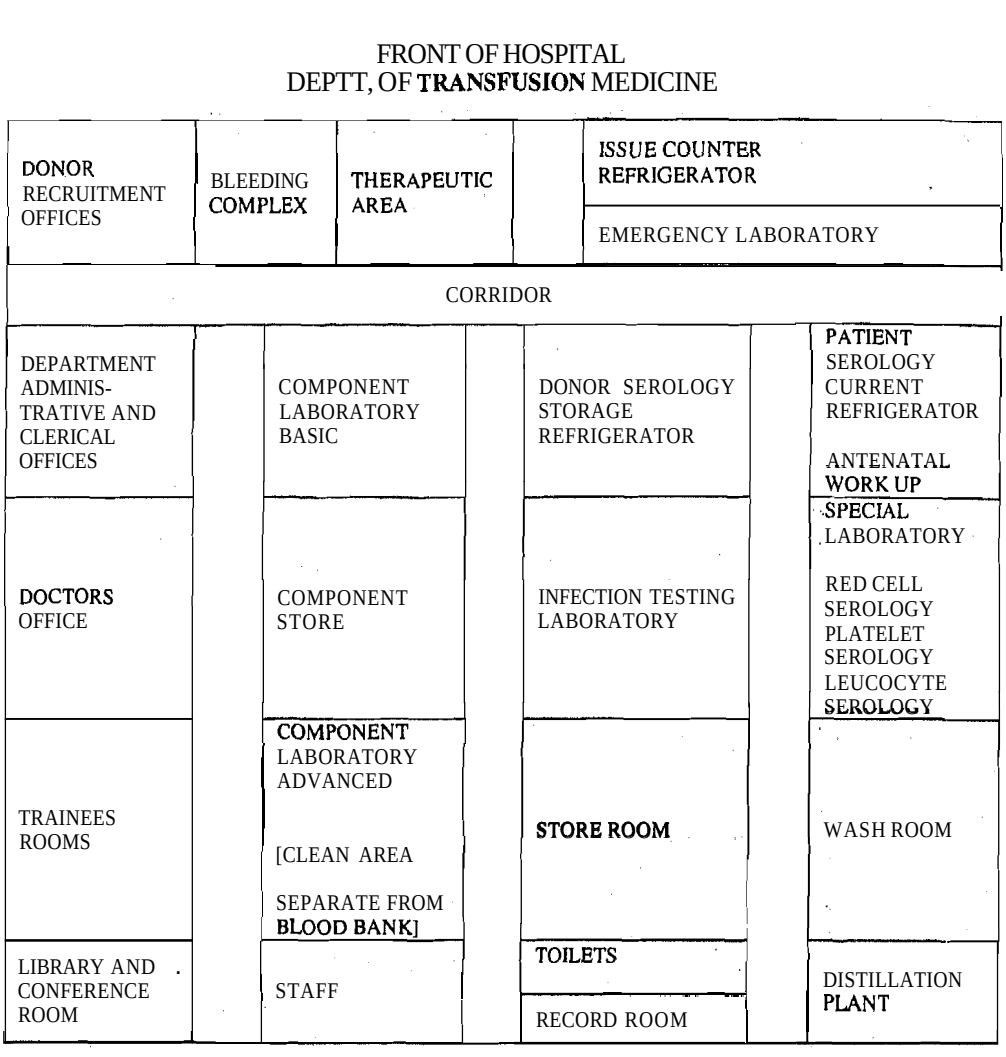
	Blood Rank Category		
	I	II	III
Bleeding Complex			
1. Reception Room	25	25	40
2. Medical Examination Rooms		15	25
3. Bleeding Room	40	55	100
4. Refreshment Room	15	25	30
5. Kitchen/Pantry	5	5	10
6. Aphcresis area			40
7. Day Care/Therapeutic area		30	50
Laboratory Area			
1. Laboratory for routine Donor work		25	50
2. Laboratory for routine patient and antenatal work		25	50
3. Laboratory for specialized work: Platelets HLA granulocyte serology			50
4, Issue Counter			20
5. Emergency Laboratory	18	20	20
6. Hepatitis, HIV, VDRL, Malaria	20	25	30
7. Wash room, distillation plant ctc.	20	25	30
8. Component basic and coagulation work		25	30
9. Component advanced freeze-drying			50
General Areas			
1. Doctor's office	15	15	20
2. Donor, Recruiter, Social Worker, clerical staff	25	30	50
3. Blood *Bank* Office	15	20	25
4. Stores	20	25	35
5. Technician's common room	15	20	25
6. Toilets	5x2	5x2	5x3
7. Trainee doctor's room			25
8. Library/Conference room			30
Total	**248**	**460**	**895**

Note: It is imperative to have bleeding room, refreshment room, donor waiting area and laboratories air-conditioned.

Minimum Area Requirements for different categories of blood bank are:

For category I : 100 Sq.M
For category II : 300Sq.M
For category 111 : 895 Sq.M

General Layout of **a** Blood **Bank**



4.5.2 Equipment

In a blood bank equipment are required for routing work, blood component work and for screening purpose of blood. In this **section** you will learn about requirement of these equipment.

A) ***For Routine Work***

1) Refrigerator: The refrigerators should maintain a temperature of 1-4° C, have audio-visual alarm system, temperature display, and recording, air circulation and **24** hours power supply. The inside should be of stainless steel and removable or pull out shelves.

   Although the number of refrigerators will depend upon the size and work load of the blood bank, yet a minimum of 3 are required, **1** for storing uniested blood, **1** for tested blood and **1** for cross-matched blood.

2) Table Top Centrifuge: Capable of 3500Xg with accurate timer in 1 min. increment up to 30 minutes' Accurate Tachometer. Acceleration to desired speed in **approximately 30 sec.,** rapid deceleration Rotor for swing head capable of taking minimum of **16-20, 12x100** mm tubes and microplate carrier. Number depends on size of blood bank but approximately equal to the number of daytime technicians.

3) Water bath 37°C with temperature control of + 10°C, of fiber glass
4) Incubator 37°C with temperature control of ± 10°C
5) Hot Air oven for drying glass ware
6) Microscope binocular
7) 1 kg balance for weighing blood bags during collection
8) Tube stripper cutter and aluminium clips to seal blood bags
9) B.P. Apparatus
10) Domestic Refrigerator for storing anti-sera, kits etc.
11) pH meter
12) VDRL Agitator
13) Blood bag stand (stainless) for keeping bag upright
14) Test tube racks/test tubes and glass slides, marker pencils etc,
15) Flexible table lamps with concave mirror
16) Blood bags—single (350 ml. and 450 ml.) and multiple (double, triple and multiple)
17) Sera for grouping and other reagents
18) Distillation nnd double distillation plant

Additional equipment for blood bank collecting more than 10,000 units:

1) Dielectric tube sealer
2) Vortex mixer.
3) Magnetic Stirrer
4) Analytical Balance
5) Laminar Air Flow
6) If using microplate technique—Microplate agitator

B) ***For Blood Component Work***

1) **Blood bank refrigerated centrifuge** for 450 ml blood bags. Swing head 5000Xg with windshield. Temperature of 0-25°C. Timer at I min. interval up to 60 min. Accurate tachometer.
2) **Freezer:** 70°C with alarm system, temperatures display, and recording device. 24 hours power supply and standby power.
3) **Freezer:** 20°C to 40°C with alarm system, temperatures display and recording device. 24 hours power supply and standby power.
4) Dielectric Tube Sealer
5) Plasma Separation Stand
6) Tube Stripper, cutter and aluminium rings
7) Platelet Agitator cum incubator for platelet storage
8) Cryoprecipitate Thawing Bnth
9) Laminar air flow
10) Weighing scale of 2 kg with sensitivity of 100 mg.
11) 1 kg, balance in 5 mg increments for weighing plasma bags
12) Computers, Printer etc.

C) ***For Screening of the Blood***

1) Elisa System with washer, incubator and Reader
2) Kits for HIV, HbsAg, HCV, VDRL

D) ***Apheresis System:*** If apheresis procedures are carried out.

4.5.3 Staffing

	Blood bank Category		
	I	II	III
Bleeding Complex			
1. Jr. Doctor	1	1-2	2
2. Nurses	2	3	4
3. Social Workers	1	2	3
4. Lab. Attendant	1	1	2
Laboratory			
1. Technical Supervisor		1-2	4
2. Technical Assistant	2	4	8
3. Lab. Technician	4	11	13
4. Lab. Assistant	1	2	4
5. Lab. Attendant	2	4	5
Donor Organiser			
1. Associated/Clerical Staff	Part time	1	2
2. Social Worker	2	5	10
(For mobile teams)			
3. Vehicle + Driver	Part Time	1	3
Service Staff/Clerical Staff			
1. Clerk Typist	Part Time	1	2
2. Store Keeper	-do-	1	1
3. Cleaner Sweeper	-do-	1	2
Medical Doctor—MD (Transfusion), MD (Pathology)			
1. Professor			1
2. Asst. Professor/Reader		1	1
3. Lecturer		2	3

Check Your Progress 2

1) List the areas which a blood bank should have.

Donor recruitment area.
Bleeding Complex
Therapeutic area
Laboratories
Admin + clerical offices
Teaching facilities

2) List the facilities to be provided within the transfusion centre.

Water supply ; Steam ; Distilled H_2O
Electricity
Sewage
Storage
Gas : high pr. air vacuum.
Communication

3) Minimum area requirement for different categories of blood bank:

I 100 sq m.

II 300 sq m.

III 895 sq m.

4) Equipment for blood component work:

4.6 POLICY AND PROCEDURES

Every blood bank should maintain document carrying Policy and Procedures being followed in the form of **Standard Operating Procedures**. Each person working should strictly follow the laid down protocol for every procedure. It is beyond the scope of this section to describe in details regarding each procedure. However, some important aspects regarding Donor Selection, proceeding with bleeding of donor and processing the donor's blood is being highlighted. Similarly how the patient's blood is to be processed is being mentioned.

Selection of Donor and Bleeding Donor

In order to protect the donor as well as the recipient, each blood donor must be screened prior to each blood donation by medical history and limited physical examination on the day of donation. Whenever a decision is made regarding acceptance or rejection of a blood donor, these two goals should be kept in mind, i.e., safety of donor and safety of recipient.

The donor should have:

1) Age: Between 18 to 65 years.
2) Body weight: 110 lbs. or more for 450 (± 45) ml of blood collected in 63 ml of CPD anticoagulant plus up to 30 ml for additional tubes.
3) Temperature: Less than 37.5° C or 99.5° F.
4) Pulse: Between 50-100 beats per minute.
5) Blood pressure: systolic between 90-180 mm Hg; diastolic between 50-100 mm Hg.
6) Haemoglobin: 13.5 g/dl (male) and 12.5 g/dl (female); or minimum haematocrit: 41% (male), 38% (female). (Copper sulfate is often used as rapid haemoglobin screen.)
7) Specific gravity: > 1.055 (male) and > 1.053 (female)

Deferral

1) Permanent: History of viral hepatitis, history of jaundice of unknown cause, malignant tumours, leukaemia, convulsion after infancy, fainting spells, abnormal bleeding tendency, known positive HbsAg test, serious cardiopulmonary disease, high risk behaviour, drug addicts.
2) Temporary: Conditions requiring rest or medication—cold, flu, diabetes, tuberculosis, syphilis and other infections, and diseases of the heart, lungs, kidney, stomach, or liver.
3) The period of deferral may vary for many other conditions like various vaccinations, major surgery, termination of pregnancy or delivery, dental or minor surgery, and symptomatic bronchial asthma.
4) A minimum of 72 hours deferral is made for a donor who has consumed aspirin.

5) It is very important to permanently defer a donor with an answer in affirmation regarding **high risk behaviour**.

Under the directive of Honorable Supreme Court of India it is illegal to take blood from any professional donor. Best is to take blood from non-remunerative voluntary donors.

Other Important Considerations

1) Identification: Full name, address, telephone number, age. and sex, race (helpful for special typing).
2) Consent: A written consent of the prospective donor is required.
3) Preparation before donation: Eat a regular meal, avoid fatty food, and no alcohol within 12 hours prior to donation.
4) Exceptions: A physician can make exceptions, especially for therapeutic bleeding, auto transfusions, immunization and especially rare blood donors.

Phlebotomy

1) Bleeding of the donor should be smooth and painless.
2) Strict aseptic procedures must be followed and all disposables used.
3) The venipuncture site should be free of skin lesions of an infectious nature. Arms should also be examined for needle marks (a sign of drug addiction)
4) The donor blood bag, sample tube, and donor record should be properly identified and labeled before drawing blood.
5) Plastic blood bags with additional satellite bags should be selected according to need. For instance, a single bag may be used for whole blood, double bags for red blood cell concentrates, triple bags for platelets or cryoprecipitate, and quadruple bags for both platelets and cryoprecipitate from the same donation.
6) Each bag should be examined for defects and anticoagulant inside inspected.
7) Thorough mixing of blood in the bag and tubing is essential. Stripping the tubing several times before sealing is important.
8) After phlebotomy, establish that there is no leaking from the puncture site and that the donor is in satisfactory condition before leaving the room. A compress or adhesive bandage should be applied to the phlebotomy site.
9) Donor should be made to rest for 15-20 minutes before being asked to get up. He should be then taken to the refreshment room for light refreshment which may include fluids like tea/coffee/milk/juice/cold drink etc. and some snacks.
10) Ensure that donor is in a fit condition to leave. In case the donor complains of giddiness or faints, immediately make him lie down with foot-end raised. Check his vitals and reassure him.
11) Give necessary post donation advice to the donor.
12) Every donor must be thanked before he leaves the blood bank.

Labeling and Storage of Donor Blood

a) Donor Blood should be stored at 1-4°C in proper blood bank refrigerator.
b) Untested, tested and cross-matched blood should be stored in separate refrigerators.
c) Standard coloured labels should be used for labeling the donor units.
d) The donor bag number, date of collection, date of expiry, blood group and other relevant information should be properly and boldly incorporated on each bag.
e) Ensure suitable information to be made available on the cross matched label, so that the blood goes to the **correct patient**.

Tests on Donor Blood

1) ABO and Rh Typing: Confirmation of donor's blood group and antibody screening (for irregular antibodies) should be carried out in the donor laboratory. Every 'Rh-negative' donor must be tested for Du.

2) Every donor's blood must be tested in Infectious diseases laboratory for HIV I and II, Hepatitis B, VDRL and Malaria. Though it is not yet mandatory but it is desirable to screen the donor's blood for Hepatitis C also. The blood bank must have separate facilities for carrying out these tests in its own premises. Strict confidentiality should be maintained about any positive results. It is imperative that written documentary proof should be maintained of the results.

All the relevant procedures must be maintained in the Standard Operating Procedure Manual, which should be accessible to the staff doing these tests. Technicians who perform these tests should record the results in appropriate registers with due date and initials. Second technician who will also sign results should counter check all results. Every patient's blood should be tested for confirmation of the blood group.

Pretransfusion Testing of the Recipient's Blood

1) His/her first and last name, age and sex, bed number plus hospital number and other relevant available record must positively identify the recipient.
2) Specimens must be labeled at the bedside with the full name of the patient, date, identification number, and the initials of the person drawing blood. The particulars must match with those given on the requisition form.
3) If the blood sample has to be drawn from the intravenous (I/V) tubing, it should be flushed with saline and the first 5 ml of blood discarded.
4) When additional transfusions are requested, a new specimen should be obtained at each 48 hour interval to identify an incompatibility from an antibody developed by an anamnestic response.
5) Hemolyzed blood samples should be avoided as they may mask hemolysis of donor erythrocytes in the cross-match.
6) It is good practice to wash red blood cells routinely before testing.
7) ABO and Rh typing should be done on every recipient before blood is issued.
8) Antibody screening is much more important in a patient than in the donor. Therefore, it must be carried out in each patient. The antiglobulin test should be included routinely for antibody screening.
9) Compatibility testing or crossmatching should be done on every unit of blood to be transfused to the patient.

Issue of Blood

Only a hospital employee (Doctor, Nurse or Nursing orderly) should receive the blood on behalf of the patient. Person receiving blood and technician issuing the blood should sign in the issue register. Blood should be transfused without delay. All empty bags should be returned to the blood bank within 24 hours.

Movement of Donor Blood

Donor blood after collection is moved into either the untested refrigerator for storage till screening tests are over, or moved to the component preparation room, if components are to be prepared.

The pilot tubes collected along with the blood bags are sent to the routine laboratory for grouping and serological work up, and to the infectious disease laboratory for tests for hepatitis, syphilis, AIDS etc.

Once the components are prepared and the tests on the pilot tubes are completed, the donor blood is moved to the labeling area, where each unit is appropriately labeled with blood group and other relevant information.

The labeled and tested blood is stored in the stock refrigerator. Each morning sufficient number of donor units is shifted from the stock refrigerator to the refrigerator, which stores the blood to be cross-matched.

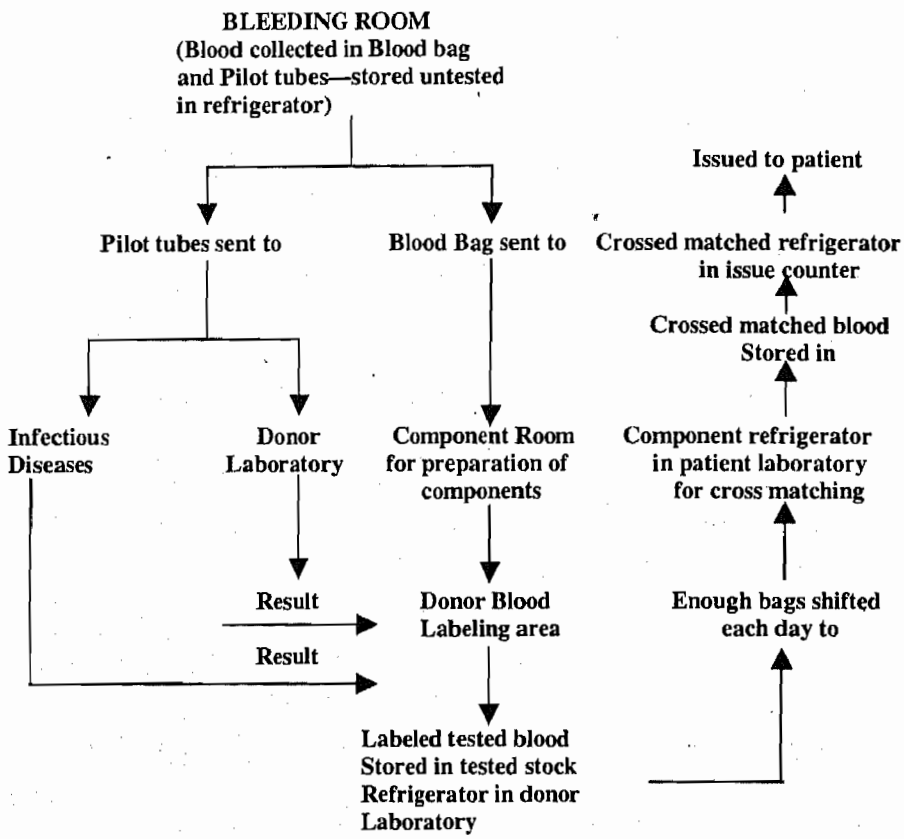
Once the blood is cross-matched the blood unit is moved to the refrigerator enmarked for this purpose and kept in the issue room for issue to the patient.

Movement of Patient Blood

The person on duty there receives patient samples in the counter room. Emergency requests are separated and proceeded on priority for immediate grouping, crossmatching and issuing of the blood.

Routine requests are serially numbered and sent to the patient laboratory for serological workup.

MOVEMENT OF EACH UNIT OF DONOR BLOOD



Cross-matched bag is labeled with cross-match sticker that carries all the relevant information about the patient and is sent to the crossmatched refrigerator till the time it is issued to the patient.

4.7 MANAGERIAL ISSUES

The last two decades have witnessed an increased awareness in the field of blood transfusion. Advances in basic sciences such as immunology, biotechnology, genetics, cryobiology, physiology as well as technical progresses in instrumentation have together created a significant impact on transfusion medicine. **A greater stress has been laid on voluntary (non-remunerated) blood donation since the hazards of commercial blood has resulted in endangering the life of the recipient from dreadful diseases like hepatitis and AIDS.**

The major aim of blood transfusion has been to make the transfusion safe and beneficial. The other aims of improvement in blood have been in prolongation of the shelf life of blood, its optimum utilization and development of synthetic substances to supplement the human source. Through better understanding of red cell metabolism, the red cell preservatives now improvised, can preserve the red cells for transfusion up to 49 days as against 21 days earlier.

The development of **cryobiology** has enabled the preservation of cells and plasma for prolonged storage for years, in frozen state. The emphasis is now rightly put on the use of various components of blood based on the requirement of the patients, since this helps to utilise one unit of donated blood for more than one patient.

With the use of the **cell separators, the pheresis procedures** help separate and collect platelets, granulocytes and plasma in enough quantity from a single donor. Therapeutic applications of these cell separators have also enabled clinicians to reduce morbidity and mortality from many diseases.

Improved serological techniques have reduced the incidence of transfusion reactions. Introduction of new and more sensitive methods for screening of donors has helped in prevention of transmission of diseases such as hepatitis and AIDS. Methods of HLA (leucocyte antigens) typing have been useful for transplant surgeries.

Efforts are now on the way for use of artificial substitutes for specific components of blood. Perfluorochemical emulsion Fllusol-DA and polymerized stroma free haemoglobin solutions have been tried as red cell substitutes. Genetic engineering techniques have isolated recombinant-DNA clones for adequate and safe production of plasma proteins especially factor VIII. The dependence of human source for the reagent will also be reduced if the hybridoma technology is applied for preparation of reagents.

Recent advances in the **field of instrumentation** have even invaded blood banks. Several autoanalysers for blood grouping, antibody detection and quantification, and for various ELISA procedures are now available. These equipment would be cost effective in large centres, where the blood collection is very high and manual processing is difficult.

The factors, which influence the progress in transfusion medicine, can be viewed broadly under three major groups, which are the issues of great managerial importance.

1) Technically the progress is hindered due to non-recognition of this faculty as a medical speciality and inadequate training facilities for medical officers as well as technicians.

   There is tremendous growth in the reagent and instrumentation area but there appears a lack of quality control. It is certainly essential that some regulatory agencies monitor the products to ensure their validity and performance. For the smooth functioning of transfusion services apart from other voluntary and philanthropic agencies, individuals and institutions can be of immense help.

2) Socially the inadequate awareness amongst general population regarding blood donation is responsible in making this commodity very scarce.

3) Due to paucity of funds, adequate amounts of educative programmes for promoting voluntary blood donations are not available. Thus one is unable to reach the masses in making them come forward to donate blood.

Recent advances in medical knowledge have significantly increased the volume and complexity of the work of the hospital blood bank. Surgical techniques are becoming increasingly sophisticated and complex procedures more numerous. Cancer surgery, reconstructive operations, open-heart procedures, and organ transplantation all make special demands upon the blood bank.

Greater clinical appreciation of haematological physiology is reflected in requests for specific blood components, and the modern blood bank dispenses a wide variety of blood products tailored to specific patient needs. An array of techniques unknown to blood bank workers even a few years ago has come into routine use, ranging from radioimmunoassay to cytotoxicity testing. Simultaneously with advances in clinical medicine has come an explosive increase in our knowledge of immunohaematology.

Whereas the ABO system and 'Rh factor' were almost the only considerations of clinical significance a generation ago, we now recognize more than a dozen major blood group systems, each many times more complex than originally conceived, with some 400 group antigens defined as of this writing. Powerful new investigative techniques have been devised to extend our knowledge, some of which have been adapted to use in the blood bank.

Immunoglobulin structure and the role of complement in red blood cell sensitization are now understood with considerable insight, and this knowledge has led to increased appreciation of the mechanisms of antibody-mediated red blood cell destruction. Increased understanding of the mechanisms of blood coagulation and clot lysis has resulted in major changes in approach to the patient with a bleeding disorder.

This sophistication, however, has not been without its drawbacks. Burgeoning demands for blood products have posed problems in obtaining sufficient supplies. Transfusions of 20 pints of blood to a single patient are now common place and 100 pints or more have been given in 24 hours to save a life. Awareness of the increased hazard of hepatitis transmission by blood obtained from paid donors has resulted in regulations requiring blood collection from a purely volunteer population, thus causing increased difficulty in procuring blood supplies in some areas. Widespread transfusion has caused widespread blood group sensitization, with resultant problems in antibody identification and procurement of blood of special types.

The amount of responsibility assumed by the blood bank technologist and its director has no parallel elsewhere in the clinical laboratory. There is no way for an attending physician to confirm through his own observation or judgement the adequacy of the testing performed in the blood bank until disaster occurs in form of an untoward reaction. If the clinical chemistry laboratory reports a serum potassium level of 10 mEq/dl or the haematology laboratory says the hematocrit value is 5% and the patient is jogging about the solarium, his doctor may reasonably suspect a laboratory error. But there is no way that a physician can say, "I think you are 'O', not an 'A' " as the lab says, simply by examining his patient.

In a blood bank as in no other area of the clinical laboratory the patient's life may hinge upon a mistake, be it clerical, technical, or judgmental. Errors in other areas may be irritating, confusing or embarrassing, but rarely are they immediately life-threatening. If someone errs in a blood bank, a patient may die.

The most important step in the organisation of a blood transfusion service is to appoint a person qualified and experienced in transfusion medicine to head it.

Blood banks at apex institutions or large metropolitan medical colleges having undergraduate and postgraduate teaching programmes and superspecialities should have separate departments of transfusion medicine headed by a professor.

Institutions and hospitals at other levels should have a separate Blood Transfusion Officer for whom a minimum experience of one year in a licensed blood bank with a MBBS degree from a recognised college is essential.

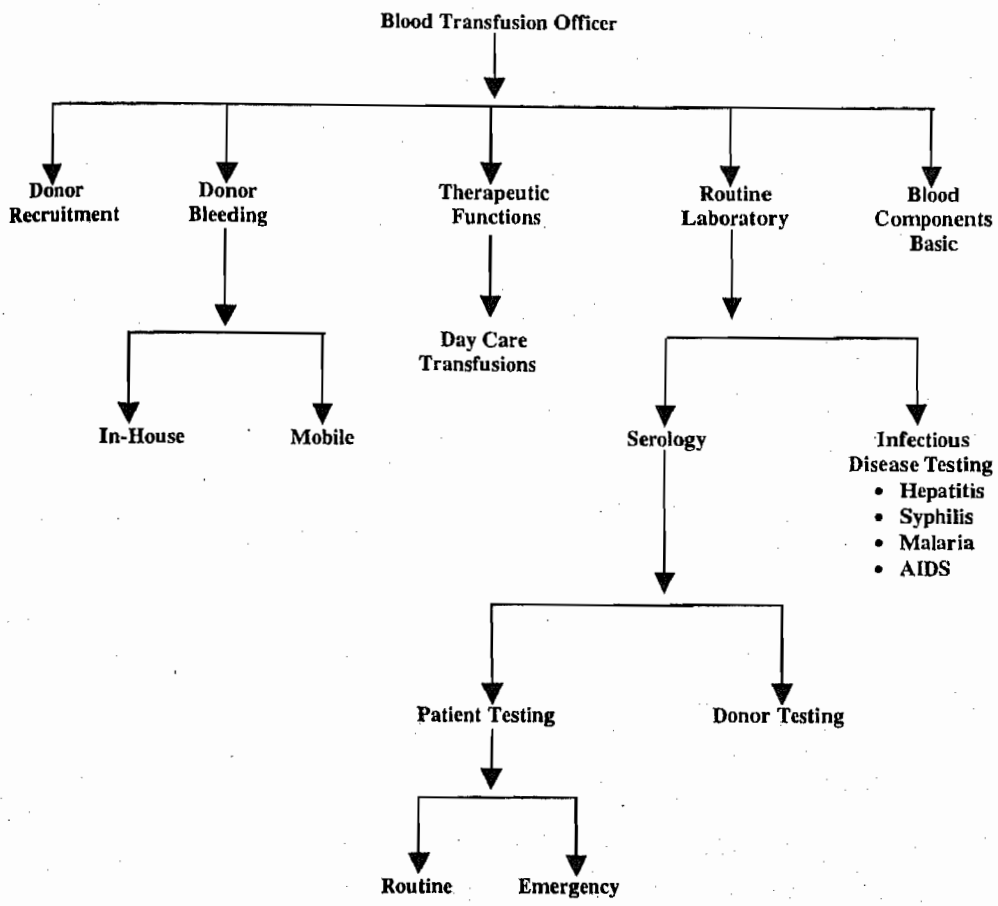
Organisation of a successful blood transfusion service is not possible without an assured supply of voluntary blood 365 days of the year. Thus a most important managerial issue of a blood bank is donor recruitment and bleeding donors.

Success in donor recruitment and maintaining donor records requires an intensive and sustained publicity and educational compaign by means of mass media i.e. television programmes, publicity pamphlets, letters and telephone calls to schools, colleges, service oriented organisations like Rotary, Lions etc. Such work requires trained staff headed by a donor organiser and including, social workers, nurses, clerical staff, good telephone facilities, vehicles and drivers.

Organisation and Structure

In recent years two fundamental changes in donor recruitment have taken place: a shift from individual responsibility to community responsibility for blood replacement and from paid donors to voluntary donors.

For many years, motivation for blood donation has focused on individual responsibility to ensure that present and future blood needs of the donor and/or his family are met. This approach may create a hardship for those who are not qualified for blood donation or for those who have no one else to donate for them. Hence blood replacement, as a community responsibility has become more acceptable. Motivation based on group or community responsibility has been successful in many countries. A pluralistic approach to donor recruitment embracing individual and community responsibility is favoured by many, since it utilizes both forms of motivation that have been demonstrated to be effective. Indeed, there appears to be a need for both individual and/or community responsibility to provide an adequate blood supply in response to the demand.



Based on present usage, if about 1% of the population donate 1 unit of blood each per year the nation's required blood needs would be met. Organised institutions or groups are rich sources of qualified blood donors.

Inventory Control

Ideally, no blood or blood components should be allowed to outdate. Although it is impractical or even impossible in small hospitals, every effort should be made to reduce such waste. Effective inventory control and an efficient system of transportation system can be of great help to improve the shelf life. Although accurate figures are not available, outdating of blood probably approaches 10%.

With computerisation of blood transfusion services and advances in telecommunication systems, there is no doubt that effective inventory control can be achieved. Regionalisation of Blood Transfusion Services can play a vital role towards this aim.

Blood Transfusion Committee

To ensure appropriate use of blood and minimise wastage, it is essential for a transfusion committee to meet periodically as part of medical audit.
Members of the committee would consist of the Medical Director/Administrator of the Hospital, Blood Bank Chief, representatives from each clinical department specially those, which consume large quantities of blood, representatives of the nursing staff and the blood bank technical staff.

The functions of the Transfusion Committee are to ensure safe transfusion practice for the hospital. This involves two main divisions i.e. systems audit and clinical practice audit.

Systems audit consists of blood bank procedures i.e.

1) No. of units transfused of whole blood and blood components.
2) Patients transfused and units transfused per patient.
3) Proportion of whole blood to red blood cell, transfused.

4) Crossmatch to transfusion reaction.

5) Out date rate.

6) Transfusion reactions.

7) Number uncrossmatched and fresh unit requests.

8) Turn around time from receipt of sample and issue of blood.

9) Emergency requests.

10) Units returned unused.

11) Surgical cancellation due to unavailability of blood.

12) Late requests for preoperative crossmatch.

13) Distribution of requests.

Clinical Practice audit would consist of criteria and justification for transfusion of whole blood, red cells, and various components into audit and paediatric patients.

4.8 SUPREME COURT JUDGEMENT AND DIRECTIONS (1996)

4.8.1 Supreme Court Judgement

- Establishing national and state councils of blood transfusion
- Activities of national and state councils to cover entire range of services related to blood transfusion
- Developing good quality technical manpower for transfusion services
  - — training of technical personnel
  - — post graduate course
  - — drug inspectors training
- Institution for conducting research on various areas of transfusion medicine
- Banning unlicensed blood banks within one year
- Banning professional donors within two years
- Income tax exemptions for donations to councils
- NACO/Co-ordinating the development of developing a national blood transfusion network in India
- Hindustan Latex Ltd. engaged to assist NACO in preparation of a comprehensive plan for setting up of a national and state councils.

4.8.2 Supreme Court Directions

1) The union government shall take steps to establish forthwith a National Council of Blood Transfusion as a society registered under the Societies Registration Act. It would be a representative body having in it representation from Directorate General of Health Services of the Government of India, the Drug Controller of India, Ministry of Finance in the Government of India, Indian Red Cross Society, private blood banks including the Indian Association of the Blook Banks, major medical and health institutions of the country and on-government organisations active in the field of securing voluntary blood donations. In order to ensure coordination with the activities of National AIDS Control Organisation, the Additional Secretary in the Ministry of Health who is in-charge of the programme of National AIDS Control Organisation for strengthening the blood banking system could be President of the National Council.

2) The National Council has a secretariate at Delhi under the charge of a Director.

3) The basic requirements of the funds for the functioning of the National Council shall be provided by the Government of India but the National Council shall be empowered

to raise funds from various other sources including contributions from trade, industry and individuals.

4) In consultation with the National Council, the State Government/Union Territory Administration shall establish a state council in each State/Union Territory which shall be registered as society under the Societies Registration Act. The State Council should be a representative body having in it representation from Directorate of Health Services in the State, State Drug Controller, Department of Finance of the State Government/Union Territory, Indian Red Cross Society, Private Blood Banks, non-Governmental Organisation active in the field of securing voluntary blood donations. The Secretary to the Government in-charge of the Department of Health could be President of the State Council.

5) The State Council should have its headquarters at the premises of the premier medical institution or hospital in the State/Union Territory and should function under the charge of a Director.

6) The funds for the State Council shall be provided by the Union of India as well as the State Government/Union Territory Administration. The State Council shall also be empowered to collect funds in shape of contributions from trade, industry and individuals.

7) The programmes and activities of the National Council and the State Councils shall cover the entire range of services related to operation and requirements of blood banks including the launching of effective motivation campaigns through utilisation of all media for stimulating voluntary blood donation in educational institutions, among the labour, industry and trade, establishments and organisations of various services including civic bodies, training of personnel in relation to all operations of blood collection, storage and utilisation, separation of blood groups, proper labelling, proper storage and transport, quality control and achieving system, cross matching of blood between donors and recipients, separation and storage of components of blood and all basic essentials of the operations of blood banking.

8) The National Council shall undertake training programmes for training of technical personnel in various fields connected with the operation of blood banks.

9) The National Council shall establish an institution for conducting research in collection, processing, storage, distribution and transfusion of whole human blood and human blood components, manufacturer of blood products and other allied fields.

10) The National Council shall take steps for starting special post graduate courses in blood collection, processing, storage and transfusion and allied fields in various medical colleges and institutions in the country.

11) In order to facilitate the collection of funds for the national council and the State Councils, the Government of India (Ministry of Finance) should find out ways and means to secure grant of 100% exemption from Income Tax to the donor in respect of donations made to the National Council and the State Councils.

12) The Union Government and the Government of States and Union Territories should ensure that within a period of not more than one year all blood banks operating in the country are duly licensed and if a blood bank is found ill-equipped for being licensed, and remains unlicensed after expiry of the period of one year, its operation should be rendered impossible through suitable legal action.

13) The Union Government and the Government of the States and Union Territories shall take steps to discourage the prevalent system of professional donors so that the system of professional donors is completely eliminated within a period of not more than two years.

14) The existing machinery for the enforcement of the provisions of the Act and the Rules should be strengthened and suitable action be taken in that regard on the basis of the Scheme submitted by the Drugs Controller (India) to the Union Government for upgradation of the Drugs Control Organisation in the Centre and the States.

15) Necessary steps be taken to ensure that Drugs Inspectors duly trained in Blood

Banking operations are posted in adequate numbers as to ensure periodical checking operations of the blood banks throughout the country.

16) The Union Government should consider the advisability of enacting a separate legislation for regulating the collection, processing, storage, distribution and transportation of blood and the operation of the blood banks in the country.

17) The Director General of Health Services, Government of India, Ministry of Health shall submit a report by July 15, 1996 about the action taken in pursuance of these directions.

18) It will be open to the Director General of Health Services, Government of India as well as the National Council to seek clarification/modification of these directions or further directions in this matter.

4.9 CONTROL AND EVALUATION

The aim of blood transfusion services is to supply good quality of blood and components to the patient and avoid any risk to the donor. Hence it is extremely essential to institute strict quality control measures.

The Standard Operating Procedures Manual should be maintained in every blood bank and should carry a chapter on Quality Control measures being undertaken in the blood bank. However, for a brief information, to the readers a few of them are being mentioned as follows:

1) Blood only from voluntary donors should be accepted which minimizes the chances of transfusion transmitted diseases.

2) Proper donor history and examination and strict selection ensures good quality of blood being collected from a healthy donor and fit donor.

3) Use of disposable and Universal Precautions should be followed.

4) Strict aseptic conditions should be maintained. The collection of blood and the component formation should be done in close system to prevent any possibility of infection.

5) All the employees must follow the Universal Protection Instructions.

6) All the employees working should be protected against HbsAg.

7) Proper donor care after donation should be strictly adhered to and donor should be released only when he/she is perfectly fit.

8) The blood and components should be stored at proper temperatures continuously.

9) All the seras and other reagents should be standardized daily.

10) Cross-matching should be strictly done by Coomb's method.

11) Daily/weekly/monthly/yearly maintenance of the equipment should be undertaken as required from time to time. All the technicians should be well trained in Preventive Maintenance of the equipment.

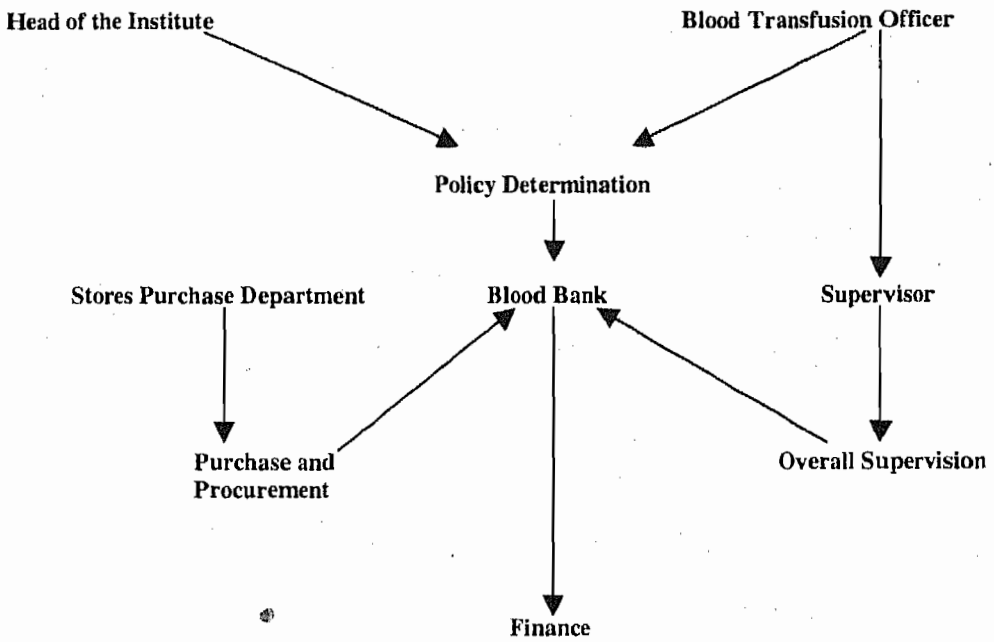
12) Proper records should be maintained involving various activities.

13) Strict inventory control and supervision as per policies laid down should be undertaken.

14) Daily stock checking of the whole blood and periodic checking of the components should be undertaken.

Coordination and Control

The line diagram on page 81 depicts the co-ordination and control mechanisms in a blood transfusion unit.



Blood Components

Cohn and associates during Second World War were the pioneers in the fractionation of plasma into its components. In some centres, the demand for these components is even more than the whole blood.

Various components prepared in modern blood banks are:

1) Packed Cells
2) Fresh frozen plasma
3) Platelet rich plasma
4) Platelet concentrate
5) Single Donor Plasma
6) Cryo-precipitates
7) Factor VIII concentrate
8) Factor IX concentrate
9) Haemoglobin

Indications

Packed Cells: Severe anaemia and edema, Chronic leukemia, Chronic hypoplastic and Aplastic anaemias, Hemolytic anaemias.

Fresh Frozen Plasma: Inborn deficiency of coagulation factors. DIC, Thrombocytopenic purpura, Neutralization of the effects of oral anticoagulants.

Cryoprecipitates: Von Willebrands disease, Chronic renal failure, Congenital platelet disorders, Haemophilia, Christmas disease.

Specific Immunoglobulins: Used for passive immunization for—Varicella, Tetanus, Hepatitis B, Cytomealovirus infections.

Hyperimmune Gammaglobulins: Primary Rh-immunization in case of Haemolytic disease of the newborns.

Fresh Blood: Massive Transfusion, Bleeding disorders, DIC, HDN, Exchange transfusion.

Fresh blood is specially ordered as certain components of the blood deteriorate rapidly on storage and these are: Platelets, Factor VIII, Factor V, Granulocytes.

Blood Transfusion Reactions

About 2-4 % transfusions lead to minor or major reactions. Though it is beyond the scope of this write up to detail them out, but the learner must have the knowledge how to handle such a case.

Causes of Transfusion Reaction

Clerical mistakes

—Up to 80% cases are due to incorrect labeling of samples

—Errors in writing the correct particulars on requisition

—Confusion in identity of the patient

Technical errors

—Wrong grouping and crossmatching

—Rare blood group

—Minor crossmatch errors, e.g. O group blood to A, B or AB group without seeing the titer which should be less than 1 : 100.

Investigations in a Case of Transfusion Reaction

The occurrence of a transfusion reaction should be immediately reported to the blood bank. The reporting authority should send: (1) A post transfusion blood sample, (2) A post transfusion urine sample, (3) A pretransfusion blood sample, if available, (4) Blood bag along with tubing.

To overcome transfusion reactions the blood bank should have:

- The patient's original crossmatch specimen, which is normally preserved for atleast 48 hours after despatching the blood or its products.
- The donor's pilot tubing/bottle, which should also be preserved for 48 hours.
- The entire laboratory and blood bank records.
- The blood bank should take immediate steps to establish the cause of the transfusion reaction. Proper records must be maintained and the results should be communicated to the concerned department.

4.10 LET US SUM UP

In this unit you have learnt that the duty of a blood bank does not end only on issuing of blood, but also includes the follow up of the course of transfusion to see that the transfusion is safe and uneventful and to investigate a case of blood transfusion reaction.

You have also learnt that on one hand while it is important for transfusion medicine to reach out to the clinical sector it is equally important for the latter to become involved with the transfusion laboratories in order to ensure quality assurance and proper handling of the blood resources.

You have also learnt that the clinical sector must keep up-to-date information on processing and automation and get ready to adopt new technologies. In near future, molecular biology techniques will definitely replace some of our current serology and become standard feature in transfusion technology. The challenge facing the transfusion medicine at the end of the third millennium is truly inspiring.

Challenge and responsibility are the daily substance of blood bank work; stimulation and gratification are the reward.

4.11 ANSWERS TO CHECK YOUR PROGRESS

Check Your Progress 1

1) a) William Harvey
   b) 1902
   c) Blumbery; 1964
   d) 1981

2) a) True
   b) False
   e) False
   f) True

3) a) convenience in storage and transportation
   b) no breakage
   c) ease to transfuse
   d) less risk of transfusion reactions
   e) facilitates various blood components separation

4) a) Recruitment of donors and maintenance of donor records
   b) Collection, storage and preservation of blood and blood components
   c) Laboratory procedures
   d) Teaching, training and research
   e) Clinical/therapeutic functions

Check Your Progress 2

1)
- Donor Recruitment area
- Bleeding complex
- Therapeutic area
- Laboratories
- Administrative and clerical offices
- Teaching Facilities

2) Water supply, electricity supply, sewage, storage, steam, distilled water, gas, high-pressure air, vacuum and communications.

3) Minimum Area Requirements for different categories of blood bank are:
   For category I : 100 Sq.M
   For category II : 300 Sq.M
   For category III : 895 Sq.M

4) a) **Blood bank refrigerated centrifuge** for 450 ml blood bags. Swing head 5000Xg with windshield. Temperature of 0-25°C. Timer at 1 min. interval up to 60 min. Accurate tachometer.
   b) **Freezer:** 70°C with alarm system, temperatures display, and recording device. 24 hours power supply and standby power.
   c) **Freezer:** 20°C to 40°C with alarm system, temperatures display and recording device. 24 hours power supply and standby power.
   d) Dielectric Tube Sealer
   e) Plasma Separation Stand
   f) Tube Stripper, cutter and aluminium rings
   g) Platelet Agitator cum incubator for platelet storage
   h) Cryoprecipitate Thawing Bath
   i) Laminar air flow
   j) Weighing scale of 2 kg with sensitivity of 100 mg.
   k) 1 kg. balance in 5 mg increments for weighing plasma bags
   l) Computers, Printer etc.

1) a) Age: Between 18 to 65 years.

b) Body weight: 110 lbs. or more for 450 (± 45) ml of blood collected in 63 ml of CPD anticoagulant plus up to 30 ml for additional tubes.

c) Temperature: Less than 37.5° C or 99.5° F.

d) Pulse: Between 50-100 beats per minute.

e) Blood pressure: systolic between 90-180 mm Hg; diastolic between 50-100 mm Hg.

f) Haemoglobin: 13.5 g/dl (male) and 12.5 g/dl (female); or minimum haematocrit: 41% (male), 38% (female). (Copper sulfate is often used as rapid haemoglobin screen.)

g) Specific gravity: > 1.055 (male) and > 1.053 (female)

2) a) Non-recognition of blood bank faculty as a medical speciality and inadequate training facilities for medical officers as well as technicians.

b) Inadequate awareness amongst general population regarding blood donation.

c) Paucity of funds

3) Members of the Blood Transfusion Committee consist of the Medical Director/Administrator of Hospital, Blood Bank Chief, representatives from each clinical department specially those, which consume large quantities of blood, representatives of the nursing staff and the blood bank technical staff.

Functions of the transfusion committee are to ensure safe transfusion practice for the hospital. This involves two main divisions, i.e. systems audit and clinical practice audit.

4) *Clerical mistakes*

—Up to 80% cases are due to incorrect labeling of samples

—Errors in writing the correct particulars on requisition

—Confusion in identity of the patient

Technical errors

—Wrong grouping and crossmatching

—Rare blood group

—Minor crossmatch errors, e.g. O group blood to A, B or AB group without seeing the titer which should be less than 1 : 100.

5)
- The patient's original crossmatch specimen, which is normally preserved for atleast 48 hours after despatching the blood or its products.
- The donor's pilot tubing/bottle, which should also be preserved for 48 hours.
- The entire laboratory and blood bank records.
- The blood bank should take immediate steps to establish the cause of the transfusion reaction. Proper records must be maintained and the results should be communicated to the concerned department.

UNIT 5 PHARMACY SERVICES

Structure

5.0 OBJECTIVES

After going through this unit, you should be able to:

- define various types of hospital pharmacy services and their drug distribution systems;
- describe the various planning considerations for hospital pharmacies;
- discuss the policies and procedures involved and the associated managerial issues; and
- discuss the role of computers in a hospital pharmacy.

5.1 INTRODUCTION

In this unit you will learn about organisation and management of pharmacy services of a hospital. To begin with you will learn about the definition, role and functions of pharmacy services. Thereafter you will learn about the planning considerations including computerization of pharmacy services. Towards the end you will learn about policies, procedures and managerial issues including control and evaluation mechanisms.

UNIT 5 PHARMACY SERVICES

Structure

5.0 OBJECTIVES

After going through this unit, you should be able to:

- define various types of hospital pharmacy services and their drug distribution systems;
- describe the various planning considerations for hospital pharmacies;
- discuss the policies and procedures involved and the associated managerial issues; and
- discuss the role of computers in a hospital pharmacy.

5.1 INTRODUCTION

In this unit you will learn about organisation and management of pharmacy services of a hospital. To begin with you will learn about the definition, role and functions of pharmacy services. Thereafter you will learn about the planning considerations including computerization of pharmacy services. Towards the end you will learn about policies, procedures and managerial issues including control and evaluation mechanisms.

5.2 PHARMACY SERVICES

The pharmacy services was earlier viewed as solely compounding and dispensing drug products for patient use but these services have changed dramatically since the early 1960s and today the pharmacy is viewed as a clinical department that can serve as a bridge between the clinical and financial aspects of drug therapy. In this unit you are going to learn about definition, scope and functions of pharmacy services. You will also learn about planning considerations, physical facilities and layout. You will also be introduced to various types of pharmacy services and staff requirement. You will be sensitized to various managerial issues involved in this service, control and evaluation techniques, role of computers in pharmacy service.

5.2.1 Definition

The pharmacy services in a hospital'can be defined as "Premises licensed for the retail sale or supply to the hospital out patients deptt. and/or inpatient areas of drugs which have qualified licensed person(s) and indulge in compounding of drugs."

5.2.2 Brief History

Prior to 1947, hospital pharmacies and dispensaries in India were manned by dispensors and compounders, Their academic background was poor, many of them being not even matriculates. The Chopra Committee (1921) and Bhore Committee (1946) focussed attention of government and thus in 1949 the Pharmacy Council of India was founded, which had recommended that the Diploma in Pharmacy to be the minimum requisite for entering the profession.

The Pharmacy Act, 1948 was passed and is the most important event towards rationalisation of pharmacy services. It was amended in 1959 and on 1st September, 1976 respectively. The objectives of the Act are;

1) To regulate the minimum education required to become a Pharmacist as a Central responsibility.

2) To regulate the practice of pharmacy as State responsibility.

Its functioning is bringing uniformity in pharmacy education and practice. Few other events are also important, such as the Drug and Cosmetic Act and Rules, 1940. Publication of National Formulary of India in 1960, formation of Indian Hospital Pharmacists Association in 1964 and the report of Committee on Drug Pharmaceutical Industry known as "Hathi Committee" (1975), who submitted its report to the Ministry of Petroleum and Chemicals and also further stressed as to how to streamline the hospital pharmacies. It had clearly given guidelines about division of pharmacies, desirable educational background and pay scales of staff and had given due importance on quality control, methods to achieve it, proper control, supervision and recommendation that, if drugs are manufactured in hospital pharmacies, the conditions of manufacture should be stringently controlled in the same manner as private manufacture of similar items are controlled.

1) Define Hospital Pharmacy Services.

Premises licensed for the retail sale or supply to the Hospital - OPD, Inpatient areas of drugs which have qualified licensed person(s) and indulge in compounding of drugs.

2) What is the Pharmacy Council of India? (1949)

3) State the objectives of Pharmacy Act. (1948)

1) To regulate the minimum education required to become a Pharmacist as a Central responsibility

2) To regulate the practice of pharmacy a State responsibility

5.3 ROLE, FUNCTIONS AND TYPES

5.3.1 Roles and Functions

Drugs as you know are the most widely used therapeutic agents in the treatment of various diseases and this further emphasizes the important role of hospital pharmacy services in patient care. Pharmaceutical functions rendered by the hospital pharmacy services can be categorized as under:

1) Demand estimation according to formulary, In the absence of formulary, establishment of specification for drug procurement.
2) Compounding and manufacturing of sterile and non-sterile products.
3) Quality control of drugs purchased and those compounded, and manufactured in the Pharmacy.
4) Supply of drugs to inpatients, wards, various sensitive patient care units like ICU, ICCU, OT's and Emergency.
5) Dispensing for out-patients.
6) Maintenance of formulary system and implementation of the decisions of the Pharmacy and Therapeutic Committee.
7) Furnishing drug information to physicians and other professional staff.
8) In-service training, teaching and research and clinical trials.
9) Patient education
10) Drug use review.

5.3.2 Types of Pharmacies

Quality of patient care should be the same in all hospitals, regardless of size or type of services. However, many hospitals, particularly those with less than 100 beds, have not yet developed satisfactory solutions to the problem of efficient and effective pharmaceutical services. Further, methods of distributing and charging for drugs differ among hospitals, with several methods in general use, e.g. no charges on all preparations in the Hospital Formulary or all or certain drugs are to be charged for. The hospital should have a clearly laid down policy regarding the extent and type of drugs and other items to be dealt with by its pharmacy services and the written policies should specifically cover the schedule for quality of drugs, therapeutic usage, rates and charges.

Depending upon the organisational policies of the hospital the pharmacy services can be of following types:

- Pharmacy for out-patients Department
- **Pharmacy** for in-patients services

  A combination of both
- A retail sale counter in the hospital
- A combination of above type

5.3.3 Drug Distribution System

The drug distribution system is the keystone of pharmacy services. Without an effective, efficient, safe and responsive system, it is impossible to implement the concept of drug use control. In addition to providing medications to patients the drug distribution system must also ensure that drugs are provided to other areas of the hospital, such as the emergency room, the operating rooms. In this era of cost control, these areas should receive increased pharmacy attention.

Drug distribution system are complex and involve the interaction of many individuals and departments, in addition to pharmacy. Over the years, a number of drug distribution methods have been explored—the unit-dose method in the mid-1960s, the floor stock and the individual patient order systems were the predominant methods of distributing drugs.

1) **Floor** Stock **System:** Many pharmaceuticals in bulk bottles were housed in the patient care division. When **a** drug order was written for a patient, the nurse would remove the appropriate drug from its bulk container and administer it to the patient. The nurse would also be responsible for reordering bulk supplies.

The floor stock system was labour intensive for nursing and lacked effective controls and was space occupying. Errors were frequent, and often the exact drug the physician ordered was not available in the floor stock supply. This resulted in the need to special order supplies, which created a delay between the time the drug was ordered and its administration to the patient. The system, by its design was not set up to respond quickly to the patient's medication needs. The floor stock system also resulted in large uncontrolled inventories on the nursing divisions.

2) **The Individual** Patient **Drug Order** System: The individual patient drug order system was introduced. In this system, most of the floor stock items, except controlled substances and such common patient items as mouthwash, antiseptics, and the like, were removed, and the nurse was required to write out a special request for each drug that the patient was to receive. Upon receipt of the drug request, which was usually sent to the pharmacy on a form similar to a physician's prescription, the pharmacist would fill the order with a multiple-day supply—usually a 3 to 7 day supply—and dispense it to the patient care area. The nurse was still responsible for removing the drug from a multiple dose container, preparing a patient label or identification card, placing the drug(s) in a small paper cup (for tablets and capsules), and administering it to the patient. Again, medication errors occurred, and the delay between ordering the drugs and having them dispensed to the patient care areas could be between 1 and 5 hours. Although an improvement over the floor stock system in reducing inventories on the nursing unit, the individual patient drug order system was still labour intensive for nursing and did not result in good drug use control and reduce precious nursing time.

Neither system used personnel resources optimally—nurses, trained in patient care, were ordering and dispensing medications, and pharmacists, trained in therapeutics, were filling orders with little or no opportunity to apply their expertise in drug use to the patient care process. Medication errors at times exceeded 10 per cent, and inventory was poorly controlled. Improvements in the distribution of drugs was clearly needed.

The introduction of the unit-dose method of drug distribution brought these improvements.

3) Unit-dose Method: In this system, pharmacists receive a direct copy of the physician's order. Medications are packaged in single-use containers and dispensed in as ready-to-administer form as possible. For most medications, not more than a 24-hour supply is dispensed.

The unit-dose system was developed to provide safe and effective drug distribution and control. Numerous studies have established that this concept is safer for the patient, more efficient and economical for the institution, and allows efficient use of professional resources.

There are following advantages of the unit-dose system over other alternatives:

- reduction in the incidence of medication errors
- decrease in the total cost of medication-related activities

  more efficient use of pharmacy and nursing personnel, allowing for more direct patient care involvement by pharmacists and nurses
- improved overall drug control and drug use monitoring
- greater control by the pharmacist over pharmacy work toad patterns and staff scheduling

- reduction in the size of drug inventories located in in-patient care areas
- greater adaptability to computerized and automated procedures.

Most hospitals do not have a pure unit-dose drug distribution system. Hospitals, however should strive to have unit dose as an essential element in their drug distribution and control programmes.

5.4 PLANNING CONSIDERATIONS

For proper services and efficiency, the pharmacy services should be established within the scope of status, responsibilities, relationships and limitations as per any other major department, with a qualified and experienced pharmacist as its in-charge. Planning for the depnrtment is guided by the establishment of administrative and professional policies of the hospital. How many items and for how many days the drug(s) is to be given to patients, again depends on the individual hospital policies. While planning for hospital pharmacy services forecasting techniques have to be used to obtain data regarding number of O.P.D. attendance, number of patients in various in-patient areas, disease pattern, comprehensiveness of drug formulary, items to be served, etc. and with such available data planning can be done for physical facilities, equipment and staffing.

5.4.1 Physical Facilities and Layout

Adequate provision of physical facilities and its correct location enhances the efficiency and productivity of hospital pharmacy. While designing, care should be taken for quick and easy flow of patients and material and user departments.

Location

Location where feasible, the pharmacy should be located preferably on the first floor of the hospital in-patient area and should be readily accessible to the elevators to ensure adequate and efficient service to various nursing stations and other departments.

The pharmacy for out-patients should be located in the O.P.D. area and as pharmacy in the O.P.D. is generally the last place to be visited by the patients coming to the out-patients department it should be conveniently located near the main exit of the O.P.D.

Floor Area

Floor Area will depend upon the size of the hospital and the services provided by the department. There are no laid down norms or criterion. However, recommended floor area is:

- 10 sq. ft. per bed in a 100 bedded hospital
- 6 sq. ft. per bed in a 200 bedded hospital
- 4 to 5 sq. ft. per bed in a larger hospital

Finishes and Lighting

The floors of the pharmacy should be resilient, smooth, easily cleaned and acid resistant. Rubber or asphalt tile and heavy linoleum are considered satisfactory. Walls should have a smooth surface with painted or equally washable finish in light colour. The finish of the cabinets and similar items should be light coloured wood or white enameled. Good lighting and ventilation are imperative. Venetian window blinds are favoured. In addition to general illumination, fluorescent lamps should be placed immediately above the prescription counter where necessary to assure adequate light; ample electrical outlets should be provided for both the pharmacy and sterile solution room. A dispensing window is needed through which prescriptions are dispensed to nurses and out-patients. Adequate number of windows to be provided as per the expected load of the hospital with provision of comfortable and adjustable high sitting arrangement. The windows construction to be in such a manner to act as mechanical barrier for infection prevention. The drug cabinet position to be within the reach of distribution personnel. A separate solution room for the preparation of parenteral solution in larger hospitals should be equipped with a water still, workbench, cabinets, resistant glass storage tank, burettes, fitted glass filters, conductivity meters, bottles, large acid-proof double sink with drainboard and graduate racks and a rectangular pressure sterilizer. The solution sterilization may be done in the central sterilization and supply section, but preferably in the solution room.

5.4.2 Furniture and Equipment

Equipment includes a prescription case and drug stock cabinets with proper shelving and drawers for a large assortment of drugs. Sectional drawer cabinets with cupboard bases are manufactured specifically for pharmacies and to fit any area. Cabinets should be such that they are readily adopted to future expansion.

Worktables or counters are required for manufacturing solutions, batches of powder, ointment and for filteration of solution. Work tables are also required for the loading of drug baskets and ward baskets. The standard counter height is 36 inches, depth of 30 inches, with minimum length of 74 inches desired.

Also necessary are an acid-proof sink with swivel faucet and with a drainboard approximately 5 feet in over-all length; a cabinet below to provide space for heavy mortars and pestles, and a cabinet with adjustable shelves above the sink for glass utensils, large graduates, flasks, funnels and beakers.

Space is required for a refrigerator of at least 8 cubic feet in the 50 bed hospital, 16 cubic feet in the 100 bed hospital and 32 cubic feet in the 200 bed hospital. A narcotic safe is necessary with proper double locking arrangement. A desk and other office equipment should be provided, including a telephone, a bulletin board and file cabinet for records and relevant literature.

5.4.3 Staffing

Considering the work load that is number of items to be served.per prescription and hours

of service to be given, requirement of pharmacist can be calculated. If the number of items to be served is between one to three, then in 8 hours duty a pharmacist can serve 150 prescriptions with half an hour break. If the items are 3 to 5 then limit to serve will be reduced to 120 prescriptions per pharmacist, although in Western countries only 100 prescriptions are served by one in one shift. Hospital having more than 200 beds need to have a Head Pharmacist and more than 200 beds should employ Chief Pharmacist and Assistant Pharmacist.

The study group on hospitals (1968) has laid down the guidelines for the staffing pattern of the Pharmacy Service, based on the number of beds in a hospital. It is as follows:

Bed Complement	*Number of Pharmacist*
Up to 50	3
Up to 100	5
Up to 200	8
Up to 300	10
Up to 400	15

It is the job of personnel department to create among different service and departments, scope of promotion to keep the workers motivated.

Recommended staff for pharmacy service in 750 bedded teaching hospital:

1)	Chief Hospital Pharmacist	
2)	Manufacturing Pharmacist	1
3)	Assistant Chief Hospital Pharmacist	1
4)	Technical Assistant (Pharmacy)	3
5)	Head Pharmacists	2
6)	Pharmacists	10

5.5 POLICIES AND PROCEDURES

The head of the pharmacy services will develop rules and regulations pertaining to the 'administrative policies of the department' and this will be done under the guidance and with the approval of the head of the hospital organisation. He will initiate and develop rules and regulations pertaining to the 'professional policies of the department' and interdepartmental with the approval and cooperation of the Pharmacy and Therapeutics Committee of the Hospital, and get that finally approved by the head of the hospital organisation.

The policies and procedures will clearly state:

- Extent (x) to which the department will prepare and sterilize certain injectable medications (including I/V fluids).
- Approved system for the possession and control of narcotics and barbiturates.
- Selection of Pharmaceuticals to be stocked in the various treatment and other areas.
- Restricted use of certain preparations, if any.
- Extent (x) to which a pharmacist will manufacture or compound pharmaceuticals.
- Dispensing of drugs, chemicals and pharmaceuticals.
- Procurement, storage and use of tax-exempt alcohol.
- Purchase procedures.
- System of record keeping.
- Role of pharmacist in education of medical and nursing staff.
- Charging procedures for drugs, etc.
- Research and clinical trials.
- Disposal of drugs.

5.5.1 Therapeutic Committee

The quality of patient care can be influenced by hospital patient care committee decisions regarding the role of drug usage process. The therapeutic committee is an advisory group that recommends policies related to drug therapy to the medical board. Every hospital, especially a teaching hospital must have a Therapeutic Committee. This committee usually consists of Physician, Surgeon, Nursing Supdtt., Pharmacist and the Medical Supdtt. as the Chairman. The committee should meet regularly, at least 3 times in a year. The functions and scope of the committee are:

- To serve in an advisory capacity to the clinicians and the hospital administrntion in all matters pertaining to drug usage.
- To develop a formulary of drugs, for use in the hospital and provide for its regular revision. Every hospital must have its own approved formulary and then it is the duty

of the administration to see that the drugs listed in the formulary are made available. Clinicians should be advised to restrict within its limits except in extra-ordinary cases.

- The committee should lay down procedures that help ensure cost-containment in drug therapy.
- To review adverse drug reactions, if any, occurring in the hospital.
- To assure quality standards in drug procurement and distribution systems.

5.6 MANAGERIAL ISSUES

The pharmacy department should be organised in such a manner so as to ensure an integrated approach to its services in compliance with the aims and objectives of the hospitals as a whole. It should also be organised in a manner that it is consistent with the Central and State laws and regulations. Since drug therapy is a key component in patient care, the impact of ineffective or inefficient drug use will have consequences far beyond economic and clinical considerations. Important managerial issues are related to:

- Control of drug costs
- Effective staff utilization
- Human relations and consumer satisfaction
- Drug pilferage

5.6.1 Control of Drug Costs

Control of drug costs can be achieved to some extent by administrative strategies like reducing drug procurement cost, inventory management, value analysis, use of appropriate

drug distribution system, computerisation and use of therapeutic equivalents in the hospital formulary.

5.6.2 Effective Staff Utilisation

Effective staff utilisntion depends on an appropriate mix of pharmacists, pharmacy technicinns nnd other support staff. Pharmacists should not be used for functions that can be performed by other support staff.

5.6.3 Human Relations

Human relations in pharmacy services are as important as in any other hospital services. Right person for right job in an appropriate slogan but to achieve it is difficult. Work load of the department should be worked out so that appropriate staff can be deployed.

5.6.4 Consumer Satisfaction

Consumer satisfaction is an important issue of this service. Especially in the O.P.D. Pharmacy which is generally the last place to bc visited by the patients coming to the out-patient department and when they reach there, they arc in a tired state and thus, it is natural for them to expect quick and courteous service from the pharmacy.

5.6.5 Non-availability of Drugs

Non-availability of drugs is an important issue often causing embarrassment to the hospital. Availability of life-saving drugs should be ensured at all times based on appropriate inventory control techniques.

5.6.6 Supply of Sub-standard Drugs

Supply of sub-standard drugs is reported frequently in different places in the country. The hospital should follow standard purchase practices and routine and/or random qualitative analytical testing of drugs should be done. The hospital therapeutic committee should supervise this.

5.6.7 Drug Pilferage

Drug pilferage is nnother commonly dealt with managerial issue. As far as possible, drugs should be purchased by generic name. After the packages are received, they should be stumped with the hospital nume-stamp, The strips of tablets and/or cnpsules and bottles containing drugslchernicnlsshould also be stamped. The seal of bottles/containers should be opened at the time of issue of the item. The procurement section should be separate from the issue and distribution section.

5.6.8 Drug Distribution System

The drug distribution system is the keystone of pharmacy services. The head of this service should ensure safe and accurate distribution of drugs and other medications to patients nnd other service area. Proper labelling of drugs nnd dosage required should be ensured and errors should be minimized to zero, Time expired drugs should be weeded out systematically,

The pharmacy service will maintain following documents:

1) Non-expendable stores ledger
2) Expendable stores ledger
3) Indent File
4) Formula file for manufacturing medicaments
5) Costing Returns
6) Report File
7) Stock verification Returns file
8) Hospital Formulary

.....

.....

.....

.....

.....

3) What steps would you initiate to abolish drug pilferage in a hospital pharmacy?

.....

.....

.....

.....

.....

.....

5.7 CONTROL AND EVALUATION

The complexity of the systems necessary to provide pharmacy services in a hospital would mandate a continuous and on-going control and evaluation system so as to develop a quality assurance programme for the service. Support from medical staff, nursing staff and pharmacy staff is essential for the hospital administration to develop such a programme. The Hospital Therapeutic Committee has a very important role in control and evaluation function of this service.

For effective control and evaluation of the pharmacy services criterion have to be developed on the basis of department's policies and procedures. There has to be an approved hospital formulary. The procurement and distribution should be clearly laid down. The entire pharmacy department should be reviewed periodically and annual verification of stock should be meticulously carried out by an independent authprity.

The Therapeutic Committee should evaluate the functioning of the service and should determine the correlation between what is actually occurring in all areas within the service and what is stated in established policies and procedures. Deviations, if any should be viewed very strictly and any changes required in the established practices should be duly implemented.

5.8 COMPUTERIZATION IN PHARMACY SERVICES

Computer utilisation in the pharmacy department is increasing, software applications have been developed for a wide range of pharmacy services, including drug distribution, clinical services, materials management, administration, ambulatory, and home care. Pressures to identify and contain costs while increasing productivity are part of the health care practice environment, and the effective use of computers is an important component in developing a contemporary pharmacy service.

Computerised pharmacy systems can generally be divided into two types—adjuncts to the hospital information system and dedicated department system:

1) Computerised pharmacy systems that are adjuncts to the hospital management information system typically use the hospital mainframe computer. In' its simplest form, datn regarding pharmacy services are entered into the mainframe, and reports are generated, usually monthly, for distribution and review by the pharmacy director. These data include financial management data, time reporting information, and reports of the number of batches by category, such as oral solid unit doses, injectables, I/V admixtures, and so forth. However, these data are of limited use becnuse they are usually presented in a standnrdised format that can be used by all departments, and there is limited ability to manipulate the datn for the purpose of answering specific questions or to run modeling or simulation analysis programmes, computer programmes that are specifically tnilored to pharmacy services and use the hospital mainframe computer. This form of computerisntion has some distinct advantages. Admission, discharge, and trnnsfer data can be obtained from the mainframe and integrated into the pharmacy system. Also, pharmacy can have access to data from other departments, such as laboratory medicine and medical records, that also use the hospital's mainframe computer. Although using the hospital mainframe computer may seem to be the "best of both worlds", caution must be taken nnd reason must temper enthusiasm. Standard computer programmes for pharmacy may be relatively inflexible in meeting the specific pharmacy's needs. Modification of these programmes may not be possible by the vendor; it is then important to know whether the data services department can make the necessary modifications. In either case there may be a cost to these modifications and its benefit must be assessed, as well as the practicality and time required to modify the system to meet pharmacy's needs.

2) Dedicated system that uses either microcomputers or minicomputers. This type of system enables the pharmacy to tailor its computer software to its needs, There is a

growing number of vendors with dedicated pharmacy systems available, and the increase in computer capabilities and cost decrease for micro and minicomputers make a dedicated pharmacy system practical.

Although there are a number of advantages to a dedicated pharmacy system, there are also disadvantages: Unless the pharmacy can have ready access to patient admission, discharge, and transfer data and data generated by other dcpartments, entry of this data for pharmacy use may be time consuming and prone to error. These disadvantages, however, have been some what reduced by the introduction of networking capabilities.

Current trends indicate that the ideal system may utilise a combination of both approaches with networking capability. Software is available to support most pharmacy applications and an increasing number of pharmacists have the ability to develop programmes to meet their specific departmental needs.

Some degree of computerisation is commonplace in most pharmacy dcpartments and ranges from simple billing procedures to marc sophisticated applications, such as pharmacokinetic monitoring. Computers were initially used to assist in financial and administrative activities. Computer programmes were then developed to support drug use systems that require a significant amount of documentation nnd record keeping.

Analysis of the economics of drug therapy will enable an institution to develop cffectivc strategies to control costs.

Computers can be used to support all aspects of the drug use process. Some examples of common computer applications in pharmacy are:

- drug data base development to support the formulary management programme
- patient identification/data
- maintaining patient profiles
- drug order entry, recall. and changes
- unit-dose fill lists
- I/V admixture work lists
- total parenteral nutrition solution calculations
- patient billing
- label generation
- floor stock control
- department cost accounting
- inventory management
- control drug documentation and recording
- drug information
- pharmacokinetic consultations
- financial reporting,

In addition to the computer applications identified, the pharmacy chief should develop a departmental management information system. The management information system should integrate key data for the purpose of enhancing decision making involved in the planning, managing, and controlling of departmental operations. A well-designed system incorporates operational, clinical and personnel information and provides periodic reports reflecting departmental operations that can be used to assist in the management decisions.

Further an effective pharmacy computer system integrates departmental data with hospital-generated data.

To develop an effective pharmacy computer system requires management and staff support. The information generated must foster accountability and responsibility throughout the department and must be focused on meeting the explicit needs of the department. It must also be collected and reported in a format that is both timely and accurate.

5.9 LET US SUM UP

In this unit you have learnt that pharmacy services in a hospital play a very important role in patient care. It is one of the most extensively used therapeutic service of the hospital. This service or department is under the supervision and control of a professionally competent and legally qualified pharmacist. It is from the pharmacy that all the medications are supplied to the nursing units and other services; pharmaceuticals and injectables are prepared; narcotics and other prescribed drugs are dispensed to the patients and professional supplies are stocked and dispensed. Thus the hospital pharmacy has the role of manufacturing, compounding and dispensing drugs and other therapeutic substances that may be used in a hospital. Smaller hospitals may not have a regular pharmacy department and may only maintain limited stocks. Hospital pharmacy services have changed dramatically in the recent past. These changes have paralleled the changes in the drug technology and in the health care system. The pharmacist who heads the pharmacy department must be licensed and be able to provide a full range of pharmacy activities, however whether the department manufactures certain solutions or drugs is a matter of hospital policy. The extent of activities in the department are to be governed by the laid down organisational policies of the hospital.

5.10 ANSWERS TO CHECK YOUR PROGRESS

Check Your Progress 1

1) It is the premises licensed for the retail sale or supply of drugs to the hospital outpatient department and/or inpatient areas and it has qualified and licensed person(s) and indulges in compounding of drugs.

2) Prior to 1947, hospital pharmacy and dispensaries in our country were manned by dispensors and compounders. Their academic background was not adequate. In view of this the Chopra Committee (1921) and the Bhore Committee (1946) recommended reforms and thus in 1949 the Pharmacy Council of India was founded, which recommended Diploma in Pharmacy as the minimum academic qualification required for entering the profession.

3) The Pharmacy Act, 1948 is the landmark towards rationalisation of pharmacy services. It was amended in 1959 and again in 1976. The objectives of the Act are to:

   a) regulate the minimum educational qualification required to become a Pharmacist, as a Central responsibility.

   b) regulate the practice of Pharmacy as a State responsibility. This act has brought uniformity in this field.

Check Your Progress 2

1) Pharmaceutical functions rendered by a hospital Pharmacy are:
   - Demand estimation of various drugs in the formulary.
   - Compounding and manufacturing of sterile and non-sterile products.
   - Dispensing for outpatients/inpatients and other user areas in the hospital
   - Academic functions, like teaching and training.
   - Quality control of drugs purchased and those manufactured or compounded in the Pharmacy.

2) Various types of Pharmacy Services are:
   a) Pharmacy for out-patients department.
   b) Pharmacy for in-patients services.
   c) A combination of both above.
   d) A retail sale counter in the hospital.

3) The Drug Distribution System is the keystone of Pharmacy Services. It has to be a system which is effective, efficient, safe and responsive. It is a complex system and involves interaction of many individuals and departments with the Pharmacy. Various methods of drug distribution are:
   a) The floor stock system
   b) The individual patient drug order system
   c) Unit-dose method

Check Your Progress **3**

1) Location of a hospital Pharmacy is very important and a well-located Pharmacy can be more efficient and more effective. It can enhance the productivity of the department. Location should be such that the flow of patients and materials is quick and easy. The Pharmacy for out-patients should be located in the O.P.D. and as Pharmacy is the last place to be visited by the patients and/or their attendants, it should be conveniently located near the main exit of the O.P.D. The Pharmacy for wards, in-patients and other user areas should be located preferably on the first floor of the in-patient area in the hospital. It should be readily accessible to elevators to ensure efficient and adequate service to various user-areas.

2) The physical facilities to be considered for hospital pharmacy are:
   - location of the department
   - recommended floor area
   - considerations for finishings, lighting and ventilation
   - separate solution room

3) The equipment required is:
   - various types of shelves and cabinets
   - worktables/counters
   - refrigerator, its size and capacity
   - narcotic safe

4) The factors are:
   - staff requirement will depend on hospital policies and the work load of the department
   - the recommendations of the study group on hospitals, 1968

Check Your Progress 4

1) The Policies and Procedures should be:

- administrative policies and
- professional policies, as approved by the Head of the hospital organisation
- policies and procedures related to drug preparation, dispensing, procurement and storage

2) Structure of Therapeutic Cummittee is such that it consists of a Physician, a Surgeon, Nursing Superintendent, Pharmacist and the Medical Superintendent is the Chairman.

Functions of Therapeutic Committee are to:

a) serve in an advisory capacity to the clinicians and the hospital administration in all matters pertaining to drug usage.

b) develop a formulary of drugs, for use in the hospital and to keep it regularly up-dated.

c) laydown procedures to help ensure cost-containment in drug therapy.

d) review drug reactions, if any.

e) assure quality standards in the procurement and distribution of drugs.

3)
- Expendable store ledger
- Non expendable store ledger
- Indent File
- Formula File
- Costing Returns
- Report File
- Stock Verification File
- Hospital Formulary

Check Your Progress 5

1) The various issues are:
- control of drug costs
- appropriate drug distribution system
- availability of drugs
- inventory control
- quality control of drugs
- drug pilferage

2) Human relations and consumer satisfaction are two very important issues for a hospital pharmacy. There should be appropriate and adequate staff strength and its deployment should be such that staff utilization is most effective. The services provided to the consumers should be quick and courteous.

3) Following steps will be initiated in order to abolish drug pilferage:
- purchase drugs by generic name
- stamping of packages, strips and bottles
- seal to be opened at the time of issue of a bottle/container
- security checks
- motivation of staff

Check Your Progress 6

1) The Hospital Pharmacy should have an in-built monitoring and evaluation system for its proper functioning. Such a system can go a long way in providing better patient care and making the service more cost-efficient and more cost-effective. It will require support from Pharmacy Staff, Medical and Nursing Staff. Therapeutic Committee can play a very vital role in this field. There should be periodic review and verification of stocks and documents.

2) The Therapeutic Committee has a very important role in monitoring and evaluating a Pharmacy, as this Committee recommends policies related to drug therapy and it also develops a formulary for use in the hospital. It assures quality standards in the drug procurement and distribution system. This committee can recommend necessary changes in the department practice(s), if required. It correlates and analyses the actual performance of the Pharmacy with the laid down norms. Thus, the Therapeutic Committee has a very vital role in monitoring and evaluating a Pharmacy.

Check Your Progress 7

1) The various applications of computerisation in a pharmacy are in the areas of:
   - drug distribution
   - costing
   - materials management and inventory control
   - administrative

2) The various types of pharmacy computerisation are:
   - department system
   - as adjunct to hospital M.I.S.
   - a combination of the two

UNIT 1 PROBLEMS IN OPD

Structure

1.0 OBJECTIVES

After going through this unit, you should be able to:

- identify problems usually encountered in OPD by patients;
- enumerate problems in running a smooth OPD services;
- assess the quality of OPD services provided; and
- apply problem solving methods for quality improvement.

1 1 INTRODUCTION

You have already learnt about the importance, functions and need of OPD services, In this unit of practical manual you will learn about the problems faced by the patients and the hindrances to smooth functioning of the OPD. You will also learn how to inspect an OPD to study the problems, and also carry out a problem solving exercise in case of an actual problem situation.

1.2 REVIEW OF THE SITUATION

Out Patient Department (OPD) as you know is the part of hospital with physical, medical and other facilities to provide care to patients who are not registered as inpatients. It includes Emergency OPD, General OPD and Referral or Speciality OPD.

1.2.1 Significance of OPD

You have already learnt in Block 1 of this course about the significance of OPD in the unit on OPD.

To recapitulate your memory:

- it is the first point of contact with patient.
- it is window to any health care service provided to the community—"Shop window".
- it is an inseparable link in the hierarchical chain of progressive health care.

  a good OPD service reduces morbidity and mortality rates.
- it is stepping stone for health promotion and disease preventioq.
- it acts as a filter, reducing the number of admissions into the hospital.
- rising cost of hospitalisation has enhanced the need to keep hospitalisation to the minimum and thus enhances the importance of OPD services.

1.2.2 Functions of OPD

You have also learnt about the functions of OPD in the unit on OPD.

Rekindling your memory, you shall find that OPD:

- is ideal for early diagnosis of any disease with modern techniques and for prophylactic examination;
- provides Ambulatory and Domiciliary treatmenl to all cases which can be treated at clinic **or** at home;
- is a route for inpatient admission;
- provides after care and medical rehabilitation if necessary after discharge from hospital;
- carry our health promotion activities;
- trains medical, nursing and paramedical personnel;
- maintains records and collects data for epidemiological and social research; and
- participates in various preventive activities such as:
  - well baby clinic
  - ante-natal clinic
  - school health programme
  - health education and nutrition advice
  - immunisation
  - early reporting of communicable diseases.

1.2.3 Problems in OPD

You will appreciate that any disruption in the smooth functioning of OPD affects the patients directly **or** indirectly. There are numerous problems, one can think of. However, the most common problems in any OPD are:

i) Non-responsive rereption and apathetic staff.

ii) Wild search of speciality OPDs by patients.

iii) Appointment jumping.

iv) Long waiting hours at each point of contact.

v) Non-availability of reports of various investigations.

vi) Inadequate time given for each.

vii) Poor rapport **or** communication between doctors and patients.

viii) Non-availability of equipment and supplies.

1.2.4 Alternate Solutions

On analysis of various problems in OPD, you shall find that the following could be the alternate solutions. These are alternatives found by previous administrative researchers. However, you can come up with better solutions to your problems during the study. You have to choose the best course of action amongst these solutions to solve your practical problem.

The most common alternate solutions are:

- **Appointment system** in OPD to reduce the waiting time.
- 24 hrs. **registration system** to fix appointments for old cases and accommodating emergency cases as early as possible, again to reduce waiting time.
- Separate general and emergency OPD, to attend the serious cases on priority.
- **Selective attachment of services** e.g. having surgery and urology OPD close by because many of the surgical cases need urology assessment also. This will reduce the patient traffic in other OPD areas.

- Filter clinics: Clinics in the ground floor with junior doctors so that minor ailments like cough, cold can be treated and sent back so that they do not overcrowd the speciality OPD.
- Starting the OPD in time to reduce the waiting time and prolonging OPD time with another shift of doctors to provide services to maximum number of patients.
- Satellite Clinic: Community outreach clinics of the hospital will reduce the OPD load in the main hospital and the community will get special care at its door steps.
- Sufficient waiting area with adequate resources to cater the load.
- Sufficient space for future expansion.
- Efficient department of hospital administration for day to day redressal of problems.

1.3 MATERIALS AND METHODS

The various tools and techniques which can be used for assessment of OPD services of a hospital are:

i) Visit to OPD: The principles of direct observation of OPD is to check the accessibility, visibility, convenience and expandability of the OPD. These four principles will help you assess the general planning of OPD e.g. the size, site, assessment of funclional zones, etc. This would further help you to get a bird's eye view of the OPD process e.g. the waiting time, convenience, accessibility of services; the flow of patients.

ii) Operational Research Techniques: By using operational research techniques you can quantify the services required for the given OPD and derive the solutions to the problems mathematically. The various operational research techniques which can be used are:

- Queing theory
- Holding and lifting capacity
- SWOT analysis
- Activity study/Work study

iii) Review of the various policies and procedures: This will help you to qualify and quantify the lacunae in physical facilities, equipment and stores, and activities you have found by the above methods.

iv) Interview: Patients interview with the help of a questionnaire will go a long way in improving your public relations both internal and external because a hospital is for its patients and patient satisfaction is the key to the services you provide.

1.4 ACTION PLAN

After reviewing the various materials and methods to assess the quality of service provided you should concentrate on the exact plan of action. This means, how the study should progress, the various details to be observed, analysis of results of various operational research techniques applied, reporting the results of questionnaire and interview which you have developed.

These will help you in qualifying and quantifying the problems and design alternate solution and select the best course of aclion amongst them.

14.1 Direct Observation

By direct observation it is meant that you should basically observe the structural and process criteria in OPD.

i) See whether the location of OPD is easily visible to public, accessible and conveniently placed for the patient. This is a subjective observation.

ii) See the adequacy of the size of OPD in context to the patient load and the extent of other facilities provided. McGibony has estimated a OPD load of two patients1 bed/day.

iii) See the OPD site in relation to its need for;

- separate entrance without cris-crossing the inpatient services.
- sharing of investigation facilities with inpatients.
- unidirectional flow of patients.
- liberal parking space.
- space for future expansion.

iv) Assess whether the planning principle of "Design follows function" holds good or not, i.e. whether the OPD has been divided into various functional zones or not.

a) Public area should have:

- Reception and Enquiry
- 5% rise for ramp
- An area for record keeping. Ideal is 5-25 file draw per 10-50,000 cards of 5" x 7" size.
- An area for registration. McGibony recommended one registration desk for 12-30 patients per hour.
- Waiting area: The main waiting area of OPD should be 1 sq.ft/patient with a minimum of 400 sq.ft.
- 1 WC/100 patients and 1 toilet150 patients.

b) Clinical area should have:

- Subsidiary waiting area i.e. waiting area in front of doctor's consultation room. It is estimated to have 8 sq.ft/patient for 1/3rd attendance in subsidiary waiting area.
- Consultation room separate for each doctor with a screened area for examination which may be shared by two doctors. A consultation room should be at least 160 sq.ft.
- Treating and dressing room for each speciality of 120-160 sq.ft.
- Ancillary facility includes injection room and pharmacy.
- Injection clinic should accommodate 10-20 patients at one time with a space requirement of 6-8 sq.ft per patient.
- Auxiliary facility includes Laboratory, Radio-diagnosis, Blood Bank, Screening clinic and room for Medical Social Service Officer. Each of these area should constitute 150-200 sq.ft.

c) Administrative area includes: Business Office, Housekeeping Service, Storage area for materials. It should be approximately 150 sq.ft. McGibony has recommended that of the total area of OPD:

Public area should constitute	10-15% of area
Clinical area should constitute	40% of area
Administrative area should constitute	15% of area
Circulation area should constitute	25-30% of area
Wall and partition area should constitute	10% of area.

1.4.2 Evaluation of Process

The procedures and activities in the OPD can be evaluated by analysing the various utilisation pattern, flow of activity and use of operational research techniques.

i) **Flow Concept:** The flow concept defines the patient load in the various areas of OPD. This would help you to extend your services accordingly. It has been estimated that out of the patients coming for primary care in OPD:

- 20-40% attend injection room
- 5-15% attend the dressing room
- 5-10% attend the pharmacy/dispensary

- 5-10% go for the pathological investigations
- 2-5% attend the minor theatre.

ii) **Holding capacity:** Holding capacity is the adequacy of space to hold the patients in waiting areas. All OPDs with more than 2 floors should have lifts with adequate space.

iii) **Activity Sampling:** You have to assess the utilisation pattern of man and material in relation to workload by conducting an **Activity Sampling.** Activities of each category of personnel has to be defined and the time spent in each work has to be estimated. This is otherwise called as **work study.** This would also help you in assessing the cost effectiveness of labour in OPD.

Material utilisation has to be assessed vis-a-vis the workload, to analyse any wastage therein.

iv) **SWOT Analysis** : The analysis of the Strength, Weakness, Opportunities and Threats of a hospital is a must before analysing the services in its OPD. This would help you in reviewing the policies and procedures of the service provided and seek necessary solution.

v) **Queing Theory:** This is an operational research technique to quantify the waiting time of patients in each speciality and suggest alternate solution to reduce the queue and waiting time. The queueing theory has been developed in the attempt to answer the behaviour of queue, average waiting time and average time spent in the system. To study the queue you have to collect data of pattern of arrival of clientele, interval between the clients or we should know the arrival pattern and service time. The objective of knowing queueing theory is to determine:

- How many channels are required to provide, that average given length will not be unreasonable.
- How to schedule arrival so that queue length does not fluctuate too much.
- The cost of queue and cost of service should be beneficial.

vi) **Systems Analysis:** This is also an operational research technique in which you need to analyse the policies and procedures; qualify and quantify the service in relation to number of hospital beds; treatment of patients in relation to art of care and time spent with each patient and the development of good rapport between doctor and patient.

vii) **Diagnostic and Therapeutic Process:** You have to assess each procedure in relation to quality and quantity of test e.g. in an x-ray, you need to see the quality of x-ray, taken, the waiting time for a single x-ray, the type of x-ray, its adequacy in relation to the type of patient and his clinical need, the number of x-rays per day.

1.4.3 Evaluation of Outcome

You have to assess the outcome of OPD service in relation to patient satisfaction and cost benefit and cost effective analysis.

a) **Patient Satisfaction:** You can assess by developing a questionnaire about the quality and quantity of service provided. This can also be assessed by interviews of patients, number of complaints.

b) **Employee Satisfaction:** You need to assess the satisfaction of the staff working in OPD by questionnaire so as to improve the service and keep the employees motivated.

c) **Cost Benefit Analysis:** You have to assess the benefits (in term of aid provided for clinical diagnosis) out of any services in terms of cost incurred in providing such a service.

d) **Cost Effective Analysis:** You further need to assess each service provided in terms of its cost vis-a-vis its effectiveness to provide the required service e.g. Break Even Analysis can be adopted to study the cost-effectiveness of an equipment, say an x-ray machine.

At the end of this whole process you shall be able to qualify and quantify the **OPD** service provided in any hospital. The analysis of this action plan will help you in developing the alternate solutions and select the best course of action.

1.5 ACTIVITIES

Activity **1**

Now you have studied the problems in OPD in detail and the ways and means to analyse it and finding a solution to it. Therefore, now you are required to visit an OPD in your vicinity and analyse the problem therein as per the checklist given below. You are also required to study the problem given at Case Study, carry out the tasks specified therein, and prepare an action plan as required.

Checklist for a Visit to OPD

i) ***Evaluation of Structural Criteria***

a) Location vis-a-vis community and transport facility

b) Site and size of OPD in relation to workload

c) Type of OPD services provided vis-a-vis the needs of the community.

d) Adequacy of labour and facilities of space, equipment and stores vis-a-vis the workload in OPD.

e) Functional zones of OPD and its adequacy in relation to the OPD patient load.

ii) ***Evaluation of Process Criteria***

a) Evaluation of flow of patient traffic keeping in mind the flow concept, holding capacity and lifting capacity.

b) Assessment of waiting time by use of various operational resaarch techniques e.g. queuing theory.

c) Utilisation of man and material by doing a work study and activity sampling.

d) Evaluation of policies and procedures of the hospital for OPD with the help of SWOT analysis and system analysis and analysis of records.

e) Evaluation of quality and quantity of clinical care to patients in relation to art of care, cure provided, diagnostic accuracy and rapport between doctor and patient, and analysis of records.

f) Evaluation of diagnostic and therapeutic procedures both quality and quantity wise.

iii) ***Evaluation of Outcome Criteria***

a) Assessment of patient satisfaction by use of questionnaire and interviews, number of complaints and conflicts.

b) Assessment of employee satisfaction; grievance procedure for both patients and employees.

c) Assessment of outcome of service in terms of cost-benefit and cost-effectiveness.

Activity 2

In order lo practically orient you to live problems in OPD situation, a case study is given below simulating a problem in one of the OPDs. You are expected to study the case and complete the task given in it.

Medical Superintendent (MS) of more than 800 bedded hospital is receiving complaints for some time that the patients have to wait for long time for consultation at specialist OPDs. In Cardiology OPD after waiting for long hours hardly a minute is given for consultation. Even at times the ECG machine is not available for examination. In Surgical OPD sterile surgical dressing was not available for treatment of last few patients. MS on enquiry found that large number of cases were registered every day for specialists consultation out of which 30-40% cases could have been disposed of at lower level. Consultant Cardiology on enquiry stated that there was a long waiting list for ECG and Ultrasound examination. Sometimes the technicians are absent which adds to the problem.

Consultant surgeon stated that supply of sterile dressing may be inadequate, Officer incharge CSSD stated that there was no short supply of dressing and issues were made according 'to the demands. After a preliminary enquiry the MS formed a committee to investigate all aspects of functioning of OPD and related supportive services to make recommendations for remedial measures.

- Define the problem
- Critical analysis of the problem
- Possible reasons of the problem
- Collection of facts and figures
- Alternative solutions to the problem
- Selection of best alternative solution with reasons
- Action plan and remedial measures

On completion of both the activities, you should submit the reports to the academic counsellor of your Programme Study Centre.

1.6 LET US SUM UP

In this unit we have helped you in recapitulating the need and importance of OPD, the functions of OPD, the problems encountered by patients in OPD, the tools and techniques to evaluate the OPD service both qualitative and quantitalively, to analyse a given situation by a case study and to design alternate solutions.

UNIT 2 ORGANISATION OF EMERGENCY CARE

Structure

2.0 OBJECTIVES

After going through this unit, you should be able to:

- identify the problems in provision of emergency care in the hospital;
- plan a study of the problem;
- apply the problem solving method; and
- develop appropriate solutions to solve these problems.

2.1 INTRODUCTION

In this unit of practical manual you will learn to critically examine the provision of emergency care in the hospital. Emergency care should be of high quality, cost effective and compassionate. Administrative measures must be in place to ensure that this happens.

Emergency care in the hospital is primarily provided at the casualty or accident and emergency departments and in the intensive care units. These departments are important points of entry into the health care system and serve a clientele that demands modern efficient facilities, appropriately trained staff and state of the art health care. The emergency care is provided in an environment, which is stressful, demanding and uncertain both for the care providers and beneficiaries.

Hospital administrators (health care managers) in this scenario are constantly confronted with problems. Conditions encountered that initiate the need for problem solving are varied and multifaceted e.g. deficiency in service, mistakes and defects, breakdowns on delays and inefficiencies etc. **A** general problem solving method presenting an orderly process by which hospital administrators can approach this important task is described. An example of the case study is presented,

2.2 REVIEW OF SITUATION

The key issues which needs to be reviewed to ensure the operational success of emergency care services in the hospital are:

- Premises
- Personnel
- Plant (Equipment)
- Policies and Procedures

Premises

You have already studied the various aspects of planning and designing which need to be considered. A well-designed casualty or intensive care unit meets the needs of the medical staff as well as the patients. Facilities ensure provision of optimum medical care and increased customer satisfaction.

Personnel

The staffing norms of the emergency services have been enumerated earlier. The key issue

is the staff morale from the administrative point of view. It is directly linked to whether their needs and wants are being met. It is the responsibility of the hospital administration to satisfy the staff needs, allow for individual wants and balance these with overall hospital goals and resources. Well-trained and motivated personnel are vital to provide efficient emergency care in the hospital.

Plant (Equipment)

A wide variety of equipment is required for provision of emergency care. This equipment has to be dedicated, functional and provided with a back up. The equipment may be directly required for patient care e.g. monitors or ventilator or indirectly for various support services e.g. laboratory or radiological equipment. Appropriate communication and information management systems are these days critical to provision of high quality emergency care.

Policies and Procedures

Preparation of definite policies and procedures for emergency care is essential. These guidelines if well written and consistently applied, can raise the level of care and ensure consistency in the provision of that care. These are used by the staff to set their priorities and tasks without frequent reference to hospital administration. Written policies and procedures allow the emergency services to move from reactive to proactive mode with positive addition to quality of care being provided.

Problems

The problems in delivery of emergency care in the hospital have traditionally been identified through rctrospcctive reviews of written medical records, patient complaints and staff concerns.

There are basically five sources of problems:

- Failure to appreciate 'the importance of the task.
- Insufficient training of medical, nursing and paramedical staff.
- Inadequate support services or staffing,
- Failure to follow established policies, procedures and protocol.
- Lack of properly functioning equipment on supplies.

2.3 MATERIALS AND METHOD

Once a probable cause of the problem is evident you would require to collect relevant data on information about its various aspects. You will have to decide on the tools and techniques to use for the study of the problem.

Sources of Data

You may collect the relevant information through:

- Questionnaire
- Interview
- Document study
- Observation study
- Work study
- Operation Research Techniques

Method

The problem solving method involves:

- Problem identification
- Problem definition and/or goal statement
- Problem analysis

  Alternative solutions
- Recommended action
- Implementation and evaluation

UNIT2 ORGANISATION OF EMERGENCY CARE

Structure

2.0 OBJECTIVES

After going through this unit, you should be able to:

- identify the problems in provision of emergency care in the hospital;
- plan a study of the problem;
- apply the problem solving method; and
- develop appropriate solutions to solve these problems.

2.1 INTRODUCTION

In this unit of practical manual you will learn to critically examine the provision of emergency care in the hospital. Emergency care should be of high quality, cost effective and compassionate. Administrative measures must be in place to ensure that this happens.

Emergency care in the hospital is primarily provided at the casualty or accident and emergency departments and in the intensive care units, These departments are important points of entry into the health care system and serve a clientele that demands modern efficient facilities, appropriately trained staff and state of the art health care. The emergency care is provided in an environment, which is stressful, demanding and uncertain both for the care providers and beneficiaries.

Hospital administrators (health care managers) in this scenario are constantly confronted with problems. Conditions encountered that initiate the need for problem solving are varied and multifaceted e.g. deficiency in service, mistakes and defects, breakdowns on delays and inefficiencies etc. A general problem solving method presenting an orderly process by which hospital administrators can approach this important task is described. An example of the case study is presented,

2.2 REVIEW OF SITUATION

The key issues which needs to be reviewed to ensure the operational success of emergency care services in the hospital are:

- Premises
- Personnel
- Plant (Equipment)
- Policies and Procedures

Premises

You have already studied the various aspects of planning and designing which need to be considered. A well-designed casualty or intensive care unit meets the needs of the medical staff as well as the patients. Facilities ensure provision of optimum medical care and increased customer satisfaction.

Personnel

The staffing norms of the emergency services have been enumeraled earlier. The key issue

is the staff morale from the administrative point of view. It is directly linked to whether their needs and wants are being met. It is the responsibility of the hospital administration to satisfy the staff needs, allow for individual wants and balance these with overall hospital goals and resources. Well-trained and motivated personnel are vital to provide efficient emergency care in the hospital.

Plant (Equipment)

A wide variety of equipment is required for provision of emergency care. This equipment has to be dedicated, functional and provided with a back up. The equipment may be directly required for patient care e.g. monitors or ventilator or indirectly for various support services e.g. laboratory or radiological equipment. Appropriate communication and information management systems are these days critical to provision of high quality emergency care.

Policies and Procedures

Preparation of definite policies and procedures for emergency care is essential. These guidelines if well written and consistently applied, can raise the level of care and ensure consistency in the provision of that care. These are used by the staff to set their priorities and tasks without frequent reference to hospital administration. Written policies and procedures allow the emergency services to move from reactive to proactive mode with positive addition to quality of care being provided.

Problems

The problems in delivery of emergency care in the hospital have traditionally been identified through retrospective reviews of written medical records, patient complaints and staff concerns.

There are basically five sources of problems:

- Failure to appreciate 'the importance of the task,
- Insufficient training of medical, nursing and paramedical staff.
- Inadequate support services or staffing.
- Failure to follow established policies, procedures and protocol.
- Lack of propetly functioning equipment on supplies.

2.3 MATERIALS AND METHOD

Once a probable cause of the problem is evident you would require to collect relevant data on information about its various aspects. You will have to decide on the tools and techniques to use for the study of the problem.

Sources of Data

You may collect the relevant information through:

- Questionnaire
- Interview
- Document study
- Observation study
- Work study
- Operation Research Techniques

Method

The problem solving method involves:

- Problem identification
- Problem definition and/or goal statement
- Problem analysis
- Alternative solutions
- Recommended action
- Implementation and evaluation

Problem Identification

Problem is identified by the difference between what is actually happening (the actual) in a situation and what one wishes to have occur (the optimal). To determine a problem area it is necessary to gather, examine and interpret information from all sources available and to decide whether the problem area warrants attention.

Problem Definition

Problem is defined in clear and specific terms. A clearly stated problem structures the entire problem solving process as to what has to be done to solve the problem and evaluate its outcomes. Efforts are then focused towards providing a solution to the problem. Goals flow from the problem statement. A goal is then simply a restated problem.

Problem Analysis

After the problem is identified, it must be analysed. Analysis entails the following steps:

- To determine why the problem exists
- To identify the personnel, facility, equipment or guidelines which will solve the problem/achieve the goal
- To analyse the ability of personnel involved to accomplish the goal.

Alternative Solutions

Based on analysis, the next step is to develop various alternative solutions that have potential to solve the problem or achieve the goal. Relevant data/information collection is important at this stage. After the ideas are listed, then each solution should be studied for anticipated positive and negative results.

Recommended Action

Following analysis of alternative solutions, one line of action must be chosen. It is unlikely that any one solution will have no negative consequences. The recommended action, should, therefore, have the highest probability of reducing the gap between 'the actual' and 'the optimal' and lowest probability of negative consequences.

Implementation and Evaluation

After a recommended action has been specified it has to be implemented i.e. put into action. Evaluation is important till the action is completed.

2.4 ACTIONPLAN

How to proceed with study?

After deliberation on the problem you have decided to proceed with the study, then you would need to draw up an action plan.

This action plan will include:

- Programme of the study.
- Time schedule of the study.
- Day wise list of activities.
- Visit to the department/unit.
- Checklist of points to be checked,
- List of personnel for interview.
- Checklist of points to be clarified.
- Schedule of interviews.
- Development of Questionnaire.
- Administration of Questionnaire.
- Checklist for observation study.
- Checklist for document/record study.
- . Development of worksheets (if required).
- Record keeping.

- Analysis of data/information.
- Preparation of report.
- Presentation of report.
- Formulation of course of action.

2.5 ACTIVITIES

Activity 1

In your hospital review the following aspects in emergency services and intensive care units:

Premises		Location, Space, Waiting Area, Treatment Area, Facilities etc.
Personnel	:	Adequacy, Availability, Training Motivation etc.
Plant/Equipment	:	Availability, Maintenance, utilization etc.
Policies and Procedures	:	Admission and Discharge, Treatment, Scheduling of medical coverage, Equipment Maintenance, Drugs, Infection Control, Visitors, Medicolegal cases. Housekeeping etc.

Develop a manual containing various policies and procedures for your intensive care unit/ emergency medical services (EMS).

Activity 2

In order to practically orient you to the problem in emergency care, a case study is given below simulating a problem in one of the emergency procedures.

A 500 bedded hospital having a 12 bedded ICU for medical cases including four coronary care cases. A separatc ICU exists for surgicnl cases. Recently a case of severe heamatemesis was sent at night by the casualty department to the medical ICU but the case was not accepted firstly because a bed wns not available and secondly doubt existed whether the case should not go to surgical ICU. It was referred to surgical ICU again who refused to admit being a medical case. In this process one hour was lost and the patient died on the stretcher, without any medical attention. Reports were also received that acute cardiac cases needing constant observation and care are being treated in the general medical wards due to non-availability of beds in ICU. Medical Superintendent during his visit on different occasions found that retention of certain cases in ICU was unnecessary as their condition improved and they were fit to move to a general ward. He also noticed at times some of the cardiac monitors, and respirators were not in working order. Sometimes at night only interns and student nurses were managing ICU. Medical Superintendent ordered an enquiry to ascertain reasons of mismanagement, and to formulate detailed operating procedures for ICU.

- ☞ Identify the problems.
- ☞ Define the problcin.
- ☞ Critically analyse the problem.
- ☞ Alternative solutions to the problem.
- Selection of best alternative solution with reasons.
- ☞ Action plan and remedial measures.

2.6 LET US SUM UP

In this unit you learnt that as a hospital administrator the key issues to ensure operational success of emergency services in the hospital are premises (well planned facilities), personnel (well trained and motivated), plant (dedicated and functional equipment) and policies and procedures (well written and consistently applied). You came to know about the main sources of the problems in emergency care. The problem solving method was presented for developing appropriate solutions, An action plan to undertake a study of the problems was outlined.

UNIT 3 QUALITY ASSESSMENT IN CLINICAL LABORATORY SYSTEM

Structure

3.0 OBJECTIVES

After going through this unit, you should be able to:

- understand the system of quality assessment in clinical laboratories;
- ensure parameters and procedures for performance of laboratory lest under quality assessment guidelines;
- establish the process of internal and external quality control in periodic monitoring performances of laboratories; and

identify the problems/bottlenecks in functioning of the system..

3.1 INTRODUCTION .

In this unit you will learn about definition, type of quality control and implementation of it in the laboratory system, You will be introduced to scenario of functioning of laboratories in this country with regard to quality control system; various factors involved in quality control, procedures of accreditation, status of'accreditation in the laboratories; authorities of accreditation; Registration and Licensing problems of laboratories. You will also learn about the need for training and research requirement. Towards the end you will learn about the steps to maintain minimum standards of laboratory quality assessment and various ongoing programmes in the country.

3.2 QUALITY CONTROL AND QUALITY ASSURANCE IN LABORATORY SYSTEM INCLUDING BLOOD BANK

It is imperative to provide referring physician with a quality diagnostic test report, Quality Control measures have been well established in Laboratory medicine for many years but its applications is inadequate. One needs to understand the difference between Quality Control (QC) and Quality Assurance (QA).

a) **Quality Control** is a surveillance process in which action of people and performance of equipment and materials are observed in a systematic and periodic way so that it provides a record of consistency of performance and actions taken when performance does not conform to standards established in the laboratory. In other words Quality Control focuses mainly on technical, procedural and process issues. Quality Confrol is a statistical system for measuring the reproducibility of degree of precision in laboratory procedures. It is an excellent means of improving lahoratory efficiency. The programme ensures the quality results for treating physician/surgeon and better progress for patients.

b) **Quality Assurance** is a continuous process of assuring that all laboratory services involved in the delivery of patient care have been accomplished in a manner

appropriate to maintain excellence in medical care. Quality Assurance (QA) is a broader concept and deals with outcome. It requires constant attention of chief of laboratories. Quality Assurance level is at three steps i.e. Pre-analytic, Analytic and Post-analytic which is depicted in Fig. 3.1.

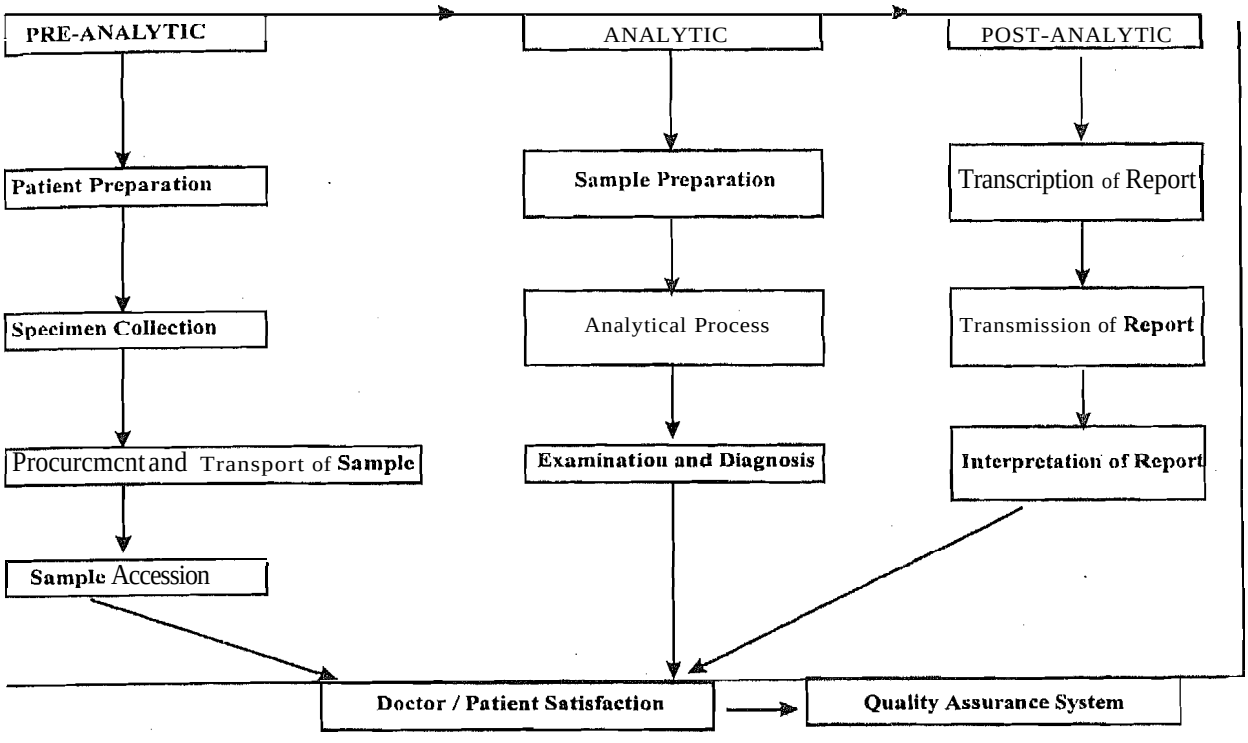

Fig 3.1 : Quality Assurance Level

Quality Assurance measures when appropriately implemented, will improve the quality and sensitivity of reports but it is not easy to design QA procedures. Major goal of QA should be in continued improvement and not in finding flaws and mistakes. Quality improvement is unlikely to occur in an atmosphere of fear. Quality Assurance measures when appropriately implemented, will improve the quality, sensitivity, specificity of diagnostic reports. It is also possible that QA measures improve purposes. Quality Assurance could be divided into:

i) Internal Quality Control (IQC)

ii) External Quality Assurance (EQA)

IQC programme aims at improving performance of single laboratory during day-to-day operation and provides immediate impact on the activities of the laboratory. EQA involves many institutions, provides information retrospectively, and has no direct influence on the output of the laboratory on the day of the test. EQA measures are necessary to ensure acceptable basis for inter-laboratory compatibility. It has to be remembered that both IQC and EQA are essential for ensuring high standards in diagnostic laboratories.

Components of QA in Diagnostic Laboratories

It is essential to assess the quality of work done in laboratory with reference to reliability of report considering precision and accuracy. The internal and external coinponents to be evaluated and checked for achievement are shown in Table 3.1.

Table 3.1 : Components of Quality Assurance in Diagnostic Laboratories

Internal Components	External Components
Personnel	• Procedures
— Qualifications	— Source and type of material
— Continuing education	— Standards for evaluation and diagnosis
• Specimens	Type of Programmes
— Acquisitions	— Education
— Handling	— Evaluation
— Preparation	
• Precision and Accuracy of test reports	
• Performance Evaluation	

3.3 ASSESSMENT, EVALUATION OF QUALITY SYSTEM

The following are basic requirements before any system of evaluation, accreditation procedures adopted for certification:

1) A laboratory to be evaluated should be legally identifiable and if the laboratory is a part of larger organisation, information on its relationship and ownership to be declared.

2) The laboratory should have managerial staff with authority and resources needed to discharge their duties. The working personnel should be qualified and experienced.

3) Authority of appointment to be notified and documented.

4) Standard operative procedures (SOP) for laboratory and working laboratory manual should be available and to be as per documented norms available in the country. Any change in system to be notified in the premises of accrediting or licensing authorities.

5) Each supervisory staff to be designated as technical/administrative with all responsibility notified to them. The quality manager should have a direct access to the highest level of management at which decisions are taken on laboratory policy or resources.

6) The Organisation Chart of the institute and the laboralory should be available as document support in evaluating system so as to create clear organisational charts indicating the key functions with recognisable lines of authority and responsibility.

7) Personnel involved in laboratory testing procedures, supervisors and managers have to maintain the confidentiality, impartiality and integrity of laboratory reports and system of working. The clear set of rules and guidelines to be notified at the time of appointment and periodically or at any amendments.

8) Documented procedures for audit and review as per policies of organisation should be available so as to ensure quality system is fully implemented and practiced.

9) Documents should be available indicating certified internal quality control system and external quality assessment for audit review and Quality Control Certification.

10) Laboratory should have an established programme for calibration and verification of its measuring and test equipment, National and International reference standards used to be notified.

11) Documented procedures should exist for the purchase, reception and storage of consumable materials used for technical operations of the laboralory.

12) The laboratory should have documented procedures for the receipt, retention or safe disposals of calibration or test items, including all provisions necessary to protect the integrity of the laboratory. All laboratory waste to be disposed as per guidelines issued From the government as per Notification Act.

3.4 LABORATORY MANAGEMENT

The efficient operation of a clinical laboratory and the effective delivery of medical laboratory services to the clinicians and their patients require a complex integration of expertise in medical, scientific, and technical areas; of resources in the form of personnel, laboratory and data processing equipment, supplies and facilities; and of skills in organisation, management and communication. Laboratory incharges, and supervisors must also be aware of the various accreditation standards and governmental regulations thal apply to laboratory practice and must ensure quality laboratory performance. The laboratory exists for the sole purpose of providing diagnostic and management information For the physician, to aid in the case of the patient. Automation of information processing with the use of laboratory computers, enabling productivity improvement and error reduction, now constitutes the standard of practice for diagnostic laboratories of almost every size. In the recent years, considerable emphasis has been placed on automated equipments.

Laboratory management is a complex task dealing with many aspects such as, laboratory planning and organisation, budgetary functions, realistic staffing, instrument selection and maintenance, inventory control and control of operations. Manager or a Director as the

laboratory head, who is the highest authority in technical matters and administration of the department, must have ability of leadership and supervision. The head of the laboratory should also be conversanl with various accreditation standards and governmental regulations. One should not just take up the job of managing a clinical laboratory attracted by monelary benefits but also one should realize the vast responsibility involved as the laboratory reports have a direct impact on the health care of the patient. The clinical laboralory management requires expertise in medical, scientific and technical areas. The person should have resources in the form of personnel, equipments, supplies facilities, skill organisalion, management and communication. A clinical laboratory should stand on firm goals and objectives. In order to achieve their objectives, the clinical laboratory should have adequate facilities, equipment and supplies and adequate number of qualified personnel. The objective of a clinical laboratory is to assist the medical professional, with reliable quality report which is a vital component of excellent health delivery system which is shown in Fig. **3.2.**

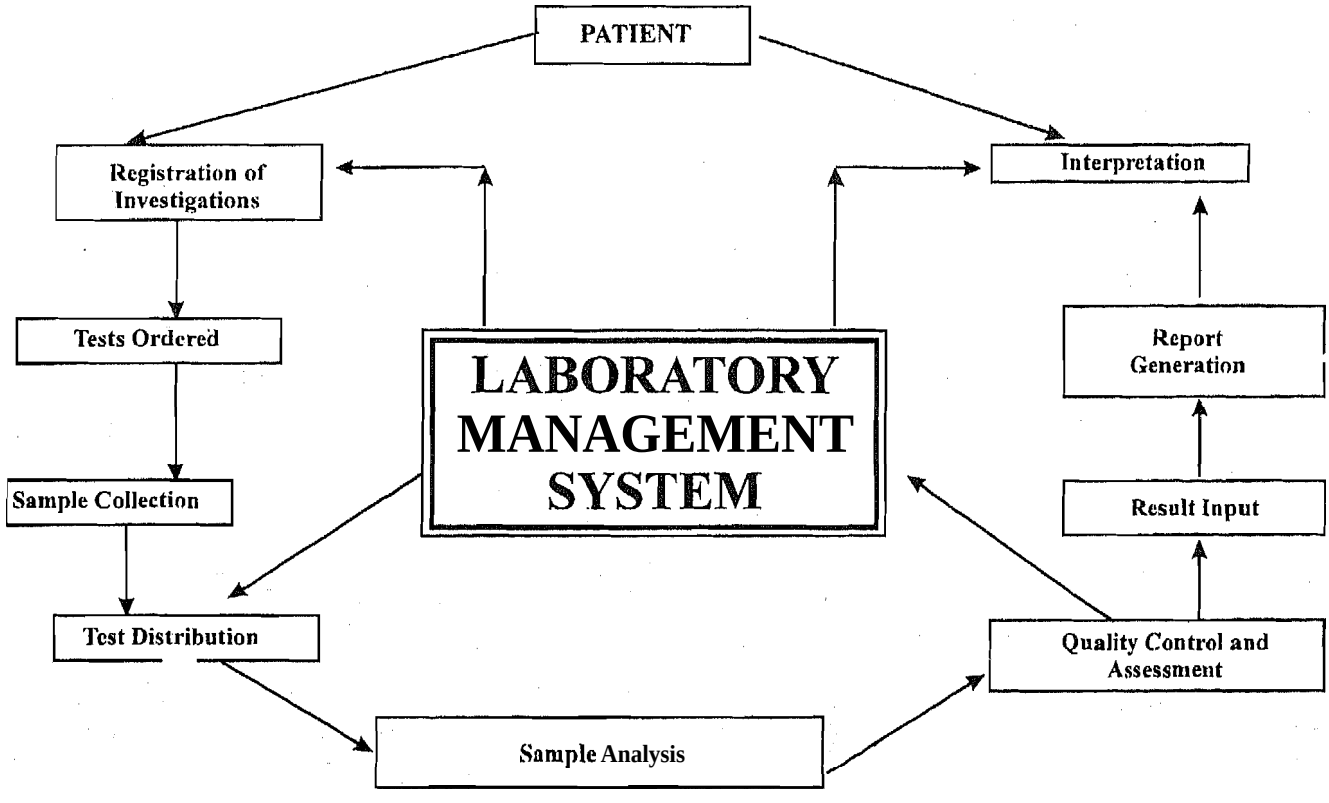

Fig. 3.2 : Laboratory management system

The following are considered Io be as essentials for organisation and planning of hospital laboratory management:

1) Concept of practice
2) Purchase, product specification function equipments, reagents etc.
3) Human resources
   i) Managerial duties and responsibilities
   ii) Leadership and motivation
   iii) Personnel management
   iv) Manuals procedures
   v) Job description and selection of staff
   vi) Inservice and CME programmes
   vii) Staff meetings
   viii) Personnel records
   ix) Performance appraisals
   x) Discipline and disniissals
4) Quality Control and Assessment
5) Information and Financial Management

3.5 PROBLEMS OF MANAGEMENT

The discipline of laboratory services can be viewed as a bridging endeavour linking the basic medical, biological and physical science with medical practice. Those working in clinical laboratories have the existing opportunity and challenge to apply advances in the science to assist their clinical colleagues in making diagnostic, therapeutic and prognostic decisions. In this role one has to serve as a clinical consultant to the clinician and the patient. To be a successful person in laboratory services one must be skilled in all these functions and be aware of all these external influences affecting the practice of laboratory medicine. Problems in management of laboratory services are mostly of general nature and specific problems of laboratory though not frequent but crucial in management. The most prominent problems are listed below:

1) Inability to maintain an adequate staff which may be due to an inefficient number of trained workers or inefficient use of the personnel available.

2) Lack of technical knowledge among working personnel.

3) Lack of work attitude, sincerity, devotion of work and indifferent personnel behaviour.

4) Lack of recognition of dignity of work and lack of job satisfaction.

5) Low morale in the laboratory.

6) Inability to perform one or more test when a key individual is absent.

7) Communication gap between officers and subordinate staff.

8) Recurring or persistent misunderstanding with the hospital administrator.

9) Frequent or recurrent confusion concerning requisition or reports of laboratory work. It makes little difference how accurately a pathologist perlorms a requisition test, if the report does not reach the doctor until 48 hours later, or if the result is reported on wrong patient.

10) Frequent 'rush' orders for reports.

11) Non-availability of updated modern technology.

12) Lack of quality control and standardization.

13) Paucity of inservice training programme (CME).

14) Lack of norms for technical staff.

15) Over loading of number of investigations as a whole and load work beyond capacity.

16) Management of irregularities, policy decisions with regard to screening committees, purchase committee etc.

17) Store receipts; purchase delays; substandard material/supply; increase lead time etc.

18) Lack of repairlmaintenance services equipments.

19) Malpractice of various kinds and nature.

20) Lack of promotional avenues and revision of cadre. Uniformity parity of scales, etc.

21) Lack of laboratory waste and disposals.

22) Lack of medical audit.

3.6 CONTROL, EVALUATIONAND CONSUMER SATISFACTION

Perfection in the management of laboratory issues is essential. Every problem has its own solulion and control. Quality control and assessment is integral part of management. Maintenance of services, supply of material, equipment maintenance, preventive and corrective measures, personnel management are components of evaluation in the procedures. **A** quality report and patient satisfaction is the final goal of evaluation programme of a laboratory.

For making a visit to laboratory for collection of relevant data a check list has been given at annexure in the end of this unit.

Patients are the foundation of medical practices, efforts should be focussed on satisfying needs of those who seek care. Quality service is a key for practical success. Opinions and

definitions of quality services and patient satisfaction are numerous. Patient satisfaction is determined by each individual according to his or her needs and experiences and recording to the actions and interactions of managerial laboratory services.

There was a time when patient satisfaction was fairly non-complicated whatever the result of investigation submitted to patient considered satisfactory both by the patient and treating physician. Today, the proliferation to technology and quality standards has changed expectations. The approach to consumer satisfaction is shown in Fig. 3.3.

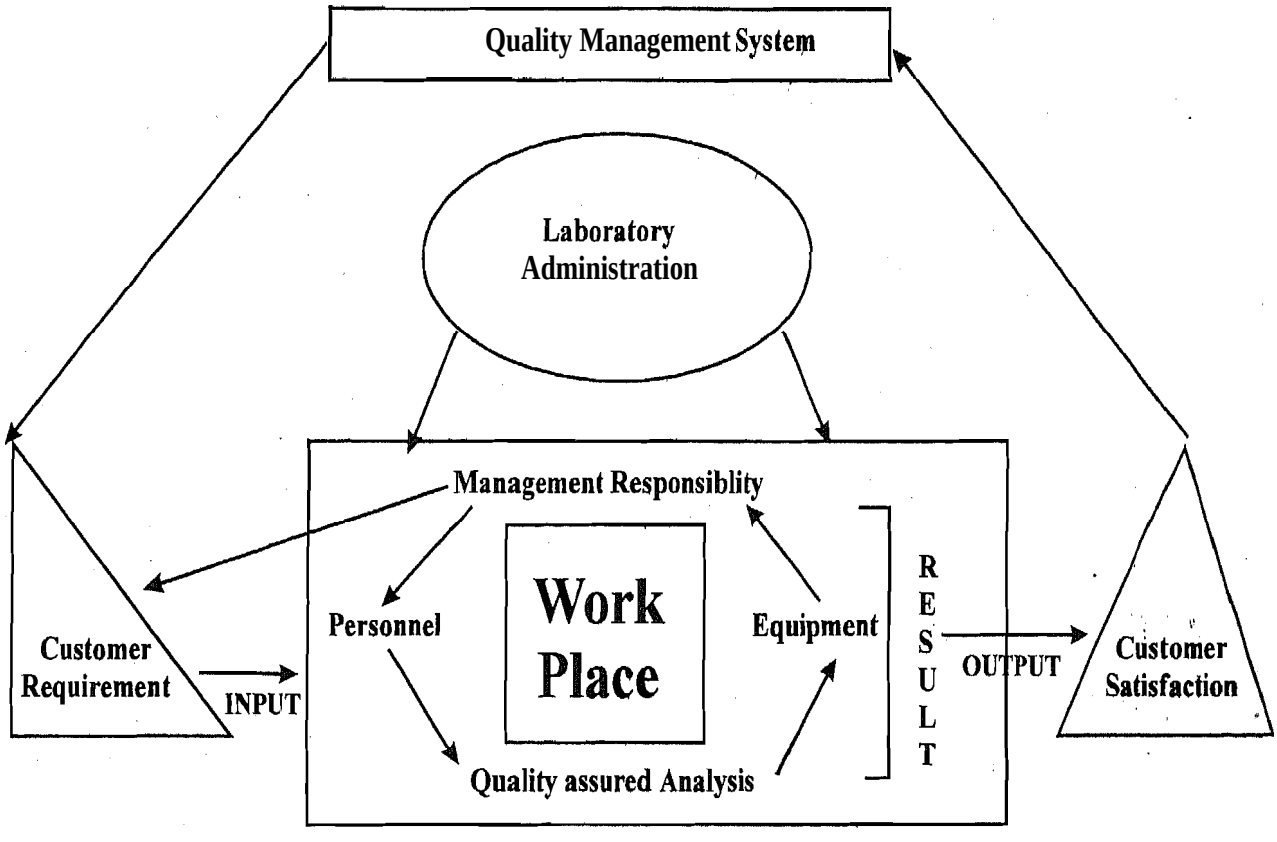

Fig. 3.3 : Approach to consumer satisfaction

The four critical elements of quality service (Quality Diamond) are:

- Customer
- Continuity
- Expectations
- Commitment

You should not ignore or minimize the importance of any of the elements of Quality diamond which are critical and shown in Fig. 3.4.

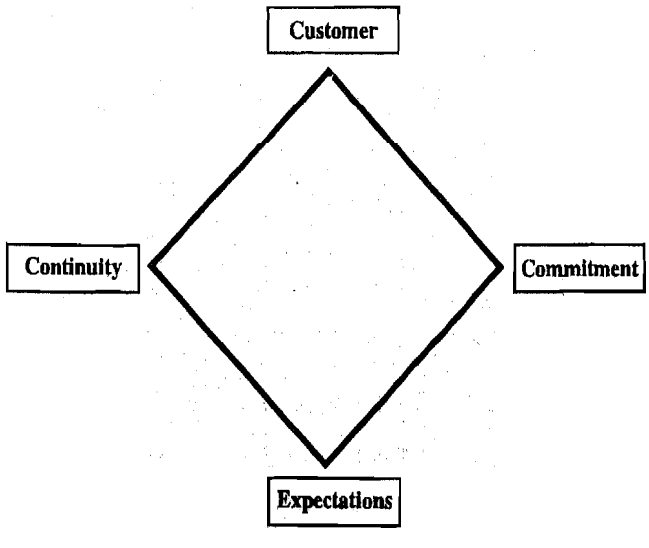

Fig. 3.4: The Quality Diamond

3.7 ACTIVITIES

In order to understand the operational aspects of functioning of laboratory, the pre-requisite; processing units; quality control; final reporting, the interpretive pathology; informative management and receipts of report to consumer and lastly the disposal of laboratory waste are few important aspects needed in evaluation proformas for preparing brief reports.

You are required to visit a Hospital Laboratory of more than 200 beds and evaluate the services, rendered. of this unit. The report should be submitted to the Counsellor in the Programme Study Centre.

3.8 LETUSSUMUP

You have learnt about laboratory and laboratory services play an important role in patient care services. You have also learnt about the important concepts in management, planning policy, Laboratory Quality Control and Assessment System, accreditation value of Total Quality Management (TQM). Further, problems of management control, evaluation and importance of consumer satisfaction have been emphasized.

Annexure 1

Proforma for Laboratory Services Visit

1) Name of the Hospital/Institution Visited

(500 Beds and above)

(Less than 500 beds)

2) Type of Laboratory Visited

a) Clinical Pathology

b) Haematology

BLOCK INTRODUCTION

Hospitals are a multidisciplinary set up. All tlie disciplines and expertise is pooled for the care of the inpatient in particular and community at large. The support and utility services are being covered in this and in tlie next block of this course.

In this block you will learn in particular about the services meant for the care of inpatient.

Unit 1 of this block deals with organisation of sterile supply meant for the suffering patients. The utility of sterile supplies in the control of nosocomial infection is well known. This helps reduce the cost of treatment and also helps to cut down the duration of indoor stay of patient. This in effect leads to a lower average length of stay, and better utilisation of bed capacily.

Unit 2 deals with the maintenance of patient records. The need of adequate records has been one of the important recommendations of the various committees during the last over five decades. With the recent evolution in Information Technology it has become much easier to maintain proper records of patients in the Hospital. Yoll will also learn about constituents of proper medical tecords and various administrative aspects. The maintenance of proper records has always been important in respect of medico legal cases. In view of the recently coming in of Consumer Protection Act in the field of health care the emphasis on proper medical records has to be heightened. In this unit you will learn about different statistical data which are essential for evaluation of the functioning of tlie hospital arid also serve as an administrative tool.

Unit 3 deals with linen and laundry services. In this unit you will learn about the need of proper linen to be made available in adequate quantity and at tlie right lime. For the up keep of linen the utility of laundry and associated processes (cleaning, calendering, processing etc.) have also been discussed in this unit.

Unit 4 deals with dietary services. Diet for tlie patient in a hospital is as important as supply of drugs. You will be learning about tlie planning, organisation and management of dietary services in this unit. The effect/utility of full caloric value, nutritious diet served aesthetically can not he untlerstaled. The dietary services have also to be economical and proper care taken to avoid wastage and pilferage, which has been discussed in this unit.

Unit 5 deals with the important aspects ofhousekeeping. You will learn in this unit the importance of good housekeeping. Apart from the aesthetic effect good housekeeping goes a long way in eliminating/reducing the chances of infection. You will also learn that good housekeeping is an important factor affecting the morale of the attendants and thus help the hospital improve its image in the clientele and the community. These aspects have been discussed in this unit.

UNIT 1 STERILE SUPPLY SERVICES IN HOSPITALS

Structure

1.0 OBJECTIVES

After going through this unit, you should be able lo:

- understand various terms used in relation lo the sterile supply services in the hospitals;
- the aims and objectives of sterile supply services in the hospitals;
- physical facility-required for such a service or planning and design considerations for a CSSD;
- various methods of sterilisation, its usages, advantages and disadvantages;
- equipment and manpower planning for such a services;
- operating policies and procedures; and
- methods of quality control or performance evaluation on the functioning of CSSD.

1.1 INTRODUCTION

In this unit, you will learn the process of sterile supply services to the wards and various departments such as operation theatre, out patients department and so on, Studies in USA have identified the nosocomial infection rate to be 3% in 1997 with a

cost of 1 billion dollars in the year to the country. Authentic statistical data regarding the magnitude of the problem in our country is not available. However, on a rough estimate the rate varies from 5% to 25% or more, prolonging the hospital stay of the patient and higher cost of care to both recipient and provider of the services.

The discovery of causation and transmission of disease by micro-organisms led to the development of aseptic techniques and sterilisation processes. In 1928 the American College of Surgeons initiated centralisation of all surgical supplies and dressings in one unit for supply to all departments of the hospital. Thus, the concept of Central Sterile Supply Department (CSSD) began in the hospitals and it become a major tool for the reduction of hospital acquired infections.

During the Second World War the British Army established a CSSD in Cairo for supply of sterile items to mobile units in forward areas. In USA the first CSSD was established in 1945. In UK a CSSD unit was introduced in Adden Brook's Hospital, Cambridge in 1957. In India Safdarjung Hospital, Delhi and Christian Medical College, Vellore established their CSSD during 1957-60.

Prior to 1928 the usual practice was that each ward unit had its own autoclave thus duplicating facilities. Centralising the functions of Sterile Supply Department provided the following advantages:

- Sterilisation processes are carried out by appropriately trained personnel.
- Uniform sterilisation processes for all hospital units.
- Facilitates quality control of sterility of supplies.

1.2 DEFINITION AND SCOPE OF SERVICE

Central Sterile Supply Department (CSSD)

It is a department within a health care facility in which medical or surgical supplies and equipment are cleaned, prepared, processed, stored and issued for patient's use.

The scope of service varies vastly from hospital to hospital. The items are either stocked at the CSSD or at the central stores from where these are issued to the users. The user department sends these to CSSD for sterilisation or further issue to the departments for reuse. With the use of more and more presterilised disposable items, the scope of CSSD is gradually reducing since the items are disposed off after using it once. Normally the following items are catered for by the department:

a) Needles and glass syringes

b) Rubber goods (Rubber gloves, catheters and tubings)

c) Treatment and diagnostic sets and trays (lumbar puncture, sternal puncture and paracentesis sets, to name a few)

d) Dressing

e) OT linen and instruments

f) Intravenous sets

g) Infusion fluids for renal dialysis

By custom diets, medicines including blood, crystalloid and laundry are not included in the functions of this department.

Theatre Sterile Supply Unit (TSSU)

Some hospitals have a sterile supply unit as an integral part of operation theatre. These are known as TSSU. These units may be in addition to CSSD to cater to the emergent requirement of operation theatre or when the requirement of sterile supply is so large that necessity is felt to provide additional unit as an integral part of

operation theatre. In small hospitals where major work pertains to operation theatre and requirement of sterile supply to the department is bare minimum, there may only be TSSU or CSSD itself is integral to operation theatre.

1.3 AIMS AND OBJECTIVES OF CSSD

Aim

To provide all departments with an adequate supply of reliably sterilised materials on-line, from a Central Sterile Supply Department where safe sterilisation is conducted under controlled conditions at minimum possible cost thus contributing to reduction in the incidence of hospital infection.

objectives

1) To provide on-line supplies of sterile instruments. linen packs and other sterile items required for patient care.

2) To maintain accurate record of effectiveness of cleaning, disinfection and sterilisation process.

3) To monitor the quality of sterilisation.

4) To maintain an inventory of supplies and equipment.

5) To provide a safe environment for patients and staff.

Check Your Progress 1

Whst are the objectives of CSSD?

.....

.....

.....

.....

1.4 PLANNING AND DESIGN CONSIDERATION

1.4.1 Structure and Location

The CSSD should be located in close proximity to the areas it serves and to the areas that serve it for efficiency of function. Major users of the service are operation theatre, labour room, casualty and the wards units with this in view, the CSSD should preferably be located near the OT complex or in close proximity to these areas. Since the major requirement of CSSD is of steam, the availability of boiler service nearby is also necessary. As a rule of thumb following is suggested:

1) Hospital of 100 beds : CSSD in OT (i.e. TSSU)

2) Above 100 beds : CSSD in Service Area

3) Above 500 beds : CSSD in Service Area and TSSU in OT

Layout

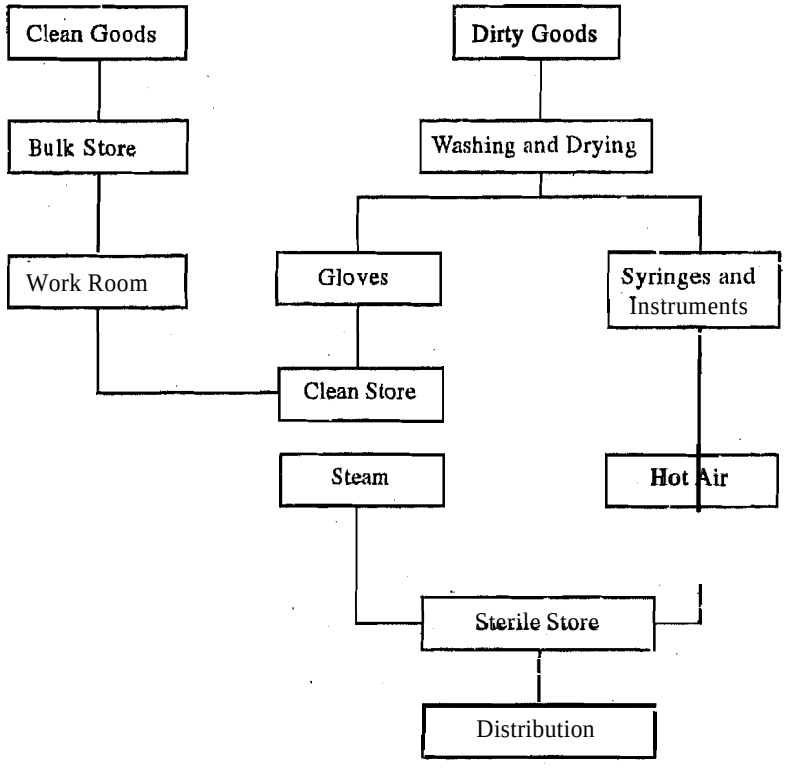
The functional areas in a CSSD should be so arranged that equipment and materials progress in a logical sequence from receipt of contaminated and used items to sterilisation, storage and issue of sterile items. **There should be no mixing of sterile and contaminated items.** To achieve this, the division as under should be planned:

1.4.2 Organisation of Work Flow

The important steps in this process from receipt of the used articles to issue of sterile items is indicated in the work flow diagram given below:

A. Work Flow Diagram

B.



Disinfection

Chemical disinfection to be used for heat/labile items:

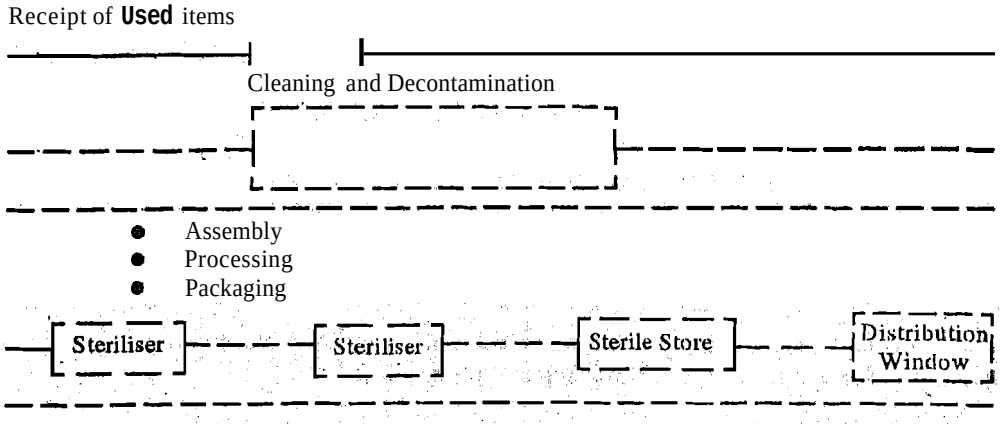
- Thorough cleaning prior to disinfection is necessary.
- Disinfectants must be carefully diluted to manufacturers specifications. Monitoring of disinfectants used should be carried out at a specified laboratory.
- Indicator strips to test the activity of 2% glutaraldehyde should be used prior to insertion of instruments.

Heat Disinfection for clean solid steel items only.

- Boilers must have a functional thermostat, a time lapse lock and thermograph.
- Washer disinfector used for cleaning and disinfection prior to sterilisation should be monitored by internal thermostats,

Accurate record keeping for the above monitoring systems must be carried out. Periodic check of records must be done.

Typical Layout of CSSD



Space Requirement

As a general guide for a Hospital of up to 400 beds, area of 1.64 sq. m/bed will be required for CSSD.

For a Hospital with >400 beds, area of 1 sq. m/bed will be sufficient. The total area needs to be divided to provide the following facilities:

Facilities	In **Sq. Meters**
Entrance	10.50
Lockers	7.00
Staff change room	7.00
Dirty receipt and Disassembly	7.00
Washing, disinfection and decontamination	17.50
Assembly	10.50
Linen processing	10.50
Sterilisation	14.00
Sterile storage	21.00
Distribution	10.50
Trolly wash	7.00
Trolley Bay	10.50
Bulk store	10.50
.Duty room . .	17.50
Toilet	3.50
Total per 100 bed Hospital	164.50

Note:

1) Walls, ceilings, floors, and work surface should be of smooth and of washable materials.

2)' Ventilation system:

   a) Should be designed to maintain circulation of air from clean to contaminated areas.

   b) Maintain Air changes of 10/hours

   c) Maintain positive pressure ventilation in sterile storage area.

   d) Storage system should be designed to enable items to be stored at least 8" from the floor, 2" from outside walls a'minimum of 18" from ceiling fixtures.

Equipment in CSSD

The under mentioned type of equipment needs to be provided in the CSSD such as Jetwater cleaning gadgets, ordinary cleaning brushes and ultrasonic washers,

1) Cleaning and decontamination devices

2) Hot air ovens for instrument drying and dry heat sterilisntion

3) Glove processing unit for processing of surgical gloves

4) ,Instrument sharpners e.g. needle sharpners

5) Steam, dry heat, gas or chemical autoclaves

6) Testing apparatus for efficiency of sterilisation

7) Others — Trollies, works surfaces, maintenance and repair equipment, telephones.

Cleaning and Decontamination **Devices:** The clean up or wash area needs to be provided with counter top work surface made up either of stainless steel top or of same hard easily washable material such as Kota Stone. These are to be fitted with large size sinks with foot operated taps. The ultrasound washers have been found to be very useful by ensuring adequate cleanliness with reduction in clean up or wash time by 50% or more. These washers produce ultrasound waves which when transmitted through solutions containing inert molecule set. These molecule in violent motion which loosens all surface material such as hactcrias. dried blood or anything else adhering to the surface.

Glove Processing Unit: The unit is available for glove sorting, washing, testing powdering, packaging and finally sterilisation. The glove room should be separate from other work areas so that powder does not contaminate other articles. The room should be properly sealed with rubber beadings for the purpose.

Autoclaves: The common method in use is steam sterilisation for which sterilisers of varying capacity and type are available. Dry heat, gas or chemical sterilisers are also available and used depending upon the requirement. Details from the manufacturers must he obtained and requirement worked out depending upon the work load and capacity of the equipment. Vacuum type steain sterilisers which are much more efficient and require less time to reach the required temperature rue generally used in the CSSDs of the hospitals in India. These are fitted with in-built cheeks and control system. The details have subsequently been discussed in Unit 3 of this block.

Testing Apparatus

Indicator tapes: Time, temperature and pressure sensitive tapes are available in the market. These tapes are put on the package. These do not indicate the sterility of items but merely indicate the items have been subjected to the required temperature pressure or have: undergone the required time cycle of processing.

Bacteriological indicators: Several indicators are available which compare known population of thermophylic spore bearing colonies before and after autoclaving. These indicators are placed in the centre of pack and after autoclaving are sent to laboratory for colony growth and count. The result is usually available after 24-48 hrs.

Stock

To ensure continuous availability of sterile items to the users at least five times the average daily requirement should he available as uuder:

– 1 1/2 x Average daily requirement in use in wards/deparuments so that there is inbuilt reserve in user departments

+ 1 1/2 x Average daily requirement in sterile state in CSSD

1 x Average daily requirement under processing

1 x Average daily requirement in reserve in **CSSD**

Organisation

The administrative head of CSSD is an administrative person whereas technical head of the facility is a Microbiologist. Under the administrative head there are CSSD Managers/Supervisors who supervise the work of personnel working in the CSSD. Normally there are 2 CSSD personnel per 100 beds.

2.5 STERILISATION PROCESS

Definition

Sterilisation is a process of freeing an article from all living organisms including bacteria, fungal spores and viruses.

Sterilization processes in use in hospitals in India are:

1) Heat sterilisation:

   3 By Steam

   b) Hy Dry Heat

2 ETO Sterilisation

3) Chemical Sterilization

4) Radiation Sterilisation performed by ISOMED at BARC, Mumbai (not suitable for Hospitals)

1.5.1 Heat Sterilisation by Steam

Steam destroys micro-organisms by irreversible denaturation or heat coagulation of cellular proteins. Advsntages of steam sterilization are as follows:

- Economical
- Steams contains enormous energy in the form of latent heat
- Does not require purging fitness prior to use (as in ETO sterilization)
- If used in a vacuum, penetration of steam occurs throughout the item.

Equipment

Two types of steam sterilisers:

— Gravity displacement,or downward displacement steriliser which displaces air from the chamber and load by gravity.

— Pre-vacuum steriliser which removes air from the chamber and load by a vacuum pump. This is a more rapid method,

Controls

Air removal efficacy of pre-vacuum sterilisers should be regularly monitored.

Controls carried out should be by means of micro-processors rather than manually.

Requirements of Control System:

- Online data on all stages of sterilisation cycle
- Storage of date

- Diagnostic programme for engineering services
- Automatic leak test cycle

Quality of Steam

- Steam should contain less than 3% moisture
- Steam at 0.92 to 0.95% dryness is best for sterilisation

  Steam supply pressure should be checked weekly by preventive maintenance department

- Regular weekly preventive maintenance to be carried out
- To avoid contaminated steam from entering steriliser, steriliser should not be operated during boiler below down.

Material Compatibility

The effect of steam on all material to be sterilized should be assessed in terms of corrosion, flexible properties, impact resistance, tangible properties, comprehensive strength, burst strength, tear strength, colour, permeability and optical transmission. This should be documented.

Preparation of Items for Sterilisation

1) **Rinsing**

2) **Cleaning:** thorough cleaning of items to be done. Ultrasound washers to be preferably used.

3) **Drying** of all articles to be done.

4) **Inspection** and **assembly:** Inspection for defects, breakages and then appropriate assembly.

5) **Packaging:** Items should be packed in porous material e.g. linen and papers. Individual packs should not exceed 25 cm x 25 cm in size. Weight should be less than 5 kg.

6) Labelling of each package should carry nomenclature of item, contents of pack initials of packer, date and initials of person who carried out sterilization.

Loading

All surfaces of items must be directly exposed to steam.

Instruments should be opened and disassembled. While loading care should be taken to allow adequate room for all items to allow steam penetration and circulation. Pouches must be placed on edges in loose contact with each other to allow quick removal of air.

Operation

Manufacturers' guidelines to be strictly followed. In case power failure cycle must be repeated.

Each type of steam steriliser is designed to achieve specific cycle parameters, usually 134° C for 3 minutes on 121° C for 15 minutes.

Unloading and Cooling

Load should be left in the steriliser until all steam has escaped and items are cooled.

- Cooking items should be placed separately on wiremesh racks and handled on] when entirely cool.

Record Keeping

The following documentation is to be maintained for a period of 2-3 years:

- Steriliser instruction manuai.
- Records of preventive maintenance, calibration and repair.
- Load records including contents of each load, duration and temperature of cycle, initials of operator, date, number and time of cycle.

Flash Sterilisation

Flash sterilisation allows quick sterilisation of "one of a kind" device that is urgently required for reuse. Flash sterilisers achieve a temperature and pressure for sterilisation in minutes.

Check Your Progress 3

i) .....

ii) .....

iii) .....

iv) .....

b) Individual pack size should not exceed ..... and weight should be less than .....

c) Flash sterilisation achieve a temperature and ..... for sterilisation in ..

1.5.2 Sterilisation by Ethylene Oxide Gas

Ethylene oxide kills micro-organisms by altering the DNA of micro-organisms by the process of alkylation. ETO may be used undiluted or diluted with carbon dioxide or nitrogen.

ETO is supplied in small cartridges of 100% Ethylene oxide snd large cylinders containing a mixture of 12% ETO and 88% other halogenated hydrocarbons.

Sterilisation by ETO is done for those items which cannot be subjected to heat sterilisation. Delicate surgical instruments such as cystoscopes, heart lung machinery, other electrical equipment, costly cathetar and implants are sterilised by this method.

Containment Area

ETO sterilisers should'be located at a place physically separate from other work areas. .This area must be large enough to ensure ETO dilution and provide adequate space for loading, unloading and maintenance of steriliser and aerators.

Preparation of Load

All items to be sterilised must be thoroughly cleaned.

Humidification

- All areas utilised for sterilisation process must have humidity of 35-70%.
- All moisture must be wiped from items to be sterilised.

  Moisture content of the steriliser and packing is important to facilitate penetration of ETO.

Packaging

Packaging material should be highly permeable to ETO and air. Paper should be used for packaging. Before sealing, all excess air should be removed to avoid bursting. The packaging pouch should not be folded. Instruments should be placed in perforated trays or wire mesh bottomed trays.

Loading

Items with similar aeration times should be sterilised together. Items should not touch steriliser chamber walls.

Operation

Cycle **parameters:** Manufacture's instructions should be followed, Common exposure conditions are temp. of 37-60°C, exposure time 105-300 minutes and chamber humidity of 45-75%.

Unloading

Following precautions must be followed during unloading:

- Steriliser without purge cycles—must be placed with an exhaust hood. Door must be opened and left open immediately on completion of cycle. The operator should enter the room after 15 min.
- Steriliser with purge cycles—can be unloaded immediately after the door is opened.
- Steriliser with built in aeration—aeration cycle occurs subsequently with sterilisation. This type is best for operator safety.
- Sterilised items must be immediately transferred lo aerator.
- Butyl rubber gloves must be worn by operator.

Aeration

Aerators should be used according to manufacturer's guidelines. Duration of aeration depends on composition, thickness design, weight of item and its packing.

- Permissible residual levels of ETO
- Size and arrangements of items in aerator
- Aeration is necessary before an item sterilised by ethylene oxide can be used to prevent its toxicity or side effects.

Precautions for Safety

- ETO is a toxic gas. Breathing apparatus for emergencies must be stored in an easily accessible place near ETO area.
- The permissible exposure level of ETO is 1 ppm/8 hours.
- Personal exposure to ETO should be minimised by:

  a) using a steriliser with purge cycles,

  b) use of exhaust system to exhaust gas to outside,

  c) use of exhaust hood over steriliser,

  d) use of alarm to indicate completion of cycle,

  e) use of metal baskets for sterilisation loads, and

  f) alarms to alert personnel in case of leaklspill.

1.5.3 Sterilisation by Dry Heat

This is carried out for sterilisation of items such as cutting instruments, vaseline gauge etc. in which steam cannot penetrate adequately. Uniform heating of items is achieved by means of a fan for forced air circulation.

Time and temperatures used in hot air sterilisation are:

160° C x *60* min.

170° C x 40 min.

180° C × 20 min.

150° C × 6 min. for some pharmaceutical products.

Equipment

- Indian standards IS 3119-1978 provide guidelines regarding specification of hot air sterilisers.
- Sterilisers must be automatically controlled.
- Steriliser door should have automatic locking system.
- A thermometer should be provided along with the temperature chart recorder.
- A lock out system should be installed to prevent overheating.

Precautions

- Steriliser should have interlocked doors. Door should be opened only when cycle is complete.
- Chamber should not be overfilled.
- Good thermal contact must take place between load items and their containers which can be wrapped in aluminium foil to facilitate this,

1.5.4 Radiation Sterilisation

This is one of the most effective method of sterilisation. Gamma rays provided by a source such as cobalt 60, caesium 137, or Electron beam generated by Linear Accelerator. This process is already being employed by ISO MED at BARC for bulk sterilisation of disposable items. This method cannot be employed at the hospital level due to high cost of equipment and safety standard requirement.

Advantages

- Reliable.
- Can penetrate all types of packing,
- Large and diverse shaped articles can be sterilised.
- There is no residual radioactivity at 2.5 mega roentgens.

Disadvantages

Glass becomes dark.

- Cotton loses tensile strength.
- Food may get undesirable flavours.
- Not practicable in hospitals.

1.6 OPERATIONAL CONSIDERATIONS

1.6.1 Functional Activities

a) **Rinsing** preferably to be carried out in CSSD. If done in wards it must be done by a trained person,

b) Cleaning: Manually or by ultrasound washers for ensuring adequate cleanliness,

c) **Drying:** All items must be appropriately dried

d) **Inspection and Assembly:** Each item must be inspected for functionality, defects and breakages,

e) Packaging must be done in porous material e.g. linen, paper. Each pack should not exceed 25 cm x 25 cm in size and 5 kgs in weight.

f) **Labelling:** The labelling note on pack must carry:

- Nomenclature of article
- Contents of pack
- Initials of packer
- Initials cf person who carried out sterilisation
- Date of sterilisation
- Shelf life

g) **Sterilisation** must be carried out by trained personnel on sterilisers in good state of maintenance and repair as per manufacturers' specifications.

h) **Storage:** Sterile and unsterile stores should be separate and there should be no intermixing of the items between the two stores.

i) **Distribution:** Distribution systems must ensure efficient delivering of appropriate items to the point of use without compromise of function and sterility en route.

1.6.2 Distribution Systems

Distribution Systems in use are:

1) Milk round **system:** Includes daily topping up of each OTs/wards stock levels to a predetermined level. If one round is made stock provided should be 50% extra of average daily usage and 25% extra if two rounds are made daily.

2) **Grocery system:** Wards send requisition to CSSD and stock is supplied accordingly,

3) **Clean for dirty exchange system:** One clean item for a used one is usual.

1.6.3 Operating Policies

a) **Procedure manual:** A standard manual of policies and include staff deployment, operating procedures maintenance of equipment, storage, receiving and issue of items, operating schedules, sterilisation, packing and labelling procedures should be laid down.

b) **Training:** Personnel should be adequately qualified and trained by means of classes and on-the-job.training.

1.7 MONITORING AND PERFORMANCE EVALUATION

1) Monitoring of sterilisation and disinfection processed should be under the gnidance of a medical microbiologist.

2) Recycling of disposable items should be controlled by Hospital Infection Control Committee.

3) The recommendad standards for monitoring equipment should be met. Good manufacturing practice (Drug and Cosmetic Act', 1996) should be followed.

4) Wet packs must not be accepted as sterile.

i) Steam Sterilisers are monitored by leak rate test and air removal tests.

- Thermocouple testing and air detection test to be performed at installation, recommissioning and yearly intervals.

- Each cycle should be validated by accurate thermographs.
- Colour change chemical indicators sensitive to pressure and temperature to be applied to each pack.
- Biological indicators should be used at installation and routinely at periodic intervals.

ii) Ethylene **Oxide Sterilisation**

- Biological indicators (Bacillus subtilis) are used for monitoring with an incorporated chemical indicator (results available within 24 hrs.)
- The following parameters must be ensured:

  Temp. 37-60° C, Exposure time of 105-300 minutes and humidity of 45-75%.
- Appropriate aeration time as per manufacturer's specifications must be ensured.
- Local exhaust ventilation checks to be carried out daily. ETO levels to be tested in specified laboratories (1 ppm/8 hours).
- If vaccum is used leak test must be carried out.

iii) Dry Meat **Sterilisation** to be limited to heat stable glass or steel.

- Chemical indicators to be used with each cycle.
- Biological indicators to be used weekly.
- Monitoring to be carried out by comparing temperature to a Master Temperature Recorder.

c) Dry heat sterilisation to be limited to .....

1.8 MANAGERIAL CONSIDERATIONS

1.8.1 Maintenance and Repair of Equipment

As per manufacturer's specification there must be a specified schedule for preventive maintenance and record keeping of maintenance.

1.8.2 Inventory Management

a) Inventory management should identify:

- Items required
- Reorder levels
- Quantity to be ordered

— Schedule of ordering

— Cost of items

b) Regular inventory performance monitoring to be carried out to assess user satisfaction, inventory turnover/frequency of out-of-stock, frequency of overstocking and response time between order and receipt.

c) Record keeping and data analysis to be carried out for effective inventory managzment.

1.8.3 Budget Considerations

a) Assessing demand

b) Capital cost is considered under:

- Physical space and layout including scope for expansion'
- Processing and sterilisation equipment
- Initial investment on instruments, online expenditure of consumables e.g. pnckaging materials, indicators etc.

c) Maintenance cost including labour cost, replacement cost and cost of consumables.

d) Additional costs—cost of development, inventory carrying costs, cost of quality control.

1.9 LET US SUM UP

In this unit you have learnt that with the advance of medical technology and interventional techniques, the challenges to the **CSSD** to provide appropriate sterile supplies has enlarged.

You have also learnt that with an effective **CSSD** the rise in incidence of Nosocomial infections with corresponding increases in mortality, length of stay and costs can be brought down.

Further you have learnt that the perspective scope of the CSSD has enlarged from that of an autoclave steriiisation unit to a department that addresses the larger, vitally important issue of Hospital Infection Control throughout the Hospital.

You have also learnt about the planning and design consideratins, operational considerations and sterilisation processes. Towards the end you have learnt about some of the managerial issues in CSSD inventory, monitoring and performance evaluation,

1.10 ANSWERS TO CHECK YOUR PROGRESS

Check Your Progress 1

a) To provide online supplies of sterile instruments, linen packs and other sterile items required for patient care.

b) To maintain accurate record of cleaning, disinfection and sterilisation process,

c) To monitor the quality of sterilisation.

d) To maintain an inventory of supply and equipment.

e) To provide a safe environment for patient and staff.

c) Heat stable glass or steel

UNIT 2 MEDICAL RECORDS DEPARTMENT

Structure

2.0 OBJECTIVES

After going through this unit, you should be able to:

- define the inedical record;
- enlist the purposes of inedical records in relation to patient, doctor, hospital and medical education and research; and
- enumerate the steps in planning and organisation of medical record department in a hospital.

2.1 INTRODUCTION

In the first unit of this block yo11 have learnt about the planning and die organisation of CSSD. In this unit you will learn about another important area of hospital i.e. Medical Record Department. In tlie beginning you will learn about the definition of medical record including its purpose, planning, organising and staffing consideration. You will also learn about physical facilities planning, procurement and flow of medical records. Further you will learn about the storage and retrieval of medical records including functions and reports and return in a hospital. Towards the end of this unit you will learn about the medico legal aspects of medical records.

2.2 DEFINITION

Continuous development has taken place in the field of medical records over the period from the initial primitive form. The first medical records unit was established in 1667 at St. Barthlomew's Hospital in England followed by the practice of maintaining Patient's register ill Pennsylvania Hospital in the USA in 1752. The impetus to the idea of proper inedical records in the Form of standardised inpatients records came in USA from the American College of Physicians and American College of Surgeons in the first quarter of the current century.

In India, medical record keeping bas not developed to the same extent as in western hospitals. Bhore Committee (1946) first stressed the importance of keeping adequate

The individual at the OPD record room sends the folder to the appropriate deparunent on the presentation of token. The folder is deposited back after the visit.

To achieve the unique task of maintaining and storing medical records'in good order a medical records department is an integral part of hospitals irrespective of its size and type. In asmaller hospital, PHC or a subdivisional hospital it may be in the form of medical record section rather than a full-fledged medical records department.

2.3 PURPOSE

The medical record is indispensable from the standpoint of the patient, the doctor, and the hospital and for medical education and research. The purpose it serves in relation to these aspects is as under:

The patient: You will agree that the primary reason for record keeping is to improve the care of the patient. It is essential for immediate diagnosis, treatment and for the future welfare of the patient. Every illness, however, minor involves study and examination to the extent that it is impossible for any individual to keep all details in mind. The written report is evidence that the patient's care is being handled in a scientific manner. Other points in relation to this are:

- It serves to document the clinical story of the patient's illness and course of the disease.
- It serves to avoid omission or unnecessary repetitions of diagnostic and treatment measures.
- It assists in continuity of care in the event of the future illness.
- It serves as evidence in the event of when the legal question arises.
- Provides necessary information for insurance, contributory health scheme or for the employment purposes.

The doctor: From the point of view of doctor, the medical records serves as:

- Assurance of quality, quantity and adequacy of diagnostic and therapeutic measures undertaken.
- An assurance of orderly continuity of medical care.
- Evaluation of medical practice.
- An aid in research and the continuing education of health professionals,
- A protection in the event legal question arises.

The hospital: From the hospital point of view the medical records are necessary for following purposes to:

- Document the type and quantity of work undertaken and accomplished.
- Furnish proof of the type and quantity of care rendered to the patient.
- Evaluate the proficiency of the individual doctor, for administration and clinical purposes.
- Evaluate the services of the hospital in terms of accepted norms and standards.
- Protect the hospital in the event of legal matters.
- Serve as an administrative record of personnel performance and staffing needs, for budget preparation, justification for physical facility allocation and utilization, for statistical data for administrative use and evaluation, for estimating equipment and supply utilization and needs.
- Assist in future programme planning.

Medical **education and research:** Medical records can also be used for the medical education and research in following ways:

- Recorded observations are the basis for all clinical research.
- Group studies of records by the medical staff serve to further the education of doctors and other health personnel.
- Medical records supply pertinent data for the use by public health authorities in control of the diseases.

2.4 PLANNING, ORGANISATION AND STAFFING

Medical records department is generally organised on the basis of individual hospital. However, at times, such department in a larger hospital may cater for a group of smaller hospitals in situations where computerisation of record keeping has been done. The main factors that govern the organisation of work in a medical records department are:

- Medical records should always he available when required and in the form they me required.
- Adequate liaison should exist between different groups of staff using medical records to enable to give due consideration to matters such as design and contents, method rind storage availability, use and movement of records.
- Procedures should cause patients the minimum of waiting and inconvenience.

The overall responsibility for the efficient functioning of the medical records department is that of the administrator. However the department should function under the direct supervision of medical record officer/librarian who should he given authority commensurate to the responsibility assigned.

Necessary assistance to the functioning of medical records department is given by the 'Medical Records Committee' which is policy making body and which meets periodically to reviews the forms, records, existing policies and procedures. It evaluates the functioning of medical records department. The committee is composed of:

- Representative of the clinical discipline
- Representative of the nursing staff
- Member from the pathology services
- Administrator

Organisation

The medical records department is generally organised as undet:

Admission and Inquiry Office: You must be knowing that all admission lo the hospital takes place through this office, You will also appreciate that this office initiates documentation of inpatients, maintains records of all admissions, discharges and deaths, collects the documents after discharge and forwards the same to the central record office for further processing. It keeps up to date information of bed state of each ward. This office operates round the clock and provides all necessary information to the patients and their relatives. In the hospital where charges are levied for any services this office may also be performing the task of collecting and depositing the cash unless there is a separate billing section.

To perform the assigned tasks the office has following sections:

- Admitting office
- Admission check desk
- Census desk and
- Inquiry office

Central Record Office: The central record office is organised to perform the following functions:

- Receipt, checking, assembly and storage of all medical records of discharged patients.
- Discharge analysis and statistics.

  Coding of all diagnosis as per international classification of disease.
- Indexing of all discharged patients by disease, doctor and so on.
- Making records available for medico legal purpose.
- Issue of medical certificates of various types.
- Send notification of all communicable diseases to the public health authorities
- lssue of all records to the medical officers whenever required.
- Preparation of monthly abstracts and annual statistical details.
- Dealing with inquiries from Life Insurance Corporation regarding disease and cause of death of the insuree.
- Training of all categories of personnel.
- Storage of all types of forms used in the hospital.

Keeping this in view the medical records department is organised as under:

- Office for Medical Record Officer (MRO) and Asst. MRO.
- Document processing area comprising of :
  - Assembly and deficiency check desk
  - Incomplete record control desk
  - Coding and indexing desk
  - Discharge analysis and vital statistics desk
- Record storage
  - Activc-record storage
  - Inactive record storage

Out Patient Record Section: As discussed earlier in all modern hospitals attached to teaching institutions an elaborate system of documentation and storage is established for out patients. These records are as important as that of inpatients. However, with the overwhelming load of outpatients and other factors most hospitals in the governmental sector do not maintain OPD records in India.

Staffing

The staffing of medical records department. depends upon the size, type and services being provided by the hospital. Dr. J. R. McGibony has suggested staffing pattern for a 500 bedded non-teaching hospital as under:

•	Medical Record Officer	1
o	Medical Record Technician	4
o	Clerks	3
o	Peon	1
•	Statistician :	1 (on part lime basis)

For comprehensive services in addition to MRO staff as under may be considered for a teaching hospital of 500 bed and above. Each category of personnel should be computer literate.

- **Admission and Inquiry Office**
  - Asst. Medical Record Officer : 1
  - Medical Record Technicians : 5
  - Medical Record Attendant : 4
  - Receptionist : 5
- **Central Record Office**
  - Asst. Medical Record Officer : 1
  - Medical Record Technicians/ Asst. Medical Record Technician/Clerks : 8
  - Medical Record Attendants 8
  - Statisticai Asst. 1

2.5 PHYSICAL FACILITIES

While planning physical facilities for a medical record department, you sbould take following into consideration:

Location

Central admission and inquiry office should be located near the main entry of the hospital in close proximity of the outpatient department and accident and emergency services as the majority of the patient in the hospital come to these departments and admitted through these areas. Outpatient record section should also be located in the outpatient department near its main entrance. Central medical record office may form a part of administrative wing. Since this office deals with inpatient records, it should he in close proximity to the inpatient areas.

Space and General Facilities Requirement

a) **Admission and Inquiry Office: A** space of 125-175 sq.ft. is considered adequate. Counter should be aesthetically made to facilitate easy communication between staff and clientele. General office equipment will mainly be required for the staff working here. Separate counters for admitting clerk, receptionist handling information and billing clerk should be provided. The room should have adequate waiting space with facilities for waiting, toilet for the staff, patient and their attendants. Telephone with facility local calls/STD must be made available,

b) **Central Record Office**

i) The space requirement depends upon the size of hospital. As a rough guide a space of 2 to 3 sq.ft. per bed may be sufficient. The details are as under:

50 bed hospital—150-175 sq.ft.

100 bed hospital— 225-250 sq.ft.

200 bed hospital--450-500 sq.ft.

500 bed hospital—1000-1200 sq.ft.

ii) This area may be sufficient 10 store inactive medical records also. The space for this may be in the general record storage area or on a separate floor. Space ranging from 120 sq.ft. to 500 sq.ft. with adequate shelves will be required.

iii) In addition to the coinputers if the functioning is computerised, general office equipment for the medical record technicians/clerks will be required. Adequate facility for holding meetings, medical staff/trainees to pursue the record needs to be catered.

c) **Out Patient Record Section:** Average 2-3 square feet per bed of space is required for outpatient record section also. A space of 150 sq.ft. for the 50 bed hospital to 1200 sq.ft. for a 500 bed hospital may be adequate for the outpatient records. Separate counters for the registration of old and new, male and female patients are to he provided. Counter 24" wide, 40" high with file drawers beneath it is required. Wailing area adjacent to registration furnished with chairs, benches, announcement boards and health education visual aids need to be catered.

2.6 PROCESSING OF RECORDS AND THEIR FLOW

Steps in **Initiating Records:** Flow chart showing development and movement of medical records upon the admission of a patient is given in Fig. 2.1.

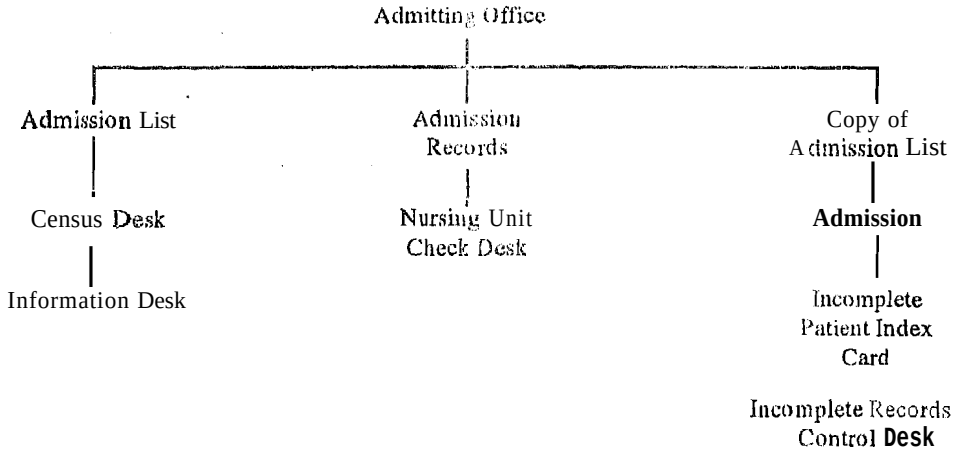

Fig. 2.1: Flow Chart Showing Development and Movement of Medical Records upon Admission of a Patient

Whenever a patient present for admission the steps involved are:

- Initiate **Inpatients** Records: The admitting office keeps assembled set of blank clinical record forms which are initiated whenever the admission of a patient takes place.
- **Pill in a Patient Index Card:** Usually a 3" x 5" card with patients identifying data such as name of the patient, address, date of birth, sex, name of father and so on is filled at the time of admission of the patient. This card is retained in a file in alphabetical order to give information regarding patient.
- Inscribe **in an** Admission **Register:** The identification data of a patient with date of admission as and when admitted.
- Identifying Number: Each patient is given a unique identifying number, which is recorded in all the documents. Unit or serial system is followed in assigning the number. Under the unit system the patient on his first admission receives a number which is the identification of all the documents pertaining to him in all subsequent visitsladmissions. All documents are filed in the same folder. This system is suitable for hospital serving a population of defined catchment area and ordinarily gives repeated care to the patient over a long period. Under the serial system the patient receives a new serial number on each admission and records for each admission are filed separately or brought forward and filed together in the rolder of the most recent admission. Most hospitals begin a new series of numbers at the beginning of each fiscal year with the admission number followed by the year such as 1973-99.
- Medical records so initiated on admission containing patient's admission number and identification **data** are sent to the ward with the patient.
- a The important actions taken by various functionaries at the admitting office are summarised below:

a) **Admitting Office**

- Initiates patient's hospitalisation record
- Assigns admission number.
- Prepares Admission record:
  - i) Admission number
  - ii) Identifying Data
  - iii) Signature of authorisation.
- Sends patient to nursing unit.
- Sends admission record to nursing unit.
- Sends copy of admission record to admission check desk.

b) ***Admission* Check *Desk***

- Receives admission advice from Admitting office.
- Checks patient index for previous admissions.
- Enters this admission on patient index card of previous admissions.

  If no previous admission, make new patient index card.
- Sends index card to incomplete record control desk.
- Sends records of previous admission to nursing unit.
- Prepares record folder with admission record and name and sends it to complete records control desk.
- Makes entries to accession register.

c) **Census** Desk

- Prepares admission list from admitting office.
- Collects discharge patient records from nursing units daily.
- Prepares discharge list.
- Prepares census reports.

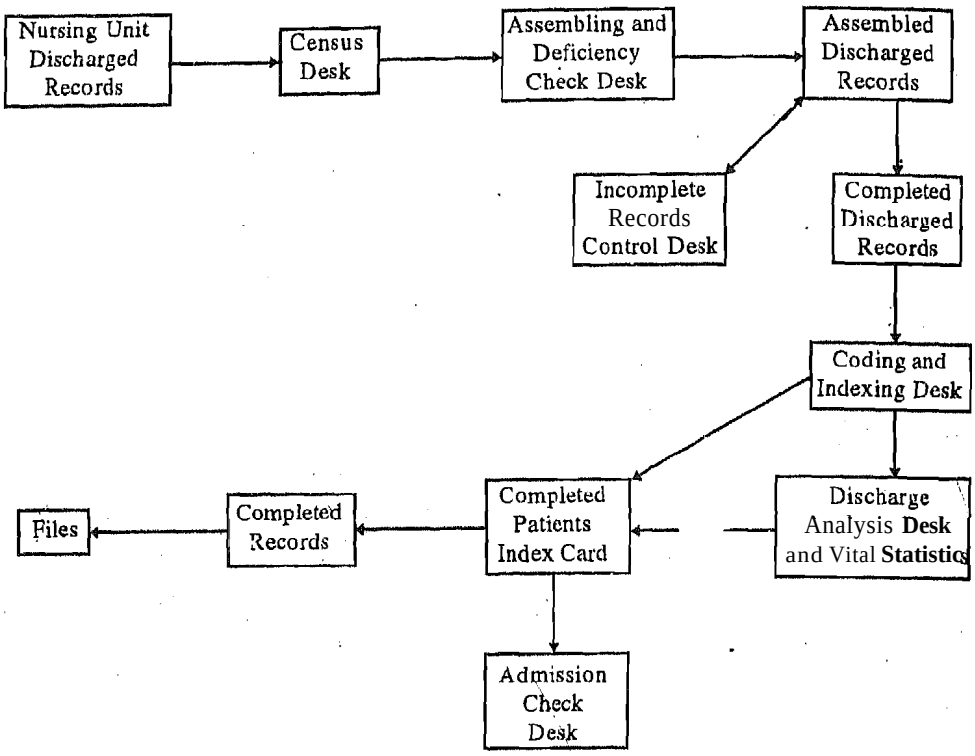
Medical *Records* at the Enpatient **Unit:** The patient document in the ward are filled in by the attending doctors, residents and interns for history, physical examinetion, orders for diet, treatment, operation procedures and progress notes. Nurses fill in the charts for temperature pulse, and respiration.

Medical *Records* Upon Discharge: The attending doctor completes all the entries in the clinical case documents including preparation of discharge summary and discharge slip. Case documents are submitted lo the medical records department. The movement of medical records and action taken upon discharge are depicted in Fig. 2.2. .

At the medical records office action taken by the various functionaries is summarised below:

a) ***Assembling* and deficiency *check* desk:**

- Receives discharge patients record from census desk.
- Assembles records in standard order and staple binds.
- Checks deficient entries on record.
- Sends records to incomplete control desk.



Pig. 2.2: The Chart Showing the Movement of Medical Records upon Discharge of a Patient

b) incomplete record control desk:

- Receives discharge records frcm assembling desk.
- Receives index card from admission check desk.
- Maintains "In hospital" file of index cards of patients not discharged.
- Maintains gone "home file" of index cards of patients discharged but whose records are incomplete.
- Sends reminders to doctors of incomplete records.
- Completes patient index card for discharge patients whose records are complete.
- Sends index card to admission check desk for filling
- Sends records to discharge analysis desk.

c) **Vital statistics desk**

- Collects birth reports, enters data into the birth register and submits reports to municipal authorities.
- Collects death reports, enters data into death register and submits report to the municipal authorities.
- Collects infectious disease reports enters data into the register (If maintained) and submits reports to the municipal authorities.

d) **Discharge analysis and administrative statistics desk**

- Receives records from incomplete records desk.
- Enters discharge date in accession register.
- Analyses and develops statistics and daily, monthly or annual reports for entire hospital, each service, each doctor, as required, on such items as:

  a) Admissions

  b) Discharge

c) Births

d) Deaths

e) Rates

f) Gross results

g) Hospital days

b) Length of stay

i) Occupancy

j) Patient by age, sex, religion and geographic distribution

k) Operations

1) Autopsies

m) Consultants

n) Occupations

o) Others

e) Coding and indexing **desk**

- Receives records from discharge analysis desk.
- Codes diagnosis and operation on medical records, using international classification of disease and operations.
- Enters data into 5x8 inch diagnostic and operation index cards.
- Prepares medical statistics.

f) **Completed records control desk**

- Receives records from coding desk.
- Checks for full processing,
- Places records in folder and stores vertically in peimanent file shelves for quick and easy accessibility.
- Make available records on readmission of patient and for research and group studies.
- Maintains record of withdrawn medical records, sends reminders for return.

Draw a chart showing the movement of Medical Records upon discharge of a patient,?

.....

.....

.....

2.7 CODING AND INDEXING

Coding

In each medical records International Code Number is assigned to the diagnosis based on "International Classification of Disease" issued by the World Health Organisation. This is to bring about accuracy and uniformity in the reporting of the, diseases by the various hospitals.

Indexing

The various forms of indexing as under of the medical records is done depending upon the purpose:

a) **Alphabetic or Master Index:** Indexing basecl on patient's name sequenced in alphabetic order. The primary purpose of a name index is to provide entry into the filing system and finding out medical record for a patient. The patient index card is usually 3"×5" card giving identification data, registration number, address, date of admission, date of discharge, diagnosis and department to which admitted.

b) **Disease index:** Disease index is a catalogue of cards of 3"×5" or 5"×8", maintained to find outgroups of clinical records of patients having the same diagnosis. Besides patient's identification data, age, sex , result of treatment and complication may be also mentioned.

c) **Operation index:** It is a calalogue containing the details of patients who have undergone the operations. Additional details such as site, procedure used, postoperative complication as a result may be documented.

d) **Physician's index:** Catalogue containing the details of all patients treated by particular physicians. Analysis of such records may be utilized for evaluating the performance of a physician. Columns can be made in the card based on the information desired.

e) **Unit index:** Details of all the patients treated in a particular unit are indexed. These records may ultimately be utilized to evaluate the performance of a particular unit.

2.8 STORAGE AND RETRIEVAL

Storage

Completed medical documents are stored in the main medical records by following a filing system. The following factors are considered for an effective filing system:

a) Compactness to reduce physical effort and cost of storage space.

b) Accessibility for speedy location and identification.

c) Simplicity for understanding of all concerned.

d) Economical both in the cost of installation and operation.

e) Elasticity to expand according to future requirement.

f) Tracer system for document in circulation.

System of Filing: Any one of the following can be followed for filing:

a) **Decentralised system:** Under this system inpatient and outpatient department have their own individual records and file them independently within the department. If a patient is transferred from one department to another the file may be loaned to other department. This system is labour intensive and the operating cost are higher.

b) **Centralised system:** In the centralised system, medical records arc filed centrally in the medical records department. The centralised system is more efficient, provides better control and followed in most hospitals.

Methods of Filing: The various methods available are:

a) Numerical method

b) Alphabetical method

c) Chronological order

d) Terminal digit system

e) Mid digit system

Numerical method of filing is the commonest method in use. As already discussed in Section 2.6, each patient is given a unique number at the time of his registration/ admission and the filing is done in the numerical order. This method is most suitable for retrieval of files. The disadvantage of the system is that the files are added to one end of the system, which usually is the furthest from the working area and most active for retrieval and filing purpose.

In alphabetical and chronological order, the filing is done in alphabetical sequence of their names and sequence based on their date of admission respectively. The system requires maintenance of indexes to allow access to the documents as maintained in the libraries.

The terminal digit system consists of six numbers. In case the numbers are less than six digits, zeros are added to precede the number. Terminal two digits are the primary numbers, whereas the two middle digits become the secondary numbers and the last two digits being the sequence number of a particular file. Dividing the storage spaces into 100 equal parts running from 00 to 99 creates the primary section. The primary section is further sub divided in 100 equal parts again running from 00 to 99. To retrieve a particular file say 123456; one should locate primary section 56 and secondary section 34. Thirteenth file is in the secondary section will be the required file. In die middle digit system, the middle two digits are the primary number, the first two digits the secondary number and the last two digits the sequence of file in the secondary section.

Filing Procedure

Types of Files: It is useful Io use files of different colours for different years for easy retrieval and identification. Files should be of uniform standard size depending upon the size of forms in use in a hospital. For the most forms a standard size of 8½"×11" is preferable. The filing jacket should be ½" bigger than the length and width of the biggest form in use.

Filing: The three types of filing procedure are generally used are as under:

i) Vertical

ii) Suspended

iii) Horizontal

The vertical system is universally used in which the file are kept vertically on its spine or edge and supported by the other files or cards within the section. Open storage steel racks with shelves of standard size are suitable for the storage. This system is economical, affords easy reference, adaptability and scope for extension.

In the suspended system especially made filing cabinets are required and the records are suspended from frames in drawers in the cabinet. The system is fairly costly and not easily adaptable but the securily of the documents is better.

In horizontal filing the medical records arc inserted in folders/files which are kept one upon another in a chronological order. The retrieval of records is difficult and storage in orderly manner cannot be maintained. Whenever any record is taken out, it usually upsets the other records.

Microfilming of Medical Records for Storage: In large teaching hospital the space for medical records storage may pose a big problem. Microfilming may be the only answer for inactive storage of medical records. The advantages of microfilming are:

a) **Saving of space: 90%** of the space can be saved if the records are microfilmed.

b) **Easy accessibility:** Due to easy storage in a smaller area, the accessibility of the records to students, faculty and staff become very easy.

c) **Protection:** Micro filmed records cannot be easily tempered.

d) **Elimination of misfiring:** Incorrect filing of the records is impossible after the same has been filmed. They can be easily classified and stored.

e) **Saving of time and manpower:** More economical in the long run because it reduces the waste of time and manpower.

Microfilming requires special equipment such as microfilming camera, processors, viewing machine, duplicating and photostating machine in addition to certain expendable items such as microfilming rolls, fixer and developer. Micro filming technicians will also be required for the purpose.

Computerisation of Medical Records: Technological advances and decreasing cost of computerisation have brought about revolutionary changes in the medical records system, their storage and retrieval. Key to the future is the computerisation of medical records. Today it is possible to even store all types of images such as that of X-ray, CAT Scan and MRI. By networking the system throughout the hospital, it is possible to give desktop access to doctors, nurses, technicians and administrators and yet maintaining the confidentiality of the whole syslem.

Retrieval of the Medical Records: The retrieval of medical records is usually required for any of the following purposes:

a) When the patient attends to follow up

b) Patient is admitted in the ward or casualty for observation.

c) When the files are issued to research workers for academic purposes

d) For medical reimbursement and

e) For producing in the court of law for medico legal purposes.

The method of retrieval will depend upon the system of storage being followed in an institution. In a conventional system where medical records have been stored in shelves, the file is traced by the number allotted. The file folder is taken out and a tracer card is placed in its place as a marker. The tracer card contains basic information regarding the recipient of the document such as the name of the borrower, purpose for which the documents are required, date of issue, identification data of the docuinents issued and the signatures of the individuals issuing and receiving the documents. The tracer card remains in its place until the file is returned.

2.9 REPORTS AND RETURNS

Wide ranging reports and returns can be generated in the medical records department. The basic purpose of these reports are:

a) Evaluating the quality of care being rendered'

b) Locating the deficiencies in:

   i) **Means:** Staff, physical facilities, equipment including plants and machine.

   ii) **Methods:** Operating policies and procedures

   iii) **End results:** Outcome of the benefits derived by the community from the hospital

c) Effectiveness of hospital administration and

d) Prevention of the diseases.

The types of reports and their frequency will vary with the type of hospital and their administrative requirement. The reports may be generated daily, weekly, monthly, quarterly and annually depending upon the requirement. The reports generally pertains to:

a) Vital Statistics

b) ADT Analysis (Admission, Discharge and Transfer Analysis)

c) General Health Statistics

Comprehensive list of such reports and returns cannot be laid out since there will be so much variation from hospital to hospital. Some of the reports that can be commonly generated by the hospital are:

a) **Reports Related to Hospital Bed**

- Daily Census
- Maximum patients on any one day
- Minimum patients on any one day
- Daily average
- Bed occupancy rate
- Total patient days care
- Bed turn over inlerval

b) **Admission**

- Daily admission
- Daily admission unit/speciality wise
- Total admission over a period
- Patients distribution by age, sex, religion and region

c) **Discharges**

- Daily discharges
- Total patients discharged over a period
- Days of care to the patients discharged
- Average length of stay

d) **Deaths**

- Daily number of deaths
- Total deaths over a period
- Total deaths over 48 hours
- Total deaths under 48 hours
- Net death rate
- Gross death rate
- Foetal death rate
- Maternal death rate
- Infant death rate
- Post operative death rate
- Anaesthetic death rate

e) **Work load statistics**

- Total number of outpatients:
  - New cases
  - Repeat cases

- Total number of operations
- Total number of X-ray and other related investigations
- Total number of lab investigations/lab wise investigations
- Department wise workload statistics

f) **Hospital Care Evaluation Statistics**

- Post operative infection rate
- Post operative complication rate
- Caesarian section rate
- Autopsy rate
- Consultation rate
- Rate of normal tissue removed
- Percentage of disagreement between final and pathological diagnosis
- Gross result of treatment, i.e., patients recovered, improved or not relieved

Following will give you clear understanding of some of the most commonly used terms:

Admission

Admission is the acceptance of a patient by the hospital for inpatient service, which may be for investigation and/or treatment. Normal babies born in the hospital are not considered as admissions. The premature or diseased newborns are considered admission, As a general rule the newborn figures are not mixed up with other hospital data. These figures should he tabulated separately.

Discharge

Discharge is the release of an inpatient. Death of an admitted patient is also considered as discharge.

Hospital **Deaths**

Death of an admitted patient is considered as a hospital death. Death of a patient in the casualty, OPD or in an ambulance, before the actual admission of the patient is not counted as the hospital death.

Total deaths of hospitalized patients is known as Gross Deaths. Total deaths after 48 hours of admission is considered net deaths.

Patient Day

A patient day is the period of service rendered to an'inpatient between the census taking hours of two successive days. While counting, the day of discharge of an inpatient is not counted, irrespective of the time of discharge. Similarly the day of the admission is counted always regardless of the time of admission.

Patient day is a valuable unit used fox expressing the various activities of a hospital such as patient days of service rendered during a given period, cost of food per patient per day etc.

Bed Complement

Bed complement is the number of hospital beds normally available for use by the in patient. It includes the following types of beds:

a) Adult beds

b) Crids

c) Bassinets for use of infants other than new borns

d) Incubators for prematures

e) Casualty ward beds

f) Post-operative ward beds

g) Intensive cure unit beds

h) Isolation beds

i) Staff sickness beds

The following types of beds are not included in the bed complement of a hospital:

a) Recovery room beds

b) Observation beds of casualty

c) Examination beds

The methods of calculation of some of the commonly used statistics are given below:

Average Daily Census

Average daily census is the average number of patients in the hospital at a given time per day and is expressed as:

$$\frac{\text{Sum of daily census for a given period}}{\text{Number of calendar days in the period}}$$

Death Rates

a) Gross death rate:

$$\frac{\text{Total number of hospital deaths during a given period} \times 100}{\text{Total discharges (including deaths) during the same period}}$$

b) Net death rate:

$$\frac{\text{Total deaths of in patients after 48 hrs of admission during a given period} \times 100}{\text{Total discharges (including deaths) during the same period}}$$

c) Specific death rate:

$$\frac{\text{Number of net deaths in a ward or department during a given period} \times 100}{\text{Total discharges (including deaths) in that department during the same period}}$$

Net death rate is used as a indicator of quality of care in an institution. In advanced countries the value of this rate is about 4%. In India in the teaching hospitals it is about 6-7%. Similar institutions dealing with more or less the same type of clinical material should show similar death rates. Excessive death rates of the hospital should be investigated.

Percentage of Occupancy or Occupancy Rate

It is the ratio of actual patient days expressed as a percentage of the maximum possible patient days (based on bed complement) during any given period. The formula is:

$$\frac{\text{Number of patient days (based on discharges) during a given period} \times 100}{\text{Bed complement} \times \text{days during the same period}}$$

Average Length of Stay

Average length of stay is the average number of days of service rendered to each discharged patient during the given period of time. Patient days are compiled from the discharge summary of discharged patient, The formula is:

$$\frac{\text{Total patient days during a given period}}{\text{Total discharges (including deaths) during the same period}}$$

Turnover Interval or 'T' Interval

'T' interval is the average period in days a bed remains vacant between one discharge and another admission and is expressed as:

$$\frac{\text{The maximum patient days–Actual patient days (Bed complement x period) during a given period}}{\text{No. of discharges (including deaths) during that period}}$$

The value of 'T' may be negative or positive.

i) A negative 'T' is indicative of scarcity of beds and over utilisation.

ii) A long positive 'T' is indicative of under utilisation because of either defective admission procedures or poor quality medical care.

iii) A short positive 'T' is indicative of optimum utilisation.

'T' interval is a very sensitive index of hospital utilisation. It can also be used to assess the bed utilisation of different nursing units and departments.

Anaesthesia Death Rate

$$\frac{\text{Number of deaths due to anaesthesia x 1000}}{\text{Number of patients anaesthetized during a period}}$$

Post Operative Death Rate

$$\frac{\text{Post operative deaths x 100}}{\text{Total operation during a given period}}$$

The usual value of this rate is 1 to 2%. But it varies greatly with the type of surgery being undertaken in an institution.

Maternal Death Rate

$$\frac{\text{Total deaths of obstetric patients x 100}}{\text{Total discharges (including deaths) of the obstetric wards}}$$

The usual value is less than 0.25%. Excessive rate should be enquired into.

Neo-Natal Death Rate

$$\frac{\text{Total deaths of neo-nate during a given period x 100}}{\text{Total viable newborns discharged (including deaths) during the same period}}$$

A new natal death rate of more than 2% should he investigated.

Autopsy **Rate**

$$\frac{\text{Number of pathological autopsies performed x 100}}{\text{Number of deaths during a period}}$$

An autopsy rate of more than 15 to 20% indicates enquiry type of medical staff, progressive in outlook.

Caesarean Section Rate

$$\frac{\text{Total caesarean section performed x 100}}{\text{Total viable births during a period}}$$

The normal' value of this rate is 3 to 4%. A higher caesatean section rate should be enquired in to.

Consultation Rate

$$\frac{\text{Total written consultation during a period x 100}}{\text{Total discharge (including deaths) during that period,}}$$

A consultation rate of more than 15 to 20% is indicative of high quality of medical care.

Bed-Death Ratio

An extensive study of vital statistics and hospital data of different areas has revealed that a close relationship exists between the deaths in a population and number of hospital beds needed. It has been found that 0.5 general beds are needed per annual death in a population.

In a population having 10 deaths per 1000, 5 beds per 1000 are needed in the acute general hospitals for optimum medical care.

If total number of annual deaths in a regions are 200, ,then this population needs 100 general beds. This formula is used extensively for planning medical care facilities in a region.

2.10 MEDICO LEGAL ASPECTS OF MEDICAL RECORDS

The medical records are not merely a collection of paper recounting the tale of patient's stay in the hospital. It is an important legal document and can help the patient, aid and protect the doctor and act as a big shield to any institution. To meet the legal requirement and avoid complication at a later date, medical records must fulfil the following criteria:

a) **Complete:** The records must contain sufficient data to identify the patient, justify the diagnosis, warrant treatment and outcome. These must contain all basic records, nurses' bedside record and special records as applicable,

b) **Adequate:** The documents should not be sketchy. It must contain all necessary form and all relevant clinical information.

c) **Accurate:** Document should be so made that it is easily subjected to quantitative analysis.

d) **Legible:** The records must be legible which can'be easily deciphered at a later stage. The names of all the signatories must be written in capital letters/affixed with the rubber stamp.

Ownership of the Medical Records

The medical record is the property of the hospital and not of the patient, the clinical department or the attending doctor, The hospital is the owner and the custodian of the document. The patient also has no proprietary right in the medical record, The attending doctor should give the patient desired information. He is also given a brief summary of his condition; the result of various tests and types of treatment carried out in broad terms. Similarly the doctor has no proprietary right over the medical recotd: When he is given access to the record of a patient, it is a courtesy extended by the hospital and not as a matter of right.

The medical records must be considered from two points of view:

a) **As a personal document:** The information contained in the medical record is confidential and privileged and cannot be publicly divulged without the consent of the patient except under due process of law. If a patient is admitted to another hospital, the written information can be forwarded through the administration if requested for. Information with regards to the condition of the patient and the date of admission, discharge, death or birth of child can only be furnished to the friends or relatives.

b) **As impersonal** document: As a impersonal document the contents of the medical record can be used for education, research and information to public health authorities and so on without revealing patient's identification data. However in public health interest some personal information is required to be divulged whenever notification regarding disease is made.

Indian Evidence Act of 1872 as Amended

Medical records are the documentary evidence under tlie act and may be required to be produced by a witness who may be a hospital representative or the treating medical officer in some of the situations discussed below:

a) **In the** court **of law:** The medical document may be summoned by the court in the following types of suits:

The liospital will be required to produce the same as and when asked for.

- Malpractice suits against tlie hospital employee or the hospital itself in the civil court personal injury suits arising out of negligence or fault of others and authorisation for medical examination operation ctc. Medical examination carried out without the consent, expressed or implied will usually amount to action assault. Similarly any surgical intervention or procedure without consent will also tantamount to assault. The facts rendered in the medical document can be invaluable evidence in deciding all such cases.
- Cases in consumers courts.

Medico legal cases in the criminal courts: As soon as the case is declared medico legal, the medical officer is required by law to give a report about injuries to tlie police whether treated outdoors or indoors. In all such cases the hospital cannot be forced to hand over tlie original record to the patient or to the police. They arc however required to be produced in tlie court whenever summoned to do so.

b) **Life Insurance Corporation** of **India: LIC** frequently asks for details of hospitalisation or cause of death of the patient to dispose claim that arises of insurance policy. Release of such information without the prior consent of the patient is permissible because the patient has waived his claim of this privilege at the time of taking a policy by signing a declaration lo this effect.

c) **Income tax:** Under the proviso of section 38(5) of the Act income tax officer can call for the hospitalisation records and the information has to be made available for which no prior permission from the patient is necessary.

d) **Patients** will: If a patient other than in a mental hospital expresses the desire to make a will he is ordinarily allowed to do so. If any questions arise at a subsequent stage regarding tlie mental state of the patient at the time of making the will, hospital medical records may be called for to decide on this point.

e) **Queries regarding birth or death:** Vide Act 18 of Registration of Births and Deaths Act, 1969, all birth and death occurring in the hospital are to be notified to the registrar of births and deaths (Municipal bodies/cantonment Boards), This is done by making certificate to this effect and by making necessary endorsement in the medical documents. Any questions arising to this effect, the hospital may be required to produce the required certificates/documents.

Retention of Medical Records

The factors affecting the retention period of medical records are:

- Need of the patient
- Medico legal requirement
- Education and research requirement

With the applicability of the Consumer Protection Act, it must be borne in the mind that even an innocuous looking case may turn out to be very serious and retention of documents must be done for sufficient long period. As a general guide the documents be retained for the following periods:

a) OPD records : 5 years

b) Indoor records : 10 years

c) Medico legal records : Permanently

Safety of Records

Responsibility of safety of records lies with the administration. Proper records of their movement must be kept during its transit from indoor to medical records department or whenever a document is taken out for education/research. A single person should control all medico legal records of the hospital, perferably medical record officer or any other officer designated by the hospital administrator.

Medico legal record should always be kept in safe custody, i.e. under lock and key. Separate medico legal record movement register should be maintained at the medical records department. Any movement of the medico legal record along with its purpose, should be recorded in the aforesaid register. A responsible person from the medical records department should he detailed to present the medico legal records in the court of law whenever the need arises.

UNIT 3 LINEN AND LAUNDRY SERVICES

Structure

3.0 OBJECTIVES

After going through this unit, you should be able to:

- define the term hospital linen;
- describe the importance, roles and functions of linen and Laundry services;
- list the types of laundry services and categories of linen;
- describe parameters of planning, organisation and staffing of linen and laundry services;
- enumerate the steps of main process of laundry and procedures of washing;
- explain briefly the systems of distribution of linen;
- list the various administrative policies and pr'ocedures; and
- describe linen control and quality assurance programmes;

3.1 INTRODUCTION

Out of all the supportive services in a hospital, linen and laundry are one of the important services. The main objective of this service is to provide adequate quantity

UNIT 3 LINEN AND LAUNDRY SERVICES

Structure

3.0 OBJECTIVES

After going through this unit, you should be able to:

- define the term hospital linen;
- describe the importance, roles and functions of linen and Laundry services;
- list the types of laundry services and categories of linen;
- describe parameters of planning, organisation and staffing of linen and laundry services;
- enumerate the steps of main process of laundry and procedures of washing;
- explain briefly the systems of distribution of linen;
- list the various administrative policies and procedures; and
- describe linen control and quality assurance programmes;

3.1 INTRODUCTION

Out of all the supportive services in a hospital, linen and laundry are one of the important services. The main objective of this service is to provide adequate quantity

of the right quality linen to the indoor patients—the operalion theatres—OPD and other areas and to the medical and para-medical personnel engaged in medical care services provision in hospital. In this unit, you will learn about the planning, organisation and management of this important service. To begin with you will learn about the what constitute good laundry service in a hospital, its importance, and various types of organisation of laundry services. Further you will learn about various planning considerations including physical equipment.

You will also learn about main laundry processes including linen control programme and distribution of linen. Towards the end, you will learn about various administrative problems and procedures including quality management.

3.2 DEFINITION

The word laundry is derived from launderer/laundress--which means washerman or washerwoman. By hospital linen we mean all clothings made of cotton, linen or wool or synthetic fabrics, which are used by the patient or for him. Linens or textiles are composed of certain basic fabrics which are spun into yarn. Yarn inturn is woven into cloth by one or more of the basic weaves.

It is recommended that fabrics used in hospital have certain specific qualities so that it may not affect adversely on the health of patients, medical and para-medical personnel. The linen must have proper moisture repelliency, dry efficiency, surface fluff, strength etc. It should be static safety and must not be of high flammability.

For the hospital linen service, from the administrative point of view, due consideration should be given to the three basic factors i.e. service, quality and economy.

- Service involves frequency of changing patient linen, linen control, distribution procedures and duration of time at the laundry.
- Quality involves the sanitation of linen, its visual appearance and the microbial status.
- Economy involves the consideration of what it actually costs the hospital to provide linen service per patient per day.

3.3 IMPORTANCE, ROLES AND FUNCTIONS

The importance of providing clean linen to the patient can be discussed under the fallowing headings:

i) Cross Infection

Providing of clean linen to the patient, frequent change of linen and its effective washing serve as a well known preventive and hygienic measure in controlling cross infection in hospital.

ii) Patient's Comfort and Satisfaction

A patient not only expects hut demands clean bed and body linen during his stay in the hospital. Supply of adequate clean linen helps in ensuring patients satisfaction. Fabrics, properly chosen, can give comfort, warmth or coolness to the patient.

iii) Aesthetic Aspect

Clean linen in a ward makes it look more cheerful and aesthetically beautiful and pleasant. It pleases the patient and the staff working in the ward. For decorative value specific fabrics may be cboosen.

iv) Human/Public Relation

Clean ward displaying bright, crisp and clean linen makes pleasant impact on all who work or visit in the hospital. The good impression instills confidence in the patients

and the public, and enhances their faith in the medical services rendered by the hospital. Simultaneously, it bespeaks of competence and efficiency of the medical care service.

3.4 TYPES OF LAUNDRY SERVICES

i) **In-plant System**

Here a hospital runs its own laundry. The system can only be justified for very large hospitals and teaching institution as it is very expensive.

In this system, the hospital has its own linen and laundry and all the activities of the hospital laundry service like washing, mending arid replacement are done in the hospital premises.

ii) **Rental System**

In the system hospitals hire laundered linens from rhe contractor. The contractor is also responsible for the replacement as well as laundering of patients and staff linen. The main advantage of Rental Linen Supply System is that the hospital does not have t o spend much for this vital service.

iii) **Contract System**

Here, hospitals own their linen but have no means of laundering. Washing, conditioning and pressing are carried out on contract basis from outside. In some cases, however, a subsidized contract type is prevalent and in such case the hospitals provide water and washing area within the hospital premises.

iv) **Co-operative System**

A single laundry is run on co-operative system to cater for a number of hospitals. This system is very economical. It can ideally be adopted for government hospitals/a group of smaller liospitals.

The centralised laundry tends to be more beneficial for the smaller hospitals than the larger hospitals as many small hospitals share the services of highly qualified laundry managers and most modern machineries and automation. The centralised laundry organisation can maintain standardization of linen for all tlie hospitals and evolve common policies of purchase, supplies and maintenance of linen.

3.5 CATEGORIES OF LINEN IN HOSPITAL

Hospital linen can be classified in the following categories:

1 **Store Linen**

i) Patient linen:

a) Body linen

b) Bed linen

ii) Staff linen: Linen used by the hospital staff such as apron.

iii) Departmentlservicc linen: Linen used by the departments.

2) Laundry Linen

Here, the linen is classified according to the processes it has to undergo for washing.

i) Soiled *Linen*

The linen that has been used by the patient is termed as soiled linen. It undergoes the usual process of collection, washing, conditioning and pressing. To avoid hospital

infection, it has been suggested that sorting of soiled linen should not be done in a ward or operation theatre area. They must immediately be placed in washable bags properly marked or labelled, and must be sent to laundry.

ii) ***Infected Linen***

The linen contaminates by infected material such as pus, blood, body discharges etc. is termed as infected linen. Contaminated/infected linen is collected in polythene bags secured by red ribbon and it is least handled. It goes through the process of sluicing and soakage in disinfectant solution prior to passing through the normal process of washing, conditioning and pressing. Baby napkin is always considered as contaminated linen.

iii) ***Foul Linen***

This type of linen contains faeces, excretions and blood stain. In the past, for this type of linen, hand sluicing was done, by Nursing Orderlies or sweepers.

After sluicing, this type of linen was sent to laundry for washing. Now-a-days, this type of linen is collected from the patient care area in water proof containers and sen to central sluicing plant from where, after sluicing, the linen is sent to laundry for washing.

iv) ***Radio-active*** Linen

Linen contaminated by a radio active inaterial is segregated and monitored with suitable detector. The articles are put into a special washer rcscrved solely for this purpose and when found to be free from detectable radiation'these are sent to the hospital laundry and processed with other linen.

3.6 PLANNING CONSIDERATION

3.6.1 Linen Requirements

Linen requirements are calculated based on operational planning of areas of different activities.

- Fixed areas (OPDs and other departments)
- a Operation Theatre and labour room
- Indoor and private ward etc.

The requirements for fixed areas, OTs and labour rooms are based on the actual performance, whereas, requirements for indoor and private wards are estimated at the rate of 2 to 3.5 kg of dry linen per patient per day, For planning purposes, it is just sufficient for alternate day change of linen.

Ideally a hospital having 100% bed occupancy sliould have six sets linen per patient as given below:

1) One set in patients' bed

2) One set,en-rou te to laundry

3) One set in process in laundry

4) One set ready for use ,

5) Two sets for active storage for work and use in case of emergencies.

2.5 kg/bed/day can be taken as average which is with alternate day change sets of linen will be sufficient.

Replenishment System

Once the numbers of beds and tlie specific quota of linen are fixed, replenishment of linen is made on the basis of the total number of different linen items sent for condemnation.

It is always better to put tlie year and mode of issue. Whatever linen condeinned should be deducted from the perpetual inventory and additional input should be made. This system will provide the figure of total input of linen in tlie course of the year. IS the number of condemnation is very high, it needs immediate investigation.

3.6.2 Mechanised Laundry Service

Mechanised laundry service has already been established as tlie best method for washing of linen. It is not only convenient but safe, dependable and cheaper in comparison to other methods. Due to lack of knowledge, the introduction of mechanised laundry in Indian hospitals is rather poor.

Report of tlie study group on hospitals (Jain Committee) in the year 1968, has recommeiided very clearly that "Mechanised laundry should be adopted as method of washing linen in teaching hospitals." Small hospitals should group together and obtain benefits of mechanised laundry. Even very smaller hospitals should employ domestic washing machine. Rao Committee has again emphasised the need of machanised laundry system.

3.6.3 Physical Facilities

Space and accommodation requirement:

1) Location of Laundry

The location should be convenient to the user units and on tlie ground floor. If possible, the laundry sliould be in the close proximity to CSSD and dietary services due to common requirement of steam from boiler plant.

2) . Floor Area/Space Requirement

It is always better to have space more than what is actually required in view of future expansion. According to Dr. J.R. McGibony, tlie area for laundry for a teaching hospital in India sliould be at least 5800 sq. ft. According to a survey of Delhi hospitals the space requirements is 10 sq. ft. per bed or 10 sq. ft. for 2.5 kg of linen per day. In term of number of beds to the space requirement is cited below:

No. of Beds	Space
200-350 bed	3750 sq. ft.
350-500 bed	4000 sq. ft.
500-650 bed	4500 sq. ft.
>-650 bed	5000 sq. ft.

3) **Physical Layout**

'U' type, 'Rectangular' type or any other form may be adopted as considered suitable keeping in view scientific workflow and availability of space.

4) **Design of functional areas.**

Reception Bay → Sorting Area → Sluice Room → Main Washing Area: washing, hydro extracting, Drying → Ironing Area → Clean Storage Area → Issue Bay

Ancillaries

- Laundry Manager's Office;
- Stores;
- Tailoring Bay;
- Worker's Rest Room;
- Toilet;
- Boiler Room

5) **Material and Decor**

i) Flooring should be smooth, non-slippery, water-impervious.

ii) Walls should have a smooth, washable surface and should bc free from all unnecessary corners, edges or projections, which could become a cleaning and mainteuance problem. Walls should be painted in soothing pastel colours rather than white to reduce glare.

iii) Ceiling should be smooth and washable surface and should be high enough to allow installation and repair of all equipments. The main laundry building should have a clear headroom of 14 ft., and the roof should be built free from dust collecting surfaces.

iv) Doors should be wide enough to admit heavy machinery and trolleys.

6) Ventilation

Recommended air changes are 10/hour. Exhaust Sans should he provided on a liberal scale, so as to provide a comfortable environment throughout (lie year to enhance personal comfort and efficiency of the workers.

7) **Lighting**

Day light should be used whenever possible. Good lighting is an important factor for increasing productivity and quality of work. It should be free from glare and shadows.

8) Power Supply

Usually it is 220 or 440 watts, 3 phase, alternating current, connected to alternative standby generator. The distribution panel must be readily accessible, preferably located near the load centre away from the direct path of escaping steam or vapour. The power requirement are as under:

i) For motorised equipment : 25 kw/h/25 kg, of linen loaded in a drying tumblers

ii) For lighting: 3 Watts per 1/sq. ft. of floor space.

9) Steam

Requirement is 170°C with 100 PSi. Ideal is 178°C at 100 PSi. I-Iowever, specification given by the manufactures of washers and caldering machine must be adhered to.

10) Water

Provision of adequate water supply throughout the day is of great importance. 'For washing every kg of linen, 30 litres of hut water at a temperature of 70°C to 80°C and 10 litres of cold water are required. The hot water supply should be piped to the

laundry directly from the boiler room. For general planning 100 litres of water per bed per day is required for laundry purposes.

If hardness of water exceed 3-4 grains, then water softening plant should also be used, otherwise, scaling of elements will be a constant problem. Linen also acquires yellow hue if washed with hard water.

11) Fire Safety Measures

Provision of fire extinguishers is a must throughout the laundry. workers should be aware of the use of fire extinguishers and must be trained for fire fighting. They should be instructed not to smoke inside the laundry. No electrical equipment should be left on after the working hours.

12) **Toilet, Locker and Shower Facilities**

Enough facilities should be provided so that worker should change their clothes before they start to work and before going home afler work. Facilities to wash and clean theinselves should be provided. Soap, Oil etc. should be made available.

13) **Sewing Room**

The sewing room should be located near the clean linen and pack preparation room so that wrappers, surgical or obstetrical drapers etc. found torn and reparable could'be sorted out, stitched and stored there, so enough space should be provided for the sewing function.

14) **Laundry Manager's ,Office**

This office should be located as centrally as possible so that the manager may properly supervise the entire laundry operalion. The walls should include large vision panel to allow for full view of each area.

3.6.4 Equipment Requirements and Maintenance

Equipment planning must be done based on single eight hour shift per day. As and when expansion of hospital takes place a second eight hour shift can be started doubling the capacity of laundry without adding any equipment. The following type of equipments ace generally required for the mechanised laundry:

The number of equipments required inay be estimated considering the linen load i.e. total weight of linen (in kg, or lb.) to be washed. For practical purposes the following factors—the number of beds; the proportion of superspeciality and surgical beds; cost incurred; space available; number of laundry shifts per day; and capacity of the equipment etc. should be taken into account.

1) Trolleys (Dry linen trolleys—diff capacity 50 and 100 kg., Wash room trolleys—diff capacity 50 and 100 kg)

2) Sluice Machine—(15kg capacity)

3) Boiler(s) (Boilers which generate steam or hot water are required for laundry)

4) Washing Machine(&-50-1 00 kg.

5) Hydro Extractors—50 kg.

6) Drier(s) '(Drying Tumblers)—25-50kg.

7) calendering Machine—(single roller) 80" × 60"

8) Steam Bed Press—(47" x 14" × 9")

9) Electric Irons (Hand Press)

10) Sewing Machine

11) Ironing Table (For using hand presses)

12) Weighing Scales

13) Fire Extinguishers

14) Air cornpressure for calendering machine

The laundry machines are available in different capacities in India from 5 kg to 100 kg. The number of machines and its capacity is calculated on the basis of total quantity of dirty linen to be washed divided by working hours so that linen need to be washed per hour is known and accordingly machines can be purchased, On the basis of 2½ kg linen per bed to be washed the requirement of machines can be calculated.

Maintenance of Equipment

Installation and commissioning should be under close supervision and every stage of it should be inspected and checked properly. Warranty period and after sales service should be well defined. Record of initial cost, operating cost should be recorded and maintained. Availability of spare parts should be ascertained. Various utilisation rates and ratios should be found out periodically. 'Log book' and 'History sheet' of the equipment should be maintained. Breakdown periods and down time for all equipments should be maintained. First level maintenance should be carried out diligently by the user. System of regular and timely repairs either by in-house staff or on 'service contract' should be adopted.

Check Your Progress 2

1) Enumerate 'the sets of Linen required per patient.

.....

.....

.....

2) Fill in the blanks:

a) Acoording to survey of Delhi Hospitals the space requirements is ..... of linen per day.

b) In terms of bed the space requirement for 200 to 350 beds is ..... and for 500 to 650 beds is .....

3.6.5 Organisation and Staffing

Number of Personnel Required

The operator must be trained. He must know how to operate it otherwise even a good machine will yo out of order in no time. It is always better to ask the supplier to train the operators, before the hospitals take charge. It has been found that one dhobi/ laundry operator can handle at least 55–60 kgs of linen or one dhobi for 30 beds.

Apart from laundry operational staff, a manager should be made overall incharge. He must be Diploma holder in machanical engineering with experience to run laundry for 5 years. If laundry is going to function more than one shift, then, every shift must have a supervisor as Incharge of the shift.

i) **Parameters of Staffing**

(e.g. for 500 beded teaching hospital)

1) Linen Load @ 2.5 kg/Bed/Day

= 2.5 x 500 = 1250 kg/Day

2) Staff (Laundry Operator) @ 1 Per 60 kg/Day = 1250/60 = 20 (Excluding Manager)

— Manager 1

— Laundry Supervisor 1

— Laundry store keeper 2

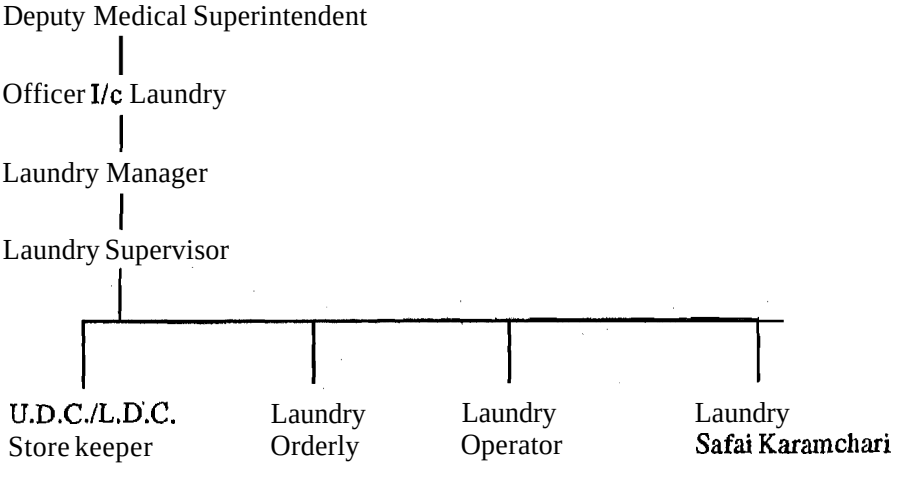
— Laundry orderlies		6
— Tailor/Mender		1
— Safai Karamchari		1
— Washermen/Laundry operator		17
Receipt ← Sorting		2
Sluice		1
Washing Machines	4	
Extractors	2	6
Driers		2
Calendering		4
Steam Press		1
Folding + Storage.		2
Despatch/collection	2 (By Laundry orderlies)	

Other supporting staff

• Boiler Attendant	3
Electrician	2
• Mechanic	1

Note: The supporting staff can be dedicated to the laundry or made available from the pool of engineering services of the hospital.

ii) **Organisational Structure**



Manpower Deployment

Suitable pattern may be adopted for deployment of personnel for the desired shifts i.e. Morning, Evening and Night.

3.7 LAUNDRY PROCESSES

3.7.1 Main Laundry Process

Generally, delivery and collection of linen is made by laundry staff. After receiving the linen in laundry if not infected, soiled or fouled, it is weighed. If it is infected or fouled then it is processed through sluicing machine. In sluicing linen is washed with cold water to remove dirts, vomitus, faecal matters, blood and body fluids deposited on clothes. Dirty linen after weighing undergoes following processes:

- Washing: For optimum removal of dirts from clothes combined action of detergents and mechanical movements of clothes through water is required and applied in mechanical washers.

  Hydroextraction: By process of centrifugation, hydroextractor machine extracts or expells water from damp washed clothes.

- Drying: Drying tumbler agitates the hydroextracted mass of washed linen inside a cylinder so that steam passes through tlie clothes at high temperatures. This results in drying of linen.

- **Calendering/Hot** Ironing, Pressing or Hand Ironing: Flat bed steam press consists of concave, convex presses with tiny holes for passage of steam. Fabrics get pressed by mechanical pressure and steam.

- Mending

  Folding, packing

- Distribution/despatching and collection

3.7.2 Operational Aspects of Washing

It consist of the following procedures:

a) Breaking

This is the first operation of adding soap chips and detergents like washing soda or commercial detergents to high temperature water in the washing machine and allowing the mixture to break and build up suds.

b) **Sudsing**

Soiled linen are thrown in the basket containing the soap suds and machine is operated to agitate there by causing the suspension of dirt. Multiple sudsing of shorl duration alternated by 3 minute rinses is more effective than continuous sudsing or rinsing.

c) Bleaching

Commercial bleaching agents like Tinopal, Chlorine bleach or hydrogen peroxide may be used. Bleaching suds should not exceed 10 minutes duration and the temperalure should not be more than 160°F.

d) **Rinsing**

Rinsing is flushing water through the linen in the machine to remove suspended dirt, detergents or bleaching agents.

e) **Starching**

This is better done after the final washing operation. Light, medium and heavy starching should be consistently and uniformly done to the linen.

f) **Souring**

This is done to neutralise the alkalinity in the wash lo give a good finishing appearance to the linen. By adding a mild acid like boric acid or any fluoride acid in the washing operation, the washed linen is freed of the yellowish colour.

g) Blueing

This should be the last operation. Any commercial blue will serve the purpose.

h) Ironing

Calendering machines, flat work ironers and tiand-presses may be used for this purpose. Normally 70% of washed linen will be for flat iron work, 25% rough dry and 5% press work.

3.7.3 Washing Formula

Washing Formulae

		Cotton white 100 lbs dry weight	Cotton coloured 100 lbs dry weight	Woollen 100 lbs. 100 lbs dry weight
1.	Washing Soap Chips	1.5	1	1.5
2.	Washing soda	1	0.5	–
3.	Bleaching powder	0.5	–	–
4.	Whitener	0.05	–	–
5.	Starch	–	1	–
6.	Temperature	140° F-160° F	150° F	60° F

Note: It should be adjusted to the degree of hardness and softness of the water.

Life of Linen

The life of linen is determined by the following factors:

a) overall availability of sets of linen.

b) Type of laundry system under operation in the hospital. An in-plan1system will ensure a longer life span.

c) Type of the detergent being used for washing purposes and effectiveness of the Linen Control Committee. As per general experience 15-20% of the linen being used in the hospital becomes unusable after a period of 3 months or after 35 washes.

3.8 LINEN DISTRIBUTION SYSTEM

In most of the hospitals, three common types of linen distribution systems are practised:

3.8.1 Centralised Linen Distribution System

In this system, the issue of linen and linen circulation is controlled by a central linen room; which is also responsible for linen replacement, repair and condemnation.

1) Centralised Linen Services

There are four patterns of issue of linen from the central linen room:

i) ***"Clean for Dirty" Exchange System***

In this system, the issue of clean linen is done in place of dirty linen,

ii) ***Topping*** Up ***System***

Under this system, the daily ward stock is calculated on the basis of 24 hours requirement. And this agreed ward stock is replenished every morning by the staff of central linen room.

iii) ***Exchange Trolley System***

To avoid handling by too many people in many of the hospitals in USA, average daily stock of linen is supplied to the concerned hospital area and the linen is replaced by another trolley the next day.

iv) ***Pack Systeni***

In this system, linen packs (full set of required linen for one patient) are prepared in the linen room, and in a trolley these packs are distributed every day to each ward and patient care areas.

2) **Decentralised Linen Services**

Under this system, the various units, wards, operation theatres etc. are allotted with required quotas of linen articles. Washing is done by the laundry. For the purpose of linen exchanges, sister incharge of these areas send the dirty linen to the laundry and from laundry the linen comes back to these areas, after washing. In this system, linen are labelled and are marked, to avoid missing and mixing with that of other areas. Sister Incharges are responsible for storugc and maintenance of linen.

3) **Mixed Linen Service**

In the mixed linen supply system, the special areas e.g. Operation Theatres, Private Wards etc. are given required quality of sufficient linen and they run the linen supply on the basis of decentralisation, whereas rest of the areas follow centralised linen supplies.

3.8.2 Linen Inventories

Regular record of total quantities of clean and dirty linen, daily load, average daily load, and of how many old and new linen are in circulation in hospital, should be maintained.

3.8.3 Maintenance of Linen

Maintenance of linen plays an important role particularly in a hospital. It should be done right from the time of purchase of linen to the condemnation.

Check Your Progress 3

Enumerate the main laundry processes.

.....

.....

.....

3.9 ADMINISTRATIVE POLICIES AND PROCEDURES

Every hospital should have a manual on its Linen and Laundry Services and it should define in clear terms the policies and procedures to hc followed. While developing the manual the following points should be taken into consideration:

1) Collection and Despatch of Line

- Centralised System
- Separation of Soiled and Fouled Linen
- Collection

  Daily: from OT, ICU, CSSD, Labour Room

  Alternate Days: from Wards

  Timings, Routes of Tracrion etc.

2) Policy for Equipment

- ISI Standard Bquipments
- Annual Maintenance Contract

3) Training of Staff

- Proper Handling of Machines

- Fire Safety Precautions
- Optimum Use of Detergent

4) Detergent Stock

Adequate Buffer Stdck

5) Washing Formula

6) Cooperative System

7) Standardization of Linen

8) Quality Control

3.10 LINEN CONTROL

Linen Control Committee must be constituted to oversee the linen control programme. Members of the committee should be chosen from those working in Store, Laundry, Purchase Section, I-Iospital Management of the Institution and having experience of seleclion, purchasing, use and handling of linen.

One of the members of linen committee offer IC laundry must be selected as incharge of Linen Control Programme.

Elements of Linen Control Programme

1) Linen Purchase: Adequate quantity of good quality linen should he purchased and made available in hospital for use.

2) Centralised Control of linen and laundry services generally ensures better control over the laundry workers.

3) Proper locking of stock room and restriction of number of persons having access to them.

4) Proper scaling of containers and bags during transit of linen from one urea to another, and system of receipt at each stage.

5) Fixing of responsibility to staff holding the charge of linen in different areas

6) Constant and positive supervision at all the stages of linen circulation.

7) Regular physical verification to pinpoint the extent and type of loss with proper preventive action hy the administration.

8) Frequent and adequate condemnation of linen articles.

9) Proper maintenance of all the records.

10) Proper security arrangements at the exit of hospital areas. Reduction of exits to a minimum level.

3.11 QUALITY ASSURANCE

Quality assurance programme should be developed, Some of the points to be taken into consideration while developing quality assurance programme in hospital laundry are presented in the form of questionnaire as given here under:

Organisation and Personnel

1) Whetlier the hospital laundry is properly staffed?

2) To whom the laundry manager is responsible aiid whether the organisational hierarchy is proper or not?

3) Proper layout, dressing room and rest room with toilet facilities for laundry employees.

4) Laundry workers—whether trained or not?

5) Working hours per week/per day.

6) Precautionary 'measures to prevent laundry accident.

Physical Plant and Equipment

1) Location of the laundry in relation to the boiler room, steam pressure, source of hot water, electrical capacity.

2) Proper lighting with no glare and glaze.

3) System of ventilation ideal or not.

4) Whether steam is exhausted properly from laundry?

5) Disturbance due to noise and vibrations.

6) Daily work load (lb or kg) and the capacity of the plant.

7) Proper work-flow is maintained or not'?

8) Maintenance system (including preventive maintenance)—by laundry personal/by engineers/by contractor it exists or not.

Linen Handling

1) System of delivering dirty, stained, infected and contaminated linens to the laundry. How is it marked for identification?

2) System of control—accounting for linen sent to the laundry, physical counting when laundry leaves the floors and again when it is sorted. Record keeping is proper or not?

Laundering Process

1) How is linen sorted for wash loads?

2) Normal wash load and the length of time requiring to complete the washing cycle.

3) Test conducted to adjust the washing formula to the actual condition of hardness of water.

4) Steps taken to remove stains.

5) How is the laundering of special fabrics, such as woolens and silks, handled? What precautions are taken to prevent fading of drapes etc.

6) Time taken between the receipt of dirty linen for laundry and stage when they are ready for delivery.

7) At what points are damaged linens detected and mended'? Person responsible for mending.

Linen Control

1) What authority does the laundry manager have in determining the quality and quantity of linen to be purchased? Other departments are consulted before purchase or not. What tests are done for durability before purchase'!

2) What inventory records are kept lor the linen in stores and in circulation?

3) Record to determine the length of service the linen gives. Is the linen marked of the date it is put in service?

4) Total cost of linen replacements per month. What part of this amount is represented by worn and discartled linen and theft? What is the ratio of linen in circulation to the number of beds in the hospital?

5) How is clean linen delivered and by whom, how often?

6) In what areas of this hospital are coloured linens used? Is the laundry responsible for the dying of linen?

7) How often is a physical inventory verification held?

8) What group of hospital employee are furnished uniform? How often are they laundered? What procedure is followed in issuing these uniforms?

Sewing Room

1) Location in relation to laundry.

2) What items are stitched/made in the sewing room?

3) What type of machine is found in the sewing room?

4) What means of marking new linen? At what places of the sheets arc markings placed?

5) Personnel employed and differentiation of their duties.

Costs

1) What is total laundry cost?

2) What is the respective distribution of laundering costs to various user departments?

3) What factors are used in determining laundry costs?

4) Policy of laundering of personal linen of employees. At what charge if personal linen of employees is laundered.

5) Which of the laundry machines are deprecialed. What depreciation schedule is followed?

6) What is the present valuation of the hospital laundry?

3.12 LET US SUM UP

In this unit you have learnt the important roles of linen and laundry services in controlling cross infection, ensuring patients comfort and satisfaction, good public relation, and enhancing elegance/aesthetic look of the wards in hospital.

It-is also learnt that out of various types of laundry services, mechanised laundry service has emerged as the most preferred system of laundry which can render desired service, expected level of sanitation of linen at reasonable cost particularly for bigger hospitals or smaller hospitals that could group together to set up centralised mechanised laundry service.

Jain Committee and Rao Committee of union government emphasised tlie need of mechanised laundry service for hospitals. By proper planning, organisation of Mechanised Laundry Service, and pursuing quality assurance programme, hospital managers/authorities will be able to meet the desired linen need of hospitals.

3.13 ANSWERS TO CHECK YOUR PROGRESS

Check Your 1'1-ogress 1 .

1) Hospital linen means all clothing made of cotton linen, wool or synthetic fabrics which arc used hy the patients or for him.

2) a) In-plant system

   b) Rental system

   c) Contract system

d) Co-operative system

Check Your Progress 2

1) Six sets

i) One set for patient beds

ii) One set en-route to laundry

iii) One set in process in laundry

iv) One set ready for use

v) Two sets for active storage for work and use in emergency.

2) a) 10 sq.ft. per bed or 10 sq.ft. for 2.5 kg.

b) 3750 sq.ft., 4500 sq.ft.

3) i) Trolley, ii) Sluice machine, iii) Boiler(s), iv) Washing machine, v) Hydro extractors, vi) Drier (Drying tumblers), vii) Calendering machine, viii) Steam bed press, ix) Electric Iron (Hand Press), x) Sewing machine, xi) Ironing table, xii) Weighing scales, xiii) Fire Extinguishers, xiv) Air cornpressure for calendering machine.

Chech Your Progress 3

a) Washing

b) Hydroextraction

c) Drying

d) Calendering, hot ironing, pressing or band ironing.

UNIT 4 DIETARY SERVICES

Structure

4.0 OBJECTIVES

After going through this unit, you should be able to:

- understand the functions of dietary services of a hospital;
- outline the planning requirements of such a service;
- explain its organisation and management; and
- identify various management issues.

4.1 INTRODUCTION

In the earlier units of this block you have learnt about various utility services of a hospital inter connected with these, dietary services is another important area which aims at improving the patient care.

In this unit you will learn about the planning and organisation of dietary services of a hospital. To begin with, you will learn about the role and functions of dietary services department in a hospital. Thereafter you will learn about various planning considerations which one need to take into account while developing a dietary services department. Towards, the end you will learn about some of management issues including policies, processes and control mechanisms.

Hospitals these days receive patients of varying nature, with different cultural background, with varied food habits and with different diseases. The clinicians and dieticians have not only to meet the requirements of patients as per their nature of diseases, their nutritional status and to tackle any problems related to underlying pathological conditions. In fact the doctors and the dieticians have to coordinate their activities in the best interest of patient care. Dietary service is one of the most important hospital supportive services contributing to the recovery of health, through scientifically prepared diets, educating the patients attending the hospitals for treatment regarding use and utility of different foods and balanced diets.

Dieticians or the Food Service Managers have to be fully involved during the Planning Process of dietary services of a hospital. Proper Planning and laying down clear cut policies and procedures will enable in smooth functioning of the service and lead to the patient satisfaction and thus better patient care. In day to day management of the

service planning of menu is critical because it affects the work schedule, purchasing plans, equipment use, production and distribution. The main objective of the department should be to provide a balanced diet to the patient as per physician's instructions, properly prepared, distributed in an aesthetic manner and considering his underlying disease condition wherever applicable.

Hospital dietary service is a service which caters to the needs of outpatients regarding diet and food counselling and provision of diet to in-patients as per their requirement considering the nature and type of disease.

4.2 ROLE AND FUNCTIONS

Todays' hospitals are committed not only Io the provision of medical care to the patients but also to the welfare of its employees and needs of the attendants of the patients and their relatives who attend and visit tlie patients. Dietary Department is responsible for the selection of food and other related items and has to have liaison with Purchase Department. Requirements of all items have to he worked out. Some items like vegetables, meat, chicken, etc., have to be purchased daily arid some items like rice, pulses and oil can be purchased at weekly/monthly basis. The items have to be received inspected and verified as per the ordered specifications. These are properly stored and supplies issued per meal everyday. Daily menu planning is done including that of therapeutic diets. The food prepared is then distributed under proper supervision of catering supervisors/dieticians. As such the functions of a hospital dietary services can be grouped under four headings:

1) Inpatient Catering

2) Diet Counselling

3) Commercial Catering

4) Education, Training and Research

1) **Inpatient Catering:** It pertains to provision of meals to the patients admitted in the hospital. It should be a balanced diet providing adequate calories, taking into account the type of underlying illness, any extra nutritional requirements and the general food habits of patients in tlie state. Different types of therapeutic diets is shown as Annexure I.

2) Diet Counselling: This service can he provided as out-patieti1 diet clinics where patients are referred by clinicians to tlie dieticians for calculating their dietary requirements considering the body weight, height, underlying disease, food, habits availability and acceptability of different foods locally depending upon the economic condition of each patient. Patients are usually given a diet chart to be followed by them along with tlie certain foods either to be avoided or to be preferred.

   Admitted patients in the hospitals especially with certain diseases like diabetes, hypertension, heart ailments, anaemias etc. are advised during admission and the time of discharge regarding food intake.

3) Commercial Catering: The service caters to tlie needs of staff members who are on duty in various shifts by way of provision of meals, tea, snacks, cold drinks etc. The service usually takes the shape in the form of staff canteens open from early morning till late evenings and the food provided works out to be cheaper to the employees when compared lo the costs run by private parties. Moreover, the administration can control tlie quality of food services.

   This type of service can be extended ro the attendants/visitors of the patient who are usually desparate to find a good quality of food at a reasonable price and at a convenient place within the hospital. The hospitals can provide this facility in a separale place other than staff canteen and even can have mobile/vending machines in certain locations like OPD, Casualty, Ward Block ctc,

4) Education, Training **and Research:** This forms an integral component of any department. The staff of the hospital like Nurses, Residents, Nursing aids,

Technicians, Cooks etc. could bc educated regarding types of foods, their caloric value, balanced diets clc. Moreover, hospitals having a full fledged dietary service department can have inservice teaching programmes for their staff members and others like diploma in dictitics and therapeutics, diploma in nutrition. Such training programme can be started with collaboration of other departments or institutes depending upon the availability of facilities.

The department on its own or in collaboration with other departments should be involved in research activities on subjects related lo its role and functions.

Check Your Progress 1

List the functions of hospital dietary services.

.....

.....

.....

.....

4.3 PLANNING CONSIDERATION

Inpatient catering is the major activity of the dietary department and proper planning leads to the economy of operation and adds to the efficiency of the service. While planning we have to consider:

1) Location and site.

2) Number of hospital beds and the specialities existing.

3) Numhcr of meals served per day and the type of foods to be served considering the local food habits of the people.

4) Catering to staff members of the hospital and number of employees.

5)' Extension of facilities to attendants of the patient.

6) Centralised vs. decentralised scrvicc.

7) Type of equipment available.

Location and Site: The area should bc located on ground floor, easily accessible to outside roads so that supplies can be carried directly lo the storage area. It should be nearer to the wards and lifts so that less time is utiliscd in carrying the food to different wards. The kitchen has to close to Boiler facility due to requirement of steam in cooking.

Number of Reds and Specialities: This will determine the work load and types of diets to be served, e.g., the requirements of neonates in neonatology ward are different than other palient. Patients admitted in the departments like Cardiology, Endocrinology may have different requirements of therapeutic diets than those in general medicine.

It will also depend upon the type of hospital e.g. a government hospital with only general beds, a government hospital with general and paying wards, a privately owned corporate hospital where patients are chargcd for meals. In a government hospital with general beds where meals are issued without any charges and the budget is limited meals catered for may kc simple without much variety in menu. In a corporate hospital where patients are charged for the scrvicc, menu's can bc elaborate and ala-carte type of meals can be preferred. Even food for each palient can be prepared and packed individually. They will as such need more staff and more space.

Food Habits and Cultural Background: The local food habits of the population Io be served will determine the daily menu in general and thus enables us to plan for equipment and space needed. People in Kashmir ate mainly non-vegetarian and rice eaters. Procurement of bulk rice cookers will be needed. Whereas in Punjab people prefer chappatis and vegetables. Type of dishes will vary from State to State. While

planning we have to consider the food habits, usual timings the food is consumed by the people and their preferences in general.

Catering to the Staff Members and Extension of Facilities: This aspect needs to be considered during planning stage. This will help us in designing the facilities. We may prefer to run staff canteen departmentally so that cost of foods served works out cheaper especially the cost of manpower and equipment etc. may not be calculated by the department while calculating cost of foods as a staff welfare measure. Moreover, the department can run such facilities on "no profit" "no loss" basis. Extension of such facilities to the attendants of the patients whether departmentally or through a contract will help in planning for staff itself. Preference now-a-days is for running such a facility on contract.

Centralised Service Vs. Decentralised Service: Having a centralised service enables effective control, eliminates duplication, helps in maintaining standards and effecting economy in operations. The centralised service should be preferred as far inpatient catering is concerned especially in a large hospital.

Separate service is better for commercial catering as there is a variation in menu and timings and also helps in maintaining accountability,

Type of Equipment Available: Preference should be given to such equipments which reduces inanpower requirements like automatic cookers, vegetable cutters, doughing machines, bread slicing machines, grinders, dish washing machines etc. These help in reducing processing time and ensures reduction in man-handling.

Check Your Progress 2

What are the advantages of centralised dietary services?

.....

.....

4.4 PHYSICAL FACILITIES AND LAYOUT

Space Requirement: Food production is the core activity of the service and the design should follow the function to minimise the labour and reduce space needs. The area and shape of the floor space will influence equip-ment arrangement and work flow patterns.

As per Dr. J.R. McGibony 50 sq ft per bed is required for a 50 beded hospital and 15 sq ft per bed in the 500 beded hospital. In U.K. 8-10 sq ft per bed of space is provided. In Indian conditions 10-15 sq ft of space can be recommended per bed for food production area for inpatient catering.

Location: It should be located on the ground floor, nearer to the service lifts, having easy access with the roads of the hospital for receipt of supplies and should be as far as possible nearer to the inpatient area. It will be preferable that the main hospital kitchen is planned within the service area of the hospital and if the equipment is running on steam boilers, the distance from the location of steam boilers should he less as far as possible, if such a service is centrally placed and feeding to other areas of the hospital especially so in a big hospital. In smaller hospital small steam generators could be used within the patient kitchen itself.

Layout: It has to be arranged in such a manner that different functions are carried out. systematically. Facilities required are:

i) Receipt and storage area

ii) Day Store

iii) Preparation area

iv) Cooking area

v) Service area

vi) Dish washing and pot washing area

vii) Record room

viii) Staff room

ix) Store area for dead stock and unserviceable items.

Receipt and Storage Area: The area should have easy outside access for receiving of supplies, loading, unloading platform with platform scales are needed. Door space should be enough to permit handling of crates. There should be enough space for storage of food items and includes shelves, racks, barrels, drums etc., which are needed to store various items. **Walk-in-refrigerators** are needed for supplies to be kept in reserve for certain food items. 15-20% of total space is needed for these activities. The storage area should be rodent free.

Day Store: In this store supplies for one day's requirement issued from main store are temporarily stocked. We need few bins and 1-2 refrigerators in this area.

Preparation Area: Preliminary preparation of food involves peeling, washing, soaking, cutting, chopping, slicing, mincing, kneading and sorting before being sent for cooking, The area should be located between the storage and the cooking area. It should have all facilities of washing with sinks, drain boards work top tables, peelers, slicers, grinders, mincers etc.

Cooking Area: This area should be located between preparation area and the point of distribution for direct flow and to avoid any criss cross traffic. It should be fitted with cooking ranges, bulk cookers, fat frying equipment, chapati puffers, baking ovens.

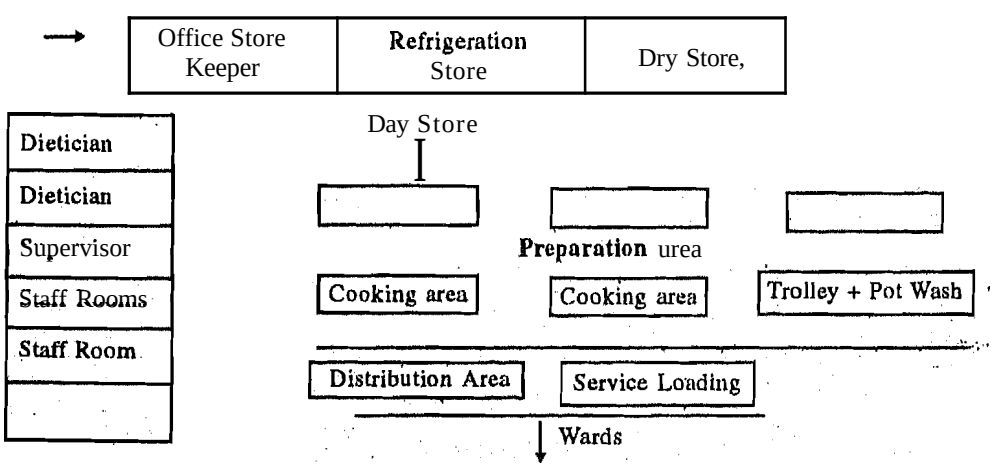
Service Area: This should be adjacent to Lhe cooking area, where the cooked food is put in the different pot and can be carried in food service trolleys which have normally a double jacket in keep the food warm till it is served. For such patients who are on different therapeulic diets and to be prepared for each patient, the food can be arranged in specially designed trays which are also loaded in the Food trolleys.

Dish Washing and Pot/Pan Washing: Adequate facilities need to be provided with proper equipment and hot and cold water. The automatic dish washing machines are also available now-a-days. Area for pot/pan washing should be separate hut adjacent lo each other preferably.

Other Facilities: The area should be properly ventilated and have good lighting arrangement. Adequate number of exhaust fans should be fixed to let out any steam and fumes. In addition we should have L.P.G. cylinder Bank, steam supply and electrical points for utilising different equipments. Flooring with tiles/kota stones for easy washing and cleaning is needed. A seminar room in a large teaching hospitals is needed for training student nurses and dieticians and other staff members.

Adequate space is needed for the offices of Catering Manager, Dieticians and other staff members working in the department. Provision should be made for staff change rooms, lockers for each worker, attached toilets and resl room for staff working there. 'A room is also needed for clerks maintaining different records.

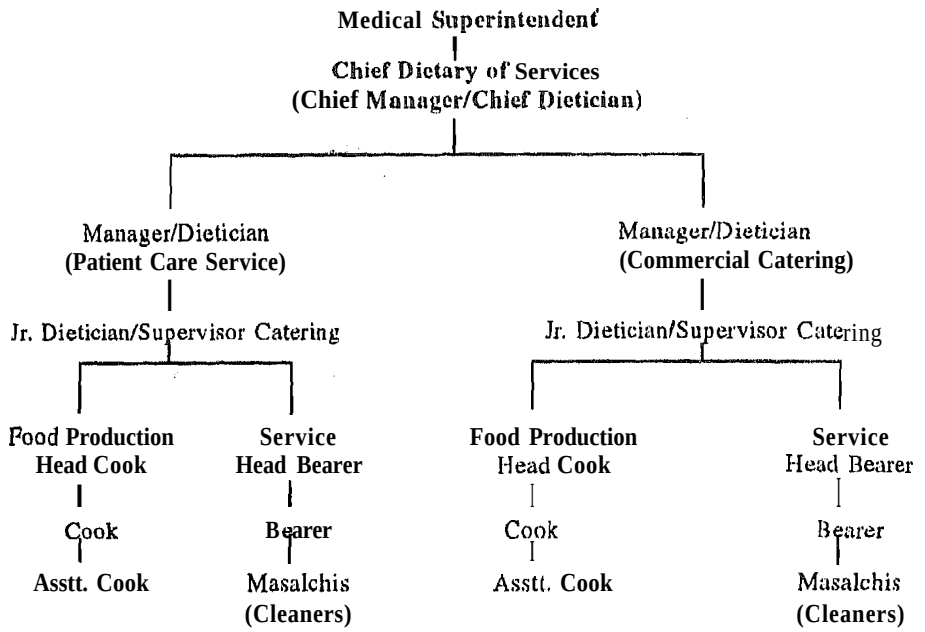
Luyout of a Patient Kitchen



Equipment: Detailed list of equipments is enclosed as Annexure II. The choice depends upon the budgetary provision, facilities to he provided rind the policies of the hospital.

4.5 STAFFING

It may not be possible to generalise the requirement of staff according to the size of the hospital. It will vary from hospital to hospital due to the differences in the type of foods served, physical facilities, equipment, type of service. Following type of organisational structure is recommended for large hospitals of 500 beds and above.



The department should be headed preferably by a person who possess a degree in Hotel Management/Catering, Dietitics and Nutrition and having experience of working in a hospital setting. The other supervisory staff should also be trained and experienced. There should also be at least 2 dieticians for hospital catering so that 1 dietician could supervise therapeutic diets and other normal diets. Number of cooks, bearers will vary, however, as a broad guidelines there should be tit least one number of service personnel (bearers etc.) for every 25-50 mid-day meals served and same numher for food preparation. The hierarchy of workers like Asstt. Cook, Cock, Head Cook has been recommended to allow the promotion of these employees from tlie point of entry. The following estiinates may be considered for staffing for in-patient dietary service:

Category of Employees	Beds						
	50	100	200	300	400	500	750
Chief Dietician	-	-	-	-	-	1	1
Dietician	-	1	1	1	1	1	2
Jr. Dietician	1	1	1	2	2	3	4
Head Cook			1	2	2	3	4
Cook	1	2	3	3	4	4	5
Asstt. Cook	2	4	6	7	8	8	1 0
Read Bearer			1	2	2	3	4
Bearer	2	4	6	7	8	10	15
Masalchis (Cleaners)	2	4	6	8	8	10	15
Total	**8**	**16**	**25**	**32**	**35**	**43**	**60**

Besides these workers, a store keeper, an orderly/porter and secretarial assistance is needed.

4.6 MANAGERIAL ISSUES

The department should be concerned with supply of proper diets at fixed timings maintaining good hygiene. The quality of preparation and cooking of different meals should be strictly monitored. The feed back from the patients/staff to whom the food is served acts as a control mechanism for improving the service. It is important to involve the staff members of the hospital like nurses, doctors, other para-medical workers in decision making like purchasing, inspection of materials; opinion and advice regarding the diets served, fixing of cost of diets for staff etc. Regular feed back from the staff working in wards regarding the diets served to the patients is equally important. The officer incharge should ensure:

1) Regular cleanliness of the food preparation area.

2) Regular maintenance of equipment and proper day to day cleaning of utensils, crockery, cutlery etc.

3) Periodical health check up of staff working in department is essential. This should be done every year. Proper health record of each employee should be main trained.

4) The employees should be given 2-3 sets of uniforms and ensure they wear it.

5) On the Job training of new employees who join the department should he done.

6) Food prepared should be checked by the dieticians before serving.

7) The menu should be displayed.

8) Dieticians and officer incharge should make regular visits towards and enquire from the staff and the patients about any observations in the diets served.

9) Budgetary provisions act as a regulatory mechanism to control costs. Working out food costs regularly (weekly/monthly), helps in guiding the department.

10) Proper maintenance of records in the department regarding materials received, daily issue, number of diets served, etc.

Check Your Progress 3

Fill in the blanks:

a) Total staff required in 500 bedded hospital will he .....

b) Number of cooks required for 300 beds hospital will be .....

4.7 POLICIES AND PROCEDURES

1) The Dieticians/Officer Incharge of the dietary services should be responsible for determining the quantity/quality of food items to be purchased.

2) Dieticians should form part of the team to identify the sources of purchase either spot purchase or on rate contract basis. They should determine the frequency of purchasing different items.

3) The procedures for purchase should be laid down. It will be economical and convenient to have most of the food items on rate contract basis fixed for a year.

4) Powers of emergency purchases whenever required should be delegated to the officer in-charge of the service.

5) The food items received should be inspected by a team comprising of 3-4 members which should include Dietician/Officer in-charge as well. After receipt of goods the stocks should be entered in the stock registers and maintain proper consumption records under the supervision of the controlling officer.

6) The storage bins, racks, cupboards, refrigerators, coolers etc. should be properly maintained and kept clean.

7) Proper sanitation and cleanliness including rodent control measures should be observed.

8) A supervisory staff should be available in the patient kitchen during all the working hours.

9) Work schedule should be planned properly avoiding split shifts as far as possible.

10) Dieticians should visit the wards everyday and have liaison with the staff nurses and the patients.

11) Requisition of different diets from the wards should be signed by the sister in-charge giving the bed number, ward number and the type of diet required by the patient.

12) Nurses should also check and supervise the distribution of meals in the wards.

13) Supplementary requisitions for those patients who are admitted late in the day, should also be entertained by the dietary department.

14) Service timings should be fixed with due regard to the traftic on floor, lifts aiid local food habits of the people in general.

15) Menus should be planned in advance and also displayed everyday on a notice board in the main kitchen. The meals should supply physiological needs and should be appealing and attractive to the patients.

16) Records pertaining to the diets served should be maintained on daily basis and compiled on weekly and monthly basis. Cost analysis of diets should be worked out every week/month.

17) Charges for meals for staff members and visitors should be fixed by a committee involving management and staff members which should be reviewed periodically.

4.8 CONTROL AND EVALUATION MECHANISM

Food service department is a major cost centre and generally labour intensive. The department should be headed by a trained person in dietetics and also hotel management/catering. This enables the department to plan and organise the affairs.

There should be a committee comprising of medical staff, nursing staff, purchase section and officer in-charge dietary service. This committee will facilitate in taking important decisions like fixing of diet scales, purchases, policies, changes in menus, fixing charges and also develop a sort of inter departmental relationship.

Officer in-charge of the dietary services (Dietician/Manager) should be able to organise the staff and its work to achieve the maximum output at the minimum cost without affecting the quality and nutritional value of the meals. Cost controls and effective management rely on the technology of various operating systems and careful resources control strategies.

There should be separate supervisors like Catering supervisor/Jr. Dietician posted for patient kitchen and commercial catering and also available in two shifts as the department has to work for at least in two shifts to cover the breakfast and dinner.

Petty thefts and pilferages are common in the food service department. These mostly involve food dishonestly consumed in the premises, stealing patient food, eating leftover foods and pilfering food items from the stores. The offenders are usually the employees of food service department, housekeeping and maintenance personnel.

Proper inspection and receipt of materials, maintaining stocks, issue of materials under authorisation of dieticians enables a proper control and check pilferage of materials. Moreover, the stores should always be locked and have very limited accessibility to the stores.

Cost control measures include cost analysis of materials consumed, working out unit costs and developing standards by adopting standard costing techniques. With this we

can develop norms and also detect any deviations and take corrective steps. This will also enable budgetary control and fixing charges for commercial catering purposes.

·Daily checking of foods prepared and served, feed back from patients and staff act as a strict control mechanism and also helps in taking corrective measures. Officer in-charge/Dieticians/Supervisors should go around the wards, talk to the patients and discuss the food problems with them.

4.9 LET US SUM UP

A good quality of food service is not only necessary for improvement of health of a patient but also an important aspect for public image of a hospital. Careful planning, proper layout, adequate equipment, efficient menu planning, proper cooking, motivated staff and adequate supportive supervision are essential for a good dietary service. In addition to these following efforts should be made by the management:

i) Proper and timely purchase of food items.

ii) Inspection-of materials received.

iii) Contacting nurses and patient in the wards by the Dieticians/Jr. Dieticians1 Catering Supervisors to get feed back from the patient and ward staff.

On a regular basis the dietary service should be evaluated by undertakings:

- Patient satisfaction surveys
- Food wastage rate
- Variety of menu
- Physical check for usual impact, temperature of food, taste and variety of food
- Method of serving
- Method of transportation
- Remarks of patients in suggestion books
- Kitchen hygiene and sanitation

Therapeutic Nutrition

The normal diet may be modified to:

1) provide change in consistency;
2) increase or decrease the energy value;
3) include greater or lesser amount of one or more nutrients;
4) increase or decrease bulk;
5) provide food bland in flavour;
6) include or exclude specific foods; and
7) modify the intervals of feeding,

Types of Therapeutic Diet

1) **High energy well balanced:** For convalescing patients and those with wasting disease or who are under nourished.
2) **Low energy well balanced:** For patients with obesity, with or without maturity onset diabetes.
3) **Very low protein, low to moderate energy:** For patients with acute glomerulonephritis or with hepatic encephalopathy.
4) **Very low protein moderate energy:** For patients with acute renal failure.
5) **Low protein sodium restricted:** For patients with chronic renal failure.
6) **High protein sodium restricted:** For patients with Nephrotic syndrome or hypoalbuminaemia.
7) **Very low fat high carbohydrate:** For patients with nausea due to hepatic or obstructive jaundice, malabsorption and steatorhoea.
8) **Low sodium low energy** : For patients with severe heart failure.
9) **Reduced saturated fats:** To lower plasma cholesterol.
10) **Gluten Free:** For patients with coeliac disease.
11) **High fibre diet:** For patients with diverticulosis and constipation,
12) **Liquid/Semi-liquid:** For patients with difficulty in chewing or swallowing or who are severely ill with ulcerative or malignant disease or G.I.T. Iract.
13) **Bland soft Diet:** To relieve symptoms in patients with peptic ulcer gastrites and some other gastrointestinal diseases.
14) **Tube Feeds:** For patients with surgery of head and neck, Esophageal obstruction, gastrointestinal surgery, severe burns, comatose patients etc.

UNIT 5 HOUSEKEEPING SERVICES

Structure

5.0 OBJECTIVES

After going through this unit, you should be able to:

- describe briefly the historical perspective;
- understand the importance of housekeeping services;
- know and plan the organisation structure, staffing pattern and training;
- know the equipment and materials requirements;
- learn the correct procedures and techniques of housekeeping;
- list the evaluation parameters of housekeeping services in hospitals; and
- know the parameters to achieve Total Quality Management in housekeeping services.

5.1 INTRODUCTION

In this unit you will learn about what constitutes housekeeping services and its important roles. You will also learn how to plan the staffing, equipment and materials for effective housekeeping. Evaluation of the housekeeping services are also dealt in this unit. As you are all aware that the hospital is not only an institution for the treatment of sick but has many attributes that of a school, hotel, cafetaria, laboratory and also a factory. The patients admitted in the hospital do not get cured only by the medicallnursing care, drugs and surgical procedures. There is a combination of factors which contribute to the healing process. Palatable food, clean linen, a congenial atmosphere and good interpersonal relationships have been recognised to be essential in the recovery of the sick in the hospital, A patient coming to an alien environment of the hospital gets tremendously influenced by its physical and social environment hence, the aesthetics and the cleanliness of the hospital premises have gradually been given more and more importance particularly in modem corporate hospitals.

The housekeeping services has its origin in the hotel industry and has along with the people's expectations of a hygienically clean and zesthetically well maintained room for stay and rest. Later the concept of housekeeping got incorporated as a hospital service also. However, there exists differences in concept and practices between the housekeeping in hospitals and hotels. Whereas a hotel liouses mostly the healthy, a hospital takes care of the sick and the injured. Control and prevention of hospital infection is one of the most vital functions of hospital housekeeping whereas in a hotel the aesthetic's receive the maximum emphasis.

Definition

Housekeeping services in a hospital is entrusted with maintaining a hygienic and clean hospital environment conducive to patient care. The hospital housekeeping services comprises of the activities related to cleanliness, maintenance of hospital environment and good sanitation services for keeping premises free from pollution. Housekeeper literally means "keeper of the house". Hospital housekeeping management may be defined as that branch of general management which deals with cleanliness of the hospital, general environmental hygiene, sanitation and disposal of waste using appropriate methods, equipment and manpower. The housekeeping services can be summarised as **"All the activities directed towards a clean , safe and comfortable environment[9]".**

Check Your Progress 1

1) Houskeeping Services had its origin in:

   a) Hospitals

   b) Hotels

   c) Motels

   d) Business organisations

2) One of the most vital effects of hospital housekeeping is:

   a) Control and prevention of hospital infection

   b) Accreditation of the hospital services

   c) Effective utilisation of hospital resources

   d) Visual cleanliness

5.2 BRIEF HISTORY OF HOUSEKEEPING

As you are all aware that women have been keepers of the house since time immemorial and this has been practiced in all primitive tribes and ancient civilisations.

In the early 19th century Pasteur Fliedner and his wife established a training centre in Germany for deaconess nurses. The schedule of training included cooking, housekeeping, laundry and linen.

In the St. Thomas Hospital in London, the nursing school was headed by Miss Nightingale. All housekeeping activities were done by student nurses. A nurse in training was supposed to scrub floors, learn other essentials of sanitation and nursing care.

In 1910, the first book on Hospital Housekeeping was published which was written by Chartotte A, Aikens. In 1930, the organisation of the National Executive Housekeepers Association was formed in America which was the first professional association of its own kind. It was not until the 20th century that housekeeping began to emerge as a speciality in its own right. I-Iistorically the housekeeping department in the housekeeping activities moved from department under nursing service to a separate department under the direction of an executive housekeeper.

You will appreciate that the housekeeping scrvices arc generally done by the housekeeping staff but nursing services do play an important role including that of supervision in the housekeeping activities of the wards/departments.

Check Your Progress 2

1) The first book on hospital housekeeping was written in 1910 by:

a) Charles Dickcns

b) Edward Earnest

c) E. Woodwards

d) C. A. Aikens

2) The first .Housekeeping Association was formed in 1930. in:

a) USA

b) United Kingdom

c) India

d) kussia

5.3 COMPONENTS OF HOUSEKEEPING

Housekeeping services in a hospital is entrusted with maintaining a hygienic and clean hospital environment conducive to patient care. It is an essential ingredient in the health care delivery system and acts as the 'eyes" and, 'ears', of the hospital.

The hospital housekeeping services comprises of the activities related to cleanliness, maintenance of hospital environment and good sanitation services for keeping premises free from pollution.

Key Responsibilities of the Housekeeping Services

- Clean room Floors. furniture, fixtures, wall, ceilings, curtains, windows and bathrooms
- Disposal of hospital wnstc
- Replace supplies in utility rooms
- Clean nnd maintain housekeeping equipment
- Exterminate bugs and pests

According to Branson and Kennox a housekeepers work may consist of some or all of the following:

a) Cooperation 'with other departments

b) Recruitment, dismissal and welfare of his/her staff

c) Supervision, control and training of his/her staff

d) Compilation of duty rosters and wage sheets

e) Checking the cleanliness of .office and rooms

f) Checking and reporting of all maintenance works

g) Control and supervision of the work of the linen room and possibly the laundry

h) Prevention of fire and other accidents in his/her department

i) Ordering and control of stores in the department

j) Keeping inventories and records of equipments. .

5.4 IMPORTANCE, ROLE AND FUNCTIONS

(The hospital is a complex combination of specialised activities. As each of these activities became increasingly important to the efficient care of the sick, each has merited a special and separate department within the hospital. Together with this departmentalisation there developed greater need for supporting administrative and organisational services. Amongst these, housekeeping activities rank high in importance. Hospital housekeeping is one of the service functions of the modern hospital). It is an activity upon which all the health giving services of the hospital depend. Housekeeping services provide the correct setting in which high standards of patient care take place. Ineffective housekeeping may lead to increase in the infection rate. Tlie aim of the housekeeping department should be to become operationally efficient so as to inspire confidence in the organisation so that the patients, their attendants and visitors feel that they are welcome.

Infections are the most common health hazard associated with poor'hospital waste management which has been magnified with tlie advent of AIDS, I-Iepatitis B virus. Used syringe needles are good reservior of infection and workers in sanitation department may suffer injuries due to improper handling. It is thus essential that housekeeping personnel be educated on proper handling of hospital waste and be provided with protective clothing including masks. Appropriate waste handling and disposal is an essential requisite for safety of workers and prevention of recycling of disposables. Protective clothing, masks, gloves gum boots must be issued to personnel engaged in handling biomedical wastes.

Objectives of Housekeeping Department

- To attain and maintain high standards of cleanliness and general up keep.
- To establish courteous, reliable and congenial atmosphere.
- To train, control and supervise staff under its establishment.
- To attain good relations with other departments.
- To ensure safety and security of all staff under tlic department and to keep superior authorities informed of day to day activities.
- Control and issue of cleaning materials and equipments.
- To maintain official records on staffing, cleaning materials and training.

Functions of Housekeeping Department

You will appreciate that the functions vary according to the lype of hospital, services provided and services expected . They can be generalised as follows:

1) Interior decoration

2) Hospital waste disposal

3) Infection control

4) Pest and rodent control

5) Odour control

6) Environmental hygiene ,

7) Sanitation and hygiene

The housekeeping function is performed in every department of the hospital. The importance of good liousekeeping has grown with the knowledge on prevention and control of hospital infection in which the housekeeping plays a major role. The prevention and control of in ection reduces the average length of stay of patient, reduces pharmaceutical costs, rninimises suffering and maximises utilisation of beds.

According to the American Association Manual on Housekeeping the main function of the housekeeping department is to maintain a clean, healthful surroundings for patients and staff members alike. Housekeeping has a direct effect on the health, comfort and morale of the patients, doctors, visitors and all hospital personnel. A well kept hospital gives the public a feeling of confidence. Amongst the important functions of liousekeeping services is to provide highest degree of efficiency and effectiveness which would ensure patients, attendants and visitors to feel tliat they are welcome and secure in hospital surroundings.

A flow chart of functions of good liousekeeping are shown in Fig. 5.1.

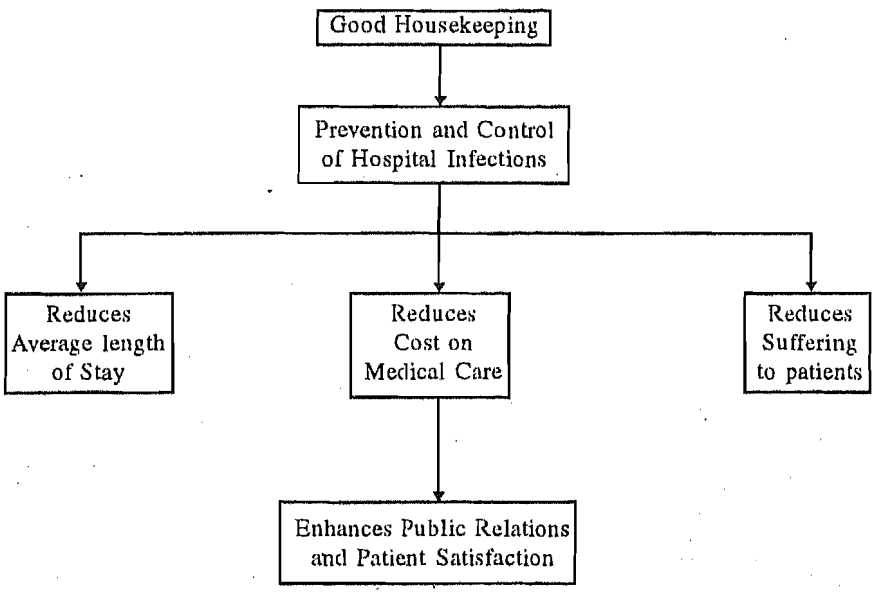

Fig. 5.1: Functions of Good Housekeeping

An appropriate housekeeping service can reduce man hours, reduce costs and raise sanitation levels. L. Broome has summed up the functions of the housekeeping services as "Anything that seriously has to do with housekeeping is of social and economic consequence to every body." In fact liousekeeping is an important variable in the provision of 'Quality Assurance' of hospital care.

Check Your Progress 3

1) A good housekeeping service is an asset which no hospital can afford to neglect. The functions of the liousekeeping department in a hospital include all except:

   a) Mechanised cleaning of floors

   b) Interior decoration

   c) Waste disposal

   d) Provision of sterile linen to operation theatres

2) The housekeeping services include:

   a) Odour control

   b) Infection control

   c) Pest and rodent control

   d) All are correct

5.5 TYPES

There arc two types of housekeeping practices carried out in health care institutions.

1) In-house

2) Out sourcing

In the in-house housekeeping the staff are employed by the health care institutions. Hospital especially the corporate ones are gradually handing over hospital services like housekeeping, building maintenance, information technology support, car parking and security on contract. In such circumstances the hospitals are not giving up responsibility for the services but bringing in expertise and resources to offer alternate solutions for delivery of services.

Out sourcing/contracting out or handing over services on contract has the following advantages:

1) It reduces the work load of the hospital management in that they are absolved of procurement activities for the services e.g. procurement of cleaning agent for housekeeping activities.

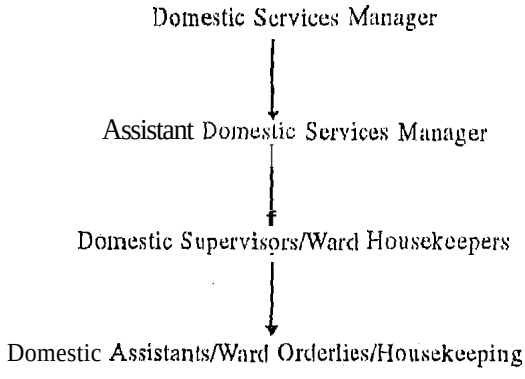
2) Manpower management and its allied activities are the responsibility of the contractor.

3) Since the service is being provided by the specialists in the respective fields, there is enhancement in the quality of services being provided.

4) There may he a resultant reduction in cost if services are contracted out.

5.6 ORGANISATION STRUCTURE, STAFFING AND TRAINING

In the United Kingdom the housekeeping services generally follow the organisation pattern as given below:



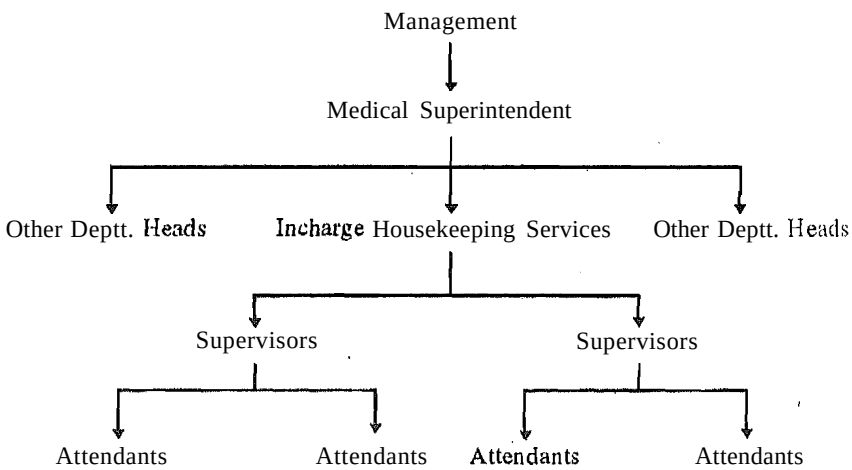
Managerial posts are graded according to a points system which relates floor area as 1 point to 500 square meters.

Designation	Points
Domestic Services Manager	20-100 points
Assistant Domestic Manager	10-20 points
Senior housekeepers	03-10 points

Domestic supervisors are responsible for the direct supervision of the domestic work in the specific area allotted to them. Generally they would supervise 10-20 domestic staff.

Keeping in view the importance of the department, it is essential that the personnel at different levels arc given adequate responsibility and authority. Moreover housekeeping services should not be clubbed with the nursing services. However coordination between those two services is essential for achieving the objectives.

A suggested structure of housekeeping department is shown in Fig. 5.2.



Pig. 5.2: Suggested Organisational Structure

Housekeeping Staff

In this section you will learn the factors determining housekeeping staff; planning modalities and training schedules.

Principal Factors in Determinutionof Housekeeping Staff

- Architectural design and planning
- Areas to be serviced
- Type of service rendered
- Amount of traffic
- Accessibility of work areas
- Type and amount of equipment provided
- Policies of the rnanagement
- Housekeeping staff's knowledge and skill

Manpower Planning

Tlie methods used fox manpower planning generally select one or two (for example from three areas of service like time, activity and patient progress) which influence the staffing and study them in detail. The proposed methods are:

a) Time study

b) Activity study

c) Patient progress sludy

Each of these approaches relies on annual estimates of staff, time available and care provided in all major areas of the services. The annual count of service are also used to supplement the result of these studies to develop a staffingpattern.

Selection of a method will be based on judgement and the selected method in turn depends on feasibility and appropriateness to the actual planning situation.

Different approaches may be grouped under two broad categories:

1) Top down approach

2) Bottom up approach

Top Down Approach

This is a method of strategic planning that relates manpower number to measures of output of activity, often through statistical methods. However, it also extends relation of these to cost and strategic priorities and constraints.

Under these category various methods are studied, which can he grouped as:

1) Simple norms/ratios

2) Statistical formula

3) Point in time establishment approach

Bottom Up Approach

This is a scientific or measurement approach and is usually based on measures of activity analysis, time study, patient dependency and professional judgement. This highlights the professional judgement at the clinical and local management level. Most of these are found suitable for hospital set up.

Work Load

You will appreciate that the allotment of work area to a sanitary, attendant depends upon the degree of cleanliness required, type of hospital, whether it is a closed or an open area, the size of the robin, kinds of drain (open/close). It also depends upon whether the housekeeping attendant is assigned to the intensive care unit, emergency, or a general wards. A sanitary attendant should generally be employed one for 10 hospital beds or for a work area of 1,200 to 1,500 square feet.

For nursing unit one sanitary attendant over 10 beds is recommended on the basis of round the clock services. More sanitary attendants may be required for intensive care units/emergency wards.

Very few hospitals have an adequate number of supervisors. The currently accepted basis for establishing the number of supervisors is one supervisor to a floor or lo a division. It is an inequitable and inconsistent pattern. It is advisable to keep a leave reserve of thirty per cent. Ideally one supervisor for 10 sweepers is recommended.

A great part of the criticism that is directed at the housekeeping department can be traced to the supervisory staff. A closer supervision will also relieve the nursing staff of supervision of all the sanitation duties being done in the ward. The supervisors will be responsible for their area of responsibility on tenns of manpower and materials. They should also be made responsible for carrying on-the-job training for the personnel working under them.

Simply assigning sanitary attendants to a division/ward which is the hospital's per unit of measurement is not a sound or accurate basis for estimating the number of personnel.

As a general rule a maid can clean anywhere from 3000 to 6500 sq ft per day. Experience and research have shown that a minimum and maximum amount of floor area which a mopper can be expecled to cover ranges from 1800 ta 4000 sq ft per man hour.

EL. Gillbert, manager of the London-Liberty in Philadelphia devised a formula which employs "work units" instead of square feet as the basis for assigning cleaning quotas. Through close observation and time studies Mr. Gilbert estimated the time required to perform each task and the amount of coverage in terms of square feet that could be

expected of the worker in daily operations. A point value was assigned to each item e.g. cleaning a chair was assigned a value of one unit, 10 sq. ft. of floor to be cleaned was also allotted one unit.

Some organisations operate cleaning schedules as per the time required to perform each cleaning operation. The most equitable method is a coinbination of work unit and timing plus the wisdom and experience of the housekeeper.

Time Needed for Tasks

The effort should always be made to make a work schedule flexible and adaptable to the hospital. A schedule should not be so rigid that an emergency situation cannot be handled.

As per Silman and Mannhalter following may be taken as standards:

	Time required per 1000 sq. ft.
Dust mopping	6 minutes
Wet mopping	12 minutes
Machine scrubbing	2 hours

It has been found that in general hospitals that when using efficient equipment, methods and management techniques the hours required for normal basic cleaning in ward areas are:

a) 52 hours per week in 30 bedded ward averaging 9.29 M (100 sq. ft.) per bed plus 12 hours per week for heavy cleaning.

b) 100 hours per week in a 30 bedded ward averaging 27.87 m (300 sq. ft.) per bed plus 25 hours per week for heavy cleaning.

Training for Supervisors

Supervisors are the representatives of management who are closest to the workers and they must be fully indoctrined in management principles and policies. The supervisors must possess a working knowledge of human relations in management.

Personnel management is perhaps the most important aspect of the executive housekeeper. No amount of technical knowledge of equipments, cleaning supplies and procedures possessed by the housekeeper will make the hospital more pleasing to look at or more sanitary unless the executive housekeeper is able to transmit this knowledge to the employees who actually do the cleaning jobs. Since the cost of personnel constitutes the main share of housekeeping expenses, the ability to schedule tasks and assess staffing needs determines to a great extent whether the housekeeping expenses are wisely spent.

Training Programme

The training programme should include on the job and class room training. The contents of the class room training should include:

1) Need for training

2) Benefits of training

3) Organisation of housekeeping departincnt

4) Personnel and housekeeping policies

5) Use/care and cost of housekeepiiig equipments

6) Use of housekeeping supplies

7) Correct method of using mops

8) Safety in housekeeping

Training is essential to develop skills and habits necessary to do a good job in the minimum time, with minimum cost and maximum effect. Uniformity of methods in carrying out housekeeping procedures saves time, effort and materials . A higher level of cleanliness in maintained when standards are met. Surface and equipments are preserved when the right kind of cleaner is used on the right item. Accidents are prevented through teaching of safety measures. Better human relations are developed when the workers is encouraged to feel the importance of his job and take pride in his work. Continuous training is needed to repeat and emphasise previous learning.

A well planned training programme in the housekeeping department is beneficial both to the hospital and the personnel of the department. The head of the housekeeping department is generally titled an executive housekeeper. He/She must be a person with intelligence, tact and poise and who has a clear concept of duties.

Most workers in 'the housekeeping department are unskilled at the time of their employment, they have varying educational and social background. It is very important that care and deligence be taken in their selection, orientation, training and supervision. Many of the jobs in the housekeeping department are monoronous and offer little change for substantial promotion yet for these employees job interest must be maintained. Furthermore, recognition and appreciation of accomplishments must be made and employees must be given an opportunity for personal growth and development within the limitations of their job.

A successful housekeeping requires considerably more knowledge than a mere understanding of effective cleaning agents and efficient cleaning procedures. The role and functions of the housekeeping have increased with the overall technological development. The management of housekeeping department in hospitals has advanced rapidly in recent years and requires not only a knowledge of technical skill but also an understanding of tlie tools of management.

The details of the job description and job analysis for housekeeping as recommended by National Council for Education Research and Training (NCERT) are enumerated below:

Job Analysis		
Task	**Knowledge**	**Skill**
A) Sanitation		
1) Supervises sanitation of the hospital environment a) Basic Cleaning — Dusting — Sweeping — Moping — Polishing — Washing	1) Basic principle of sanitation peculiarity to hospital environment 2) Basic principles of personal hygiene 3) Basic knowledge about different detergents and disinfectants 4) Different cleaning procedures applicable to different hospital area	I) Supervise the cleaning operation of cleaners 2) Check the preparation of different detergents *3)* Prepare disinfectant used by cleaners. 4) Check the function order of the equipment and the cleaning operations
2) Basic Cleaning of — different types of floors — walls and ceilings — doors and windows — furnitures and fixtures — venetian blinds	5) Basic knowledge about cleaning equipments — their operation techniques — their maintenance	5) Ensure standards and uniform cleaning operations *6)* Help the workers in learning special cleaning operations

Task	Knowledge	Skill
B. Odour Control		
1) Identity and determine the type and sources of unwanted odours in hospital premises	1) Basic principal of ventilation composition of air, air flow, humidity and temperature	1) Identification of odours in hospital premises
2) Ensure control and removal of bud odour	2) Common types of odour and their source of origin	2) Supervise the preparation of different chemicals and solutions used for removal of odour
	3) Removal and control techniques of different types of odours	3) Supervise and guide the work of cleaners and other staff engaged in odour removal and control nctivities.
		4) Check the equipments and appliances used for odour control/removal operations.
C) Waste Disposal		
1) Supervise hospital waste disposal: — collection — transportation — disposal	1) Hospital Waste — source and generation hazards of hospital waste — to hospital population and community	1) Identify the source of different waste
	2) Principal of collection of different type of hospital wastes and special precautions	2) Ensure correct method of collection, transportation and disposal
	3) Transportation methods of different types of hospital waste from the sources to the place of final disposal	3) Instruct the cleaners to use safety measures against hazards
	4) Basic principles and methods of holding and disposal of solid, liquid, pathological waters	4) Check the working conditions of the waste disposal equipments like incinerators
	5) Final disposal of waste: — sewer disposal — incineration — land filling — other methods of disposal	5) Make arrangement for labelling and segregation of pathological wastes
D) Pest, Rodent and Animal Control		
1) Identify pest and rodent nuisance in hospital	1) Basics of life cycle of pests and rodents	1) Identify pest and rodent nuisance in hospital
2) Organise and supervise the precaution, control and eradication of the pests and rodents	2) Vulnerable areas of pest and rodent nuisance	2) Select methods of control
	3) Diseases transmission by pests and rodents	3) Supervise preparation and use of different pesticides and chemicals for destruction of different types of pests and rodents
	4) Prevention, control and eradication of pests and rodents	4) Organise and supervise control eradication of pests. and rodent?

Task	Knowledge	Skill
E) Hospital Linen Services 1) Procure linen from store 2) Ensure proper storage of linen 3) Maintain linen properly 4) Issue linen in wards/ deptt. 5) Proper accounting 6) Ensure proper sorting of linen	1) Acquire basic knowledge in: — linen and their importance in hospiral — classification of linen — characteristics of linen of different types — sources of fabrics and uses 2) Linen selection, procurement, storage, physical facilities required for linen room: — preparation — mending — security, safety and control — collection of dirty and clean linen — condemnation — replenishment 3) Role of good material management in effective linen services	1) Store linen as per required storage conditions 2) Supervise sluicing and on the spot stain removal 3) Ensure collection, distribution of linen 4) Do correct accounting 5) Send linen for condemnation at right time 6) Ask for replenishment 7) Supervise packing of linen for laundry, autoclaving 8) Apprice hospital authority in case of discrepancies in demand and supply affecting patient care
F) Housekeeping Equipment Management 1) Ensure proper custody operations and maintenance of all hospital housekeeping equipment. a) Basic cleaning — Dusting — Sweeping — Mopping — Polishing — Washing	1) Acquire basic knowledge of the different types of equipment in use — Operational procedures of equipment — Safety measures in operations 2) To have working knowledge in preventive maintenance of the housekeeping equipment which includes: — maintenance scheduling — maintenance processes — fault detection — minor repairs	1) Demonstrate operations of housekeeping equipment to the staff who use them 2) Check safety arrangements during operation of equipment 3) Carry out daily and periodical check-ups 4) Take the equipment in inventory and keep in custodv. 5) Report breakdown to engineering authority.
G) Managerial Task 1) Plan, organise, co-ordinate, control and monitor all housekeeping activities for effective utilisation of resources	1) Principles of management and their application in housekeeping 2) Supervise effective use	I) Estimate and project the requirement of housekeeping 2) Maintain housekeeping record 3) Periodically assess and suggest improvement for better resource utilisation to hospital authority 4) Train and educate the cleaners and other workers under command

Training programme should incorporate the essentials of proper hospital waste handling and disposal. Personnel must be educated on the hazards of improper hospital waste handling. Provisions as enunciated by the Extra Ordinary Gazettee No. 406 dated 27 July 1998 of the Union Ministry of Environment and Forests on Hospital Waste Management should be included in the curriculum.

Check Your Progress 4

1) In general, a sanitary attendant is employed for:

   a) 10 beds

   b) 100 beds

   c) 200 beds

   d) 1250 beds

2) For housekeeping services on supervisor is advocated for:

   a) 10 sanitary attendants

   b) 50 sanitary attendants

   c) 100 sanitary attendants

   d) 200 sanitary attendants

3) A manual mopper is expected to mop:

   a) 1800 to 4000 sq.ft. per hour

   b) 4000 to 5000 sq.ft. per hour

   c) 5000 to 7000 sq.ft. per hour

   d) 7000 to 10000 sq.ft. per hour

5.7 CLEANING AGENTS

Cleaning agents are perhaps the most critical aids to housekeeping staff. The essentials of cleaning process is to remove dust and grit. While normal dusting with a cloth or vacuum cleaner removes dusts in its loose particle state, cleaning agents would be required when dust becomes grit and is stubborn to remove.

Some of the common agents used these days are:

Water is probably the most common and widely used agent as it is freely available. Warm water dissolves soap more readily than cold water, hence it must be used to remove dirty soap lather. Caution musl be taken that the water is 'soft' as no detergent is effective in hard water. Moreover, hard water does not wet the surface well which is a precondition for good cleaning action, While in modem days we have one or two multi-purpose cleaning agents it is useful to know some traditional liquid cleaning agents. Liquid cleaning agents can be either agents diluted in a little water or used directly with a dry cloth.

- Ammonia is an alkali which softens water and emulsifies grease.
- Methylated spirits are effective against grease stains.
- Paraffin is also a grease solvent.
- Turpentine is a grease and pain1 solvent.
- Vinegar is a mild acid unaffected by hard water and useful in removing light bath stains,
- Hydrochloric acid is useful in removing stubborn stains in bathrooms but care must be taken in its use as it is damaging to the skin and destroys fabrics and light bathroom fittings

- Carbon tetrachloride is also an excellent grease solvent. Care must be exercised there, too as its fumes are harmful.

Washing Soda: This agent is vastly outdated due to the advent of modern domestic detergents. However, it is particularly useful for emulsifying grease on drain pipes, gutters or stone surfaces. In a strong concentration it could be injurious to skin, fabrics, brushes, wood and paint. Washing soda is useful as a water softener.

Soda-bars: Soaps have now been replaced by excellent synthetic soapless detergents which are unaffected by hard water, In these cases rinsing is not important as these product suspend dirt and grit most effectively without leaving a smear. However, some housekeepers may not have access to these detergents and may have to rely on soaps.

Powders **and Flakes:** Powders and flakes are useful in getting instant lather but are expensive. When used, care should be taken that they are thoroughly dissolved. Being expensive, one shoyld know exactly how much powder or flake is dissolved to get an optimum benefit as also how long the resultant solution is effective. Good bar soaps are still most economical but much more strenuous than modern methodologies. They should be stored on open shelves in a dry store.

Abrasives: As they could themselves leave scratches on surfaces, their use is limited to removal of very stubborn stains on various surfaces.

- Silver sand, steel wool, glass paper may be used for removing stains on plain wood, stone or cement floors.
- Emery paper is suitable fur removing rust from steel,
- Pumice powder is used for removing stains from skins and bath tubs.
- Whitening scourers are mild abrasive for cleaning white paint.
- Nylon scourers are made today lo have an abrasive effect and yet prove less damaging to surfaces.

Polishes: Polishes fall into three types—liquid polishes, pastes, and creams. These are either spirit, oil or water based.

Spirit based: Used for metal mirrors, window panes aud bakelitc.

Oil based: Used for stained, wax polished or painted wood, linoleum and synthetic floorings with an oil or resinous base, cork or wood waste, leather and leather substitutes enamelled and lacquered metals.

Water based: Used on sealed floors, thermoplastic floors and rubber flooring. There are some basic principles applied in using polishes. They are as follows:

1) Polishes should be used only after dirt and dust on surfaces are thoroughly removed,

2) Polish must be used in small quantities as excessive polish could smear surfaces.

3) Polish should be rubbed off thoroughly as surfaces could then become sticky or greasy and thus show finger marks when touched.

4) Surfaces provided with permanent or semi-permanent polish sheens must he polished very carefully as the original sheen could be destroyed. Examples are:

   a) Wax polish must not be applied to French polished surfaces.

   b) Wax polish must not be applied to a floor treated with a shellac dressing (which is a semi-permanent polish).

   c) Metal polish must not be applied to chromium-plated or lacquered metals,

5) Polishes are expensive, therefore lhey must be stored correctly and controlled in use,

6) Palishing of floors is more economically done by polishing machines.

Selection of Cleaning Agents: General Principles

- Use mild rather than strong agents as they are less injurious to surfaces.
- Quality of products is also important. There are cheap substitutes that might show immediate results but on the long run may damage surfaces as they are likely to contain strong chemicals and abrasives.
- Buy polishes in manageable containers which are utilised within one or two sittings. The container must have reliable lids, corks, etc. as defective ones could result in wastage due to evaporation and drying.
- Multi-purpose polishes could save managing many types of polishes which requires more supervision.
- Strong smelling agents (e.g. paraffin) must be avoided due to the offensive smells they lend to the environment.
- Dust being composed of loose particles is comparatively easily removed dirt, however, owing to its adhering to surfaces by means of grease or moisture requires the use of cleaning agents as well as equipment.

Detergents are cleaning agents which when used in conjunction with water can loosen and remove dirt and then hold it in suspension so that the dirt is not re-deposited on the clean surface. There are three basic properties which the detergents have:

a) Wetting power to lower the surface tension of water and enable the surface of the article to be thoroughly wetted.

b) Emulsifying power to break up the grease and enable the soiling to be loosened.

c) Suspending power to prevent re-deposition of the soiling.

Disinfectants are often misused and rationalization of their use in hospitals is desirable for control both of infection and costs. Infections may be caused by micro-organisms which contaminate disinfectants during use especially when objects such as mops are stored in disinfectants. Unnecessary use of disinfectants is not only wasteful but may increase the microbiological hazard of the hospital environment.

Soap is cheap and effective but in hard water it does not lather readily. Soap is not effective in acid solution. At present synthetic (soap less) detergents are also in use. Toilet cleansers are crystalline powdered or liquid and they rely on their acid content. Powdered toilet cleansers consist of a soluble acidic power, bleach, finely ground abrasive to help when a brush is used and an effervescing substance which helps to spread the active ingredient throughout the water.

Window cleansers in use are a mixure of isopropyl alcohol detergent and alkali. A mixture of water and methylated spirit may also be used.

Criteria for a Good Disinfectant Cleaner

- Has good bacteriocidal properties and a wide micro-biological spectrum
- Has good cleaning properties
- Must not be highly toxic or irritating to the users
- Has some degree of odour control (not simply mask control)
- Must not be corrosive to floor.

5.8 BASIC CLEANING OPERATIONS

Dusting

Dusting is a cleaning operation to remove dirt. More specifically, it entails removing dust. The stress is on removing dust, not moving it to another place or stirring it up. The dusting technique is customarily used on furniture, equipment, ledges, window sills, woodwork and panels. Low dusting is dusting of all places easily reached by standing on the floor; it should be done at least daily to maintain a thorough and complete standard of cleanliness. High dusting refers to those areas over windows, doors, overhead pipes, walls and ceilings, and is done periodically as needed.

Two types of dusters are utilised:

1) **Treated clusters: A** treated duster is soft lint-free cloth (usually sugar—liner or flannel) treated with a small amount of oil. Treated duster are used for most dusting operations because they hold more dust and do not permit it to be scattered about the room.

   Damp duster: A damp duster is a clean piece of cloth moistened with water and wrung out dry. Damp dusters are used to dust mirrors, window shields, door glass and most other glass surfaces with the exception of windows.

Procedure

Let us examine the scientific procedure of dusting:

1) Fold cloth in series of squares. (This permits many clean surfaces.) A surface cannot be cleaned with a soiled cloth, and a cloth carelessly wadded provides insufficient clean areas.

2) To dust rootn, commence at entrance and proceed around room.

3) To prevent overlapping of strokes and skipping corners and edges, use long straight strokes. Hold cloth loosely so that it will absorb dust easily. Avoid flicking dust cloth since this action raises dust.

4) Start with highest point to be dusted and work down towards the floor.

5) Two cloths—one in each hand—may be used to save lime.

6) Inspect work. A properly dusted area will be bright and will appear clean. It will bc free of dust streaks, oily spots and smudges.

Sweeping

Sweeping is a cleansing operation to remove dirt from a floor area. It normally entails the use of a brush or a broom. This process is used on rough surfaces; a sweeping mop is employed on smooth surfaces. Sweeping should precede other cleaning operations, such as mopping or waxing. The frequency or sweeping depends upon the amount of traffic and type of surface of the area, The size of the brush and the type of sweeping stroke to be used will be determined by the size of the area and the amount of furniture or equipment in il.

Equipment

1) **Floor brush: A** wide one to sweep unobstructed areas or a narrow one to sweep obstructed areas.

2) **Sweeping mop:** To determine the most efficient size, the handle should reach the eyebrow of worker when the block is resting on floor.

In areas where there is lighl dust on a smooth surface, dusl mopping may be substituted of sweeping with a broom. Where there is a heavy amount of surface dirt, dust mopping may supplement sweeping.

Special Considerations in Sweeping Process

1) In unobstructed floor area where relatively large amount of small dirt particles accumulate, the 60-inch stroke is most efficient.

2) If dirt consists of small particles, the 3-foot push stroke is recommended. The brush may be tapped on the floor to clear it of dirt at the end of each stroke.

3) .If the outer edges of an area are particularly dirty, sweep dirt away from wall to about a foot before continuing general sweeping. Use counter brush in corners.

4) If dirt consists mainly of large particles and fine soil and if area is unobstructed, the continuous stroke may be used.

5) If area is busy thoroughfare, one side should be swept while traffic is directed to the other.

Mopping

Mopping is a cleaning operation lo rub or wipe a floor area. It entails the use of a special cleaning tool known as a mop. While mopping can be done with a dry mop, as suggested under sweeping the process usually is done with a solution. For mopping an area which is not too soiled, clear water may hc used with success. However, where there is much dirt, a cleaning solution is often necessary. It is important to know the type of surface to be cleaned since too much water may harm wood floor coverings. In order to ensure a good mopping job, mops and solutions must he clean.

Procedure

1) Fill one container two-third lull with cleaning solution. If bucket is not on cart, place on mat, tic cloth around bucket, or place on a little spilled water to avoid staining lloor.

2) .Fill second container two-third with clear warm water.

3) Sweep floor first if necessary, moving furniture to simplify operation.

4) Dip one mop into cleaning solution and wring slightly to prevent dripping.

53 At beginning of stroke, stand with feet well apart. Place mop flat on floor about 4 feet to left side. Handle at 40 degree angle. Pull mop along edge of floor next to basehoard to depth of 6 to 8 inches. This prevents splashing baseboard.

6) Take position. Move mop to right in arc-like stroke, in front of body, parallel to baseboard to avoid splashing wall. Mop stroke should he spread out for maximum coverage.

7) At end of 6 to 9 foot stroke, renew direction by lapping mop and swinging it from right to left. By developing rhythm, no time is lost in change of direction. (Ry push-pull method one-third more time is consumed. Worker is in awkward position, causing him to become tired and limiting him to lour-foot stroke.) Width of stroke depends on height and weight of worker.. Mopper works backward, continues figure "8" in front of him until mop is ready lor second dipping (after ahou t 120 square feet)

8) Dip second mop in container of clean water, wring out and rinse floor.

9) Dip the second mop again into water rinse, wring it thoroughly and dry floor using side to side stroke.

10) Continue the three steps of mopping, rinsing and drying until the area has been covered. To avoid streaks, overlap strokes.

11) Wipe off baseboards immediately with a damp cloth if any water has been splashed.

12) Change solution and water frequently.

13) Inspect work. A properly mopped floor should have a clean surface. There should be no water spots. The corners should bc clean.

14) After mopping is completed, clean mops and buckets.

Scrubbing

Scrubbing is an operation to remove dirt by rubbing and scouring while it is similar to mopping, more water is used and a brush, hand or electric, is employed to scour the surface. Electric floor machine have a disc brush attachment for scrubbing. Some also have special containers which automatically discharge the solution to the floor during the cleaning operation. Suction equipment is also available for removal of solution from the floor.

Procedure

1) Sweep floor if necessary.

2) Dampen area to be scrubbed (as described under mopping)

3) Sprinkle cleanser lightly over area which has been dampened, if necessary.

4) With scrub brush or scrubbing machine, scrub area with back and forth motion. Machine scrubs in circular movements. Start in corner of room and work towards door.

5) For particularly soiled area, use steel wool by hand or under brush.

6) Remove dirty solution with squeegees mop or vacuum. Never put soiled solution in clean container.

7) Dip second mop into container of clear water, wring out, and rinse floor with' side to side motion to avoid streaks, overlap strokes.

8) Continue wetting, scrubbing, picking up soiled solution and rinsing until area has been covered.

9) Change solution and water frequently.

10) Inspect your work a properly scrubbed floor has no soiled spots, is not streaked, and has no water spots remaining on it.

11) After scrubbing is completed, clean equipment as directed and return them to proper place.

Washing

Washing is an operation to remove soil by use of water; a cleaning agent is usually employed in this process. The technique includes removing loose dirt, washing, rinsing, and drying. The operation is used to clean furniture, fixtures, woodwork, equipment, and walls. It should be done at least once a week and more frequently if the state of cleanliness desires.

Equipment

1) Three cleaning cloths or sponges

2) Two containers

3) Cleanser

4) Ladder and scaffolding for high places

Procedure

1) Fill one container two-third full with cleaning solution.

2) Fill second container two-third full with warm water.

3) Wipe away loose dirt in area with dry, clean cloth.

4) Dip cloth or sponge into cleaning solution. Wring cloth or squeeze sponge to prevent dripping.

5) Wash small area with circular motion.

6) Dip second cloth or sponge into clear water, remove excess water, rinse-wash area with up-and-down motion.

7) Dip cloth or sponge, rinse same area with side-to-side motion.

8) Dry with third dry cloth.

9) Continue washing, rinsing and drying over entire area; overlap strokes to prevent streaking.

10) Use ladder or scaffold to wash high places or fixtures.

11) Change water frequently.

12) Inspect work. A properly washed area should be uniformly clean with no streaks; no water spilled on the floor or other furnishings.

13) Clean equipment as directed and return to proper place.

Automated Equipment: With automation being introduced in almost all areas of health care institutions, the housekeeping services arc no exception. The equipment includes vacuum cleaners, wall washing machines, floor washing and polishing machines. It is essential that the personnel utilizing these machines should he well versed with the operational methodology and maintenance. Steps should also be taken to carry out preventive and breakdown maintenance as and when required . The equipment should be brought from reliable manufacturers/suppliers and an Annual Maintenance Contract (AMC) be done for maintaining functionality of the equipment.

5.9 COSTING OF HOUSEKEEPING SERVICES

In costing in hospitals the housekeeping services are often clubbed either with the administrative cost head of the general store or the utility head. It is essential that unit costing should consider housekeeping as a separate head so that planning, budgeting and control of housekeeping activities is scientifically done.

As per McGibony the cost on housekeeping services in hospitals amounts to 3% of the total cost.

The main cost incurred in housekeeping centre is the salaries of the staff employed. The other being cost of the materials like soap, detergents etc. used for cleaning and the depreciation of the equipment used/utilised. Labour costs constitute 90-95 % of the total housekeeping services costs,

There are two alternatives for apportioning the costs of this centre among the various centres in the hospital. Such costs can be apportioned on the basis of the square foot area of each cost centre since greater the floor area greater is the time required and more are the resources consumed in cleaning. Alternatively, the costs could he apportioned in the ratio of the number of staff of the housekeeping department deputed lo work in each cost centre.

When the apportionment is done on the basis of floor area covered, it has Lo be borne in mind that the costs incurred will depend not only on the area covered by the centre but also on the importance attached Lo it e.g. the private wards catering to the VIPs might have a disproportionately higher number of sanitation staff deputed to it.

The main potential cost savings in the housekeeping department are:

a) Scheduling work

b) Avoiding pil erage and wastage in cleaning materials

c) Mechanised cleaning

Cleaning and Portering

There is evidence through work study and costing investigations carried out in a number of hospitals that there is scope for considerable improvement in minimising the cost of the cleaning and housekeeping service in some hospitals and a unit cost should help towards obtaining it. Costing should normally be done as follows:

For wards — per bed

Other parts of the hospital — per 10 square metres.

In a study at AIIMS, a 1560 bedded hospital costing of housekeeping services assessed was as follows:

a)	General store items related to housekeeping	Rs. 1.22 (per bed/day)
b)	Disinfectants	Rs. 1.29 -do-
c)	Cleaning materials	Rs. 2.24 -do-
d)	Insecticides	Rs. 2.37 -do-
	Total =	Rs. 7.12 (per bed/day)

The proportion of the cost of sanitation services per bed per day was a follows:

Manpower	86.01%
Equipment	0.16%
Materials	13.83%

It was observed that the cost of manpower and materials accounted for 86.01% and 13.83% respectively of the sanitation services. These figures were at variance with the figures which arc quoted for developed countries i.e. 95% and 5% for manpower and materials respectively.

The above variation are expected since the methods employed, cost of manpower, level, type and quantum of cleanliness and its related procedures differ in the different institutions in the various parts/countries in the world.

Check Your Progress 6

The highest cost in housekeeping services is incurred on

a) Labour

b) Cleaning Materials

c) Germicidals

d) Equipments

5.10 CONTROL, EVALUATION AND QUALITY ASSURANCE

The housekeeping department probably is the most under rated of all the hospital service departments. Many hospitals now realise that in addition to quality of care, the factors that consumers consider in choosing a hospital are location and appenranccs. It is essential that quality house keeping services are ensured.

As you are well aware that different people view quality differently. In the hospital setting the patients are the customers. Quality is based not only on patients perception (a function of their attitudes based on culture and experience) but also on the accurate synthesis of medical observations.

The relation between quality and cost though capable of breeding endless complexity is also simple in its fundamentals:

1) Quality costs money

2) Money does not necessarily buy quality

3) Some improvements in quality are not worth the added cost.

Indicators for Quality Assurance *in* Housekeeping Services

- Time taken to clean patient room

- Inspection
- Compliance with infection control and safety procedures
- No. of times repeat cleaning is required
- Time elapsed between request and performance of service
- Patient satisfaction
- Compliance with health standards.

The Indian I-Iospital Association in their Quality Assurance Programme (QAP) have listed the following as indicators of quality in housekeeping services.

1) Degree of automation
2) Number of staff
3) Training programme for housekeeping staff
4) Team spirit amongst staff
5) Are checks on effectiveness of disinfectants carried out?
6) Availability of incinerator

However, the most comprehensive quality indicators in housekeeping services have been given by Brown and Johnson in the American College of Hospital Administration Text-Colleges Visualised. The salient features of these are enumerated below:

Organisation

What is tlie organisational structure and the line of authority of the housekeeping department?

Functions

1) Does the hospital use strong deoderisers to cover up odours? What is the remedy for the hospital smell?
2) How dose the housekeeper ensure the right kind of cleaner on various floors?
3) What specific measures are taken for pest control ?

Personnel

1) What personnel policies are written for workers within the nousekeeping department?
2) Are manual dexterity and adaptibility tests utilised in the recruitment of new personnel?
3) Have job standards been established for the housekeeping staff?

Equipment and Methods

1) What type of soap or detergents are used on various surfaces?
2) What equipments are in use in the housekeeping department?

Interior Decoration

How does the housekeeper attempt to make the liospital appear friendly, warm and cheerful?

Planning

1) When tlie hospital was built was it planned with regard to the problems of cleaning and maintenance?
2) Is the hospital planned so that the housekeeping department could have adequate storage and work space if tlie hospital is enlarged?

Interdepartmental **Relationships**

1) What is the functional division of labour between the nursing service and housekeeping department?

2) How and to whom is the communication done to clean the room when vacancy occurs?

Administrative Control

1) What are the reports sent to the administration by the housekeeper incharge?

2) Is an inventory of furniture and equipment maintained?

Level of Cleaning

Roemer and Anguilar have classified the level of cleaning into three categories, namely, Level-I, Level-11 and Level-111. They are:

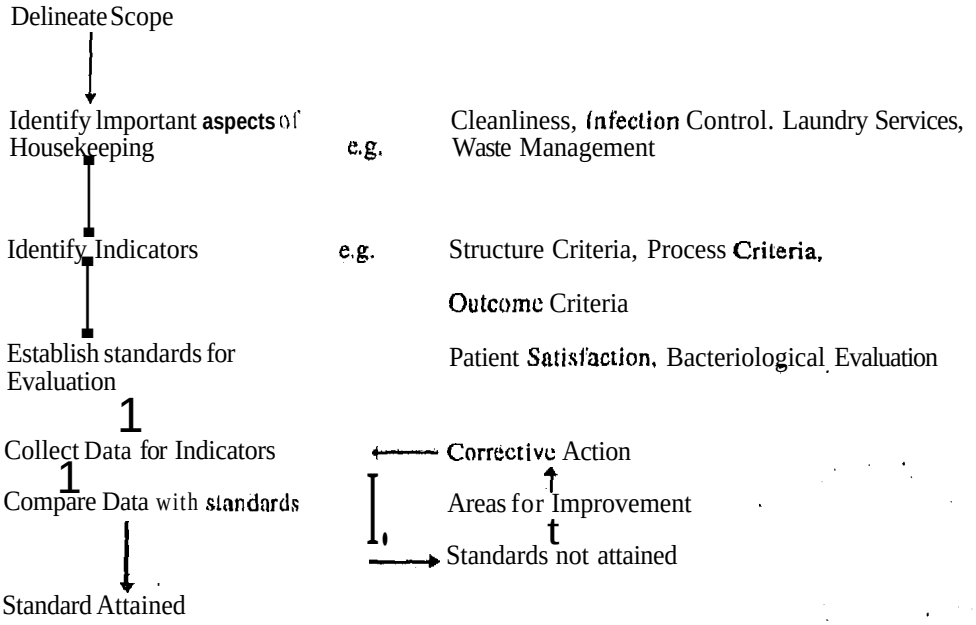
Level-I: All the floors are washed once a day with soap or detergent. Dry sweeping in prohibited except in special cases as outpatient public areas.

A random sample of ten patients should be questioned on the frequency of the floor washing and methods used. The personnel of the service should be asked about the basic instructions that they have received with regard to the cleaning .

Level-11: The institution/hospital has an individual responsible for thu cleaning and the procedures are standardized including instructions for the use of disinfectants. There are standards for the specific treatment of potentially polluting elements or excreta.

Level **III:** The committee on infections and/or a nurse epidemiologist participate actively in the preparation and supervision of the cleaning standards.

Application of the US Joint Commission on Accreditation of Health Care Organisation (JCAHO) ten step quality assurance model to housekeeping services is diagramatically shown below:



Check Your Progress 7

Housekeeping is an important variable in the provision of "Quality Assurance" of hospital care. For effective housekeeping services, all are essential except:

a) Scientific recruitment of staff

b) Training

c) Attitude of staff of all departments

d) Zero based budgeting

5.11 RECENT TRENDS RELATED IN HOUSEKEEPING SERVICES

Housekeeping is a colnplex activity requiring constant attention to many different details. The plan for tlie housekeeping department must provide for the combination of personnel, materials and procedurds in such a way as to accomplish the objective of keeping the hospital constantly clean, healthful and safe.

Some of the recent trends incorporated in tlie liospital housekeeping are as follows:

1) **Mechanised** Cleaning

In recent years there has been a shift from manual cleatiing to mechanised cleaning of wards and corridors in hospitals. Some of the hospitals in the developed countries even have centralised vacuum cleaning system built into an establishment where ducts carry dust direct to a basement dusl room and the spread of dust and micro-organisms is thus avoided.

2) **Choice** of Colours for Wards and Corridors in Hospital

It is now known lhat many colours have a similar effect on different people e.g. red, orange and yellow are found to be warm and stimulating. Green is cool and has a soothing and pleasing effect, dark blue can be depressing, pale blue is fresh and cool, white appears hygienic and cold, peach and pink may therefore be preferable to white. Hospitals are now having a more inviting atmosphere than in the past by the use of warmer colours, textured surfaces and more modern designs particularly in the public areas. Thus close carpeting, comfortable furniture and attractive soft furnishings are to be found in foyers and waiting rooms of the modem hospitals.

3) **Elimination** of Unpleasant Odours

Good ventilation and cleanliness are essential factors in controlling odours. Electrical devices which work on tlie principle of ionisation are also being used in modern hospitals.

4) Noise Control

To control noise from becoming a nuisance to the patients hospital designers are using matted excelsior, shreded asbestos or steel wool to deaden sound.

5) Manpower Planning

Manpower planning for housekeeping services is being done utilising mathematical programming. Rescheduling techniques have also been suggested to save housekeeping manpower.

6) Contract Services

Quite a few hospitals are going in for contract services in hospitals for housekeeping rather than having an inservice.

7) Infection Control

Sound housekeeping practice, has to be based on bacteriological principles. Routine cleaning must not only he effective in removing dirt but also in maintaining low levels of micro-organisms. Bacteriological testing of floors to test the effectiveness of cleaning agents and cleaning practices form the basis of scientific housekeeping in some of the present day health care institutions.

8) Pneumatic Transport System

Some modern liospital have chutes or pneumatic pipeline transport system which are used for intramural movement of waste.

9) Evaluating Detergents — Germicides for Hospital Use

Presently in the Indian market there are numerours cleaning agents and germicidal detergents available. To name a few TEEPOL-300, SPIRAL, AZAX, **BRISK: SPIC** and SPAN, SAPONA, **WIZARD,** FRESCA, POLYSAN, GERMINOL, PHOENIX and **DIAMOND.** Scientific evaluation of these must be done to assess their suitability for health care institutions.

Detergents germicides are evaluated for hospital use by scientific testing like the phenol coefficient test, use dilution confirmation test. Many corporate and other health care institutions are utilising the more effective Iodophor and Quatenary detergent germicide rater than phenolic ones. The cleaning properties of a disinfectant cleaner are evaluated by tests such as the Gardner straight time washability tests. Details of these tests have not been included in the present text.

5.12 LET US SUM UP

Housekeeping services in a hospital is entrusted with maintaining a hygienic and clean hospital environment conducive to patient care. The housekeeping related activities have a direct effect on the health, comfort and morale of the patient, staff and visitors and is an important public relations variable. It is an essential ingredient in the provision of Quality Assurance of hospital care.

Housekeeping is a vital facet of the 'image'that the hospital presents to the public. Studies conducted on patient satisfaction by various authorities have clearly established the lack of sanitation and cleanliness as important dissatisfaction attributes for patients. As Eugene aptly points out 'Housekeeping — or rather the lack of it— strikes the first lasting blow to the concerned'.

Your have also been apprised of the fact that with the advent of privatisation of medical care and applicability of Consumer Protection Act of 1986 to hospitals, and the recent Bio-medical Waste Management and Handling Rules enunciated by the Ministry of Environment and Forests it has become our legal, economic and moral obligation to react positively to the demands of the consumers. The endeavor should be to achieve optimal quality in health care in terms of professional quality and also medical quality as perceived by consumers. Failure to accomplish this may affect the image and viability of the hospital. A good housekeeping service is an asset which no hospital can afford to negtect.

Scientific hospital housekeeping is still in its infancy but its identity and importance has begun to be recognised. Tradition should not be the only criteria on which to base current procedures. Housekeeping routines should be constantly reviewed in light of new scientific findings. The unit also elaborated on the functions, components, essentials of cleaning agents, organisation structure, staffing, training, control, evaluation , quality assurance, costing and recent trends in housekeeping. The contents will enable you to plan, monitor, control, evaluate and achieve TQM in the various facets of housekeeping services in health care institutions.

UNIT 1 MORTUARY SERVICES

Structure

1 . OBJECTIVES

After studying this unit, you should be able to:

- know the role and significance of mortuary services in a hospital;
- understand the planning considerations of mortuary services;
- learn about physical facilities required for a mortuary;
- plan for the equipment needed in a mortuary;
- describe the staffing pattern and responsibilities of medical staff and technicians etc;
- understand the policies and procedures involved in mortuary; and
- develop a checklist for proper maintenance of a mortuary,

1.2 INTRODUCTION

This unit focuses mainly on mortuary services and facilities in a hospital. While studying the support and utility services of a hospital the role and importance of mortuary services cannot be under emphasised. The subject of disposal off the dead is hedged around by religious, social, and cultural beliefs and practices. Whatever these may be, however, it is necessary to provide within the hospital or its precincts, a place to which a dead body can be moved quietly and discretely, in order that other patients are not upset. It is also necessary to see that the body can later be removed from the hospital, for burial or cremation, by some exit screened from the view of patients and others in the hospital. Therefore, facilities for safe custody of dead bodies before and after postmortem are to be provided accordingly.

1.3 ROLE AND FUNCTIONS

It is the duty of the hospital to provide mortuary facilities for the dead bodies. When death occurs in Wards, the body is immediately shifted to mortuary until other formalities of the hospital are completed.

In a big teaching hospital, mortuary is used for the following purposes:

- To keep the bodies of the patients dying in the hospital, until the relatives claim them and arrange for their disposal.
- To keep the unclaimed dead bodies until their disposal is arranged by the hospital authorities. This is done by arranging either for their burial or cremation;
  i) through hospital funds, or
  ii) through religious and charitable organisations. Sometimes the dead bodies may be handed over to Anatomy Department of Institutions requiring for teaching purposes.

  To receive dead bodies requiring pathological postmortems pending final disposal.
- To receive dead bodies brought to the hospital for medico legal postmortem and store in the mortuary pending further disposal.
- The mortuary wing of a teaching hospital is also utilised for demonstration of autopsies to medical students.

The responsibility cf hospital to preserve the bodies, until handing over to relatives needs to be stressed. Thus, a need for a proper cold storage is important. The added responsibility of hospital authorities is to see that no mix up occurs and the particular body is handed over to its rightful heir/relatives for the last rites. In Govt. hospital, medico legal cases are admitted and in the event of death of such cases, the bodies are handed over to the police personnel for postmortem if required and bodies are never directly handed over to relatives.

1.4 PLANNING CONSIDERATIONS

Let us examine in brief the location, layout and physical facilities of the mortuary services.

1.4.1 Location

The mortuary should be located in a separate building near the pathology laboratoiy on the ground floor, easily accessible from the wards, emergency department and operation theatres. It should be located in one wing of the hospital preferably away from the general traffic routes used by the public. It must have a separate entrance and exit for relatives and for heirs I heiress.

1.4.2 Size

According to John R. McGibony, for a hospital of 50-100 beds, mortuary refrigerator should have a capacity to hold two bodies. For a 200 bedded hospital, at least three body capacity should be provided. Teaching and research hospitals require larger capacity refrigerators according to their need.

1.4.3 Number of Rooms and Layout

Covered access or portico: A covered access or portico for vehicles should be provided at the entrance, which leads to mortuary complex as a protection in wet weather, and as a screen from adjoining areas. The exit to a subsidiary road nearby car parking place is also desirable.

Autopsy room or postmortem room: The autopsy room should be constructed with spacious windows of frosted glass, adequate water supply, fluorescent lighting built in cupboards and fans. Autopsy room should provide accommodation for:

- Autopsy table of stainless steel
- Sink with running water
- Built in cupboards for keeping instruments and equipment
- Room should have a water impervious floors sloping to a drain
- Tiled walls so that whole room can be easily washed down
- Junction between walls and floors should be suitably covered,

Good natural ventilation by windows at high level is essential. Impermeable and easily washable floor and wall surfaces should be provided.

Body store: Room where the bodies can be kept should be close to postmortem room. It can be combined with the autopsy room. If resources permit, refrigerated body storage is essential. In addition, there should be a provision of a deep freezer with capacity of two bodies for decomposed bodies and where tlie body is to be kept for a longer period. The most practical arrangement is to provide chambers averaging about 6 ft.- 8 ft. high in which six bodies may be stored in two sets of three tiers. Cabinet doors should open through 180 degrees to allow the attendant to approach either side of the trolley. Depending upon the layout, a depth of 5.4 m. for the body store is usually satisfactory. A body on a loose tray or stretcher may require the space of about $3m^2$ in the cold chamber.

Trolley bay: A bay is required for two mortuary trolleys.

Office cum pathologists room: Where the doctor and police can sit and fulfil prerequisite formalities and where reports can be written. It may also be used for discussions with members of clinical staff.

Changing room: There should be separate lockers for personal clothes and for postmortem room gowns, aprons and boots.

Lavatory: Two toilets one for the staff and other for the relations of the deceased, wash basin and a shower are needed. Space required is 80 sq. ft.

Stores: Three small stores may be required.

i) **Clean store:** This is for clean gowns, aprons, rubber gloves, gumboots, towels etc. Linen items like shrouds, drapes, towels and other linen items can be stored here. It should be adjacent to the doctor's room and outside postmortem room.

ii) ***Instruments* and equipment store:** This should open directly into the post mortem room. In this area all the instruments, equipment and reserve stock instruments, electric reciprocating saw, portable trolley mounted spot light etc. are kept.

iii) **Chemical store:** Where chemical solutions for preserving tlie viscera and specimen jars and packing material are kept.

Relatives waiting area: It may be in the form of verandahs–should be pleasantly and soberly furnished and decorated so that last impression tlie relatives receive of the deceased is one of quite dignity in death. This area can also be used as a prayer area where relatives and friends of all religious denominations may like to offer prayer. A spacious hall well ventilated to accommodate about 50 persons at times will serve the purpose. Size can be of $20\ m^2$.

Room for mortuary technician and attendant: An area of $10\ m^2$ shall he required for the staff who is on duty, to arrange viewing and to assist in autopsy. Room should be readily accessible from the visitor's waiting room.

1.4.4 Space Required

Space requirement varies from hospital to hospital depending upon the workload, level of care it provides and jurisdiction of medical autopsies. For a district liospital with 200 – 300 beds, it is expected to undertake 300 autopsies per yew. As a general guideline, committee on plan project **(COPP)** has recommended an area of 6-8 sq. It. per bed.

.....

.....

.....

1.5 PHYSICAL FACILITIES

Floors: The floors should be hard and durable. It should be of material, which can be easily cleaned and moisture resistant.

Walls: The walls of mortuary should be of permanent, durable construction and there should be scope for future expansion in view of increase in workload. Finish of the walls must be impermeable and washable.

Ceilings: The ceilings should be made of materials that are easily cleaned. The height of ceilings should not be less than 10 feet in principal rooms where height of most ancillary rooms need not exceed 8 ft. The junctions between the walls and floors should be suitably covered.

Doors: Sliding or double doors of adequate width should be provided between the principal rooms to allow easy passage to trolleys, portable X-ray etc. in the postmortem room.

Windows: Natural day lighting by windows should be provided wherever possible and it is preferable for windows of principal rooms to be on the northern side. Windows generally should have opaque glass and opening side should be fitted with external fly proof screens. Windowsills should not be placed below height of 5 ft, from floor.

Corridors: Should be wide enough to allow passage of trolleys. Width should not be less than 8 ft.

Lighting: Either tungsten or fluorescent lighting may be used. In the postmortem room, special lighting should be provided to ensure adequate illumination of postinortern tables and dissecting benches. Fluorescent lighting fittings have an advantage in that they can be arranged centrally above and parallel to the axis of the table but care must be taken to ensure that the lighting is satisfactory for colour identification. Moreover, the light fittings should be so designed to avoid glare, easy to clean and maintain, Switches in wet areas such as postmortem rooms and body store where walls and floors are hosed down should be of the hose proof type. Special consideration should be given to lighting in viewing rooms. Sufficient hose proof 15 amp socket outlets mounted on the walls at a height of 5 ft, are desirable in damp areas such as PM room and body store.

Illumination: Recommended level of illumination for various rooms of mortuary are:

Rooms	Average Lumen/ Sq. Ft.
Postmortem room	25
Postmortem tables and benches	150
Pathologist/Forensic specialist room	15
Body store	10
Staff change room/waiting rooms, trolley bay, stores, corridors etc.	7-10
Value of illumination is taken at **3 ft.** above **floor** level.	

Heating and ventilation: Heating requirements can be met by conventional heat radiators / convectors which can be mounted on walls but special precaution to be taken that pipes carrying wires should be well concealed with easy access for maintenance. The recommended temperature for heating purpose required in various areas of the mortuary is 50 °F - 65 °F. Natural ventilation by fly screened windows and fresh air inlet grills should be adequate except in postmortem rooms where mechanical exhaust system is necessary. The fans should be of the variable speed type designed to produce upto 10 air changes per hour. Care must be taken to ensure that the air discharged from the mortuary does not reach adjacent areas, buildings. As a further safeguard, the rooms in the mortuary should not be in direct communication with a lift shaft or any service ducts, which have openings on other floors. If possible, deodorizing equipment may be provided in the postmortem room.

Hot and cold water supply: Arrangement should be made to provide hot and cold water supply to mortuary. Postmortem tables should be fitted with individual water hoses. All taps in the working area should be elbow-operated type.

Drinking water facility: There should be provision of drinking water in the mortuary complex itself,

Communication: As the mortuary functions under overall co-administrative control of Forensic expert, communication is always required between the department and mortuary, hospital administration and mortuary as well as police and other public agencies. There should be provision of both internal as well as external telephone line.

Air-conditioning: In view of financial constraints, a district hospital may not afford air-conditioning of the mortuary. A system that does not recirculate air is recommended.

Fire alarms and fire fighting equipment: Fire alarm system should be installed. Fire fighting equipment should be provided and fire exit routes to be clearly identified and earmarked with red paint and well illuminated.

Refrigeration: The temperature of cold room is to be maintained between 5.5 °C to 6.5 °C, thermostat control will be required for each cold chamber. Facilities to be provided to enable the chambers not in use to be switched off,

1.6 EQUIPMENT

Cold Chamber (refrigerator) to preserve the dead bodies and the temperature to be maintained between 2°C to 5°C.

Postmortem table (autopsy table): The tables are of porcelain, fire clay or stainless steel. Stainless steel is favoured. Up to 400 beds require two tables, each additional 200 beds another table. A two-tabled room needs about 40 sq, m. About 15 sq.m. of space will be needed for each additional table.

Doctor's room should have a writing table, chair, telephone, file cabinet, workman's lockers for staff working in the mortuary,

Sterilizer: A small sterilizer for instrument sterilization.

Glass cupboard to keep instruments.

X-ray machine: 30 MA portable X-ray machine with dark room.

Thin layer chromatography kit

Gas liquid chromatography

High pressure liquid chromatography

Spectrophotometer

Fume chamber

Weighing machine

Stainless steel bowl and meat cutting saw

Two large sinks with hot and cold water should be adjacent to the workplace-one for clean and other for unclean work. A flushing service and wash basin are needed.

1.7 STAFFING

The staffing depends on the size of the hospital and the complexity of its operations. Mortuary services are to be carried out round the clock.

As a general rule two pathologists or forensic experts for 150 autopsies/postmortems. Additional one doctor for every 100 postmortems.

There is a need for five morgue attendants who can be posted round the clock. They should be at least matriculates who can read and write in English and local language. This is important to ensure that wrong bodies are not delivered and to differentiate between MLC and non-MLC bodies.

There should be at least two mortuary technicians in each mortuary. At least three workers for cleaning andmaintaining the mortuary.

There should be X-ray technicians to take X-rays in case of medico-legal cases, To maintain records, a record assistant may be posted.

1.8 POLICIES AND PROCEDURES

Medico-legal postmortems should be done only during day time before sun set. Natural light and ample time is essential for apostrnortem to arrive at consensus.

Non medico-legal autopsies can be done at any time.

Protocol of Medico-legalBodies Packing

In a hospital when a death of a medico-legal case takes place it has to be informed to the concerned police station and the dead body has to be properly packed and sent to mortuary for storage. In cases where an inquest is to be done by a magistrate, the dead body should not be handed over to police even upon the written instructions of a magistrate.

Protocols for inquest

In cases of inquest, where the investigating officer feels that postmortem is essential to arrive at the cause and manner of death, he forwards the dead body, duly sealed under police escort to the authorised Medical Officer for conducting postmortem. In cases of death after natural disease process where the exact nature and process is not clear, the teaching physician can request the relative for postmortem/autopsy. After getting due permission from next of kin available on the death form/case sheet, permission of Medical Superintendent or his nominee is to be sought. Only after this, pathologist is approached to carry postmortem/autopsy. Consent for autopsy taken from deceased during his lifetime is invalid.

Identification of Bodies

Wrist *Band*: Proper identity wrist bands of all dead bodies including neonates in any hospital mortuary is mandatoiy, so that no mix up occurs during handing over the bodies to the relativeslauthorized personnel. Such mix-ups are a great embarrassment for the hospital authorities. In fact, it may lead to legal complicationsfor the hospital. Clear instructions to all the concerned to be issued. While packing the dead bodies in Wards before sending to mortuary, proper identity wrist bands to be applied, where name, age, hospital registration number, etc. are clearly mentioned as given in death certificate.

Documentation: It is essential for the mortuary staff to verify and compare the name on the wrist band before entering the case in "mortuary record book" and keeping the body in cold storage.

Hand and footprints of neonates: Fox neonates it is advisable that in addition to wrist band having the particulars of the child, mother's particulars should also be mentioned. In Wards, it is necessary to take hand and foot prints on the case sheets. This is helpful in identification in a mix up situation,

Protocols for Unclaimed Bodies

Unclaimed body to be preserved for a minimum period of 72 hours after which it could be disposed. Normally unclaimed dead bodies are handed over to either Municipal Corporation

or certain religious organisations to conduct the last rites.

In unidentified medico-legal cases, the responsibility of establishing identity of the deceased is totally that of the investigating officer conducting inquest, usually in such cases photographs and finger prints are taken, which help in identity establishment even' at a later stage,

Clothing and belongings are preserved as they also help in identification of deceased in many situations. In medico-legal cases they are preserved by the investigating officer, while in non-medico-legal cases they are preserved by the hospital authorities.

An unclaimed dead body can be handed over to a medical college/Anatomy Department. for teaching purposes, under the Anatomy Act. by the hospital authorities.

Protective clothing for staff: Mortuary staff to be provided with protective clothing like gloves, gowns, boots, etc., while handling dead bodies, universal precautions and maintaining cleanliness are the two important aspects to be followed.

Medical check up of staff: In addition to universal precautions while handling dead bodies, all the mortuary workers should be screened for pulmonary tuberculosis periodically. The workers should be vaccinated against rabies and hepatitis B.

1.9 MONITORING

Check list of things to be verified daily and monthly and half-yearly.

Daily **Check**

a) Temperature checks of cold storage: Cooling system of mortuary to be checked daily so that temperature is maintained and the bodies are not decomposed.

b) To check the cleanliness and hygiene of the mortuary.

c) Coinpressor check

d) Cold storage: Thermal graph of the cold storageis-to be checked every day.

e) Gas pressure

f) Temperature

g) Water level

Monthly Cheek

a) Oil fan motors

b) Wiring

c) Tests for leaks

Half-yearly Check

a) Grease compressor motors

b) Replace compressor oil

In addition to the above checklist, the following points are also taken consideration.

Occupancy Rate

Occupancy rate of the bodies in mortuary to be noted. If the present facilities axe not enough, hospital authorities can plan for extra facilities in the same area if there is ample space or plan in a different location.

Maintenance of **Negative** Pressure

The pressure need to be monitored regularly and maintained within prescribed limits.

Identification system of dead bodies is done properly or not. The wrist band on the left side with the name, IP number etc, to be checked with the death certificate before keeping the body in the cold storage.

Proper Record Keeping

Preventive maintenance of the equipment to be done. For this proper recording is necessary.

1.10 LET US SUM UP

In this unit you have learnt that a Mortuary is an important place in a hospital, which has been neglected for a long time. It is a common experience in our hospitals to find mortuary located in far off isolated corner of the hospital with primitive facilities for body preservation and autopsy performance. Instead of a pulsating enquiry centre of modern medicine, it remains a dead house. In the concept of a modern hospital, it is recorded as an important speciality. It is also a sensitive area in terms of public relations of the hospital. Sanctity of the 'Dead' is a universal concept and is intimately related to the cultural background of the community. Therefore, recent trend is to remodel the mortuary with modem facilities.

1.11 ANSWERS TO CHECKYOUR PROGRESS

Check Your Progress 1

1) ● To keep the bodies of the patients dying in the hospital, until the relatives claim them and arrange for their disposal.

To keep the unclaimed dead bodies until their disposal is arranged by the hospital authorities, This is done by arranging either for their burial or cremation;

i) through hospital funds, or

ii) through religious and charitable organisations. Sometimes the dead bodies may be handed over to Anatomy Department of Institutions requiring for teaching purposes.'

- To rpceive dead bodies requiring pathological postmortems pending final disposal,
- To receive dead bodies brought to the hospital for medico-legal postmortem and store in the mortuary pending further disposal.

- The mortuary wing of a teaching hospital is also utilised for demonstration of autopsies to medical students.

2) i) Clean Store

ii) Instruments and equipment store

iii) Chemical store

3) Space requirement varies from hospital to hospital depending upon the workload, level of care it provides and jurisdiction of medical autopsies. For a district hospital wit11 200-300 beds, it is expected to undertake 300 autopsies per year. As a general guideline, committee on plan project (COPP) has recommended an area of 6-8 sq. ft. per bed.

Check Your Progress 2

1)

Rooms	Average Lumen/ Sq. Ft.
Postmortem room	25
Postmortem tables and benches	150
Pathologist/Forensic specialist room	15
Body store	10
Staff change room/waiting rooms, trolley bay, stores, corridors etc.	7-10

Value of illumination is taken at 3 ft. above floor level.

2) Cold Chamber (refrigerator) to preserve the dead bodies and the temperature to be maintained between 2°C to 5°C.

Postmortem table (autopsy table): The tables are ofporcelain, fire clay or stainless steel. Stainless steel is favoured. Up to 400 beds require two tables, each additional 200 beds another table. A two-tabledroom needs about 40 sq. m. About 15 sq.m. of space will be needed for each additional table.

Doctor's room should have a writing table, chair, telephone, file cabinet, workman's lockers for staff working in the mortuary.

Sterilizer: A small sterilizer for instrument sterilization.

Glass cupboard lo keep instruments.

X-ray machine: 30 MA portable X-ray machine with dark room.

Thin layer chromatography kit

Gas liquid chromatography

High pressure liquid chromatography

Spectrophotometer

Fumechamber

Weighing machine

Stainless steel bowl and meat cutting saw

Two large sinks with hot and cold water should be adjacent to the work place-one for clean and .other for unclean work. A flushing service and wash basin are needed.

Check Your Progress 3

1) As a general rule two pathologists or forensic experts for 150 autopsies/postmortems. Additional one doctor for every 100 postmortems.

There is a need for five morgue attendants who can be posted round the clock. They should be at least matriculates who can read and write in English and local language. This is important to ensure that wrong bodies are not delivered and to differentiate between MLC and non-MLC bodies.

There should be at least two mortuary technicians in each mortuary. At least three workers for cleaning and maintaining the mortuary.

There should be X-ray technicians to take X-rays in case of medico-legal cases. To maintain records, a record assistant may be posted.

2) i) Wrist Band
   ii) Documentation
   iii) Hand and foot prints of neonates

3) Unclaimed body to be preserved for a minimum period of 72 hours after which it could be disposed. Normally unclaimed dead bodies are handed over to either Municipal Corporation or certain religious organisations to conduct the last rites.

In unidentified medico-legal cases, the responsibility of establishing identity of the deceased is totally that of the investigating officer conducting inquest, usually in such cases photographs and finger prints are taken, which help in identity establishment even at a later stage.

Clothing and belongings are preserved as they also help in identification of deceased in many situations. In medico-legal cases they are preserved by the investigating officer, while in non-medico-legal cases they are preserved by the hospital authorities.

An unclaimed dead body can be handed over to a medical college/Anatomy Department for teaching purposes, under the Anatomy Act. by the hospital authorities.

4) Daily Check

a) Temperature checks of cold storage: Cooling system of mortuary to be checked daily so that temperature is maintained and the bodies are not decomposed.
b) To check the cleanliness and hygiene of the mortuary.
c) Compressor check
d) Cold storage: Thermal graph of the cold storage is to be checked every clay.
e) Gas pressure
f) Temperature
g) Water level

Monthly Check

a) Oil fan motors
b) Wiring
c) Tests for leaks

Half-yearly Check

a) Grease compressor motors
b) Replace compressor oil

In addition to the above checklist, the following points are also taken into consideration.

- Occupancy rate:
- Identification of bodies:
- Proper record keeping:

- enumerate the authorisation of an ambulance, its design, staffing pattern and essential equipment of an ambulance;

UNIT 2 TRANSPORTATION SYSTEM – AMBULANCE SERVICES

Structure

2.0 OBJECTIVES

After going through this unit, you should be able to:

- describe the patient transportation system in general and its development;
- enumerate the authorisation of an ambulance, its design, staffing pattern and essential equipment of an ambulance;

- understood the various physical facilities of ambulance service department; and
- understood the organisation of ambulance and emergency care service of few developed countries.

2.1 INTRODUCTION

There is need to bring awareness by inclusion in the academic curriculum of doctors and paramedical staffs of emergency care management techniques and vital role played by transportation system in over all emergency services management and day to day patient care management.

All citizens of the country have moral and legal duty to attend to the needs of emergency cases and road site accident victims. Life and limb saving measures are basic principles of emergency care, All over the world concept of Critical Care Medicine (CCM) has already taken deep roots in the health care system. In addition carrying of sick patients for seeking opinion of doctors, specialists, laboratory investigations, day care surgery, hospital admissions, inter ward patient transfer, post surgery transfer and delivery has become a routine task of Ambulance Services Department. Hence, operation of ambulance services has become a specialised activity and needs detailed knowledge and constant monitoring by health professionals and civic service administrators. This unit devoted in detail regarding operation of Ambulances.

Illness creates social, economic and medical dependency. The sick whether emergency or less serious but requiring medical care, need not only medical treatment, but also personal and psychological support, safe transportation system, humanized care, empathy and at times hospitalisation.

Throughout history, societies have accepted such need, as a responsibility of community and have created various facilities to provide the necessary services. Hospitals of present era are not symbols of ivory tower considered earlier but supposed to the community institutions meeting the need and demand of community consisting of urban, rural poor and rich alike. In view of changing ethos, hospitals and health services have undertaken complex noted and multipurpose roles including transportation services. The transportation system consists of two types viz. intramural and extra mural.

Ambulance services for emergencies in hospital and outside in the street form very important segment of this transportation system. All hospital administrators need to know various types ofintramural i.e. internal transportation system and extra mural i.e. external transportation system in health care delivery system. Transportation system encompasses not only ambulance services but also for transportation of personnel, material, equipment, linen and food articles, system like lifts, dumb waiters, trolleys, escalators, lorries and trucks and aircraft etc. This is one of the very important supportive services, which if not well planned, will, create perpetual problem in patient care in community and in hospitals.

Trauma has become one of the biggest killers in both developed and developing countries. Ambulance plays a major role in care and saving precious lives of trauma victims. In USA more than 100000 persons die due to accident and 100000 are disabled every year. In a study carried out in USA it was reported that 18.0 percent deaths were salvageable if expert emergency aid was available. In another study it was found that in 163 high way death cases 23.0 percent of death could have been prevented if adequate and prompt treatment was given. This is the finding of a study in a developed country where emergency services are highly well established and advanced. The mortality and morbidity figures are going to be much higher in underdeveloped and developing countries. University of Michigan (1971) in a study of 159 autopsy cases who died of motor vehicle accident, reported that at least 18.0 percent victims could have been salvaged, had they received adequate treatment at the site, enroute and immediately at arrival in hospital as per National Safety Council of United States. It is estimated that 20,000 lives would be saved annually with better attention at the site of accident during transportation and on arrival at the hospital.

In India the magnitude of problem of motor vehicle accidents or other accidents and emergencies is difficult to assess accurately due to lack of authentic data and also lack of any nodal agency monitoring these figures statistically. However, fatality rate of 60 per 10000 motor vehicles is very high in India compared to 5-15 per 10000 in developed countries.

India has got only 1.0 percent of global vehicle fleet with share of road deaths as 6.0 percent. One state reported more than 4526 deaths in first five months in highway accidents in 1997 and 4637 seriously injured. People die daily in highway accidents. In 1996 total 9021 people were killed aiid 5387 people were seriously injured on 10 national highways in Maharashtra as per published reports. If figures all compiled for all states, the figures would be more than a lakh. Srntistics indicated that, on an average 24 deaths occurred in 2212 road accidents. Main reasons for the accidents was phenomenal growth in number of vehicle. 'Country has to accordingly make provision for management of tliese increasing number of accident trauma cases.

In this course we shall study the fundamental concepts and need of early patient evacuation, various modes of patient transportation system and all aspects of ambulance vehicles commonly used for patient treatment and evacuation for emergency cases and during natural calamities. The knowledge about immediate medical attention at the site, life saving measures, continued treatment during transpostation and early evacuation at the centre of excellence, CAT centre, or tertiary treatment centre in patient transportation system, is essential for hospital and a health administrators and planners.

2.2 PATIENT TRANSPORTATION SYSTEM – GENERAL

Patient transportation system encompasses not only Ambulances but nlso wide range of mechanical systems and transports in and outside hospital used to carry or shift patients. However, ambulance is most widely used transportation system.

Ambulance, lift, escalator, trolley, stretcher, train, ambulance train, car, truck, rickshaw, bicycle, bullock cart, helicopter, ambulance-helicopter, aircraft and animals lilce horses and mules are used for transportation of patients depending upon location, type of patient, economic status, social strata, terrain, physical facilities and degree of illness. But in day to day life in urban area particularly, conventional ambulances transport patients as we see being used in hospitals. Inside hospitals aiid from local area to hospitals ambulances ore normally being used. During last two decades one has noticed sea change in types and design of ambulances being used. One sees highly modern, equipped and mobile hospital in ambulances. There are ambulance vehicles, which are mobile Corollary Care vans capable of dealing with all types of cardiac emergencies at any peripheral or remote place. There are number of institutions and private organisations which have mobile Intensive Care Unit (ICU) used for tackling critically ill patients requiring resuscitation and continued critical care. In last few years mobile operation theatre which is ambulance based called OT on wheels has also been built for carrying out surgery in remote areas.

In this unit we will mainly focus on Ambulance services only which is main patient transportation system all over the world.

2.3 DEVELOPMENT OF AMBULANCE SERVICES

Early historical record are very scanty and do not mention much about transportation system of patients. In fact, historical records give little evidence of any vehicle specifically designed to transport the sick and injured. Bullock carts and horses have been used for lifting the sick and injured from battlefields. Sick were often left to die at home or those wounded in battle were left on the battlefield to die. It is only after 17th century that there are some records of any form of organised transportation system of the sick and wounded, In

France during 1762 for the first time organised transport was provided which was named as "Hospital Ambulant" which literally meant was as mobile hospital. Wheeled trolleys were brought in use in France during 1880. Its origin for military purpose is mainly credited to Dominique Joan Lary (1792) a French Military Surgeon. At the beginning of 20th century horse drawn vehicle were commonly used in England. In 1903, motorized ambulance transport was introduced in civil practice. That was the beginning of ambulance services in transportation system of patients. First World War and Second World War contributed towards further development of patient transportation system. However, maximum development occurred after Second World War and during last two decades due rapid developments in the field of science and technology and particularly in the field of automobile industry and automated data processing technology.

2.4 AIM AND OBJECTIVE OF AMBULANCE SERVICES AND DEFINITION OF AMBULANCE

Major objective is to transport the sick and injured as quickly and comfortable to hospital as possible where effective medical care can be rendered by qualified compctcnt medical, nursing and paramedical staff.

Objective of ambulances service is to provide prompt emergency treatment, safe transportation with continued treatment to hospital for further treatment.

Definition of Ambulance

One would wonder that Ambulance can also have a definition. But it is so. Though there is no single accepted definition of Ambulance but various attempts have been made to define an Ambulance. An ambulance as defined in Webster's dictionary is an "Organisation for rendering first aid". From this the word has come to be used for "a vehicle equipped for transporting those who are wounded injured or sick".

Hospital O and M Services Report No 8 (1964) has defined ambulauce as: "Ambulance transport includes all ambulances, sitting case cars, hospital car service vehicle and railways accommodation provided at the expense of local health authority.

2.5 ROLE AND FUNCTION OF AMBULANCE SERVICES

Ambulance is an out reaching limb of the hospital based emergency medical services. An efficient, promptly responding, well-equipped ambulance service staffed with competent personnel is considered one of the essentials of well-organised emergency department. Whether an injured patient survives after reaching the hospital depends not only on the nature of the injuries sustained but also on the adequacy of first aid and efficiency of the transportation from the accident site.

Mackay (1969) brought out in the study report that in 43.0 percent of deaths in Motorcycle riders and vehicle occupants, they might have had a greater chance of survival, if some medical treatment had been available at the scene of accidents within 10 minutes.

According to the special accident prevention committee, it is the third biggest country in the world contributing the maximum number of road accidents. As against national standard of 352 vehicles for a population of 10,000 there are 3500 vehicles fora population 10,000. Seventy three percent of these are two wheelers. It is distressing to learn that state estimated in 1997 number of road accidents deaths as a whole in the range of 30,000 to 40,000 per year. In India it has been estimated that one person dies on road every 12 minutes,

Death Rate: India – 5011000 Vehicles and Sweden –411000 Vehicles

The above statistical data on road deaths due to motor vehicle accidents compels hospital administrators to plan for efficient emergency treatment at site, safe transportation and continued treatment during evacuation and in hospital on admission. Many deaths and disabilities are preventable if efficient ambulance services are available to deal with such situation. Well-equipped and staffed Ambulance forms an integral element of accident and emergency service department in any district.

Role of Accident and Emergency department in saving many salvageable lives and reducing morbidity has been well realised in last two decades all over the world by hospital and health administrators. Concept of on the spot, during transportation and in Intensive Care Unit care by intensivists and traumatologist and Critical Care Medicine experts has completely revolutionised the principles of planning, designing, staffing and equipping of Accident and Emergency Services Department, Community and health administrators have become quite conscious of the necessity of having a efficient well designed state of art emergency and Trauma treatment centre in each district. There can be no efficient Accident and Emergency Services Department or Modem Centralised Accident Trauma Treatment (CAT) centre without fully equipped and staffed Ambulance Services.

Not only for accident and trauma emergencies but other emergencies like Myocardial infarction, cerebral haemorrhage, foreign body throat, bum, gun shot wound, fracture and injuries etc., immediate treatment on the spot by expert medical staff and proper evacuation by a trauma or Critical Care Medicine (CCM) trained staff of Ambulance, is a vjtal factor in

saving life. Hence, the role of ambulance is not only carriage of patient but infact, it is highly mobile hospital to provide prompt comprehensive medical, surgical and resuscitative cover till the patient is institutionalised.

Utilisation of Ambulances

Requests for the use of ambulance services arise from the following individuals, organisations and services:

a) General practitioners, police and members of the community calling ambulance to the scene of accident or other emergencies.

b) General practitioners nursing homes arranging out-patient booking of ambulance by telephone.

c) Hospitals requesting transport on long and short notice for:

   i) Patients to be admitted

   ii) Out-patient or accident or emergency cases to go home

   iii) Out-patients attending by appointment

   iv) Discharged inpatients to go home

   v) Patients to be transferred from one hospital to another

   vi) Transfer to patients for special investigations like Cardiac Catheterisation, Cardio-thoracic Centre, NMR Centre end Radio Isotope Centre etc.

d) Local health education authorities for the conveyance of children or handicapped persons to and from establishments.

e) For conveyance of children and staff for immunization programmes.

2.6 TRANSPORTATION OF PATIENTS, STAFF AND VISITORS

Ambulances are mainly meant for patients and emergency care medical staff and if used for any other purpose, will loose patient time and also become unserviceable early due to premature wear and tear. Ambulances should have only essential staff consisting critical care medicine trained Doctors, Nurses and paramedical staff. Ifrequired it should have stretcher-bearer who are well-trained in carriage of various types of serious patients and accidents victims.

Visitors and relatives should preferably use other types of vehi[illegible] one or two relatives may be permitted to accompany very critical patient mainly to hel[illegible] paramedical staff in caring of patients. No dead bodies should ever be carried by Ambulance. This has psychological effect on other patients. Ambulances are likely to get heavily infected if dead body was having gas gangrene or any communicable and infectious diseases. It is not a hearse van. There is need to educate public on this subject through various public information media.

No stores should be carried by ambulances and during war time also only patients are to be evacuated and no arms or ammunition as per Geneva convention. Ambulances should not be converted into Ioad carrier vehicle.

Priority for Utilisation Ambulance

The quality of service given to out-patients must be considered in the light of the four

traditional priorities applied within the ambulance service. These arc :

a) Accidents and emergency call.

b) Conveying patients and out-patients to hospitals and clinics etc.

c) Returning out-patients to the homes from hospitals etc.

d) Carrying patients being discharged from hospitals or transferred between hospitals.

c) Whenever there is insufficient transport to meet all requests arising simultaneously, the above priorities should operate as accepted principle,

2.7 CLASSIFICATION AND TYPES OF AMBULANCE

Ambulance can be of following types:

2.7.1 Surface Ambulance

These arc Ambulance, playing on roads, the make and body varies depending upon the manufacturer, Some are on heavy chassis. In the present era light body ambulances designed and built, as ambulances arc available. In many makes of ambulances arc available depending upon which make of vehicle has been used e.g. maruti van, gypsy, swnraj mazda, eicher and so on. These can go on congested roads and narrow streets in cities, being smaller in lengths, width and short in height.

2.7.2 Helicopter Ambulance

Most of the developed countries have helicopter ambulances for Ferrying sick and wounded patients. These are well equipped with trained staff in rescue and resuscitation task, Their response time is too short required for lifting emergencies.

2.7.3 Plying Ambulance (Ambulance Aircraft)

Many developed countries have airplanes converted or modified into ambulance. These are suited and ideal for mass casualties, disaster medical relief and such rescue missions. France, Russia and Australia have these ambulance services since long and well recognized all over the world for their efficient and prompt emergency care services,

2.7.4 Ambulance Trains

For rushing the medical relief team to accident or disaster site and evacuation of mass casualties, Railways have Accident Medical Relief Van and Armed Farces, ambulance trains. These have specially designed and suitably modified coaches for lying and sitting patients with all necessary fitments for medical and surgical treatment during transportation. Ambulance trains are supposed be having trained and dedicated staff for move at short notice.

2.7.5 Centralised Accident and Trauma Services

In last two decades due to many fold increase two wheeled and four wheeled transportation system like cars, motorcycles, trucks. buses the number of accident trauma cases on roads in India and all over the world has gone up by more than 200%. It has also been proved in number of studies that 30% to 40% case are salvageable and need not die provided immediate expert medical aid is provided. Over a period of time role of an efficient Emergency Services Department providing critical care to accident and trauma cases due to various reasons, has been well realised. Since percentage of trauma cases is more than two third of the critical emergencies, it has been found to be one of the major killers, the organisation and development of Trauma services has evinced significant interest over last two decades. A plan was envisaged to have a well-organized Centralised Accident Trauma (CAT) centre, which would be linked to all hospitals in the city and all emergency ambulances would also linked by telemetry. Object of any CAT Services or Emergency Medical Services System (EMSS), is to deliver medical aid to the accident victim as quickly as possible and rapidly

transport the injured to specialised centre or specialised care facility, so as to give him the needed immediate critical care and subsequent life support system till fully recovered.

2.8 DESIGN, STAFFING PATTERN AND EQUIPMENT OF AN AMBULANCE

2.8.1 Design

Committee on Ambulance Design Criteria (1973) has stated that a vehicle should not be termed an ambulance, unless it is designed, built, equipped and staffed to cope with medical emergencies outside the hospital. Ambulance "is defined as a vehicle for emergency care, which provides a driver compartment and patient compartment, which can accommodate two emergency medical technicians and two lying patients, so positioned, that at least one patient can be given intensive life support during transit, which carries equipment and supplied for optimal emergency care at the scene as well as during transport, for two way radio communication, for safeguarding personnel and patients under hazardous conditions and for light rescue procedures and which is designed and constructed to afford maximum safety and comfort and to avoid aggravation of the patient's conditions, exposure to complication and threat to survival".

2.8.2 Scale of Authorisation of Ambulance

Holding of ambulances by hospitals is on adhoc basis and not related to workload, responsibility of providing first aid or critical care at site and during transportation. Broadly, it is not scientifically related, strictly to nature and quantity of workload.

Authorization can be scientifically laid down only when the patient caseload in a district or on dependent area of responsibility is worked out and norm is evolved keeping all variables in view. However Report of the Hospital Review Committee on Delhi Hospital (KN Rao Committee 1968) recommended following scale of authorisation and state that "nuinber of ambulance should be sufficient to meet the requirement:

a) 100-200 beds – 3 ambulances

b) 200-300 beds – 4 ambulances

c) 300 beds and above – 6 ambulances

In each section one ambulance besides those provided by Municipal Corporation should be ear-marked for conveying the cases of infectious diseases. However, it is evident that scale recommended can meet hardly only intra mural requirement and not the requirement outside hospital on regular basis for Accident and Emergency Cases, One or two ambulance will always be off road for preventive maintenance or breakdown maintenance and while planning for number of ambulances, this also has to be kept in view. Scales recommended in 1968 requires review in view of population explosion, many fold increase in number of vehicles and consequent increase in number ofaccident, trauma and emergency cases. Number of ambulances authorised will have direct effect on manpower authorisation and planning for facilities and training.

2.8.3 Staffing Pattern of Ambulance

Each ambulance should carry with it always two-trained stretcher-bearers for lifting and carrying patients to ambulance. Hence, normally ambulance will have two team consisting of ane ambulance driver and two stretcher-bearers. It would be preferable to have nursing orderlies who have higher educational qualification and better knowledge of patient care. They should be trained how to lift cardiac patients, spinal cord injury patients and a case of fracture femur. The ambulance service like the casualty department is required to work 24 hours of the day, and works on all holidays and Sundays. It should run in all three shifts. Hence, staffing pattern should cater for three shift duty, relief duty and Sunday and holidays.

A suggested scales of the staff is as under:

Ambulance	Drivers	Stretcher Bearer/Nursing-Orderlies @ 4 per Ambulance + leave reserve + staff for three shifts system.
02	07	10
03	12	15
04	16	20
05	20	24

Doctors: So far doctors are concerned, they may go with the team depending upon the type of emergency, accident or disaster.

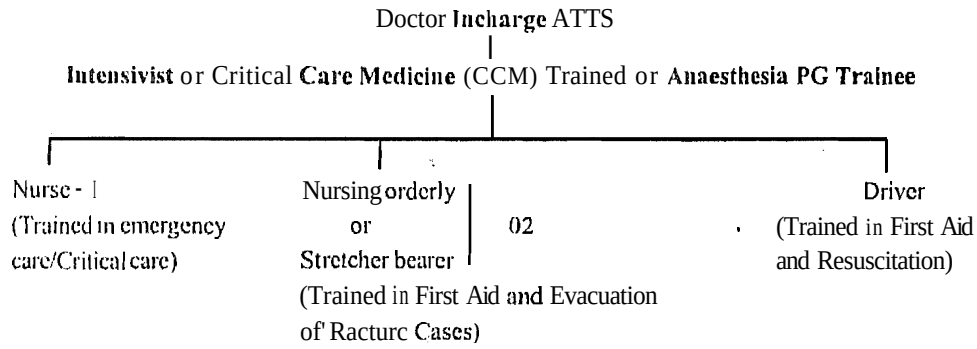
CCRI Trained Nurse: A Critical care medicine (CCM) trained nurse in each ambulance would be ideal for better management and supervision of emergency case.

Nursing Orderly and Stretcher Bearer: Each ambulance is required to have minimum 4 Nursing Orderlies or Stretcher-bearers all the time for lifting the accident victims and serious or comatose patients to ambulance. All these paraniedical staff are to be trained in first aid, resuscitation procedures and lifting of various types of serious accident cases without causing further damage or pain to the patient.

Call Response Time: Ambulance along with team should be in a position to move in less than two to three minutes once call is received.

Summary of Ambulance Staffing Pattern

For efficient Ambulance Transportation and Treatment System (ATTS) following dedicated medical nursing and paramedical staff should be available with cacli anibulance and located near ambulance bay or parking area, as in case of a fighter crew who jumps in fighter aircraft in case of any air warning system being sounded.



Shift System : The above staff should bc available in all three shifts round the clock. Staff should be particularly alert and checked randomly for their alertness in the night since ambulance, public vehicles and medical Facilities are not easily available and emergencies need to be attended promptly.

Rehearsals : Periodic rehearsals and practices should bc carried out to keep/staff, equipment and vehicle in a state of readiness and also to train new staffjoining the team on account of leave relief, hospitalisation and superannuating.

2.8.4 Equipping of Ambulances

It is not necessary that all ambulances should have only one scale and kind of equipment. Ambulances meant for different roles e.g. Mobile Emergency, Bums Unit. Coronary Care Unit, mobile dialyses unit and Mobile Operation Theatre will have some very specialised equipment. But few essential equipment must be present in all ambulances as laid down by bulletin of American College of Surgeons (1970), and these are:

- Portable suction apparatus with wide base tubing and rigid pharyngeal suction tip.
- Hand operated bag mask ventilation unit with mask of all sizes.

- Oropharyngeal airways – all sizes
- Mouth of mouth artificial ventilation airways – adult and children
- Portable oxygen equipment
- Mouth gags
- Sterile intravenous infectious (plastic bags with administration kit)
- Universal dressings, sterile gauze packs
- Bandages of all types
- Sterile burn sheets (two)
- Traction splints (lower limbs)
- Padded splints assorted
- Spine boards
- Safety pins
- Sterile obstetrical kit
- Anti poison kit
- BP instrument and stethoscope
- Two way communication system

In addition some of the ambulances should have equipment like, instant X-ray film processing equipment, operating fools, Operation Theatre (OT) Table and OT lights etc. for carrying out surgical procedures. Mobile QT vans can play a major role in delivery of primary arid expert health care to health starved population in most of rural and urban slum population,

In addition to the above items, the following items are also needed in most of emergency ambulances:

- ECG Monitoring equipment
- Defibrillator

  Respirator – portable small
- Ambu Bag with facility for attachment of all size of tubes
- Suction appara tus (paddle and battery operated)
- Drinking water storage containers
- Blood bottles of common blood groups
- Facility for doing cross matching of blood
- Generator on wheel to be towed by Ambulance to keep the equipment functional (OT light, X-ray machine, monitoring equipment etc.).

2.9 ADMINISTRATION OF AMBULANCE SERVICES: POLICIES AND PROCEDURES

Administration: Ambulance services should be under a department. Either it may be A and E Department or better where a Transport department is established for coordination and supervision of services.

Transport **Manager:** There should be an Officer Incharge known as Transport Manager for over all coordination, control, maintenance and administration of ambulance and other transport of hospital. He should act as a nodal point for inquiries by doctors, nurses and patients on all aspects of ambulance facilities.

Vehicle Supervision: **A** vehicle supervisor is required for day to day supervision and administration to organise and oversee reports.

Transport Clerk: A clerk is required for necessary secretarial work of transport department.

Store-keeper (Transports): A store-keeper is required on full time basis for keeping record of vehicles and ambulances going out for repairs, accounting, payment for repairs and mileage recording. Issue ofpetrol, diesel oil and lubricant, leave record of drivers, stretcher-bearer and other connected correspondences. Unless transport section or Ambulance Transport Section depending on type of organisation has got separate store-keeper with proper accounting and filing procedure, chances of pilferage and misuse of vehicles cannot be ruled out. Meticulous record keeping is essentially required for auditing purposes.

2.10 AMBULANCE SERVICES DEPARTMENT

2.10.1 Physical Facilities

a) **Parking**

Most important point to see is that it should be easily accessible by patients and public, Ambulances should have well known fixed covered parking places, so that these special 'Vehicles do not deteriorate due to extremes of weather and also from early locating point of view. Ambulances parking should have adequate space for easy and early turning around of

ambulances. It should be well sign posted and illuminated. In Accident and Emergency Service Department or Centralised Accident Trauma Service (CATS) Cantre, it should be able to go right at the entrance gate of the department. The parking should be at prominent place and in such a way that patients can easily be loaded and unloaded.

b) **Location**

Ambulance should be located at a central place near to Accident and Emergency Services Department under one roof for easy access, better utilisation and coordination. It should be easily approachable by other general public vehicles.

c) **Space**

Should be adequate for parking number of ambulances at a time depending upon size of hospital or organisation and its holding of ambulances. There should be nearby large space for parking ofprivate cars, vans, taxis of civil public and relatives coming to hospital for treatment at OPD, hospital admission, laboratory investigations or to see admitted relatives and friends.

d) **Floor**

There should be cemented non-slippery flooring easily washable with sloping surface,

e) **Design**

For running a 24 hrs prompt and efficient ambulance services both for intramural and emergency call duty at emergency or accident site, it is ideal to have an Emergency Ambulance Services Department well sited and properly planned and constructed under one building near the A and E department, Following additional facilities should be planned:

i) Ambulance Control Room : For receiving calls, fixing appointment for ambulances etc.

ii) Each Ainbulance garage of rhe size of 200 sq ft each

iii) Patient loading and unloading area.

iv) Relatives and visitor's lobby with male and female toilet facilities

v) Doctor's duty room

vi) Nurse's duty and rest room with toilet facilities

vii) Paramedical staff duty and rest room with toilets

viii) Drivers and stretcher bearer's duty and rest room with toilet facilities

ix) Ambulance communication robm

x) Ambulance repair and washing area with facilities for water supply system

xi) Ambulance clerk and store keeper's office

xii) Spare parts store room

xiii) Trolley bay

f) Illumination

Area should be well lighted during day and night. Illuinination of 400 lux can be considered as basic light level in most of the areas. There should be provision for emergency lighting system to overcome problems of power failure.

g) **Public Toilets**

Large number of visitors, relatives, Police and Staffpersonnel would be visiting ambulance services department Male and female urinals, toilets for public and patients including wheel chair patients are required at a convenient place.

h) **Janitor Closet**

Janitor closet of the size of 40 sq feet for house-keeping and cleaning material is essential.

2.10.2 Training of Staff

Training of all categories of ambulance staff is extremely essenrial. There should be laid down syllabus with laid down periods for the basic capsule course for orientation of doctors, nurses, and nursing orderly, nursing technicians, stretcher-bearer and drivers. Subsequently for updating the knowledge and skills, refresher course should be planned and held through-out the year. Minimum every three months there should he mock rehearsal or exercise to know the preparedness of staff in case of air strike or bombing etc. Each ambulance crew member should be fully trained in emergency medical and surgical procedures, resuscitation techniques, ECG recording, wireless communication system and tele medicine relay system.

To meet the requirement each medical college, big and small hospitals should have a laid down critical care medicine and resuscitation training programme running under Accident and Emergency Services Department. Doctors and paramedical staff from peripheral hospitals, PHC and general practitioner should also be encouraged and given due opportunity to attend such courses.

The training of staff of ambulance team is of paramount importance. Patients must be lifted and loaded by trained and experienced staff. It is important that trained team handles the patient depending upon the nature of urgency, fbr example, a case of fracture T-3-4-5 vertebra or fracture femur would require expert and delicate handling than a case of fracture rib or ulna. Cases of asphyxia or mine blast, poisonous gas poisoning, crush injury leg or eighty percent burns due to explosion, need special handling.

Prompt removal of foreign body, objects causing penetrating injury, positioning of patient to avoid further injury to tissues, nerves and vessels causing pain and likely gangrene is immediate task of ambulance crew. Immediate simple first aid measures like tying of tourniquet and packing by gauze piece if bleeding wounds, preventing further blood loss and consequent shock and death are immediate concern and responsibility of ambulance staff. Subsequently maintenance of treatment, iv drip, tackling of any cardiac arrest or fall of BP, etc. while transporting patient to hospital for treatment is the responsibility of ambulance staff. Hence education and practical training of ambulance crew is essential which will save number of salvageable deaths and preventable complications and disabilities.

2.10.3 Communication System in Ambulances

Efficiency and effectiveness of ambulance-based emergency medical care system and emergency call response, totally depends on online efficient dedicated and assured two-way communication system, All ambulances should have wire less communication system and linked with concerned hospital or ambulance control organisation. An electronic keyboard with memory system that can convey the patient related call and information system to a similar display panel in the receiving hospital emergency department might be installed. In the present era of satellite communication system, computers global cord less telephone and e-mail, no difficulty is visualized in providing communication system in ambulance, and hospital receiving the emergency patients, The system should be on 24 hours so that any emergency call can be received by Hospital or ambulance control organisation or centralised Accident Trauma Centre and ambulance staff is directed to proceed at the site of emergency or accident,

The drivers should be made familiar with the various areas and roads of city or concerned area of operation before hand. Ambulance should have detailed map of city-roads so that if required they can be asked to refer to the map.

French Ambulances have detailed map of city on electronic date board including names of street and house numbers so that they have no difficulty in reaching the exact location in 3-5 minutes. It should be done by our hospital also. All doctors, nurses, paramedical and driver staff of ambulance transportation system arc required to be trained in operating communication system with ease and for this training in handling of communication system needs to be given to staff. To check efficiency and call response time, during day and night exercises needs to be carried out at periodic intervals. This will enable organisation to maintain state of alertness,

2.11 AMBULANCE AND EMERGENCY CARE SERVICES OF DEVELOPED COUNTRIES

2.11.1 France

France has got fully developed, extremely efficient unique organisation of Accident and Emergency services. The system established during last three decade is called 'SAMU' (Service D' Aide Medical Urgente). It practically covers the whole country. Service is run by medical personnel manning central control and by a number of specially equipped ambulance called SMURS (Service Mobile D' Urgence etude Reanimation). Ambulances carry resuscitation and monitoring equipment, an ambulance team, consisting of one emergency first aid trained driver and one stretcher bearer and the medical team (a senior doctor and a medical student). These ambulances reach any spot within 3-7 minutes after receiving the call.

SAMU cover the whole country. The secret of efficiency of SAMU is a permanently manned control centre comprising a manned switch board, Radio communication network and a medical secretariat consisting of a controlling doctor and other senior medical staff with a specially equipped and designed ambulances called SMURS.

2.11.2 Soviet System of Emergency Transportation

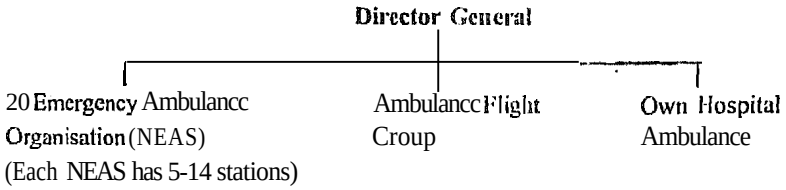
Basic principle of the Soviet System of emergency medical care is known as the SICORAYA. Attached to each polly clinics is a minor emergency care facility called "Neotlozhnay" for giving 24 hour and weekend services to patient. In erstwhile USSR, there were 35 doctors/ 10,000 population compared to 10 Doctors/10,000 in UK. SKORAYA Services of Moscow is highly efficient organisation having 200 Ambulances for day time and 100 Ambulances for night time with specially trained para-medical staff and medical officer.

2.11.3 Japan

Most emergency services are rendered by private clinics and private hospitals. The organisation and availability of EMS is influenced by Japan's compulsory Health Insurance scheme. Public and private carriers provide emergency service transportation and few hospitals have their own ambulances. The major fleet of ambulance is with the Tokyo Fire Service Department. They also have few helicopter ambulances. The fire department ambulances strive to achieve the goal of service within three minutes. There are special telephone booths with no payment for call for emergency medical services.

2.11.4 Israel

In Tel Aviv with more than 10 lakh population Emergency Services arc provided by fire emergency stations. The organisation which maintains the emergency care services is a society similar to Red Cross and is called "Magen David Adom" Ambulances both for primary transportation from scene of accident to emergency care station and for secondary transportation from station to hospital. These arc:



2.11.5 Australia

Ambulance services are centrally controlled by each state with locally organised operating units. The size of operating units varies between states. The range is from one vehicle volunteer service to about 100 vehicles. Ambulance officersare specially trained officers for the job, Ambulancc services receive call on emergency telephone number or on wireless with special frequency. They are also in contact with casualty department through Radio Control. In early 1970's fixed wing Air Craft and helicopter ambulance services bavc also been added to the fleet for emergency treatment and transportation.

2.11.6 United Kingdom

UK has high developed and efficient Accident and Emergency Services called British Accident and Emergency Services also known as – "Flying Squads".

2.11.7 *West* Germany

West Germany has A and E Services similar to France. In addition the country has very wide and comprehensive stand-by Helicopter cover.

2.12 STATE OF AMBULANCE SERVICES IN THE COUNTRY

Much needs to be done to improve the condition of present ambulance fleet. Number of committees appointed by government of India from time to time have commented on tlie state of ambulance services and recommended measures to improve tlie services. Improvement in Ambulance services has to be taken up as one key result area (KRA) by Hospital and Health Administrators of the country. Extract of some of the important Committee reports and tlacir recommendations are enumerated below for better understanding of the problems.

2.12.1 Report of the Health Survey and Planning Committee, 1961 (Mudaliar Committee)

While commenting upon Employees State Insurance Corporation report stated that – "It was obvious that ambulance facilities were not available to the extent they ought to be. There was a need for hospital authorities to rcvicw their arrangements for authorisation of ambulance transport. Committee observed that clinical procedures for requisitioning transport and controlling ambulance operations tend to be unnecessarily complicated and there was scope for closer cooperation between hospital and ambulance authorities.

2.12.2 *Report* of the Hospital Review Committee on Delhi Hospitals, 1968 (M.N. Rao Committee)

In none of the hospitals supporting ambulance service can be said to be satisfactory. Each hospital had one or at the most two vehicles. even those were old. Most of the time these were off the road. Sanctioned ambulance staff was not adequate to provice 24 hours cover. It was generally found to be inadequate for the needs of a vast area, and particularly in areas where public transport was poor anti difficulties were very great. In addition, tlie type of ambulance used were only a transport vehicle and had no resuscitation equipment as there was neither a nurse, doctor nor materials for this service. As a part of civic amenity the corporation should liave a fleet of ambulance. It recommended that all ambulance vans should at least have a trained nurse.

Although reports of these committees' are quite old yet state of ambulances liave not much changed.

2.12.3 Primary Health Care and Integration *of* Ambulance Services

There is no means of transportation of critically sick and injured patients from rural areas. Patients have to be transported by first available vehicle likes tractor trolleys, trucks or buses. Many precious lives are lost daily due to lack of this vital service. There is need to create a pool of ambulances or speedy general vehicles modified into critical care vans and locate them in Primary Health Centres (PHC) or Taluka hospitals or tehsil headquarter from where these can be easily mobilized.

These Ambulances can also be used for patient care logistics also. Returning empty ambulances can carry essential medical supplies, special laboratory investigation results and also autoclaved dressing and equipment For use in Primary Health Centres from District Hospital.

The ways and means of transportation of the sick and injured are important factors in reducing death, disabilities and other serious effects of injury and illness. The first purpose of an ambulance service is to reduce mortality and morbidity for emergency patients and the second purpose is transportation. The aim can be achieved, provided ambulances are designed, equipped and staffed properly on scientific basis. As man behind machine matters, similarly it is the trained ambulance staff which is very important factor for operational efficiency. For achieving the ultimate objective, efficient response communication system should be reliable, on line, and state of art. Most ambulances are poorly constructed, equipped and manned for managing emergencies which needs to be improved and made as one of the key result areas by Hospital Administrators.

2.13 LET US SUM UP

In this unit yon have learnt as to what is meant by an Ambulance,~!hatis real definition of an ideal Ambulance, and its role in life, limb and disability saving. Aim of Ambulance services has been clearly brought out including role in Primary Health Care and related logistics. Very important aspect of equipping of ambulances with various instruments and emergency drugs and equipment has been brought out. You have also learnt regarding important aspects of administration, policies and procedures of Ambulances Services. After having studied this unit you should be able to organise an efficient and effective ambulance services 'in any Hospital or Organisation you serve.

2.14 ANSWERS TO CHECK YOUR PROGRESS

Check Your Progress 1

1) Ambulance, lift, escalator, stretcher, trolley, train, car, cycle, bullock cart, helicopter, and animals.

2) France

3) Dominique Joan Larry (1392)--a French Military Surgeon

Check Your ***Progress*** 2

1) Transfer sick and injured promptly and provide life saving treatment at the site of emergency and during transportation.

2) Provide prompt emergency treatment, safe transportation with continued treatment,

3) Ambulance should be designed, built, equipped and staffed to cope with emergencies.

Check Your ***Progress*** 3

1)
- Surface Ambulance
- Helicopter Ambulance
- Flying Amblance (Ambulance Aircraft)
- Ambulance Trains

2) Centralised Accident and Tauma.

3) For design criteria, refer to sub-section **2.8.1** of this unit.

4) For staffpattern for ambulance, refer to sub-section 2.8.3.

5) For important items and equipment, refer to sub-section 2.8.4.

UNIT 3 SANITATION AND WASTE MANAGEMENT

Structure

3.0 OBJECTIVES

After going through this unit, you should be able to:

- describe'the history of hospital waste management;
- understand the various processes involved like, Generation, Segregation, Transportation, Collection, Storage, Treatment and Disposal;
- enumerate the different modalities of treatment of hospital waste; and
- list out the harmful effect hospital wastes pose to the community.

3.1 INTRODUCTION

In this unit you will learn about the concepts of hospital waste management (HWM) as well as the Bio Medical Waste Management and Handling Rules, 1998.

Hospitals have been existing in one form or the other since time immemorial but there never has been so much concern about the waste generated by them.

The environmentalists have been up in arms against the casual manlier in which hospital waste is treated in our country.

The last few decades have seen a rapid mushrooming of hospitals, both in Govt. and corporate sector to cater to the needs and demands of the increased population. Correspondingly there has been an increase in the quantum of waste generated by them. It is ironical that the very hospital that brings relief to the sick can created health hazards due to improper management to the waste generated by it, Unlike in the developed countries, the concept of HWM has not really cauglit up in India. It is time we realise the importance of HWM and the need of sensitizing the top level managers orienting them with various types of waste, their generation. segregation, collection and transportation and final disposal. The

3.0 OBJECTIVES

After going through this unit, you should be able to:

- describe the history of hospital waste management;
- understand the various processes involved like, Generation, Segregation, Transportation, Collection, Storage, Treatment and Disposal;
- enumerate the different modalities of treatment of hospital waste; and
- list out the harmful effect hospital wastes pose to the community.

3.1 INTRODUCTION

In this unit you will learn about the concepts of hospital waste management (HWM) as well as the Bio Medical Waste Management and Handling Rules, 1998.

Hospitals have been existing in one form or the other since time immemorial but there never has been so much concern about the waste generated by them.

The environmentalists have been up in nnns against the casual manner in which hospital waste is treated in our country.

The last few decades have seen a rapid mushrooming of hospitals, both in Govt. and corporate sector to cater to the needs and demands of the increased population, Correspondingly there has been an increase in the quantum of waste generated by them. It is ironical that the very hospital that brings relief to the sick can created health hazards due to improper management to the waste generated by it, Unlike in the developed countries, the concept of HWM has not really caught up in India. It is time we realise the importance of HWM and the need of sensitizing the top level managers orienting them with various types of waste, their generation, segregation, collection and transpartation and final disposal, The

owners should be on the generators of hospital waste, and proper segregation of the waste at source is the "sine quanos" of a successful waste management programme. It is the factor, which has led the Ministry of Environment and Forest to prepare the Bio Medical Handling and Management Rules, 1998. We have to preserve the earth for the future generation. We shall study in detail how we can do so.

3.2 IMPORTANCE OF HOSPITAL WASTE MANAGEMENT

A modem hospital is a complex multidisciplinary system, which consumes lots of items for the proper delivery of medical care. All these consumable leave some amount of unusable leftovers which are called as hospital wastes.

These wastes are generated as a result of patient care activities like diagnosis, treatment, immunisation or research. These wastes have the potential to transmit various viral, bacterial or parasitic diseases to the staff, patients and general population at large.

The fast recovery and health of the staff of the hospital directly depends on a clean and hygienic environment. Hence it is very important that all the hospital waste is managed in a proper and scientific fashion. It is also vital that the whole hospital be kept clean and in a satisfactory state of hygiene.

Health hazards associated with poor hospital waste management are:

a) Injuries from sharps to all categories of hospital personnel and waste handlers

b) Nosocomial infections to patients from poor infection control and poor waste management

c) Risks of infections outside hospitals for waste handlers, scavengers, and (eventually) the general public and some times change in microbial ecology resulting in antibiotic resistance.

Therefore, it is imperative to have a scientific system approach towards handling and ,managing hospital wastes.

3.3 TYPES OF HOSPITAL WASTE

By now it is amply clear to you that hospitals of today are over crowded with patients, their relatives and visitors as well as the hospital staff, In urban areas due to the shortage of space the hospitals are of a vertical structure with improper aeration.

The quantum technological jump has also resulted in state of the art diagnostic and therapeutic activities there by generating lot of waste material,

W.H.O. has classified wastes generated in hospitals into the following types:

a) ***General Waste:*** These wastes are by and large generated from offices, administration areas, stores, kitchen, laundry etc.

b) ***Sharps:*** Hypodermic Needles

Needles attached to tubings

Scalpel blades, razors, nails etc.

Broken glass pieces

c) ***Infected Waste:*** Equipment and instruments used in various diagnostic and therapeutic procedures.

Laboratory waste e.g. Cultures, stocks and samples

Wastes from surgeries (tissues and organs removed during surgery) and autopsy.

d) Chemical ***Waste:*** Formaldehyde used for preserving tissues

Fixer and developer used in radiology department

Solvents used in laboratories e.g. xylene, acetone, ethanol, methanol chloroform, ethylene etc.

e) Radioactive ***Waste:*** Generated from

i) Research activities

ii) Clinical laboratories

iii) Nuclear Medicine labs.

f) Cytotoxic ***Drugs:*** Various anti cancerous drugs used for treating malignant conditions are very corrosive to human skin and tissue.

Quantity of hospital waste generated

Various studies carried out by different groups have revealed that the quantity of wastes generated from hospitals in our country ranges from 1-2 kg/bed/day. I-Iowever this figure is higher in developing countries like USA, UK etc. where the figures are 5-6 kg/bed/day.

3.4 IMPLICATION OF HOSPITAL WASTE

The implication of hospital wastes are manifold. Since hospital is an established social organisation the wastes from hospitals have effects on the hospitals staff, the environment, general public etc.

3.4.1 On Hospital Employee

The staff working in hospital is exposed to various wastes and as such it would be worthwhile to mention some important points related to the problems.

Primarily the hospital staff are the ones who are involved in generating, collecting, storing and treating the wastes. All the personnel are exposed and are totally at risk of getting an infection, which could be transmitted through air, blood, faeces, oral routes etc.

In day to day activities all personnel are used to working with needles, blades, glass etc. which are usually sharp objects. An injury due to these sharps is very common. This is the most common route of entry of any kind of infection. Air borne infections find their entry through the nose. Hospital employees having tuberculosis is another common phenomena. Dreaded infections like AIDS, Hepatitis are not uncommon lo be transmitted to the staff handling infected patients.

The practice of universal precautions is, therefore, mandatoiy. The idea is to consider each patient to be a potential reservoir of infections. The hospital authority should provide adequate numbers of gloves, footwear, protective eye, head gears, masks and gowns. The staff working in high risk areas should also be immunised against tetanus, Hepatitis elc.

3.4.2 On Public

As envisaged earlier the fact that hospitals are social organisation, the general public as regards hospitals are attendants and visitors patients, people staying close to the hospitals, vendors and suppliers and above all the masses.

Hospital waste do have some impact on the health of the masses but this fact has been blown out of proportion by the media. More over the public today is becoming more and more aware of the possible harmful effects of hospital wastes.

The very fact that heaps of wastes dumped on a particular site in or outside the hospital or emission of incinerator fumes gives an impression in the citizen minds that they could be harmful to the society. Adding to this is the activity of rag pickers who pose a threat to the society.

However various studies carried out have revealed that the chance of getting infection from sharps on other wastes are very minimal.

3.4.3 On Environment

The air inside the hospital could be contaminated and contain bacteria or viruses from a grossly infected patient of Tuberculosis, Chicken Pox, Rabies etc. which could pose a threat to the community. Many a times excreta or other body fluids from laboratories, autopsyroom or mortuary could give rise to a foul smell around the premises. Liquid and other chemical wastes flowing out of the hospital is another potential hazard. Radioactive wastes are another serious threat to the environment if adequate measures of protection are not taken in to account according to the laid down procedures.

Many a times even treatment technologies like incinerators or microwaves could give out poisonous gases like furan, dioxene etc. or high amount of particulate matter or other chemicals.

General wastes accumulated for a greater period of time might be a breeding ground for many organisms.

3.4.4 On Hospital Acquired Infection

We shall in this section discuss in detail about the hospital acquired infection and the implication of hospital wastes on the same. The various modes of transmission are:

a) Aerial route

b) Oral route

c) Contact route

d) Parenteral route

e) Through equipments and materials used

The sources and reservoir of infection could be:

i) Patients own flora

ii) The flora of another patient (Cross infection)

iii) Environmental sources

iv) Contamination by patients, attendants and hospital staff.

A host of micro-organisms could be responsible as;

- Enterococci
- Non hemolytic streptococci
- Anaerobic coccs
- Claustridium Tetani
- Flavo Bacterium
- Klebsilla
- HIV
- HBV

Therefore, the role of hospital waste in hospital acquired infection is of paramount importance.

Measures to minimise health risk due to medical waste:

a) Select safe or less hazardous substitute for chemical agents

b) Use closed storage for volatile agents

c) Use proper ventilation and exhaust fans as per norms

d) Use appropriate protective clothing with arrangements of disinfection and disposal.

e) Popularise use of colour and emblem code on container bags.

f) Introduce monitoring and surveillance for problem areas on high risk situation

g) Proper disinfection and sterilisation practices to be followed

h) Universal precaution measures to be followed

i) Hospital infection control committee to be formed with a microbiologist as its chairman and adequate delegated nurses, supervisors and paramedical personnel as members to monitor infection in the hospital.

Check Your Progress 1

1) List the various types of wastes generated in a hospital,

.....

3.5 LEGAL AND ETHICAL ASPECTS OF WASTE MANAGEMENT

The notification served by the Ministry of Environment and Forests, Govt. of India on 27th—July, 1998 called as Bio-medical Waste (Management and Handling) Rules. These rules have been made by the Central Government, in exercise of the powers conferred by sections 6, 8 and 25 of the Environment (Protection) Act 1986.

Any violation to these rules are punishable by 5 years rigorous imprisonment or a fine or Rupees five thousand. The main rules are as under:

Bio-medical Wastes are to be handled only according **to these rules.**

Rule 6 pertains to:

Setting up of Bio-medical waste facility

Rule 6 (1) "Every hospital, nursing home, clinic by whatever name called, generating bio-medical wastes, shall install an incinerator or any other facility in the premises or shall set up a common facility in accordance with the directions given by the appropriate authority within a period of nine months from the date of commencement of these rules".

Rule 12 emphasizes:

Responsibility of generators and operators of bio-medical waste facility.

Rule 12 (1): "a generator or operator of bio-medical wastes facility shall take all measures as the Central Government may, with a view to preventing damage or adverse effect to the environment and the life sustained in it, notify in the official gazette from time to time in this behalf."

Rule 12 (2): "A generator or operator of a bio-medical waste facility shall house in the month of January every year a detailed information about the types and quantities of bio-medical wastes collected or handled by him during the preceding year to the appropriate authority.

Rule 13 deals with:

Segregation, packaging, transportation and storage.

Rule 13 (1): "An authorized person handling any bio-medical waste shall segregate all categories of such wastes prior to its storage, transportation, treatment and disposal."

Rule 13 (2): "All segregated wastes shall be subject to specific treatment and disposal methods as given in Schedule IV."

Treatment and disposal

Rule 14 (1) : "All bio-medical wastes shall be treated and disposed off strictly in accordance with the treatment options specified in Schedule IV."

Rule 14 (2): "All such wastes which are required to be destroyed by incineration or any other treatment and disposal option specified in Schedule IV and duly approved by the appropriate authority shall be heated and disposed off only in a facility authorized under these rules."

Rule 14 (3): "All such wastes which are not incinerable shall be prc-treated, disinfected and shall be disposed off in an environmentally sound manner by the authorised person in such sites identified by the appropriate authority for this purpose."

Rule 14 (4): "All sdch wastes arising from handling of living or non-living pathogens and genetically engineered organism or products therefrom shall be treated and disposed off by such methods as the Central Government may, notify in the official Gazette."

Rule 14 (5):" "No person shall dump, discharge or dispose or cause to be dumped, buried, discharged or disposed any such waste in any place other than a site identified for the said purpose by the appropriate authority."

Rule 14 *(6):* "Every authorised person shall take all precautions and safety measures including the provision of protective clothing, masks, gloves, gum boots and such other protective aids as may be necessary for affording protection, to all the persons engaged in handling bio-medical wastes or exposed to such wastes, against infections due to handling or exposure to bio-medical waste. Washing and bathing facilities shall be provided in such premises."

Rule 14 **(7):** "All treatment and disposal facilities shall be located at the specified area away from general services area of the hospitals, nursing homes, veterinary institutions and other organisations. For the common facility, suitable sites shall be identified by the appropriate authority and shall be located in areas away from public places and residential areas."

Rule 14 **(8):** "All plastics shall be disinfected and shredded and shall be disposed off in an environmentally sound manner or shall be recycled by reprocessing the shredded wastes."

Rule 14 **(9):** "The treatment and disposal of all such wastes shall be in accordance with the standards prescribed in Schedule V."

Rule 14 (10): "Every hospital, nursing home, clinic, laboratory, by whatever name called, generating bio-medical wastes shall not dispose off such wastes on open land, municipal dustbin and let the untreated liquid into the sewers."

Rule 14 (11): "No person shall recycle or reuse or cause to be recycled or reused any such waste except glassware. Provided that such glassware are disinfected and reused for in house purpose only."

Rule 15 declares the necessity of:

Maintenance of Records.

These records, as the rule notifies, shall be subject to inspection and verification by the appropriate authority from time to time.

3.6 WASTE CLASSIFICATION, COLLECTION, SEGREGATION AND STORAGE, TREATMENT AND DISPOSAL

Collection of the garbage and its segregation at source in the first step of management, it is the key to whole process,

For streamlining the process, waste has been classified and is stored in different coloured bag, receptacle and the staff should be able to recognise the appropriate container for each particular type of waste:

Classification used in developing countries:

a) General Non hazardous wastes – **Black** colour

b) Sharp (whether infected or not) – Yellow

c) Infected wastes (not containing sharp) – Yellow colour

d) Chemical and pharmaceutical other than cytotoxic drug, rodioactive wastes, high pressure container – Red **bag**

e) Clinical waste that required autoclaving – Blue bag.

Container and colour coding for disposal of bio-medical wastes
(As per proposed MOEF guidelines)

Waste Category	Waste Class	Types of Container	Colour Code
Category 1	Human anatomical Waste, blood and body fluids	Single use containers/ plastic holding bags	Red/Yellow
Category 2	Animal and slaughter house waste.	Single use containers/ plastic holding bags	Orange
Category 3	Microbiological and Biotechnologics wastc	Single use containers/ plastic holding bags	Yellow
Category 4	Waste sharps sturdy containers of	Reusable/single use plastic glass or metal	Yellow/Blue
Category 5	Discarded medicines	Reusable/sturdy cardboard/glass/plastic holding bags	Yellow/Blue
Category 6	Solid wastes	Plastic bags/Sac	Yellow/Black
Category 7	Disposables	Reusable/sturdy containers/plastic holding bags	Yellow/Black
Category 8	Liquid waste	NA	NA
Category 9	Incineration ash	Plastic bags/Sac	Black
Category 10	Chemical waste	Plastic holding bag	Black

Labelling

Use of label/symbol is useful in identifying type of waste, which will be helpful in taking further steps for treatment and disposal. Some of the important labels/symbols are mentioned below:

Recommended colour coding by Sulabh International Institute of Health and Hygiene

Use of minimum number of colours which is quite in agreement with the suggestions by the team from A.I.I.P.H. Calcutta.

As per present practice since no segregation of solid waste is carried out at source, it would be not practical to introduce segregation of solid waste in 10-12 category containers at the source. Rather it is considered to be appropriate in our country to introduce immediately three container system in each point of generation of solid waste (wards/laboratories etc.) in hospitals. Sulahh Institute of Health and Hygiene team of study also share the same view.

It is recommended to introduce following containers in each ward, laboratory etc. for segregating solid waste at the source of generation.

The colour coding varies from nation to nation. It is essential that this should be standardised at national level.

Category		Type	Waste Category
A	Green Container	Covcrcd	General waste (food waste, kitchen waste i.e. Putrescible part)
B	Red Container	Covered	Microbiological;Surgical, Human Anatomical organs, Tissues, blood and body fluids etc.; Pathological infectious waste contaminated with blood, secretion etc.; Soiled Cotton Dressing, bedding; Animal Waste; Research laboratory waste etc. (incinerable)
C	Yellow	Covered	Disposables, plastics, PVC, Polythene, sharps e.g. needles, blades, scalpels etc.; Cardboard, Thermocoals, discarded Glasswares etc.

The container for storage may be:

A) ***Dustbin with lid:*** The dustbin should be used to collect garbage with cover. It should be made ofplastic or metal and be fitted with cover to limit problems with flies or insects, small enough to be carried. It should not be easily destroyed by rats, cats or dogs.

B) ***Plastic bag:*** *It* may be suspended inside a frame that has a lid to cover the opening of the bag at the top or inside. A rigid ring with the top fold over the rim of the bin will entail extra expenditure.

C) ***Plastic bins***

D) Metal birrs

E) ***String paper sacks*** (made of craft paper, which retains its strength even when wet.)

The extra expenditure in buying plastic bags is insignificant and recommended on the grounds of improved hygiene and convenience

The reusable containers should oe smooth and well rounded and should be cleaned and disinfected regularly, tailing which there may be chances of developing unpleasant odour and problem with flies.

The size and number of receptacles should be decided keeping in view the expected amount of waste produced in different unit which should be collected twice a day or more often from operation theatres or intensive care rooms.

The containers should be:

Not too heavy, smooth and rounded, and maximum size of 100 litres for dry waste and 50 litres of waste water. It can be then easily handled by one man.

Each receptacle should be closely labeled to show the ward or room where it is kept. The plastic bags should be marked with room number before use. This precaution detects and avoids incident or accident caused by waste.

Plastic bags should not be filled completely so that it should be possible to seal and tie it without difficulty.

Sharp Objects

Sharp objects pose dangers due to following reasons:

- Needles act as reservoir of pathogen in which the pathogen may survive for a long time due to presence of blood.
- Sharps enter directly into blood stream by puncturing the skin.

- Due to great demand of syringes there is great rush to procure syringes and needles in hospital wastes.

Containers/Bags for sharp

Sharp should be collected in separate container. Criteria of special bag should be:

Firmly closed, it should have minimal dangers of contents spilling or falling out, strong enough not to bc punctured and leaked out.

It should be provided with handle, which is not part of any close device.

A special system should be used which encapsulates the sharp in polymer, which is formed when water is added to powder that is kept at bottom of the sharps container. Encapsulation prevents scattering of needles if the containers get damaged.

Other types of containers may be used like discarded tins and milk powder tins.

It should have a horizontal line to indicate when the container is ¾ full.

It should be preferably made of materials, which can be incinerated.

It shouldcomply with the specification given in British Standard 7320 : 1990.

Sharp used at home by nurses visit or self treatment, as in diabetic cases, should never be deposited with domestic soiled waste. They should be stored in hard plastic or metal. Awareness and public programme can tackle this problem.

Garbage **collection** centres

Covered and protected garbage collection centres should be used for collection of general waste.

Central storage area

Prior to-incineration on site or prior to transport for disposal of site, clinical waste is required to be stored, treated separately from general waste storage area and should be clearly identified with clear warning sign.

This area should be kept locked with key available to staff throughout 24 hours.

Only authorised persons are allowed to enter. It should be easily accessible to internal transport and office transport.

Location

It should be constructed away from hospital building, food preparation and storage area, and public places.

Construction

It should be covered, situated on wide drain with innpervious hard standing, well lit, well ventilated, and protected from entry by animals and insects.

Capacity

It should contain a minimum capacity of two day storage.

Removal

It should be removed daily for disposal.

Refrigerated storage

It is required for hospital where wastes have to be stored in bulk for up to 48 hours prior to collection for disposal.

Freezer unit will serve the purpose where water is less frequent than once every day.

Storage for Smaller Units

Since half life of most radioactive materials used in hospitals is in the range of hours or days or storage is needed for a month or so before disposal, and radioactive waste should be kept in suitable containers which prevent any dispersion of contents.

A plastic bag or large container can or drum is appropriate container, it should be closely labeled to show:

The radio nuclides (S) name, and activity on a given date and period of storage required and the containers should have radioactive symbol and marked Radioactive *Waste*.

Container with radioactive waste should be stored either in a specifically marked a general store for radioactive substance or in a store reserved for radioactive waste.

Handling and Transfer

Handling and transfer leads to closer contact with wastes, leading to high hazards. Attention should be focused on following points:

The transportation of clinical waste off site should be carried out in specially designed vehicles, with a fully enclosed body and a bulk head separating the drivers compartment from the local compartment.

Safety Precautions

It is responsibility of management to ensure safety. The measures are:

- Employee should be provided with approvedprotective clothing and footwear,
- Training should be imparted to drivers, collectors and other handlers on risks of the waste, other instructions, precautions taken in the event of spillage by accidents.
- Services of emergency telephone should be made available.
- They should be protected by immunisation.

VehicleTrolley for Transport

Various types of vehicles are being used for transfer of waste:

A) Wheel Barrow

Small transport vehicles, like wheel barrow can be used for small quantity of garbage, which can be made of different sizes. With certain modification it can be given the shape of covered vehicle,

B) Cycle rickshaw garbage carrier

For smaller medical units and even in bigger units it can be uscd as transfer vehicle to carry waste, it can be divided in two compartments, one for biodegradable and another for non biodegradable waste, .

C) Garbage lorry

Garbage should preferably be carried by covered lorry. Waste cardboard, waste paper, etc. can be carried by open trolly.

A vehicle uscd for the transport of bags of clinical waste should be fitted with a fully enclosed body, lined internally with stainless steel or aluminium to provide a smooth impervious finish for easy and effective cleaning, all corners and angles should be covered to prevent lodgements of waste matter. A bulkhead should separate the drivers compartment from the load compartment. The load compartment should be refrigerated particularly for transporting clinical waste over long distances in hot climates. The load compartment of an

unrefrigerated vehicle for transporting waste over short distances should be provided with the ventilation system, e.g. root vents.

Clinical waste collecting van should not be used for any other purpose. The load identification sign using the biological hazards label and the name and address of the haulier, together wit11 his telephone number, must be shown on the sides and rear of the vehicle when collecting and transporting clinical waste.

The following points must be kept in mind:

- They should not have sharp edge, which could tear open waste bag during loading and unloading.
- It is properly and carefully designed.
- It should be technically and manufacturally strong so that minimum effort and inconvenience is experienced.
- Waste in categories BCDE (i.e. except all non-hazardous waste) should never be transported with general municipal waste.
- Special vehicle should be used for hazardous waste to prevent access to direct contact with wastes by transport operator, the scavengers and the public.
- Open topped skips should never be used for the transportation of clinical waste.

Waste Duct in the **Hospital**

In some modern hospitals pneumatic pipe line transport system is used for waste movement. While such system reduces the need for manual handling of waste, they can give rise to hygienic and technical problems. The disadvantages are:

- It ends to scatter waste.
- It emits foul odour.
- It generates insects.

Cleaning and Disinfection of Transport Vehicles

Vehicles used for clinical waste collection shall be thoroughly cleaned and disinfected immediately following any internal spillage. The cleaning should be carried out on a proper surfaced area with the drainage running to the foul sewer. They should carry at all times supply of plastic bags, protective clothing, cleaning tools and disinfectant to cleanse and disinfect any matter or thing which has been contaminated by any spillage of waste during loading, transport or unloading.

Documentation of Consignment

Correct documentation and recording of clinical waste is necessary to comply with the Environmental Quality (Scheduled Wastes) Regulations, 1989, which require a consignment note stems to be implemented for the transport of waste from the hospital to the incinerator (as practiced in Malaysia vide Environmental Quality Regulation Act, 1989).

Example: **Consignment** note for transport of waste **from** hospital **to** the incinerator

For the carriage and disposal of clinical and related wastes:

- Name of the hospital,
- Name of officer incharge wastes, in hospital,
- Quality of waste collected,
- Name of collection driver and his signature, and
- Operator at disposal site.

Treatment

Treatment is a process by which waste is modified before it is finally disposed off, so that it can no more act as source of pathogen.

The reasons for treatment are:

- To make waste free from microorganism.
- To reduce in volume for better transport and storage.
- To make part unrecognizable to become more acceptable, and
- To convert it more unusable like syringes and needles.

Disinfection

It is a process of distribution or removal of pathogen which gives rise to infection. I-Iospital waste in category of infectious waste should be disinfected before final disposal as it contains pathological micro-organism responsible for diseases.

Disinfection should not be used if sterilization facilities are available.

Indication for use of disinfection

Disinfection is required in following situation.

Instruments and equipment that come in contact with skin mucous membrane before use of any skin piercing instrument or equipment.

Contaminated instruments and equipment, and contaminated floor, surface like that of trolley tops, table tops, trays, cloths, beddings, beds, crockcry, enamel, stainless steel utensils and other articles like bed pan, milk bottles ctc. and wards and O.T. from time to time.

Methods of disinfection/sterilisation

a) Thermal

   Dry

   Wet

b) Chemical (Formaldelyde, ethylene oxide, etc.)

c) Physical methods

   Irradiation

   Microwaves

   Ultraviolet

Test of Disinfection

It is preferable to carry out an independent test to determine and confirm the desired dilution necessary for particular purpose.

Capacity test (Kalsey and Sykes, 1969) (Source: HAI Guidelines, Health Deptt., Govt. of India)

The capacity tests are designed to simulate the natural conditions under which the disinfectants are used in hospitals. The main features of the test is that instead of one addition of a large inoculum of the test organism, the additions arc made in increments with or without organic matter. This gives a measure of the capacity of the disinfectant to cope with successive bacterial invasions.

Procedure

1) Prepare the disinfectant dilutions in water of 300 ppm hardness. Any number of concentrations may be tested, however, the critical ones are the recommended dilution, and dilutions 25 per cent stronger and 25 per cent weaker than the recommended dilution.

2) The inoculum is prepared in clean or dirty condition. The clean inoculum is prepared by suspension of the test bacteria in broth to concentration of 10^{0}C.F.U./ml. The dirty inoculum is prepared by suspending test bacteria to a concentration of 10" C.F.U./ml. in 20 per cent in activated horse serum or 2 per cent yeast suspension.

3) Disbibute the disinfectant dilutions in 2 ml. Aliquots in two rows of tubes. Add 1 ml. of the clean bacterial suspension to the first row and 1 ml. of dirty bacterial suspension to the other.

4) Remove a sample after eight minutes and transfer tive drops on the surface of a nutrient agar plate by a dropper pipette (50 drops/ml. capacity).

5) Two minutes later, i.e. 10 mt., after the first addition add a second increment ofbacterial suspension. Sample after 8 minutes as before.

9 Repeat the process after 8 minutes, thus giving a total of three increments.

The plates are incubated at 30 to 32°C for 48 hours before reading the number of colonies in each drop are counted. The disinfectant is regarded satisfactory at the said dilution, if the number of colonies from the five drops collected after the second increment is not more than five.

The in-use tests of Kelsey and Maurer (1966) are performed to check the end results of disinfection. Samples are taken from disinfectant dilutions in use in the hospitals for any purpose such as the thermometer, cheatle forceps, laboratory fluids, mopfluid etc.

Procedure

Transfer one ml. of the disinfectant fluid into a tube containing 9 ml. of the diluent. The diluents used for different groups of disinfectants are listed below:

1) Nutrient broth for alcohols, aldehydes, hypochlorites and phenolics.

2) Nutrient broth containing twin 80 (3 per cent) for disguanides hypochlorite detergent mixtures, lodiophores, phenolic detergent mixtures and quartemary ammonium compounds.

Withdraw a small dilquot with a 50 ml. dropper pipette and place 10 drops separately on the surface of nutrient agar in duplicate, incubate both the plates for 72 hours one at room temperature and the other at 37°C Growth from more than five of the ten drops in either of the plates indicates a failure of disinfection,

Disinfectants can be used at a concentration/dilution indicated against them for clean and contaminated situation.

Chemicals

Disinfection by use of chemical by ethylene oxide gas, it is used commonly for sterilisation of plastic disposable materials, live syringes and needles transform sets, etc. it is inferior to heat and radiation.

Disinfectants

Concentration/dilutions of the different disinfectants to be used in clean contaminated and grossly contaminated conditions.

(*Source:* HAI Guidelines for Control, Health Deptt., Govt. of India.)

Recommended Concentration/Dilution		
Disinfectants	**Clean Contaminated**	**Grossly Dirty**
1. **Chlorine releasing compounds**	0.1%	1.0%
- Sodium Hypochlorite	1 g/l (100 p.p.m.)	10g/l (10.000)
- Liquid bleaches usually 5% available Chlorine.	200 ml/l	200 ml/l
- Calcium hypochlorite (Usually 70% available chlorine)	1.2g/l	14.0g/l
- Sodium-dichlorisoisocyanurate (NaDCO) (Usually 60% available chlorine) (More stable, available as tablet!; of 1.5 g available chlorine)	17.0/g/l	1.7 g/l
- Chloramine Slow chlorine release (More stable than 1.2) (25% available chlorine)	20g/l	20g/l
2. **Iodine compounds**		
- Tincture of iodine (Iodine 0.5% + alcohols 70%)	2.5%	2.5%
- Polyvidone iodine (PVI) (Usually 10% Sol. (1% iodine) Polyvidone iodine (Betadine)	2.5%	2.5%
3. **Aldehydes**		
- Glutaraldehyde (Activated) (Cidex: 2% Glutaraldehyde)	2.0%	2.0%
- Formaldehyde-formaline (40% Sol. of Formaldehyde end 10% Methanol in water.	5% 2% formaldehyde	10% 4% formaldehyde
4. **Alcohols**		
- Ethylalcohol	70%	70%
- Isopropylalcohol	70%	70%
- Methylated Spirit (Denatured alcohol)	70%	0%
5. **Hydrogen Peroxide** (30% stabilised sol.)	6% (freshly prepared)	not recommended
6. Phenolic **compounds**		
- Phenol (Carbolic acid)	5.0%	10%
- Cresol	2.5%	5.0%
- Lysol (Saponified crcsol)	2.5%	2%
7. **Chloroxylenols**		
- (4.8% V/V is marketed as Dettol)	4.0%	10.0%
- 1 + 0.1% EDTA	3.0%	6.0%
8. **Diguanides**		
- Chlorohexidine (1.5% V/V) (Habitant)	5.0%	10.0%
- Chlorohexidine + Cetrimide (Savlon)		
9. Ethylene **Oxide gas**	450-800 mg/l	

The choice of disinfectants depends on number of factors such as effectiveness, stability, availability and price.

Proposed Method for disinfection of commonly used articles/materials/surface in order of preference

All articles and surfaces to be disinfected, must first be cleaned and washed with warm water preferably containing detergent.

Materials	Methods
Ampoules	Disinfect with alcohol/Methylated spirit/PVI before cutting
Skin	Tr. Iodine/alcohol
Thermometer	Keep in gluteraldehyde/PVI/Hexachlorophenes/Chlorthexidine + cetramide (savlon) for at least 10 minutes before next use.
Articles/Ware/Stainless steel/Enamel plated/ Plastic, **e.g. Bottles/Bowls**	Wash with warm detergent, disinfect with carbolic acid/chlorine releasing compound/PVI/Formaldehyde/Phenolic compounds, chloroxylenols/Hexachloro phenes/Chlorhexidine
Surface	
Floor/Walls/Trolleys/ Furniture/Sinks/Wash basins	Wash with detergent, disinfect with chlorine releasing compound/carbolic acid/PVI/Hexachlorophene
Humidifiers and Incubators	Fill daily humidifiers with sterile distilled water containing 0.1% silver nitrate. Clean and disinfect with chlorine releasing compounds/ activated glutaraldehyde/alcohol or carbolic acid.
Crockery/Cutlery	Wash with warm detergent solution, keep boiling water for 10 minutes, expose to steam. No chemical disinfectant should be used.
Laboratory	Phenolic compounds, (carbolic acid) chlorine releasing compounds/ chlosoxylenolsand hexachlorophene
Syringes and needles	Chemical disinfectant must not be used for needles and syringes.
Instruments	Keeping concentration recommended for grossly oneatle forced contaminated articles, or PVI/chloroxylenols, glitter aldehyde. Change the disinfectant daily.
Equipment	
Catheters/Cystoscope/ Endoscope/Laproscope	Chemical disinfection only as last resort, if sterilisation by heat is riot possible. Immerse in activated solution of Gluteraldehyde/ carbolic acid for 4 to 10 hours or more.

Only vegetative bacteria, fungi and viruses are killed by immersing in surface disinfectants for 30 minutes.

Other Methods of sterilisation and high level disinfection in health care settings.
(*Source:* I-IAI Guidelines for Control, Govt. of India, 1992)

Heat

1) ***Moist***

A) ***Above*** 1000°C

Autoclave; steam under pressure usually 15 p.s.i., (LBS/sq/in) equivalent to 121°C for 20-30 minutes. A pressure of 30 psi equivalent to 140°C for 5 minutes can be used rarely.

i) Simple autoclave.

ii) Steam jacketed autoclave is most suitable for hospital practice.

iii) Pressure cooker achieves 15 p.s.i. equivalent to 121 °C for 20-30 minutes, can be used for sterilisation.

There are two types of pressure cookers i.e. Household pressure cooker, WHO/UNICEF modification of pressure cooker.

B) *At 100 °C*

Boiling for 20-30 minutes, is used for instruments and equipment when autoclaving is not possible, achieve high level of disinfecting.

C) *Below 100 °C*

Low temperature steam formaldehyde (LTSF) sterilizer; steam at subatmospheric pressure at a temperature of about 75 °C. With formaldehyde vapours holding time usually 1 hour.

2) ***Wet Heat***

Sterilisation by moist heat steam under pressure is done by various types of autoclaves. It is achieved through autoclaving at 160° C under high pressure.

In 1978 the first commercial steam steriliser was set up in California to process medical infectious waste.

It practically reduces waste volumes, plastic materials meet and get disfigures.

The waste in biogas is placed in sealed pressurised chamber and heated up to 250° C for approximately 30-60 minutes.

There is emission of offensive and toxic substance with odour.

Hydroclaving whose steam is produced by providing thermal energy through steam of jacketed chamber (Conadian technology) The pressure and temperature consideration is shown below in the chart:

Gauge Pressure	Temperature in	Degrees	Centlgrnde
Pressure above atmospheric (I B./sq.in.) (p.s.i.)	Complete alr discharge	Half air discharge	No air discharge
10	115	105	100
15	121	112	100
20	126	118	109
30	135	128	121

3) ***Dry Hent***

Hot air oven: 160 °C-180 °C for 60-120 minutes.

A method of choice for sterilisation of glass ware, including all glass syringes, blunt instruments and materials impervious to steam or water like waxes, petroleumjelly, oil and powders.

High Level of Disinfection

It is a process of destroying all microorganism. However some spores may survive particularly if initially present in large number.

By exposing to vapour of ethylene oxide (ethylene oxide steriliser) and formaldehyde (formaldehyde disinfector) and low temperature steam formaldehyde steriliser.

By soaking in chemical disinfectant and like activated solution of glutaraldehyde and carbolic acid for prolonged period.

Indicated in sterilisation of

- Instrument and equipment like vaginal speculam, proctoscope, laryngoscope, flexible fibroelastic endoscope, etc., which come in contact with membranes.
- Chemical disinfectants must never be used for syringes and needles.

Microwave

It is being used in the *USA*.

Microwave heats the material by energising water molecule and the substances get heat from inside to outside the mass.

The technology started in early 1980s in Germany. It has been approved in 40 states of the *US*, including Canada, European and Brazil, the first being installed in West in Salem North Carolina in 1990. It is also approved by CPCB of India.

The method consists of placing the sealed bags on a bucker hoist. See details in technology description.

There are two types

A) Small microwave ovens of small quantity of wastes in laboratories.

B) Large microwave systems for treatment of large quantities.

Pressure (p.s.p.)	Temperature	Holding time (Minutes)
10	115-118	30
15	121-124	15
20	126-130	6
30	134-138	3

Satisfactory sterilisation can be achieved at 15 p.s.i./(IBS/sq. inch) pressure and a temperature of 121°C in 15-20 minutes (holding time). Household pressure cookers can achieve a pressure of 15 p.s.i. of steam and can be used with caution for sterilisation.

An inexpensive substitute for an autoclave has been developed by WHO and UNICEF by modifying pressure cooker.

An electric or gas oven can be used for sterilisation of instruments (blunt instruments, all glass syringes, glass ware) and material (wax, oils, powder, etc.) which are impermeable and can be used for this purpose the holding for 60 minutes to 120 minutes depends on the contamination of the materials to be sterilised and temperature achieved.

a) By boiling : At least 20-30 minute boiling is essential.

b) An electrical gas oven can be used for sterilisation of instruments (blunt instruments, all glass syringes, glass ware, etc.) and materials (wax, oil, powder etc.)

c) Use of solar energy for heating process should be considered for use where facility is available.

Irradiation

It is a new technology process which is difficult to operate and maintain X-rays or gamma rays have been used. Shredding or milling Is done for aesthetic reasons, it is used for sterilisation of plastic and other materials that can be damaged by heal.

It is more expensive than chemical and thermal methods.

Mechanical/Chemical Technologies

This method was introduced in mid 1980s. It consists of shredding waste using shredder or hammer and will include Pulverization. Waste is treated with liquid disinfectant (Sodium Hypochlorite). Further improvement has been made to include recirculation/recycling of liquid and counter current operation so that discharges are free from disinfectants.

There are chances of occupational exposure hazards.

Filtration

Liquid and solution of heat liable substances can be sterilised of filteration.

Types of filters used for bacteriological purposes are:

- Earthen Ware
- Asbestos
- Sintered glass
- Members of cellulose and other polymers.

The first three work satisfactorily. They retain bacteria but not viruses.

Disinfection of Linen, Blanket, Mattresses

Staff dealing with medical waste should also know important aspects of this problem.

Linen

The linen used by patients, doctors and paramedical staff may get contaminated when soiled with blood, pus, faeces or any other body fluids. These can be reused after disinfection. Though it is not waste, still it is proper to mention some important aspects.

The contaminated linen should be disinfected before going to Dhobis (Washerman).

Disinfection of linen is done by:

- Boiling
- Autoclaving with low pressure steam, and
- Chemical disinfectants.

Blankets

They are handled by:

- Exposing to Formaldelyde vapour, and
- Autoclaving,
- Liquid disinfectant can damage woollen blankets
- Dry cleaning it does not kill HIV.

Mattresses should preferably be covered with water proof material like rexin or plastic. It is done by autoclaving (big size) working in Delhi at some places.

3.7 MANAGEMENT ISSUES

Now you will learn about some of the important managerial issues involved in the management of hospital waste. These include:

i) The human element is more important than the technology. Almost any system of treatment and disposal that is operated by well trained and well motivated staff can provide more protection for staff, patients and the community than an expensive or sophisticated system that is managed by staff who do not understand the risks and the importance of their contribution,

ii) The management of medical waste requires diligence and care from a chain of people, starting with the nurse or doctor who use the equipment and supplies that become waste, continuing through to the hospital attendant or ancillary staff who provides clean bags or containers and carriers away the waste, on to the mechanics and technicians who keep the vehicles and equipments in good condition, and finishing with the person responsible for ensuring that waste is disposed off in the correct way. If any of these are careless in their work, or allow scavengers access to the waste, the chain is broken and dangers follow.

iii) The education of the general public is also important. For every patient in the hospital there may be a number of visitors, and in many hospitals families need to stay with the patient and provide food. The visitors have to be explained the behavioural requirements of the hospital with regard to hygiene and this should be done by the nursing staff and auxiliaries. Posters and leaflets should be used to bring about awareness. The general public outside the hospital gates are also affected because of the likelihood of waste being recycled; both children and adults should be aware of the

risks posed by medical waste, so that they keep away from risks themselves and warm the authorities if they see unacceptable practices.

iv) All staff, including those in waste disposal, should have regular medical check-up, and information generated by these check-ups used to evaluate procedures and precautions. Information on disposal practices and facilities should be disseminated and used, for the guidance of others and where there is a possibility of co-ordination or sharing facilities.

Issues for effective management of hospital waste:

1) Basic: water supply, cleanliness, sanitation.
2) Switch to recyclable – minimize waste.
3) Tighten security to avoid illegal trading of waste.
4) Consider legal, controlled recycling.
5) Education and awareness for proper segregation.
6) Chemical disinfection of waste at source.
7) Explore non-burn treatment/disposal strategies.

Formation of Hospital Waste Management Committee/Team

The head of the Health Care Facility (hospital, nursing home, and clinic) shall form a Waste Management Committee consisting of the following personnel:

Head of the Hospital: Chairman

Waste Disposal Officer: Secretary

Infection Control Officer

Heads of Departments

Chief Pharmacist

Additional Hospital Superintendent/Hospital Supervisor

Nursing superintendent

Hospital Engineer

Radiation Protection Officer

Stores Officer

Additional members may be appointed to this team whenever the need arises.

Wherever possible the Waste Disposal Officer may be formally appointed with overall responsibilities for the development of a Waste Disposal Plan and subsequent day to day operation and monitoring of the waste disposal system. The head of HCF may nominate another suitable officer who may be assigned the Waste Disposal Officer's responsibilities if no separate post is available,

Smaller hospitals may vary the number of members according to their need. A Waste Management Team can be formed with 3-4 members: Medical Superintendent, Waste Disposal Officer, Infection control officer, Nursing superintendent. The waste management committee shall meet once in every four weeks during the initial period of the formulation and implementation of the Waste Disposal Plan and thereafter every three months to review the system's performance. The waste disposal team should meet every week.

Functions and Responsibilities of the Members of the Waste Management Committee/Team

Head of the Institution

i) Shall apply for authorisation for the handling of biomedical waste,

ii) Shall be responsible for the implementation of the Government's policiesldirectives on hospital waste management.

iii) Shall be responsible for the segregation, treatment, collection, transportation and storage of waste within the hospital and the disposal by incineration or other means.

iv) Shall be responsible for the submission of annual detailed information about types and quantities of waste collected or handled in his institution, and for the reporting of accident.

v) Has a duty to inform the Ministry of Environment/Ministry of Health of any incorrect practices and procedures that may come to his notice in the final disposal of waste.

vi) Shall form a Waste Management Committee/Team to formulate a Waste Disposal Policy or Plan for the Hospital. Within this Plan, the duties and responsibilities of all members of staff both clinical and non-clinical shall be clearly defined and accountability indicated in the management of waste.

vii) Shall appoint a Waste Disposal Officer to coordinate and supervise the Waste Management Plan.

viii) Shall allocate adequate manpower and resources in terms of assigning hospital attendants, safai karamccharis and other ancillary workers for waste disposal and allocation of sufficient financial resources to ensure the efficient operation of waste disposal plan.

ix) Shall ensure that adequate training is given to key members both clinical and non clinical staff. He shall designate staff responsible for coordinating and implementing training courses.

Waste Disposal Officer

i) Shall have the day to day control of internal collection of waste containers and transport to the central hospital storage and then final disposal by incineration or other methods.

ii) Will be directly responsible to the Head of the Institution.

iii) The hospital supervisors, attendants and other workers assigned to collect and transport clinical waste shall be directly under the Waste Disposal Officer's line of management.

iv) The Waste Disposal Officer shall ensure that new waste bags and containers are ordered on a regular basis to maintain a continuous supply. He should liaise with the Stores Officer in the regard.

v) Shall ensure that hospital attendants and ancillary staff immediately replace used bags and containers with the correct new bag or container.

vi) Shall ensure that hospital attendants and ancillary staff immediately replace used hags and containers with the correct manner.

vii) The Waste Disposal Officer shall liaise with the Nursing Superintendent and Medical Superintendent and Heads of Departments to ensure that nursing staff and medical and paramedical staff are familiar with their responsibilities for segregation and storage.

viii) Shall liaise with Infection Control Officer, Pharmacist and Radiation Pi otection Officer (depending upon type of HCF) to familiarize himself with the correct procedures for handling and disposal of pathological, microbiological, pharmaceutical, chemical and radioactive wastes.

ix) Shall be responsible for the proper rise of the central storage facility for waste in the hospital, which shall be fenced with a lock at the entrance and caretaker.

x) Shall monitor methods of pretreatment/treatment of wastes, transportation of wastes on site and off-site.

xi) Shall be responsible for preparing statistics on the waste generated, maintaining the records and docuinentatiun.

xii) Shall ensure that the waste is not stored for more than 48 hours as per BMW Rules, 98.

xiii) Shall ensure that emergency procedures in case of accidents and spillages are available.

xiv) Shall ensure that alternative methods for disposal are available in the event of breakdown of incinerator.

xv) Shall investigate and review incidents reported during the handling of clinical waste. Shall report the accident.

Department Heads

i) Department Heads shall be responsible for the segregation, storage and disposal of waste generated in their departments.

ii) Shall ensure that all medical, technical and nursing staff in their departments are aware of the segregation and storage procedures.

iii) Shall liaise with Waste Disposal Officer to monitor working practices for failures or mistakes.

iv) Shall ensure that staff members are given training in waste segregation, treatment and disposal procedures.

Nursing Superintendent and Medical Superintendent

i) Shall be responsible for continuous monitoring of the waste segregation, treatment and storage systems at the site of generation.

ii) Shall liaise with Departmental Heads, Infection Control Officer, Pharmacist, Radiation Protection Officer to ensure that high standards of waste disposal procedures are maintained.

The Infection Control Officer

i) Shall advise and liaise with the Waste Disposal Officer on control of infection and maintaining the standards of waste disposal.

ii) Shall identify needs of all grades of staff. Shall organise training programmes for hospital staff on infection control connected with waste disposal.

Chief Pharmacist

i) Shall be responsible for liaising with other members of the Waste Disposal Committee/ Team to give advice according to the policy and guidelines on the safe disposal of pharmaceutical waste.

ii) Shall be responsible for the continuous monitoring of procedures for the disposal of pharmaceutical waste.

iii) Shall ensure that adequate training is given to personnel involved in pharmaceutical waste handling and disposal.

Radiation Protection Officer.

Have the same responsibilities as Chief Pharmacist but in regard to radioactive waste.

Hospital Engineer

i) Shall ensure that all waste storage facilities and equipment in the hospital for waste management are installed and maintained according to standards.

ii) Shall ensure that his staff are trained in principal of waste disposal.

iii) Shall ensure that his staff are trained in principles of waste incineration/autoclave/ microwave wherever the onsitc facility is installed.

Stores Officer

Shall liaise with Waste Disposal Officer and other members of the team to ensure a continuous procurement of materials and equipment according to the specifications laid down in Waste Disposal Policy and Plan.

Training and Teaching

Training is an essential component of Hospital waste Management and should involve all categories of staff, patients as well as visitors in the hospital.

Teaching of hospital waste management should be included in the medical and nursing curriculum.

3.8 LET US SUM UP

In this unit you have learnt that hospital waste management is more than a social issue or a social responsibility by the medical personnel, it is a law of the land.

All health care delivery centres e.g. clinics, dispensaries, laboratories, hospitals of all categories, Nursing homes etc. have to follow the rule and devise their own way of waste management, It is not very difficult creating an awareness and motivating them amongst fellow colleagues discouraging plastic disposable and using more and more of glass items, providing universal precautions and other supplies regularly and monitoring the waste management programme continuously will go a long way in making this a success.

3.9 ANSWERS TO CHECK YOUR PROGRESS

Check Your Porgress 1

1) a) General waste

b) Sharps

c) Infected waste

d) Chemical waste

e) Radioactive waste

f) Cytotoxic drugs

2) a) Injuries from sharps to all categories of hospital personnel and waste handlers

b) Nosocomial infections to patients from poor infection control and poor waste management

c) Risks of infections outside hospitals for waste handlers, scavengers, and (eventually) the general public and some times change in microbial ecology resulting in antibiotic resistance.

3) a) Select safe or less hazardous substitute for chemical agents

b) Use closed storage for volatile agents

c) Use proper ventilation and exhaust fans as per norms

d) Use appropriate protective clothing with arrangements of disinfection and disposal.

e) Popularise use of colour and emblem code on container bags,

f) Introduce monitoring and surveillance for problem areas on high risk situation

g) Proper disinfection and sterilisation practices to be followed

h) Universal precaution measures to be followed

i) Hospital infection control committee to be formed with a microbiologist as its chairman and adequate delegated nurses, supervisors and paramedical personnel as members to monitor infection in the hospital,

4) a) Rule 6

b) Rule 13

c) Rule 15

Check Your Porgress 2

1) a) General Non hazardous wastes – Black colour

b) Sharp (whether'infectedor not) – Yellow

c) Infected wastes (not containing sharp) – Yellow colour

d) Chemical and pharmaceutical other than cytotoxic drug, rodioactive wastes, high pressure container – Red bag

e) Clinical waste that required autoclaving – Blue bag,

2) ● Employee should be provided with approved protective clothing and footwear.

● Training should be imparted to drivers, collectors and other handlers on risks of the waste, other instructions, precautions taken in the event of spillage by accidents.

● Services of emergency telephone should be made available.

● They should be protected by immunisation.

3) ● To make waste free from microorganism.

● To reduce in volume for better transport and storage.

● To make part unrecognizable to become more acceptable, and

● To convert it more unusable like syringes and needles.

4) a) Thermal

● Dry

● Wet

b) Chemical (Formaldelyde, ethylene oxide, etc.)

c) Physical methods

● Irradiation

● Microwaves

● Ultraviolet

5) Disinfection of linen is done by:

- Boiling
- Autoclaving with low pressure steam, and
- Chemical disinfectants.

Blankets are handled by:

- Exposing to Formaldelyde vapour, and
- Autoclaving,
- Liquid disinfectant can damage woollen blankets
- Dry cleaning it does not kill HIV.

Mattresses should preferably be covered with water proof material like rexin or plastic. It is done by autoclaving (big size) working in Delhi at some places.

Check Your **Porgress 3**

1) a) Head of the Hospital: Chairman
   b) Waste Disposal Officer: Secretary
   c) Infection Control Officer
   d) Heads of Departments
   e) Chief Pharmacist
   f) Additional Hospital Superintendent/Hospital Supervisor
   g) Nursing Superintendent
   h) Hospital Engineer
   i) Radiation Protection Officer
   j) Stores Officer
   k) Additional members may be appointed to this team whenever the need arises.

2) a) Basic: water supply, cleanliness, sanitation.
   b) Switch to recyclable–minimize waste.
   c) Tighten security to avoid illegal trading of waste.
   d) Consider legal, controlled recycling.
   e) Education and awareness for proper segregation.
   f) Chemical disinfection of waste at source.
   g) Explore non-burn treatment/disposal strategies.

3) a) Department Heads shall be responsible for the segregation, storage and disposal of waste generated in their departments,
   b) Shall ensure that all medical, technical and nursing staff in their departments are aware of the segregation and storage procedures.
   c) Shall liaise with Waste Disposal Officer ta monitor working practices for failures or mistakes,
   d) Shall ensure that staff members are given training in woste segregation, treatment and disposal procedures,

MINISTRY OF ENVIRONMENT AND FOREST NOTIFICATION

New Delhi, 20th July 1998

S.O. 630 (E). Whereas a notification in exercise of the powers conferred by Sections 6, 8 and 25 of the Environment (Protection) Act, 1986 (29 of 1986) was published in the Gazette vide S.O. 746 (E) dated 16 October, 1997 inviting objections from the public within 60 days from the date of the publication of the said notification on the Bio-medical Waste (Management and Handling) Rules, 1998 and whereas all objections received were duly considered.

1) Short Title and Commencement

1) These rules may be called the Bio Medical Waste (Management and Handling) Rules, 1998.

2) They shall come into force on the date of their publication in the official Gazette.

2) Application

These rules apply to all persons who generate, collect, receive, store, transport, treat, dispose, or handle bio-medical waste in any form.

3) Definitions: In these rules unless the context otherwise requires:

1) "Act" means the Environment (Protection) Act, 1986 (29 of 1986);

2) "Animal House" means a place where animals are reared/kept for experiments or testing purposes;

3) "Authorisation" means permission granted by the prescribed authority for the generation, collection, reception, storage, transportation, treatment, disposal and/or any other form of handling of bio-medical waste in accordance with these rules and any guidelines issued by the Central Government;

4) "Authorised person" means an occupier or operator authoriscd by the prescribed authority to generate, collect, receive, store, transport, treat, dispose and/or handle bio-medical waste in accordance with these rules and any guidelines issued by the Central Government;

5) "Bio-medical waste" means any waste, which is generated during the diagnosis, treatment or immunisation of human beings or animals or in research activities pertaining thereto or in the production or testing of biological, and including categories mentioned in Schedule 1;

6) "Biological" means any preparation made from organisms or micro-organisms or product of metabolism and biochemical reactions intended for use in the diagnosis, irnmunisation or the treatment of human beings or animals or in research activities pertaining thereto;

7) "Bio-medical waste treatment facility" means any facility wherein treatment, disposal of bio-medical waste or processes incidental to such treatment or disposal is carried out;

8) 'Occupier" in relation to any institution generating bio-medical waste, which includes a hospital, nursing home, clinic, dispensary, veterinary institution, animal house, pathological laboratory, blood bank by whatever name called, means a person who has control over that institution and/or its premises;

9) "Operator of a bio-medical waste facility" means a person who owns or controls or operates a facility for the collection, reception, storage, transport, treatment, disposal or any other form of handling of bio-medical waste;

10) "Schedule" means schedule appended to these rules.

4) **Duty of Occupier**

It shall be the duty of every occupier of an institution generating bio-medical waste which includes a hospital, nursing home, clinic, dispensary, veterinary institution, animal house, pathological laboratory, blood bank by whatever name called to take all steps to ensure that such waste is handled without any adverse effect to human health and the environment.

5) **Treatmentand Disposal**

1) Bio-medical waste shall be treated and disposed off in accordance with Schedule I, and in compliance with the standards prescribed in Schedule V.

2) Every occupier, where required, shall set up in accordance with the time schedule in Schedule VI, requisite, bio-medical waste treatment facilities like incinerator, autoclave, microwave system for the treatrnent of waste, or, ensure requisite treatment of waste at a common waste treatment facility or any other waste treahnent facility.

6) **Segregation, Packaging, Transportationand Storage**

1) Bio-medical waste shall not be mixed with other waste.

2) Bio-medical waste shall be segregated into containers/bags at the point of generation in accordance with Schedule II prior to its storage, transportation. treatment and disposal. The containers shall be labeled according to Schedule III.

3) If a container is transported from the premises where bio-medical waste is generated to any waste treatment facility outside the premises, the container shall, apart from the label prescribed in Schedule III, also carry information prescribed in Schedule IV.

4) Notwithstanding anything contained in the Motor Vehicles Act, 1988 or rules thereunder, untreated bio-medical waste shall be transported only in such vehicle as may be authorized for the purpose by the competent authority as specified by the government.

5) No untreated bio-medical waste shall be kept stored beyond a period of 48 hours: Provided that if for any reason it becomes necessary to store tlie waste beyond such period, tlie authorized person must take permission of the prescribed authority and take measures to ensure that tlie waste does not adversely affect huinan health and the environment.

7) **Yrcscribcd Authority**

1) The government of every State and Union Territory shall establish a prescribed authority with such members as may be specified for granting authorisation and implementing these rules. IS the prescribed authority comprises of more than one member, a chairperson for tlie authority shall be designated.

2) The prescribed authority for the State or Union Territory shall be appointed within one month of the coming into force of these rules.

3) The prescribed authority shall function under the supervision and control of the respective Government of the State or Union Territory.

4) The prescribed authority shall on receipt of Form I make such enquiry as it deems fit and if it is satisfied that the applicant possesses the necessary capacity to handle bio-medical waste in accordance with these rules, grant or renew an authorisation as the case may be.

5) An authorisation shall be granted for a period of three years, including an initial trial period of one year from the date of issue. Thereafter, an application shall be made by the occupier/operator for renewal. All such subsequent authorisation shall be for a period of three years. A provisional authorisation will be granted for

the trial period, to enable the occupier/operator to demonstrate the capacity of the facility.

6) The prescribed authority may after giving reasonable opportunity of being heard to the applicant and for reasons thereof to be recorded in writing, refuse to grant or renew authorisation.

7) Every application for authorisation shall be disposed off by the prescribed authority within ninety days from the date of receipt of the application.

8) The prescribed authority may cancel or suspend an authorisation, if for reasons, to be recorded in writing, the occupier/operator has failed to comply with any provision of the Act or these rules;

Provided that no authorisation shall be cancelled or suspended without giving a reasonable opportunity to the occupier/operator of being heard.

8) **Authorisation**

1) Every occupier of an institution generating, collecting, receiving, storing; transporting, treating, disposing, and/or handling bio-medical waste in any other manner, except such occupier of clinics, dispensaries, pathological laboratories, blood banks providing treatment/services to less than 1000 (one thousand) patients per month, shall make an application in Form I to the prescribed authority for grant of authorisation.

2) Every operator of a bio-medical waste facility shall make an application in Form I to the prescribed authority for grant of authorisation.

3) Every application in Form I for grant of authorisation shall be accompanied by a fee as may be prescribed by the Government of the State of Union Territory.

9) Advisory **Committee**

The Government of every State/Union Territory shall constitute an advisory committee. The committee will include experts in the field of medical and health, animal husbandry and veterinary sciences, environmental management, municipal administration, and any other related department or organisation including non-governmental organisation. The State Pollution Control Board/Pollution Control Conunittee shall be represented. As and when required, the committee shall advise the Government of the State/Union Territory and the prescribed authority about matters related to the implementation of these rules.

10) **Annual Report**

Every occupier/operator shall subniit an annual report to the prescribed authority in Form II by 31 January every year, to include information about the categories and quantities ofbio-medical waste handled during the preceding year. The prescribed authority shall send this information in a compiled form to the Central Pollution Control Board by 31 March every year.

11) **Maintenance** of **Records**

1) Every authorised person shall maintain records related to the generation, collection, reception, storage, transportation, treatment, disposal and/or any form of handling of bio-medical waste in accordance with these rules and any guidelines issued.

2) All records shall be subject to inspection and verification by the prescribed authority at any time.

12) Accident Reporting

When any accident occurs at any institution or facility or any other site where bio-medical waste is handled or during transportation of such waste, the authorised person shall report the accident in Form III to the prescribed authority forthwith.

13) **Appeal**

Any person aggrieved by an order made by the prescribed authority under these rules may, within thirty days from the date on which the order is communicated to him prefer an appeal to such authority as the Government of State/Union Territory may think fit to constitute:

Provided that the authority may entertain the appeal after the expiry of the said period of thirty days if it is satisfied that the appellant was prevented by sufficient cause from filling the appeal in time.

SCHEDULE I
(See Rule 5)

Categories of Blo-medical Waste

Option	Waste Category Waste Class	Treatment and Disposal
Category 1	Human Anatomical Wastes (human tissues, organs, body parts)	incineration @deep burial*
Category 2	Animal Wastes (animal tissues, organs, body parts, carcasses, bleeding parts, fluid, blood and cxpcrimental animals used in research, waste generated by veterinary hospitals, discharge from hospitals, animal houses)	incineration@deep burial*
Category 3	Microbiology and Blotechnology Waste (wastes from laboratory cultures, stocks or spccinicns of microorganisms live or attenuated vaccines, human and animal cell culture used in research and infectious agents from research and industrial laboratories, wastes from production of biologicals, toxins, dishes and devices used for transfer of cultures)	local autoclavinglmicrowavingl incineration@
Cntcgory 4	Waste Sharps (nccdlcs, syringes, scalpels, blades, glass ctc, that may cause puncture and cuts. This includes both used and unused-sharps)	disinfection (chemical treatment @@/autoclaving/ micro waving and mutilation1 shredding ##
Category 5	Discarded Medicines and Cytotoxic Drug (wastes comprising of outdated, contaminated and discarded medicines)	incineration @/destruction and drugs disposal in secured landfills.
Category 6	Solid Waste (items contaminated with blood, and body fluids including cotton, dressing, soiled plaster casts, lines beddings, other material contaminated with blood)	incineration@ autoclaving/microwaving.
Category 7	Solid Waste (wastes gcncratcd from disposable items other than thc waste sharps such as tubings, catheters, intravenous sets etc.)	disinfection by chemical treatment@@autoclaving/ microwaving and mutilation1 shredding ##.
Category 8	Liquid Waste (waste gencruted from laboratory and washing, clconing, housckccping and disinfecting activities)	disinfection by chemical treatment @@ and discharge into drains.
Category 9	Incineration Ash (ash from incineration of any bio-niedicnl waste)	disposal in municipal landfil

Option	Waste Category Waste Class	Treatment and Disposal
Category 10	Chemical Waste (chemicals used in production of biologicals, chemicals used in disinfection, as insecticides, etc.)	chemical treatment @@ and discharge into drain for liquids and secured landfill for solids,

@@ Chemical treatment using at least 1% hypochlorite solution or any equivalent chemical reagent. It must be ensured that chemical treatment ensures disinfection.

Mutilation/shredding must be such so as to prevent unauthorised reuse.

@ There will be no chemical pretreatment before Incineration. Chlorinated plastics shall nor be incinerated.

* Deep burial shall be available only in towns with population less than five lakhs and in rural areas.

SCHEDULE II

(See Rule 6)

Coiour Coding and Type of Container for Disposal of Bio-medical Wastes

Colour Coding	Type of Container	Waste Category	Treatment options as per Schedule I
Yellow	Plastic bag	Cat. 1, Cat, 2, Cat.3, Cat. 6	Incincrationldeep burial
Red	Disinfected container1 Plastic bag.	Cat. 3, Cat. 6, Cat. 7,	Autoclaving/ Microwaving1 Chemical Treatment,
Blue/White/ Translucent	Plastic/puncture proof container	Cat. 4, Cat, 7, Destruction/shredding	Autoclaving/ Microwaving/ Chemical Treatment and
Black	Plastic bag	Cat.5 and Cat.9 and Cat. 10 (Solid)	Disposal in secured landfill

Notcn:

1) Colour coding of waste cetegories with multiple treatment options as defined in Schedule I, shall be selected depending on treatment option chosen, which shall be as specified in Schedule I.

2) Waste collection bags or waste types needing Incineration shall not be made of chlorinated plastics.

3) Categories 8 and 10 (liquid) do not require containers/bags.

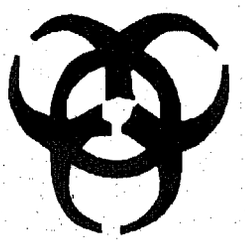
4) Catcgory 3 if disinfected locally need not be put In containers/bags.

SCHEDULE III

(See Rule 6)

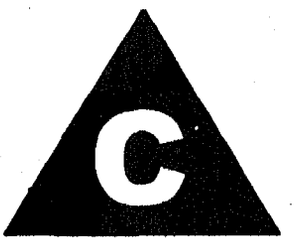
Label for Blo-medical Waste Containers/Bags

Biohazard Symbol



Biohazards

Cytotoxlc Hazard Symbol



Cytotoxlc

Handle with Care

Note: Lable shall be non-washable and prominently visible,

SCHEDULE IV
(See Rule 6)

Label for Transport of Bio-Medical Waste Containers/Bags.

SCHEDULE V
(See Rule 5 and Schedule I)

Standards for Treatment and Disposal of Bio-medical Wastes

Standards for Incinerators:

All incinerators shall meet the following operating and emission standards:

A) **Operating Standards**

1) Combustion efficiency (CE) shall be at least 99.00%

2) The combustion efficiency is computed as follows:

$$C.E. = \frac{\%CO_2}{\%CO_2 + \%CO}$$

3) The temperature of the primary chamber shall be 800 # 50°C

4) The secondary chamber gas residence time shall be at least I (one) second at 1050 # 50C, with minimum 3% in the stack gas,

B) Emission Standards

Parameters	Concentration mg/Nm³ at (12% CO_2 correction)
1) Particulate matter	150
2) Nitrogen Oxides	450
3) HCl	50

4) Minimum stack height shall be 30 meters above ground

5) Volatile organic compound in ash shall not be more than 0.01%

Note: Suitably designed pollution control devices should be installed/retrofitted with the incinerator to achieve the above emission limits, if necessary.

Waste to be incinerated shall not be chemically treated with any chlorinated disinfectants.

Chlorinated plastics shall not be incinerated.

Toxic metals in incineration ash shall be limited within the regulatory quantities as defined under the Hazardous Waste (Management and Handling) Rules, 1989.

Only low sulphur fuel like L.D.O./L.S.H.S./Diesel shall be used as fuel in the incinerator.

Standards for Waste Autoclaving

The autoclave should be dedicated for the purposes of disinfecting and treating bio-medical waste.

I) When operating a gravity flow autoclave, medical waste shall be subjected to

i) A temperature of not less than 121° C and pressure of 15 pound per square inch (PSI) for an autoclave residence time of not less than 60 minutes; or

ii) A temperature of not less than 135° C and a pressure of 31 psi for an autoclave residence time of not less than 45 minutes; or

iii) A temperature of not less than 149° C and a pressure of 52 psi for an autoclave residence time of not less than 30 minutes.

II) When operating a vacuum autoclave. medical waste shall be subjected to a minimum of one pre-vacuum pulse to purge the autoclave of all air. The waste shall be subjected to the following:

i) A temperature of not less than 121° C and pressure of 15 psi for an autoclave residence time of not less than 45 minutes; or

ii) A temperature of not less than 135° C and a pressure of 31 psi for an autoclave residence time of not less than *30* minutes;

iii) Medical waste shall not be considered properly treated unless the time, temperature and pressure indicators indicate that the required time, temperature and pressure were reached during the autoclave process. If for any reasons, time temperature or pressure indicator indicates that the required temperature, pressure or residence time was not reached, the entire load of medical waste must be autoclaved again until the proper temperature, pressure and residence time were achieved.

III) **Recording of operational** parameters: Each autoclave shall have graphic or computer recording devices which will automatically and continuously monitor and record dates, time of day, load identification number and operating parameters throughout the entire length of the autoclave cycle.

IV) Validation Test

Spore Testing

The autoclave should completely and consistently kill the approved biological indicator at the maximum design capacity of each autoclave unit, Biological indicator for autoclave shall be Bacillus stearothermophilus spores using vials or spore strips. with at least 1 ×10" sporesper mililitre. Under no circumstances will an autoclave have minimum operating parameters less than a residence time of *30* minutes, regardless of temperature and pressure, a temperature less than 121° C or a pressure less than 15 psi.

V) **Routine Test**

A chemical indicator strip/tape that changes colour when a certain temperature is reached can be used to verify that a specific temperature has been achieved. It may be necessary to use more than one strip over the waste package at different location to ensure that the inner content of the package has been adequately autoclaved.

Standards for Liquid Waste:

The effluent generated from the hospital should conform to the following limits:

Parameters	Permissible Limits
pH	6.5-9.0
Suspended solids	100 mg/1
Oil and grease	10 mg/1
BOD	30 mg/1
COD	250 mg/1
Bio-assay test	90% survival of fish after 96 hours in 100% Effluent.

These limits are applicable to those hospitals which are either connected with sewers without terminal sewage treatment plant or not connected to public sewers. For discharge into public sewers with terminal facilities, the general standards as notified under the Environment (Protection) Act, 1986 shall be applicable.

Standards of Microwaving

1) Microwave treatment shall not be used for cytotoxic, hazardous or radioactive wastes, contaminated animal carcasses, body parts and largo metal items.

2) The microwave system shall comply with the efficacy test/routine tests and a performance guarantee may be provided by the supplier before operation of the unit.

3) The microwave should completely and consistently kill the bacteria and other pathogenic organisms that is ensured by approved biological indicator at the maximum design capacity of each microwave unit. Biological indicators for microwave shall be Bacillus Subtitles spores using vials or spree strips with at least 1 × 104 spores per mililiter.

Standards for Deep Burial

1) A pit or trench should be dug about 2 meters deep. It should be half filled with waste, then covered with lime within 50 cm. of the surface, before filling the lest of the pit with soil.

2) It must be ensured that animals do not have any access to burial sites. Covers of galvanised iron/wire meshes may be used.

3) On each occasion, when wastes are added to the pit, a layer of 10 cm. of soil shall be added to cover the wastes.

4) Burial must be performed under close and dedicated supervision.

5) The deep burial site should bc relatively impermeable and no shallow well should be close to the site.

6) The pits should be distant from habitation, and sited so as to ensure that no contamination occurs of any surface water or ground water. The area should not be prone to flooding or erosion.

7) The location of the deep burial site will be authorised by the prescribed authority.

8) The institution shall maintain a record of all pits for deep burial.

SCHEDULE VI
(See Rule 5)

Schedule for Waste Treatment Facilities Like Incinerator/Autoclave/Microwave

A) Hospital and nursing homes in town with population of 30 lakhs
by 31st Dec., 1999 or earlier.

B) Hospitals and-nursing homes in towns with population of below 30 lakhs

a) with 500 beds and above — by 31st Dec., 2000 or earlier

b)	with 200 beds and above but less than 500 beds	by 31st Dec., 2000 or earlier
c)	with 50 beds and above but less than 200 beds	by 31st Dec. 2001 or earlier
d)	with less than 50 beds	by 31st Dec., 2002 or earlier
e)	All other institutions generating bio-medical waste not included in A and B above.	by 31st Dec., 2002 or earlier

UNIT 1 HOSPITAL ACQUIRED INFECTION

Structure

1.0 OBJECTIVES

After studying this unit, the student shall be able to:

- describe the implications and impact of Hospital Acquired Infection (HAI);
- discuss the epidemiology of HAI;
- discuss the routes of spread of HAI;
- discuss the methods of controlling HAI;
- discuss the composition of Hospital Infection Control Committee; and
- describe the method of active and passive surveillance.

1.1 INTRODUCTION

Hospital infection occurs in every hospital beyond doubt, but on many occasions it is .overlooked. It becomes glaring only wlien damage has been done out of proportion in magnitude to a relatively minor therapeutic procedure carried out on the patient.

Johnbell, in 1801, remarked that hospital infection exists in cvcry type of liospital. Louis Pasteur in his celebrated lecture to academic De Medicine on 30 April, 1873 said "If I had the honour of being a Surgeon, not only would I use absolutely clean instruments, but after cleaning my hands with greatest care would still have lo fear germs suspended in air and surrounding the bed of the patient."

Hospital Infection is perhaps the single most important factor that adversely affects the performance and image of the hospitals. Besides morbidity and mortality, it prolongs the hospital stay of patients, increase bed occupancy rate and thereby puts undue pressure on already strained resources of the hospital, patients, community and the country.

The magnitude of the problem is difficult to assess in our liospitals due lo paucity of available literature and data on the subject. I-Iowever, overall reported incidence of post operative wound infection in various hospitals in India range from 10-25%.

Florence Nightingle, more than 100 years ago, said "No stronger condemnation of any hospital or ward could be pronounced than the single fact that zymotic (infectious) disease has originated in it, or that such a disease has attacked other patients than those brought in with them."

No hospital can continue to perpetuate such condemnation, however, hospital acquired infections remains a problem world over. In a recent survey conducted by WIIO on 28,861 patients in 47 hospitals of 14 countries located in 4 continents, the prevalence rate of HAI of different hospitals varied from 3-21% with mean of 8.4%. The results of the survey reported in 1988 indicated that the HAI is a considerable problem, even in hospitals with means and interest in control of I-IAI. Further it is possible to reduce the incidence of infection. The authors concluded that there is a need mid opportunity for international cooperation in finding and applying effective means of prevention and control.

The problem of hospital infection has received the attention of Government of India and two high powered committees, one in 1968 headed by Dr. K.N. Rao, the then Director General of Health Services and other in 1976 headed by Dr. Sharad Kumar, Deputy Director General of Health Services, investigated in detail the problem of hospital infection in Delhi hospitals. Dr. Rao Committee suggested a multipronged attack for control of hospital acquired infections occurring not infrequently and emphasized that "The reservoirs of infections in the hospitals must be attacked, carriers must be dealt with, and rigorous asepsis in the wards and theaters introduced. Clean air, clean beddings and hygienic methods of dust removal must be recognized as basic requirements, and the use of hospitals must be strictly controlled and dictated by essential needs." Sharad Kumar Committee in 1976 recommended formulation of Hospital Infection Control Committee, maintenance of proper medical records, and medical audit (death committee), training of staff, control of overcrowding, improvement of sanitation, kitchen and laundry services.

It is necessary to strengthen/introduce the following activities in each hospital with bed strength of more than 250:

- Management of HAI control activities.
- Surveillance of HAI.
- Operational manuals for different high risk procedurcs,
- Sterilization and disinfection procedures.
- Discarding and disposal procedures.
- Manpower development in service training.
- Publication of informalion.

1.2 DEFINITION

Hospital infection can be 'liospital associated' or 'liospital acquired'. Hospital associated infections are those, that are acquired during hospitalization as well as those that are present upon admission, having been acquired prior to hospitalization.

The present topic is restricted in scope to 'liospital acquired' infection which is also known as 'Nosocomial infection' and can be defined as "Infection acquired by the person in the hospital, manifestation of which may occur during hospitalization or after discharge from hospital." The person may be a patient, members of the hospital staff and/or visitors.

1.3 EPIDEMIOLOGY

Like any other disease process hospital acquired infection has also got "epidemiological triad" i.e. the agent, host and environment. *Soundness of surveillance and control programme depends on sound epidemiological knowledge.*

a) **The Agent**

The Agent possibly includes entire spectrum of microbes e.g. staphylococci, gram -ve bacilli, occasional streptococci, viral, rickettsial, fungal and protozoal infections. It is staled that:

- Large number of all liospital infections are due lo gram -ve organisms.
- Some of infections are contributed by staphylococci (coagulase +ve phage typeable).
- Proteus, E. coli, Salmonella, Shingella, Klebsiella, Ps. aeruginosa are increasing in their involvement as causative agent of liospital acquired infection.
- Carrier stale of organism and their colonization and increased resistance of antimicrobial agents are important factors of consideration.

b) **The Host**

Decreased resistance of patients due to under mentioned factor contribute lo a great length on susccplibilities to hospital acquired infection. The factors are:

- Extremes of ayes
- Primary ailments with concomitant disease like diabetes mellitus, chronic nephritis and malignancies,
- The therapeutic p actices e.g. whole body irradiation, use of cytotoxic and immuno-suppressive drugs, indiscriminate use of antibiotics and steroids etc.
- Complicated diagnostic procedures e.g. venepuncture, types of aspirations, cardiac catheterization and length of operative procedures.
- Endogenous infections.

c) **. The Environnrent**

Everything that surround a patient in the hospital is his environment. These infection can, be acquired from:

- Other patients, hospital staff and visitors, food, water, dust and other contaminated inanimate articles;
- Durg resistance microorganism and change from non-pathogenic strain to pathogenic are found commonly.

Hospital acquired infections can be derived from:

1) **The patient's** own flora: Self infection **(auto-infection)**: The micro-organism concerned is not pathogenic under normal conditions, but underlying disease. invasive diagnostic and therapeutic procedures including immunosuppressive even antiobiotic therapy and the like, may enable it to reproducc, spread and implant itself at a site where it may produce an infection.

2) **The flora** of **another** patient: Cross-infection: In such cases, the micro-organism concerned is transmitted:

   a) ***By direct contact*** between patients (saliva droplets, patient's hands);

   b) ***By air*** (dust from fabrics carrying a patient's flora);

   c) ***By the staff***

   - who collect the micro-organisms directly on their hands or clothes and tramsinit them to another patient.
   - who harbour the micro-organisms on the mucosa of their own respiratory and intestinal tracts, where they reproduce auld are transmitted rarely by air, more often by contact (micro-organism carriers),

3) Environmental sources: **Environmental** Infection

   a) Hospital air usually harbours more bacteria which are more often pathogenic and multi-drug resistant.

   b) Surfaces contaminated by patient's secretions, excretions, blood and body fluids, animals and insects.

   c) Inanimate objects:

   - contaminated by the patients – hospital equipment (sanitary installation,, lights; tables, beds etc.), medical equipment (endoscopes, catheters, vesical probes, needles, lancets, spatula and oher instruments used for invasive and non-invasive procedure, aerosols etc.)
   - contaminated by the hands of any hospital staff in any part of the hospital (kitchen, laundry, treatment room, etc.)
   - contaminated by visitors
   - contaminated by staff who are ill or are carriers of micro-organisms
   - contaminated by food or infected water
   - contaminated by animals and insects.

In general, most of the infections caused by enterococci and other non-haemolytic streptococci, anaerobic cocci, gas gangrene producing clostridia and bacteroides are self infectious; that by S. aureus, group B streptococci, enterobacteria (E. coli, Klebsiella, proteus etc.) may be acquired either from person to person (dross infection). Infections with Clostridum tetani, Flavobacterium, P. aeruginosa and Klebsiella-Serratia-Enterobacter groups are often acquired from environmental sources. HIV and HVB in health care settings may be acquired from blood of the HIV and HBV positive patients by direct inoculation or through contact with broken skin or mucous membrane.

Man therefore occupies a central position:

1) as reservoir and source of micro-organisms;

2) as disseminator (communication routes);

3) as recipient or target, thus becoming a new reservoir,

1.4 ROUTES OF SPREAD

The organisms are transmitted by the following routes:

a) Direct **route**: Person to person carrier. hospital staff and visitors. air borne route which includes patient.

b) **Indirect** route: Through contaminated inanimate articles e.g. food and drink, dust, bed linen and equipment.

Important considerations in the mode of transmission of hospital acquired infections for instituting effective control measure are:

- Greater exposure of patients to infectious agents in hospital environment.
- Inadequate ventilation, faulty design of wards and departments.
- Non-availability of isolation rooms, dirty and clean utility room and janitor's closets in many wards.
- Over crowding in hospital wards.
- Spread of infection from undiagnosed infectious patients at the time of admission.
- Intimate contact between patients and staff and visitors.
- Inadequate and substandard aseptic procedures, including carelessness in hand washing.
- Poor kitchen service. laundry facilities and inadequate sterilization standards.
- Faulty house keeping.

Check Your Progress 1

1) Hospital Acquired Infection can be derived from :

.....

.....

.....

.....

.....

2) The organisms are transmitted by the following routes :

.....

.....

.....

.....

.....

1.5 CONTROL AND PREVENTION

1.5.1 House Keeping

i) Personal hygiene and environmental sanitation kept at high level in the hospital of any kind, is mandatory requirement towards control of hospital infection.

ii) Efficient house keeping including clean supply of bed linens and patients dress, proper bed arrangement;

iii) Frequent mopping and periodic washing of hospital wards and departments floors;

iv) Each ward must be provided with isolation facilities in separate rooms for infectious patients over and above the isolation wards.

1.5.2 Dietary Services

Ordering, procurement, preparation and distribution must be arranged through organised kitchen service. Minimum of handling must be ensured. Adequate water supply and washing facilities of food items and utensils to he made available. Where possible in larger hospitals mechanical cooking range and other facilities be provided. Sanitation of cook house and distribution centre, provision of food trollies etc. will help in reducing infection due to contamination by food. Periodic medical examination of cooks and food handlers must be done.

1.5.3 Linen and Laundry

The washing of linen can be manual by 'dliohics' or mechanical by washing machine. Special care is necessary when washing is done by 'dliohics'. The linen used by the patients, doctors and paramedical staff may be 'clean contaminated' ot 'contaminated' when soiled with blood/pus/urine/faeces or any other hotly fluids.

The contaminated linen must he disinfected before giving to 'dhobies' lor washing. The disinfection can be done by chemical disinfectant or by boiling or autoclaving at low pressure of steam. Hence the facilities for disinfection of contaminated soiled linen should be available in the hospital near the discarding of contaminated linen.

Both the 'clean contaminated' and 'contaminated' linen should be transported to laundry separately in thick polythene bags of different colours. The clean contaminated linen can he transported in thick cotton bags also.

Handling, separating and counting of even clean contaminated linen is hazardous, hence, there should bc minimum handling.

Drying of the linen in the sun after washing should be discouraged as it is usually spread on road side or other contaminated area.

Decontamination and Washing of Blankets

The cotton and acrylic/synthetic blankets are preferred to woolen blankets since they can be easily decontaminated when soiled and washing is also cheap and easy. They can be handled like linen. . Contaminated soiled woolen blankets can be decontaminated either by exposing lo formaldehyde vapours or autoclaving. Liquid disinfectant may damage woolen blankets. The only method of cleaning is by dry cleaning which does not inactivate/kill HIV.

Decontamination and Washing of Mattresses

It is advisable to cover all mattresses with water proof synthetic material like rexine or plastic. This makes the disinfection of the mattresses easier. Big autoclaves are available for disinfection of mattresses. One of the Delhi hospitals has such autoclaves. Washing is not easy and can be done manually.

1.5.4 Central Sterile Supply Department (CSSD)

Facilities of standard sterilization of all hospital supplies e.g. syringe, needles, surgical instruments, OT linen, sets of trays for diagnostic and therapeutic purpose, rubber good and other requriement will ensure economy and highest standard of asepsis and sterilization in the hospital and therby reduce the hospital acquired infection. In smaller hospitals optimum sterilization of equipment, instrument and linen to be ensured through autoclave and steam sterilizer. Frequent check to ensure standard to be carried out.

Sterilization

Sterilization is a process of freeing an article from all living organisms including bacterial and fungal spores and viruses.

All skin and mucous membrane piercing instruments (needles, lancets, scalpels, scissors etc.) other instruments and equipment coming in contact with organs and tissue during surgical procedures must be sterilized before use.

Sterilization can be achieved by Heat (dry and moist) Ionizing radiation (gamma

radiation, Ultraviolet) chemical (formaldehyde, ethylene oxide) and filtration.

However, the only practical and dependable method of sterilization in Health Care Settings is moist heat steam under pressure utilizing different types (simple, steam jacketed etc.) of autoclaves. It is important to note that temperature achieved in an autoclave depends on pressure of the steam and not pressure of the steam and air; 15 lbs. pressure of steam will correspond to 121°C whereas if 50% air is present, the temperature achieved will be only 112°C.

Satisfactory sterilization can be achieved at 15 lbs/sq inch pressure (15 p.s.i.) equivalent to one atmospheric pressure and a temperature of 121°C in 15-20 minutes (holding time). Household pressure cookers can achieve a pressure of 15 p.s.i. of steam and can be used with caution for sterilization.

An electric or gas oven can be used for sterilization of instruments (blunt instruments, all glass syringes?glassware etc.) and material (wax, oils, powders etc.) which are impermeable to steam and can withstand a temperature of 170°C. Household oven can be used for this purpose. The holding time ranges from 60 minutes to 120 minutes depending on the contamination of the material to be sterilized and temperature achieved.

Testing for Sterilizing Efficacy of Autoclave

In hospital settings where sterilization is done centrally (CSSD), it is necessary to monitor if each load has been properly sterilized. There are number of variables in sterilization by autoclave like pressure indicated by autoclave may not be only of steam due to inadequate removal of air resulting in achieving lower temperature at the same pressure, overloading of an autoclave thus inhibiting free passage of steam between the articles, breakdown of electricity during the process of autoclaving particularly during the holding time after the maximum temperature has been achieved. It may be noted that autoclave tapes on packs merely provide and indication that the process has been carried out at or more temperature at which colour of the tape changes but not that the contents are sterilized.

It is, therefore, necessary to carry out periodically biological test by putting disc or strips containing at least 106 spores of B. stearothermophilus (NCTC 10003, or ATCC 7953) in one or more packs in coolest and least accessible part of the autoclave chamber. After autoclaving, check if all the spores have been destroyed by culturing in suitable liquid medium (Tryptone soyabroth) at 56°C for 5 days.

1.5.5 Security

Large number of visitors are found visiting patients in the hospital and sometimes in prohibted areas like ICU, Post-operative areas etc. They bring along with them different body flura and leaving some of it in and around the patient which further may cause hospital acquired infection. Restricting the visitors with efficient security services decreases hospital acquired infection.

1.5.6 Engineering Aspects

Hospital designs and quality of construction goes a long way in reducing hospital acquired infection by providing better ventilation and light.

Air Conditioning

Positive pressure filtered air in hospital acquired infection prone areas reduces hospital acquired infection considerably and should be introduced ill areas viz. O.T. Complex, ICU, Nurseries, Labour Rooms etc. Good maintenance of building and 24 hours water supply further decreases chances of hospital acquired infection.

1.5.7 Nursing Care

A septic nursing care provided also reduces hospital acquired infection. This is more so in patients who are either very young or very old or suffering from chronic diseases like diebeties malitis, chronic nephritis or malignancies of those who are getting radiotherapy are immuno specific drugs. Special nursing medical care is needed whenever

complicated diagnostic and therapeutic procedures are carried out by the bed side. Above all, nursing staff must ensure strict, personal hyegene and hand washing, use of mark, due care for preparation of Seeds, sterilization of bottles and other accessories need Io be taken care of.

1.5.8 Waste Disposal

There is little awareness about the discarding and disposal of hospital waste in this country. More often than not all the hospital waste, i.e., both the household type and the 'infected' hospital waste are treated in the same manner. In many of the hospitals they are dumped at a place 'Garbage Collection Centre' from where this total waste is taken away by the Municipal Corporation's garbage collection vans. However, before it is collected by the van, a number of scavengers sort out this waste and take out everything of any value without knowing the harmfulness of the malerial.

The waste from a hospital should be divided into three parts:

a) **Household** non-infective waste: To be collected in Uiick polythene bags or plastic cans and discarded like household waste.

b) **'Infected'** sharp, liospital waste: 'Hospital waste' which is sharp and is likely to cut or pierce skin should be collected separately in puncture proof plastic container which can be closed or sealed.

c) 'Infected hospital' waste otlier **than 'sharp'** liospital waste: To be collected in thick polythene bags or plastic containers.

Both (b) and (c) above, i.e. 'infected' hospital waste should be incinerated. However, till incineration facilities are available, it is important to emphasise on the hospital authorities to take great care in discarding and final disposal of the 'hospital waste'

The only alternative to incineration is deep burial in controlled land fill sites. Needles and syringes must be destroyed mechanically before burial. The controlled till must be fenced off, and scavengers strictly prohibited.

Till the facilities for incineration or deep burial are available, all the 'infected' hospital waste must be disinfected before disposal. Thus, the authorities should give top priority to installation of incinerators in all the hospitals. Also, it must be ensured that these incinerators are in working order.

The plastic bags should be made freely available and each area must put all its waste in the plastic bags before transporting it for incineration or disposal.

Discarding and Disposal **of** Disposable Material

The awareness of the danger of acquiring HIV infection (the causative agent of AIDS) while handling blood and blood contaminated material has resulted in sudden increase in the use of presterilized disposable material. The use of disposable material has reached a stage when in a teaching hospital in Dellii, all the needles and syringes used for giving injections or collecting blood are pre-sterilized disposable, whereas in some other hospitals, only autoclaved needles and syringes. The hospitals in between these two extremes use a combination of presterilized disposable needles and autoclaved syringes in different situations, In most of the hospitals, disposable needles are reused after boiling. This practice must be discontinued immediately.

In this country, the plastic or the material with which these presterilized disposable equipments are made has got some value and are mostly removed by the scavengers and others between discarding and final disposal. Further, there is a high p ssibility that unscrupulous persons may start cycling the disposed disposable matcr d resulting in their reuse without even proper sterilization.

Therefore, the following procedure is recommended:

a) All the disposal material after use has lo be accounted for like any other reusable material,

This can be achieved by discarding the disposable material in a plastic/metal container and sealing this in the presence of a responsible person. The plastic container for piercing instruments like needles etc. should be puncture resistant. Plastic bread boxes are suitable for this purpose. Other lion-piercing material can be discarded in plastic bags.

b) The sealed or tied plastic containers containing the disposable material should be transported in closed wheel barrows to the incinerator.

c) The incineration area must be out of hounds for everyone except those working there.

The following procedure is recommended for disinfection of needles and syringes after use and before disposal, till the facility of incinerator or hot air oven becomes available:

- Do not detach the needles from the syringes after use.
- Aspirate disinfectant fluid into the syringe
- Immerse the syringe with attached needles in the disinfectant fluid horizontally in flat metal/glass tray or puncture proof plastic container.
- Keep them immersed in disinfectant fluid for at least 30 minutes.
- The needles and syringes can be removed from the disinfectant fluid and destroyed mechanically before disposal.
- Alternatively all the disposable material can be put in the hot air oven at a temperature of 160°C for 30-60 minutes. This will ensure that neither disposable material after use can go in the hands of scavengers nor there will be any possibility of its reuse.

1.5.9 Antibiotic Policy

Each hospital must have an antibiotic use policy so that indiscriminate use of antibiotics can be checked as indiscrimate use of antibiotics is known Io cause drug resistent bacterias. Hospital acquired infection due to this drug resistent bacterias are very difficult to treat and are major cause of septisemia.

1 . HOSPITAL INFECTION CONTROL COMMITTEE

To combat hospital infection, it is essential that hospitals according to its available resources and requriemcnt establish a Hospital Infection Control Committee (HICOM) and invest with authority to pursue:

- Investigation of all hospital infections.
- Establish surveillance programme.
- Provide guidance and leadership in the prevention and control of hospital infection.

1.6.1 Composition

MCOM in an institutional hospital or referral hospital should be broad based in composition with representatives of all major specialities as members i.e. Surgeon, Physician, Anaesthetist, Pediatrician, Microbiologist/Bacteriologist and Gynecologist, Nursing Matron, House Keeping staff, Engineer Service representative and Dietitian.

Microbiologist/Bacteriologist to be detailed as Hospital Infection Control Officer and should work as Member Secretary. Hospital Superintendent or his representative should be Chairman.

In a district hospital set up, the organisation should be composed of:

- Available professional specialists.

- Matron of the hospital or any other specialist officer as Infection Control Ofticer
- Medical Superintendent of Hospital as Chairman.

In a still smaller hospital situation the responsiblity can be given to one Medical Ofticer only.

1.6.2 Role and Functions

Hospital Infection Control Committee with the help of Surveillance staff ensures smooth surveillance and control of hospital infection by:

- Establishing reporting system through:
  a) Nursing Unit report daily/weekly.
  b) Individual patient report.
  c) Review of bacteriological sergicc record of the hospital
  d) Autopsy Report.
- Meet periodically to take decision.
- Lay down standards of aseptic procedures in hospitals.
- To distinguish between infection acquired in the hospital and those acquired outside
- To prepare manual for control of infection and lay down training programme of personnel.
- Take all decisions based on reports received through hospital infection control officer regarding investigation and control measures in the event of sudden rise of hospital infection rate.

1.7 SURVEILLANCE

The aim of the surveillance is to detect and record methodically all Hospital Acquired Infections (HAI). Hence the surveillance of HAI is indispensable in hospitals for infection control. Continuous surveillance allows the early detection of outbreaks. It is necessary to find out incidence and trends of HAI, causative organisms and their antimicrobial sensitivity, according to site of infection, speciality and ward/floor. This information can also be used for evaluating control measures and policies introduced from time to tune.

Patients in hospitals are more susceptible to infections than those in the community (general population). This is often related lo pre-existing disease, such as diabetes,. medical and surgical procedures, radiotherapy or immuno-suppressive treatment. Patients at extremes of age are especially susceptible to infection.

i) Community or non-hospital infection with which the patient enters the hospital.

ii) Hospital (nosocomfal) acquired infection, which is acquired in the hospital and makes its appearance either during hospitalization or after the patient is discharged.

There are predominantly four types of hospital acquired infections. They can be recorded on the basis of clinical and/or microbiological data.

1) **Urinary Tract** Infections

The urinary infections may be symptomatic (fever, dysuria, lumbar pain) or asymptomatic. Their recording depends partly on the microbiological tests performed (over 100,000 micro-organisms/ml midstream urine samples).

2) **Infections of the** Lower **Respiratory** Tract

The clinical signs of infection (coughing, pleural pain, fever and expectoration) are enough for these infections to be recorded, even if no chest X-ray or bacteriological tests have been performed.

3) **Post-operative** Infections

Any surgical wound which results in a purulent discharge must be regarded as a hospital acquired infection.

4) **Systemic Infections**

A positive blood culture revealing a known pathogen, or at least two blood cultures revealing a micro-organism rcputcd to bc non-pathogenic or opportunistic, must be taken into account and listed as hospital infection.

1.7.1 Processing of Information Collected

The information collected in this way is processed by the Infection Control Sister. A weekly, monthly and yearly report, makes it possible to compile statistics on infections by speciality or floor and for the hospital as a whole, for each type of infection.

Incidence rates and period prevalence rates should be worked out as follows:

- Tlic incidence rate corresponds Io the number of new patients developing HA1 in a given period in relation to the number of patients discharged during the same period.
- The period prevalence rate corresponds to the number of new and old patients developing HAI during a given period in relation to the number of patients discharged during the same perioa

Analysis of these various rates by the Hospital Infection Team will reveal the true dimensions of the hospital infection and make it possible to direct control operations and to develop the most effective possible strategies of action.

In order to contain specific outbreaks of infections, it is necessary to find out source/ reservoir of infection by detecting carriers, sampling the inanimate objects (equipment and material) used for patient care and air and likely mode of transmission.

1.7.2 Mode of Transmission

There are four main routes of infection that have to be watched in hospitals: (1) the aerial route, (2) the oral route, (3) the contact mute, especially the "hand borne" route, and (4) the parenteral route.

In the sequence of transmission the following factors must be taken into account; (1) the pathogen; (ii) the reservoir or source for the pathogen; (iii) the exit point; (iv) the transmission route; (v) the point of entry into the host; (vi) the susceptibility of the host.

1.7.3 Interruption of Transmission

Efforts must be made to break this sequence at its most vulnerable point, which differs from one case lo another.

It is possible therefore to:

i) destroy the pathogenic agents of the carrier staff or source patient by specific antibiotic and antiseptic therapy;

ii) control tlie source or reservoir by isolation of infectious patients and by freeing inanimate reservoir of micro-organisms by sterilization or disinfection;

iii) control the exist point by disinfection of excreta and infected material;

iv) control the transmission route by washing of hands, disinfection of equipment, change of working clothes;

v) protect the susceptible host by protective vaccination, e.g., tetanus, gas gangrene, etc.

1.7.4 High Risk Procedures

Certain activities/procedures can be said to be high risk procedures/activities. Special care is recommended for practising these procedures/activities. The following procedures need special attention:

- Injections
- Surgical procedures
- Dressing of wounds
- Management of Delivery (child birth)
- Investigative procedures
- Laboratory investigations
- Dialysis

Injections

One of the commonest procedure in any hospital is to give injections to the patients for treatment and prophylaxis, In most of the hospitals, there is a common area for giving injections to all OPD patients.

It must be remembered that intact skin and mucous membrane provide maximum protection to infection and barrier to invading organisms. Any type of injection breaks this continuity of the skin barrier, introduces material directly into the body which, if contaminated by micro-organism, will result in severe infections. Great care is necessary for the decontamination of skin area where the injection is to be given and ensuring sterility of the needle, syringe and injecting material. Needles and syringes get contaminated with the patient's blood which may be infective and cause serious diseases like Hepatitis and AIDS. Thus, it is necessary to ensure the proper disinfection of the needles and syringes after use. It should be ensured that no one gets a needle stick (piercing by the needles) either as part of their duties or accidentally.

Disinfection of the Skin

Before giving injection, the skin area should he cleaned and disinfcctcd, The ideal skin disinfection is Tincture of iodine, provided the patient is not allergic to iodine mid does not mind the colour; alternatively 70% alcohol, cidex, savlon or any other dependable disinfectant in proper concentration can be used.

Use of Needles and Syringes

The injection should only be given by autoclaved or prestcrilised disposable needle and syringe. Before giving injection, the needle must not be touched with spirit cotton wool swab, hand or any other material.

The needles and syringes should bc discarded in dependable disinfectant fluid. A common practice seen in almost all the hospitals in Delhi, is the use of plastic buckets without disinfectant fluid lor discarding disposable needles and syringes after use. This practice is dangerous and is likely to cause harm to those who subsequently handle the used needles and syringes.. Suitable disinfectant should be aspirated in the syringe. Disposable and reusableneedles and syringes containing disinfectant fluid should be kept in separate puncture-proof container (plastic or metal) by immersing them in disinfectant fluid in these containers. The reusable needles and syringes must be cleaned and washed after taking out of disinfectant fluid.

Disposal of Disposable Needles and Syringes

It is necessary to treat disposable needles and syringes like reusable material of value. It is also necessary that under the supervision of a person nominated by the Medical Superintendent, all the disposable needles and syringes should be destroyed by melting

the plastic material. The best method of disposal of disposable material is by incinceration. Disposable needles and syringes are great hazards since they are likely to be re-used and misused. The hospital policy should be to exchange needles and syringes and dispose them off centrally, preferably by incinceration or deep land fill.

Surgical **Procedures**

All the surgical procedures including dental procedures are invasive procedures and involve use of instruments, equipment and material. The duration of surgical procedures like operations is important. The longer the duration of an operation, the greater are the chances of infection. There is lot of handling of blood, tissues, organs and body fluids during these procedures. The micro-organisms get directly inoculated into the body and may enter the blood circulation if there is a lapse in aseptic precautions.

Therefore, it is absolutely essential to ensure that all the instruments, equipment and material used during surgery are sterile. Special attention is needed regarding the positive pressure of the operating area, environment of the operation theatre (low microbial counts), presence of number of persons in the theatre, anaesthesia and other activities.

Any surface which might have been contaminated with the blood or body fluid must be disinfected first by covering it with absorbent material. Disinfectant fluid should first be poured around the contaminated area and then over the absorbent material and left for more than 10 minutes. The disinfectant used should be of the concentration which is recommended for use in contaminated situations.

Tissue, organs and any part of the body removed during surgery should be incinerated/ burnt or buried deep with bleach or lime. Blood and body fluids removed during operation must be disinfected before disposal.

Dressing of Wounds

Wounds can be surgical after operations, accidental after injury or due to purulent infections (boils. abscess, carbuncles etc.) or due to underlying disease like fistula, piles etc.

The wounds can be divided into four groups: (a) clean, (b) clean contaminated, (c) contaminated, and (d) dirty. The dressing of these wounds should be clone in two separate areas; one for clean wounds and clean contaminated and the other for contaminated and dirty wounds. Thus, extreme care is necessary to use only sterile instruments, material (cotton wool and other dressing material), lotions, anti-septic and anti-bacterial creams etc.

The disposal of dressing material, disposable material and reusable instruments needs special attention. All material and instruments used and removed during the dressing should be taken as contaminated. Therefore, all the material should be disinfected, reusable instruments before sterilization and disposal instruments and contaminated dressing etc. before disposal, if incineration is not possible. Ideally, all the material should be discarded in three separate containers. Twn of the containers should be puncture proof and should contain disinfectant fluid for sharp instruments like needles, scissors, scalpel, blades etc. One for reusable instruments and other for disposable instruments including syringes and needles. Both the reusable and disposable instruments should be discarded in separate containers in which the used instruments could be put horizontally and immersed in the disinfectant fluid. The third container can be a polythene bag in the bucket. The polythene bag containing dressing material like used cotton, bandages etc. should be sealed or tied. All the material other than reusable material should be incinerated or burnt or disinfected before disposal. The reusable material after disinfection should be cleaned and sterilized by autoclaving.

Management of Delivery **(Child Birth)**

The delivery of a child is more or less crisis management. The sharp instruments are around and every one including the expectant mother in the delivery room is tense, Thus, at this time the persons conducting the delivery may get splashes of potentially infected blood and amniotic fluid and even cuts. In view of the short time available for delivery

and related procedures, the chances of exposure to HIV and other blood borne infections are much higher during deliveries than my other situation. In view of this, following guidelines may be useiul:

- The delivery of known or suspected case of I-IIV positive patient should be carried out in an area near the main area but separated from the main area.
- A HIV positive patient is more prone to infection, hence, she needs greater protection from infection from other patients.
- All instruments, equipment and material used for the delivery must be sterile and must be decontaminated after use.
- The surfaces including table tops and floors which have been contaminated by blood or amniotic fluid must be decontaminated.
- During the delivery, the team of Health Care Workers including Pediatrician and others must be exclusively involved with the delivery of I-IIV positive woman. Immediately after care of HIV positive woman and her newborn; they should change lo another set of footwear, gown etc. before handling the other patients, lo avoid person to person infection to other patients.
- Immediately aflcr care of HIV positive woman and her newborn, they should change to another set of footwear, gown etc. before handling the other patients, to avoid person infection to other patients.
- The placenta must be incinerated, burnt or buried deep with blenching powder all around placenta. The bleaching powder should be first spread in the pit made for burial and then on the placenta.

Protective barriers are recommended for all deliveries.

Investigative Procedures

The investigative procedures can be broadly divided into two categories: (a) invasive procedures, and (b) non-invasive procedures.

a) ***Invasive Procedures***

These include lumbar puncture, cut downs, tappings, aspirations, biopsy, laproscopy, endoscopy, cardiac-catheterisation, bronchoscopy and similar other procedures. During these procedures, tlic continuity of the skin or mucous membrane is lilcely to be broken and micro-organisms can gain free entry. Hence, all precautions recommended for surgical procedures should be followed for invasive procedures.

b) *Non-invasive Procedures*

These include vaginal, anal and rectal examinations, prostatic massage, measurement of intra-ocular pressure, ENT examinations; and different imaging processes like echo-cardiography, ultra-sound, X-ray and CAT scan. It is highly possible that during some of these non-invasive procedures, break in the continuity of the mucous membrane may be encountered which may result in contamination of instruments used for the examination.

The vaginal and rectal examinations are particularly hazardous. Since I-IIV and other organisms including those causing sexually transmitted diseases may be present in these situations. Therefore, only sterile instruments, equipment or material should be used for such non-invasive procedures. After use they must be regarded as 'contaminated' and must not bc used on other patients without proper disinfection and sterilization.

Disinfection of the Instruments used for Non-invasive Procedures

Immediately after use the instruments (like vaginal speculum, proctoscope etc. should be immersed in suitable disinfectant fluid for at least 20 minutes. After disinfection, they preferably be autoclaved or boiled for 20 minutes and then reused.

Laboratory Investigations

The clinical specimens are collected for different laboratory investigations. Most of these specimens are highly infective and on occasions, can cause diseases including Hepatitis and AIDS, Hence, great care must be taken in handling these spccimens. These specimens primarily fall in three categories:

a) Blood, tissue and blood contaminated material like pus and body fluids etc.

b) Body fluids like CSF, pleural and pericardial fluid, semen,. vaginal fluid and other such specimen.

c) Urine, sputum, bronchial washings and swabs from mucous membrane and skin.

The following recornmendations will bc useful for handling these clinical specimens:

a) ***Blood, Tissue and Blood Contaminated Material***

Use only autoclaved/presterilized disposable needles and syringes for collection of blood. All precautions described for giving injections should be followed strictly for collection of blood including disinfection of skin.

Use only autoclaved or presterilized disposable instruments lo remove the tissue or blood contaminated material like pus and body fluids.

b) ***Body Fluids like Pleural, Pericardial and Cerebro-spinal Fluid, Vaginal Secretions and Semen etc.***

Only autoclaved or presterilized disposable instruments should be used for collecting these material.

c) ***Urine, Sputum, Bronchial Secretions and Swabs from Mucous Membrane***

Most of these specimens arc excretions of the body and do not require use of any equipment or instrument for their collection, except bronchial secretions and rarely urine. Only autoclaved for presterilized disposable instruments or material should be used if the material to bc collected is not available as excretion.

Transportation of Clinical Specimen

All clinical specimens should bc regarded as infection risk and should bc transferred to the laboratory in spill proof screw capped bottles. Special precautions should be taken for the blood suspected to be from patients of Hepatitis or AIDS, which should bc transported in leak proof polythene bags.

Any accident, contamination or spill from the collection to disposal must bc reported and proper disinfection should be carried out.

Processing of Clinical Specimens

The blood, blood contaminated specimens and tissue must not spill on the table tops, floor, requisition forms, report forms or any other surfaces. In case of any such spilling, the surfaces must be disinfected.

Under no circumstances, mouth pipetting should be permitted for carrying out any test.

Discarding

All clinical specimens after carrying out necessary test must be discarded in discarding jar containing suitable disinfectant. Hazardous specimens like microbial culture must be autoclaved before disposal.

Disposal

All clinical specimens must bc disposed off by incinerating or flushing them. It must be

ensured that no one should come in contact with any clinical specimen without disinfection other than those who have to be associated as part of their duties.

Dialysis

Dialysis is a common procedure carried out in many hospitals. It is of two types — Peritoneal dialysis and Haemo dialysis. Infections often complicate hemo dialysis and personnel working in a dialysis unit may acquire infections during work if proper precautions are not taken, the commonest being Hepatitis B.

Attempts at complete segregation of HBsAg positive patients and their dialysis equipment proper disinfection and antisepsis, have substantially reduced the incidence of this infection. Seronegative to HBsAg staff should be fully immunize with hepatitis B vaccine.

The requirement for access to a patient's blood supply twice in each dialysis procedures makes the dialysis unit similar to a surgical unit. The dialysis unit is crowded, with,a lot of machines, wires, tubes, hoses and the cleaning is more difficult. Special instructions and training are necessary for the staff, especially regarding the cleaning of machine and equipment. Wastes from the unit should always be classified as 'infectious' because of the high incidence of hepatitis among patients.

1.8 TRAINING AND EDUCATION

It is very essential that knowledge, skills and behaviour of all categories of hospital staff is tuned to control and prevention of Hospital Acquired Infection. This can be achieved by holding lectures and demonstration session with them. Apart from it, training of few groups of functionaries specially section heads viz. Sister Incharge, OT Complex, ICUs, Labour rooms, post operative wards, sanitary inspectors, Incharge CSSD, Security, dietetics will go a long way in reducing Hospital Acquired Infection in the hospital.

1.9 UNIVERSAL PRECAUTIONS FOR HEALTH CARE WORKERS

1) All health care workers should routinely use appropriate barrier precautions to prevent skin and mucous-membrane exposure when contact with blood or other body fluids of any patient is anticipated. Gloves should be worn for touching blood and body fluids, mucous membranes, or non-intact skin of all patients, for handling items or surfaces soiled with blood or body fluids, and for performing venepuncture and other vascular access procedures. Gloves should be changed after contact with each patient. Masks and protective eyewear or face shields should be worn during procedures that are likely to generate droplets of blood or other body fluids to prevent exposure of mucous membranes of the mouth, nose and eyes. Gowns or aprons should be worn during procedures that are likely to generate splashes of blood or other body fluids.

2) Hands and other skin surfaces should be washed immediately and throughly if contaminated with blood or other body fluids. Hands should be washed immediately after gloves are removed.

3) All health care workers should lake precautions to prevent injuries caused by needles, scalpels and other sharp instruments or devices during procedures; when handling sharp instruments alter procedures. To prevent needlestick injuries, needles sliould be recapped, while the cap is placed on any flat surface and not held in the other hand. This prevents accidental needle stick in the hand holding the needle cap, Also, needles should not be purposely bent or broken by hand, removed from disposable syringes, or otherwise manipulated by hand. After they are used, disposable syringes and needles, scalpel blades, and other sharp items sliould be placed in puncture-resistant containers for disposal.

4) Although saliva has not been implicated in HIV transmission, lo minimize the need for emergency mouth to mouth resuscitation, mouth pieces, resuscitation bags, or other ventilation devices sliould be available for use in areas in which llie need for resuscitation is predictable. Although HIV has been recovered from saliva, there is no conclusive evidence that saliva is involved in HIV transmission. Nevertheless, to reduce occupational cxposurc lo HIV, mouth pieces, resuscitation bags, or other ventilation devices should bc used if available when resuscitation is necessary. Resuscitation equipment should be used once only and discarded, or be thoroughly cleansed and disinfected.

5) Health care workers who have exudative lesions or weeping dermatitis sliould refrain from all direct patient care and from handling patient care equipment until the condition resolved.

6) Pregnant health care workers arc not known lo bc at greater risk of contracting HIV infection thar health care workers who are not pregnant, however, if a health care worker develops HIV infection during pregnancy, the infant is at risk of infection resulting from perinatal transmission. Pregnant health care workers because of this risk, should be especially familiar with and strictly adhere lo precautions to minimize the risk of HIV transmission.

Implementation of universal blood and body fluid precautions for all patients eliminates the need for use of the isolation category of "Blood and Body Fluid Precautions" for patients known or suspected lo be infected with blood borne pathogens. .Isolation precautions (e.g. enteric, tuberculosis) should be used as necessary if associated conditions, such as infectious diarrhoea or lubcrculosis, are diagnosed or suspended.

1 . 1 LEGAL ASPECTS

Hospital Acquired Infection will increase average length of stay. Assuming that 10% of the admitted patients suffer from I-Iospilal Acquired Infection resulting into increased hospital stay, the country will lose on to major accounts, productivity and the treatment cost the patient and their relations will suffer from increased morbidity and may be occasionally mortality and loosen their daily earning clue to the increased hospital stay. Liligation on account of acquired hospital infection due lo the negligence of hospital authorities including doctors can bc potential litigation under Consumer Protection Act, It is in the interest of all of us that Hospital Acquired Infection will be eradicated,

1.11 LET US SUM UP

Hospital Acquired Infections are known to take place leading to large amount of morbidity and mortality and loss of square hospital resources. It also increases average length of stay in the hospitals. It is estimated that efficient hospital acquired infection measures when adopted can reduce average length of stay by 20% which when converted into gain and productivity and saving in hospital rhsources, will account very large volume, There is no way that we can eliminate hospital acquired infection altogether but our knowledge about hospital acquired infection and mesures innumunerate to control it will certainly go a long way in reducing hospital acquired infections in our health care centres.

UNIT 2 DISASTER MANAGEMENT

Structure

2.0 OBJECTIVES

After going through this unit, you should be able to:

- understand the concepts of disasters and its management;
- describe the principles of disaster planning and the objectives and purpose of disaster plan;
- describe the composition, functions and responsibilities of Disaster Committee;

UNIT 2 DISASTER MANAGEMENT

Structure

2.0 OBJECTIVES

After going through this wit, you should be able to:

- understand the concepts of disasters and its management;
- describc the principles of disaster planning and the objectives and purpose of disaster plan;
- describe the composition, functions and responsibilities of Disaster Committee;

- outline the role and responsibilities of medical, nursing staff and departments;
- analyze the disaster facilities required; and
- develop the disaster plan and modalities for response action.

2.1 INTRODUCTION

In this unit you will learn basic concepts of disaster management and principles of disaster planning. You will learn about the objectives and purpose of disaster plan, role and responsibilities of staff and the basic facilities required to meet the challenge of disasters and emergency response.

Disasters have existed ever since the existence of mankind and no community is immune to the emergencies caused by natural and manmade disasters. The disaster events result in number of deaths, injuries amongst the community, wide spread destruction of property, economic losses etc. and community requires immediate assistance to overcome its effects. Globally the toll ot death and damages in natural disasters is increasing. The cost to the global economy is estimated to be 50,000 million US dollars per year, of which a third represents the cost of predicting, preventing and mitigating disasters and other two-third represents the direct cost of damages. Death toll may vary from year to year with global mean of 2,50,000 deaths of which major disaster kills on an average of 1,40,000 people per year. The study of United Nations Environment Programme (UNEP) indicates Mat India is one of the most disaster prone countries as far as natural disasters are concerned. In this unit you will learn their importance of scientific management of disaster events and emergency response for medical care. In this unit you will also learn to relate the disaster management at national, state and district level. You will learn about the disaster characteristics, need for disaster planning, key issues involved and basic principles of disaster management. You will learn the process of development of disaster plan, its components and purpose. Tlie basic purpose of this unit is focussed on learning development of plans, response actions and issues in disaster preparedness.

2.2 BASIC CONCEPTS

The first important aspects of disaster management are to understand the disasters. The disasters are a phenomenon in themselves and have various characteristics which are crucial for disaster management. A clear understanding of these basic concepts is necessary for scientific planning, preparedness and emergency response.

2.2.1 General

The concept and definition of a disaster has altered over times, in accordance with changing concepts concerning cause and effect. The infectious diseases *were* considered inevitable disasters prior to 1700 AD. In 1950s the concept of natural disasters changed from characteristics of physical forces and resultant damages to social issues. The definition of the disaster has reflected this change with increasing attention being given to the social aspects of disaster situation and collective ability to meet the requirements of these situations. How the word "Disaster" is defined gives meaning to such descriptive terms as Disaster Prevention, Disaster Preparedness and Disaster Response etc. The disasters have been defined in various ways on the basis of degree of physical impact of the event, magnitude, disruptions of public safety, disproportion of resources in terms of special efforts required and controllability of event.

WHO defined disaster as any occurrence that causes damage, ecological disruption, loss of human life and deterioration of health and health services on a scale sufficient to warrant an extraordinary response from outside the affected community. Pan American Health Organisation (PAHO) defined disaster as an overwhelming ecological disruption, which exceeds the capacity of a community to adjust and consequently requires assistance from the outside.

W. Nick Carter defined it as an event, natural or manmade, sudden or progressive, which impacts with such severity that the affected community has to respond by taking exceptional measures.

2.2.2 Disaster Classification

Disasters have been classified in various ways but the most convenient method used is the division of disasters into two distinct categories according lo their causes:

- Disasters caused by the natural phenomenon
- Manmade disasters

Natural Disasters

Meteorological Disasters: Storms (Cyclones, hailstorms, hurricanes, tornadoes, typhoons and snow storms), Cold spells. Heat Waves and Droughts

Typological Disasters: Avalanches, Landslides and Floods

Telluric and Teutonic Disasters: Earthquakes, Tsunamis and Volcanic Eruptions

Biological Disasters: Insect Swarms, (e.g. locust) and Epidemics of Communicable Diseases.

Manmade Disasters

Civil Disturbances: Riots and Demonstrations

Warfare: Conventional Warfare (bombardment, blockage and siege)

Non Conventional Warfare: Nuclear, Biological and Chemical warfare, Guerrilla Warfare including Terrorism

Refugees: Forced movement of large number of people usually across frontiers

Accidents: Transportation calamities (land, air and sea), Collapse of building, dams and other structures, mine disasters.

Technological failures (e.g. a mishap at a nuclear power station, a leak at a Chemical plant causing pollution of atmosphere or the break down of a public sanitation system)

This relatively simple classification has been overlaid by more complicated classification scheme of various researchers. The classifications are by no means fully comprehensive as these merely indicate the numerous causes or potential causes ol' some of the more serious disasters. Tlic division between natural and manmade is to some extent an oversimplification as many disasters can be caused by either. Some of the worst calamities are often caused by the cumulative effect of several of the above mentioned factors both natural and manmade.

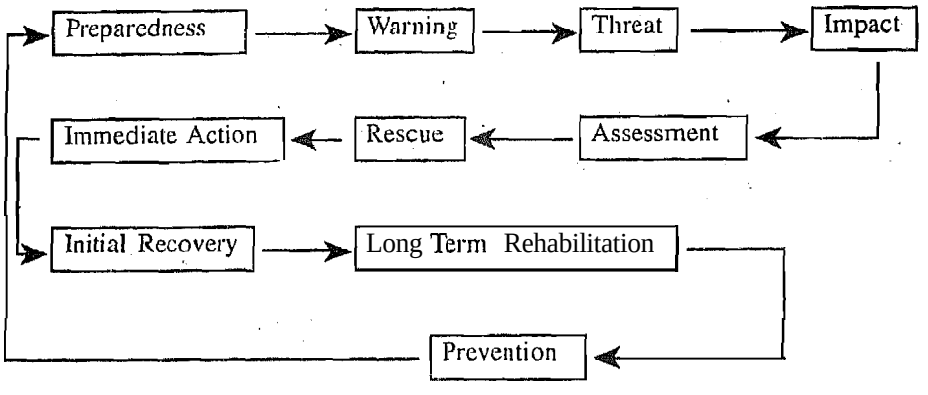
2.2.3 Disaster Process

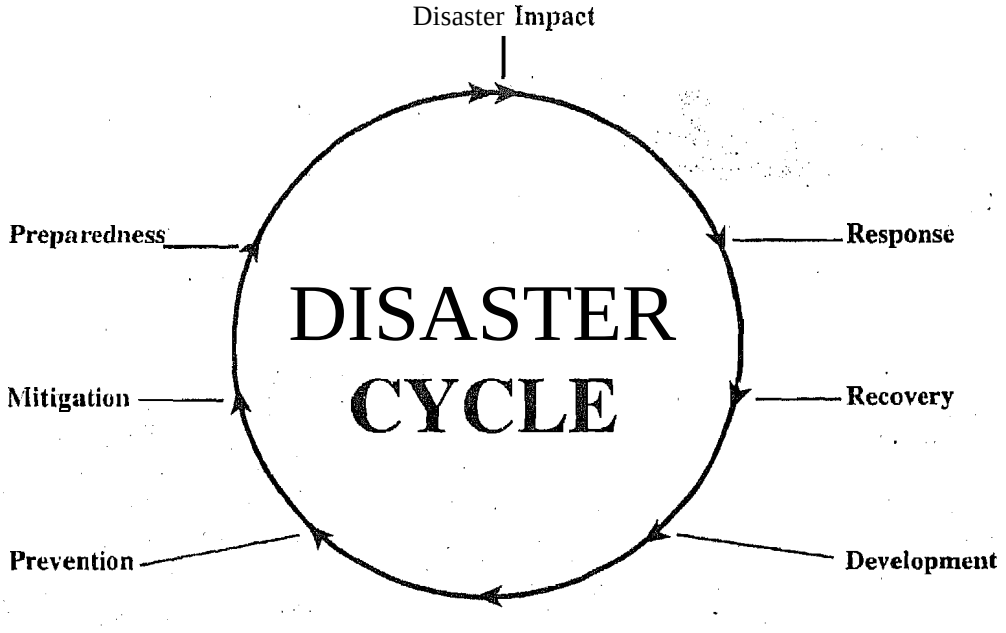
Disaster situation has been conceptualized as a process with differing phases. hi each different phase, the information, the action required, the problems encountered and people involved may be quite different. The interrelationship of these different phases and activities is important for its management. Various researchers like Powel and Rayner, Garb and Eng, Skeet, Dynes and Russell have divided disaster into various stages or phases. This artificial time division of disaster studies is an important base for planning.

Each type of phase will vary according to the type of disaster event with different time element like in an aircraft crash there may be no warning or very little warning as against floods, which may give sufficient warning for preparedness.

The disaster and its management has been considered as a continuum of interlinked activities in wliicli the cyclical nature ol various components of disaster management has been conceptualised as a disaster cycle by W. Nick Carter.

Disaster Process





2.2.4 Spectrum of Disaster Management

The spectrum of disaster management involves disaster prevention, mitigation, preparedness, response and recovery. It is essential to clearly understand these terms and the scope of activities in each of them.

Disaster **Prevention:** It covers those measures which are aimed at impeding the occurrence of a disaster event and/or preventing such an occurrence having harmful effects on communities. Prevention concerns the formulations and implementation of long range policies and programmes.

Disaster **Mitigation:** Measures aimed at reducing the impact of a natural or manmade disaster on a nation or community.

Disaster Preparedness: Measures, which enable governments, organisations, communities and individuals to respond rapidly and effectively to disaster situations. Preparedness measures include the formulation of viable disaster plans, the maintenance of resources and the training of personnel. Organising, planning, coordinating, resource planning and training are its major concerns.

Disaster Response: Response measures are those, which are taken immediately prior to, and following disasters. Such measures are directed towards saving life and protecting property and to dealing with the immediate damage caused by the disaster. Its success depends vitally on good preparedness.

Disaster Recovery: Recovery is the process by which communities and the nations are assisted in returning to their proper level of functioning following a disaster.

2.2.5 Special Characteristics

Disasters are considered phenomenon in themselves with some common characteristics. There me several facts and phenomenon associated with disaster events which requires clear understanding as these have many planning and response implications

Geography of Diasters

The geographic divisions of the total area concerned with a disaster were conceived in order to classify the arising problems and help manage them. Solomon Garb and Eveling Eng divided the area in the three major divisions:

Impact Area: Area in which the impact agent works out its full capacity for destruction. The area will vary with the lype of disaster like in aircraft or train accident the area will be relatively small. But in floods, dam burst, typhoon and storms the area will he very large.

Filter Area: It is virtually the undamaged zone from which the reserves enter the area and through which evacuees and rescue workers must pass. Serious traffic confusion often occurs in this area.

Community Aid Area: The area outside the liltcr area from where the community, special institutions and organised teams operate for performing rescue and rehabilitation roles.

Disaster Behaviour

Analysis of various disaster situations of differing magnitude and consequences carried out over a period of more than 30 years in different countries confirm that there are many common patterns of human and organisational behaviour in emergency situations. The psychology of disaster involves several distinct facets like psychology of victims before, during and after disaster, of the volunteer helper, trained professionals and the onlooker. Each-must be understood in order to cope with the problems. Pre disaster planning is dependent in large parts on what is assumed about human behaviour in emergency situations. Valid assumptions are essential for the planning and implementation of effective emergency measures and post disaster responses.

The Victim: Most people believe that a disaster is some thing that happens Io someone else not to themselves or their families. This is called the 'dclusion of personal invulnerability'. As a result they are likely to ignore or minimise warning and refrain from taking preventive measures. It can be countered by vigorous training or by imaginative action or both. These persons who have ignored all warnings before the disaster impacts often over react to warnings, rumors and wild speculations after the impact, Prompt setting up of an efficient communications system will minimise the harm from this sort of psychological pattern.

Disaster Syndrome: A form of stress or shock reaction, called a 'Disaster Syndrome' has some times been observed in the aftermath of relatively sudden and extensive disasters with acute disorientation and apparent loss of individual purpose or direction. It does not occur in a great number of people and is generally of short duration, A stress situations called 'Counter Disaster Syndrome' has been described where some uninjured or slightly injured survivors of the impact and volunteers may suffer this short duration syndrome which is marked by vigorous rescue activity.

EL Quarantilli disproved the myth about panic flights, helplessness, paralyzing trauma, anti social behaviour and low community morale during disaster situations. Recognition of the ability of people to cope suggests that as a basic premise, the actions and resources of survivors must be considered in planning for and providing assistance in emergency situation.

Convergence in Disaster

Convergence is observed to be a common problem in most disaster events and it has an important bearing on disaster management. Convergence, characterised by the spontaneous movement of large number of people and large amounts of materials towards

the zone of impact, is a common phenomenon in all emergencies. This convergence is motivated by a concern for victims, a desire to help, simple curiosity and the search for information. This movement usually outweighs the outward flow of those wishing to leave. The convergence is described to he of three types:

Personal convergence: The physical movement of people.

Material convergence: The physical movement of supplies and equipment.

Information convergence: The quest for information through the transmission of messages by word of mouth, telephones, wireless etc.

In past disasters unofficial convergence has been one of the greatest obstacles lo giving efficient help to the victims. The extent to which convergence hampers effective rescue, first aid and evacuation is usually much greater than more people realise.

It is important therefore, to understand the convergence phenomenon, its origins and possible ways of dealing with it. Convergence causes logistic and administrative problems, Studies have concluded that convergence remains largely a contextual problem which can not be avoided. Convergence cannot be completeiy blocked out but it can be channeled. Convergence of telephone calls is known *to* jam the communications channel of hospitals and the conveyance of people in hospital causes confusion. Uncontrolled convergence of relief material is likely lo create logistic problems as well as may lead to traffic jams. As convergence is likely to occur after every disaster. it requires careful consideration in order to enhance the usefulness of donations and minimise the administrative and logistic difficulties.

Leadership **in Disaster**

In any attempt to bring order and efficiency out of disorder and confusion, sound leadership is necessary. This is particularly true in disasters which arc the epitome of disorder and confusion. Past experience has shown how helpful sound leadership can be and how it can save lives and prevent suffering. By contrast, poor or absent leadership has sometimes resulted in needless extra casualties. Disaster management involves many agencies aid organisations at various stages. For a total integration and optimisation of resources of multiple channels, multiple sources have got to be systematically led by someone. The leadership principles commonly found useful in disaster situation are:

- Leadership in disaster must be shared.
- Organisation of leadership framework must be clear and well defined.
- The higher levels of leadership in a disaster should, ideally, be held by persons who already have recognised authority under existing law.
- Leadership must understand the principles of organisation and of delegation of authority.
- Leadership should be an open-ended management.

Key Issues

Disaster management implicates different sectors at different times and the need for cooperation and coordination among local, state and national agencies is never more apparent than in the case of disasters, hence disaster management necessitates a multidisciplinary approach. It is not possible for any organisation to carry the burden of the disaster plan. Disasters cannot be managed in a vacuum and many agencies have to be integrated and coordinated into the plan to prevent duplications and confusion. It is necessary to promote maximum coordination of all the community resources for tlic time when disaster may strike, Coordination is a key issue in disaster management.
Disaster is no respecter of circumstances and it is known to strike with suddenness and fury of its own with a curious l'aculty for choosing an inopportune moment to hit. The motto "preplanning prevents poor performance" is most applicable to disasters. A realistic, well-rehearsed and coordinated disaster plan executed by a well-trained system is essential to meet the challenge of disasters. The key issues in disaster management are:

- Preplanning
- Coordination and multisectoral cooperation
- Training
- Regular practice

2.3 DISASTER MANAGEMENT IN INDIA

The disaster management system of various countries indicates a need of a clear National Disaster Management Policy for establishing and maintaining adequate arrangements to deal with all aspects of a disaster threat. This policy framework should be at all levels of the national structure and organisations at national, state and district levels. Adequate disaster legislation is necessary to provide authority and assume cooperation and assistance among often competing government jurisdiction. The policy and legislation is to be supported by appropriate organisation and disaster plans. The national level organisations and plans needs to bc supported by regional/state level plans.

India is a vast country, the main land area consists of 32,37,782 square kilometers. India with 2.4 per cent of worlds land mass, seventh largest country in the world, with 15% of worlds population is the second most populous country in the world. The current estimated population of a billion has a population density of 273 persons par sq kilometer, which makes the effects of disasters very serious. India manifests many natural disasters like floods, earthquakes, cyclones and drought etc. and also the manmade disasters like chemical disasters in Bhopal, collapse of buildings, train and aircraft accidents etc. The vulnerability to National Disasters can be seen from the following:

Floods: India is one of the most flood prone countries in the world. On an average about 9 million hectares are affected by flood every year. India accounted for 115 of global deaths due to floods from 1960 to 1980's.

Earthquake: The country has about 56.3 % of total area amounting to 3.3 million sq kilometers vulnerable to seismic activities of varying intensity. The earthquake prone areas have witnessed over 33 major earthquakes within the country. During last 80 years India has lost about 70000 lives due to earthquakes.

Cyclones: India has a very long coastline of 5700 kilometers, which is vulnerable to tropical cyclones arising in the Bay of Bengal and Arabian Sea. Cyclonic storms have been causing considerable damage to life and property in the coastal area of India. The cyclone in Paradip on 30 October 1979 claimed 10,000 lives. Orissa cyclone in 1982 distressed 7 million people and Andhra Cyclone in 1997 killed 10,000 people and 23,000 cattle.

Manmade Disasters: India suffered the largest manmade disaster in Bhopal on 3rd December 1984 when chemical gases leaked killing 2500 people. 17500 were hospitalised besides incapacitating thousands.

The vulnerability of the country requires appropriate disasler plans at the national, state, district level and in each hospital. Each and every response organisation must be prepared lo play a role in disaster situations,

2.3.1 National Level

In the federal set up of India both the central government and state government share the responsibility for disaster management. The basic role of central government is supportive in providing information, financial, technical and material support. Contingency Action Plan for Natural Calamities issued by Ministry of Agriculture, Government of India is the basic document guiding disaster management in India. This brief document provides a policy statement and response mechanism. The focus of this document is mostly rclicf oriented. It is reported that the natural disaster policy is under preparations. The organisational component at the national level is:

- Cabinet Committee headed by Prime Minister

  National Crisis Management Committee under the chairmanship of Cabinet Secretary

- Crisis Management Group under the Chairmanship of the Central Relief Commissioner

- Financial arrangements are basically through the 'Calamity Relief fund'

2.3.2 State Level

The policies, organisation structure and functions at central government level are reflected in the stale government. There is no standard organisation, policies, or functional arrangements, as each stale government has its own organisation patterns, policies and plans to tackle disasters. The primary responsibility of disaster management is of the stale government for relief operations, preparedness and rehabilitation. Each slate has a Stale Crisis Management Group headed by the Chief Secretary. The senior officers from various departments form part of this group.

The state is divided in various districts, which form the basic structure of the state administration and focal functional unit with represenlation of all the elements of administration structure. The district is the basic unit for emergency plans, response, coordination, supervision and monitoring of relief operations. The district administration prepares contingency plans with specific responsibilities for implementation. The districts have District Relief Committees for relief measures and District Control Room for day to day monitoring of relief and rescue operations.

2.4 PRINCIPLES OF DISASTER PLANNING

2.4.1 Principles

Disaster Management means a planned and systematic approach towards understanding and solving problems in the wake of disasters. The effects of disasters could bc minimised, if there is pre-disaster preparedness and properly drawn up disaster plans. Some general principles of disaster planning are as under:

- It should be a continuous process.
- It should reducc the unknown in a problematic situation by foreseeing what is likely to happen.
- Plan must evoke appropriate response.
- Plan must be based on valid knowledge.
- Plan must focus on general principles.
- Plan should serve as an educational activity.
- Plan must be tested.
- Adjust planning to people rather than expecting people to change. their behaviour in order to conform with the planning.

- Greater the preparedness for probable or foreseeable events, more effective the relief operators will be.
- No two disasters are alike, but the problems that a certain kind of disaster is likely to create are quite foreseeable.
- There can be no tailor made plan for all situations, but as most elements of response are common to all disasters, a general preparedness plan will help in a more rational response in various emergency situations.
- Plans must be realistic and adaptable.
- Plans must use existing structure rather than create new ones.
- Plans must be clearly written.
- Plans at each level should be harmonised with those of the levels above.

2.4.2 Disasters and Health Problems

Disasters invariably have health consequences. The health problems in disaster could be due to either or any combination of factors enumerated below:

- Directly due to impact of drowning during floods, injuries during earthquake
- Due to delay in evacuation
- Due to non-availability or inadequate immediate medical care
- Due to disorganisation or non-availability of centres for advanced medical care
- Due to delay in transportation to medical centres.

The health hazards resulting from the disaster events depend upon a large number of factors as given below:

- Population density
- Population displacement
- Disruption of pre-existing facilities
- Disruption of normal health programmes
- Increased vector breeding
- Climatic exposure
- Inadequacy of food and nutrition

There is probably no event that so severely tests the adequacy of health infrastructure as the occurrence of a sudden disaster such as an earthquake and cyclone etc. To a large extent, well-planned health delivery systems is the most important preparation for a catastrophe. Planning, organising and coordinating health care in advance needs the utmost priority in order that a disaster stricken population may be attended in a more rational way.

2.4.3 Organisation for Medical Relief

Depending upon the location and magnitude of the disaster, first level of care is generally organised at the disaster site to provide relief and first aid to the victims. The organisation of medical relief involves two distinct facts:

- Pre-hospital care
- Hospital care

The pre-hospital phase involve despatch of first aid teams and mobile medical services to the disaster site, At site the preliminary phase involves organising on site analysis, on site treatment, stabilisation and transporting Ib selective care facility. The definitive care phase at the receiving hospital involves patient transfer, triage, continuation of treatment, second stage diagnosis, emergency room treatment, intensive care, definite diagnosis and treatment. The recuperation and rehabilitation phase continues for a long period and may even last for years as in case of nuclear and chemical disaster like in Bhopal gas tragedy victims. Medical care, which can be effectively organised at disaster sites, involves some important aspects of organisation and staffing:

- Command and Control
- Communication
- Coordination
- Triage Team
- First Aid Team
- Mobile Hospital
- Evaluation and Casualty Clearing Team

2.4.4 Principles of Mass Casualty Management

Disaster inediciue is a mass and multiple trauma medicine and it is not different from ordinary medicine, Llic distinguishing feature is its method of application and primary concern for yield and efficiency.

Some types of disasters usually result in a large number of casualties, which are beyond the routine handling capacity of the health care system. Application of principles of mass casualty management helps meet the demand of a large number of people. The principles of mass casualty management arc universal and can be applied in any mass casualty situation natural or manmade.

- Doing the best for the most within the available resources
- Triage is inescapable through out the chain of treatment

  Graded care of casualties, lirst aid life saving measures, preparation for evacuation, primary surgery and definitive treatment
- First aid measures carried out at the earliest assumes life saving significance
- First aid at the scene of disaster must be limited to monitoring and restoring vital functions
- Simple and standard therapeutic principles
- The casualty must be conditioned or treated so that the degree of urgency is lessened

Management of mass casualties can be divided into four phases, rescue, first aid, transportation and definitive treatment. Rescue in large-scale disasters in most instances must be of necessity and is performed by the survivors themselves. Tlic rescue team supports the community rescue efforts with special equipment. A reduction in mortality in llie severely injured can be achieved by early first aid. The first aid is usually limited Ib primary life support measures — the main functions of which are maintaining Airway, Breathing and Circulation. The routine practice in medical care — lirst come first treated — is inadequate in mass emergencies. Whenever time, personnel and resources are grossly insufficient to meet all the needs sorting or triage is the only appropriate way to provide a maximum benefit Ib most of the injured. The process involves sorting out those of the wounded whose progress is most favourable.

The mass casualty management involves categorizing the casualty for priority of treatment and evacuation based on the chances of survival and most benefit from

measures. There are various types of classification of casualties available worldwide but the most common categories are as under:

Category I: Immediate Treatment: Severely injured victims who can be saved if they receive appropriate stabilisation, transportation and treatment immediately.

Category II: Delayed Treatment: Urgent but less serious injuries who can be transported and treated alter the most serious have been attended to. These victims will require surgery in 8 to 12 hours,

Category III: Minimal Treatment: Walking wounded who can often be attended in small group and if ambulances are in short supply can be transported by other means.

Category IV: Injuries: Injuries, which are not serious, will generally be. treated and sent back to their homes. In a disaster event causing very large number of casualties this category may include moribund cases or so severely wounded than even immediate care would be inadequate to prevent death.

Tagging is a commonly used method to indicate priority of evacuation. Various types of tags are in vogue. Each patient must be identified with lags stating their name, age, sex, place of origin, triage category, diagnosis and initial treatment given. Usually red tags indicate first priority, yellow priority two and green priority three.

2.5 OBJECTIVES OF HOSPITAL DISASTER PLAN

2.5.1 Need for Hospital Disaster Plan

The hospitals play a vital rola in the medical care of the community during disaster situation. Disasters pose lots of challenges to the health care system and only those hospitals that arc prepared can meet the demand of such situation.

P.E.A. Savage defined disaster in terms of medical relief and hospitals as "Arrival with little or no warning of many more casualties of all types of degree and severity than the hospital is staffed or equipped to handle at that particular time." This definition focuses on organisational ability and required services, which explains the response needed. Hospitals should be prepared for two kind of disasters:

- Internal Hospital disaster: such as an explosion or a major lire
- External disaster such as floods, earthquakes, technological disasters etc.

2.5.2 Objective and Purpose

The purpose of a disaster plan is to make it possible to attend, promptly and effectively, to the largest possible number of people requiring medical care, in order lo reduce the number of deaths and disabilities. The principal objectives are:

- To prepare the staff and institutional resources for optimal performance in an emergency situation of certain magnitude

  To make the community aware of the importance of the disaster plan, how it is executed and the benefits it provides

- To train the staff as a part of educational activity
- To carry out periodic drills and its evaluation to update plans.

2.5.3 Planning Process and Development of Plan

Disaster care is, of necessity, purely emergency care and because hospital disaster operations are essentially an expansion of day to day emergency services of the hospitals A prerequisite to good disaster management is that emergency systems must be functioning well on a routine basis. The response capability of the hospital will vary from hospital to hospital based on its size, type of hospital, location of the hospital resources available and role allotted to the hospital in over all community plan.

The development of disaster plan should take into account the planning process:

- Analyse the risk and hazards in the geographic location concerned with the hospital
- Carry out vulnerability analysis of the community exposed to the risk and hazards
- The probable demand and nature of work expected during disasters
- Assess the resources available
- Determine response capabilities
- Determine the aim of Uie disaster plan based on factors enumerated above
- Determine organisation structure for disaster
- Development of organisation, allocation of role and responsibilities. Authority structure should be made clear
- Training of organisation
- Testing of the organisation
- Testing of the plan
- Periodic revision of both the plan and the organisation.

The hospital disaster plan provisions should include the following;

- Efficient system of alert and staff assignment
- Conversion of a usable space into clearly defined areas for triage, patient observation and immediate care
- Removal of casualties to more appropriate and definitive medical care facilities
- Special medical services for disaster cases
- Procedure for prompt transfer of patients within the hospital
- Security arrangements
- Establishment of a public information centre
- Evaluation of hospital services and its sources of electricity, gas, water, food and medical supplies
- Method of identifying patients who are immediately dischargable or transferable
- Special disaster.medical record and medical tag
- Planning use of OT, X-ray, blood bank and laboratory.

2.6 DISASTER COMMITTEE

The hospital disaster management committee operates at the decision making level and die action decided upon are executed by the medical staff supported by the institution's logistical and general service units. The composition of the committee should include doctors and nurses as well as administrative staff. The number, specialisation and seniority of committee members Io be decided according to the need. The membership of the committee generally includes, the following:

The Director of Hospital

In charge of Accident and Emergency Services

- Department Heads
- The Nursing Superintendent
- The Hospital Administrator
- A stall' representative

The functions of the hospital disaster committee are:

- To develop the hospital disaster plan

To develop departmental plans in support of the hospital plan

- To allocate duties to the hospital staff
- To establish standards of emergency care
- To conduct and supervise training programmes
- To supervise drills to lest the hospital plan
- To renew and revise the disaster plan at regular iiitervals.

2.7 ORGANISATION, ROLE AND RESPONSIBILITIES

2.7.1 Organisation

The hospitals needs a proper organisation for disaster management. Ideally, the organisation chart in effect during a disaster period should be the hospitals regular one, possibly strengthened and improved. The organisation chart should specify the levels of command in supervision and administration, so that duplication of effort may be avoided. The organisation should provide a definite line of authority established in each areas in advance and there should be no question over who is in charge. The organisation should include medical staff, nursing staff, administrative staff and department heads.

2.7.2 Role and Responsibilities

The effective implementation of the disaster plan would necessarily require clear assignment of the role and responsibilities in all the functional areas essential to support the plans. Clearly laid down role and responsibilities of the following would be essential:

Disastér .Coordinator: Organising, communicating, assigning duties, deploying staff and taking key decisions. .

Administrator: The responsibilities are extensive and most of the authority is executed through deptt heads,

Department Heads: Development of departmental plans to meet the requirement of the over all plan of the hospital.

Nursing Superintendent: Deployment of nursing staff and augmenting key areas of hospital.

Medical Staff: Specific authority and responsibility during initial response and reinforcement of important areas.

Nursing Staff: Role and responsibilities to support critical areas.

The following important departments play a crucial role in disaster management and therefore the role and responsibilities be clearly delineated.

- Accident and Emergency Department
- Operating Department
- Laboratory
- Radiology and Imaging
- Critical Care Units

The logistic support becomes crucial during the implementation of a disaster plan. The role and responsibilities of the following department needs to be clearly laid down to support the disaster plan:

- Planning
- Linen and laundry
- CSSD
- Catering department
- House keeping
- Medical Records
- Porter staff
- Engineering department
- Medico-social worker
- Transport
- Security and traffic control
- Communication
- Media control
- Morgue

2) What is the composition and functions of the Disaster Committee?

2.8 ORGANISING DISASTER FACILITIES

To meet the medical care demands of disaster victims, special functional areas should be set up within the hospital, which includes:

Triage or sorting area: Located with Accident and Emergency services where triage team consisting of emergency physician, surgeon, nursing personnel handle the incoming casualties. Here rapid assessment of the injury and extent of severity of the casualty's injuries are carried out by a doctor/nurse and assigns that casualty lo an appropriate treatment area.

Primary Treatment Areas: Immediately after triage casualties are sent to appropriate treatment areas. These treatment areas would include immediate, urgent and non-urgent tare areas. Those in need of immediate life saving measures are sent to resuscitation room where facilities are available for establishing airway, controlling haemorrhage supporting fractures and treating shock. Casualties should remain in the resuscitation room for the shortest possible time, further investigations and treatment being carried out in another treatment area. Urgent cases needing diagnosis, investigation and initial

treatment of their injuries receive attention in an urgent treatment area. Non-urgent casualties may be investigated, diagnosed and treated in non-urgent treatment area. Special treatment areas may be needed for the management of burns, fractures and in case of chemical or nuclear disaster victims.

Secondary Treatment Areas: The secondary treatment areas include all the wounds, critical care units and operating and diagnostic deptt etc The casualties requiring important care will be taken from primary treatment area to the Intensive Care Unit, Operating Theatres or to special receiving wards which have been evacuated to house the disaster victims.

In-patient Evacuation Holding Area The setting up of one or more wards to receive all the admitted victims of a disaster is essential if medical and nursing staff are not to be scattered around the hospital. Clearing of these designated wards should be carried out at an early stage in preparing the hospital to cope with a disaster, and personnel and equipment can be diverted to the receiving ward. Additional beds are made available in other wards by arranging for suitable patients to be discharged home or transferred to other hospitals.

Additional Facilities: The additional facilities would be required to be created like:

- Control and information centre
- Volunteer reception
- Relatives waiting area
- Media room

The staff alert, recall and deployment, immediately on receipt of information and also to sustain the activity till all the need lasts is a major issue in organising. The initial efforts should be to employ the triage team, reinforce the accident and emergency department and critical care areas. Initial minimum deployment of staff in each area must be given priority. The deployment as initial response has to be followed by the assessment of expected number of casualties of various types and degree based on the disaster event to determine the staffing need in all areas to sustain the activities to meet the requirement. The staffing requirement may continue for few days if disaster is of severe type hence the staff rest, reception and redeployment has to be planned. The need of the portering staff, documentation clerks etc. has to be considered.

The secondary treatment areas would continue to function even when the fresh cases of casualties stop arriving. Hence the staff need of the secondary care area has to be planned. It may require redeployment of staff from other areas. The relieving of the surgical team, intensivist etc. would require attention as no surgical team can carry on without relief for more than 12 hrs. Very often the largest number of casualties fall into non-urgent category hence appropriate staff will be required to care for them.

Support facilities play a vital role in managing the disaster victim. These support facilities like, CSSD Pharmacy, Dietary service, security services, transport etc. would require staff support.

2.9 DISASTER RESPONSE

2.9.1 Response

The disaster response is heavily dependent on the disaster plan, preparedness, training and periodic rehearsals. The disaster response must he in chronological order to facilitate execution. The designated hospital staff should be responsible to activate the hospital disaster plan. The Casualty Medical Officer, Hospital Administrator on duty or Senior Consultant on call can be designated for putting plan into action. Hospital plan often fails to start when disaster strikes because they are designed on an all or none response. Graded response or phased response has been suggested to overcome these problems. The graded response system in vogue are as under:

Green Alert: Should there be a sudden influx of casualties it mobilises on duty medical,

nursing and other paramedical staff Io support the accident and emergency department. It is used at frequent intervals with minimal interference with hospital activity.

Amber Alert: Prepares the hospital to admit a large number of casualties. It is an extension of green alert, which must be completed first. Receiving wards are cleared, staffed and prepared together with ICU and OT.

Red Aiert: It prepares hospitals for a major community disaster, An extension of the green and amber alert mainly in time scale involved.

In smaller hospital only two categories of Plan – a minor plan for small case load and major plan which involves stoppage of normal work of the hospital to cope with rush of disaster victims.

2.9.2 Alert and Recall

The hospital may receive the disaster alert on telephone or through casualty staff when casualties arrives. The details regarding the disaster event, estimated number and type of casualties be ascertained as far as possible, by the person receiving the alert. The designated staff should then take action for alerting and recall of the staff.

Staff alert and recall is first step in implementation of plan. A number of hospital plans have failed in the past because the alerting procedure has been too defuse. Therefore the alerting procedure need to be frequently tested as failure at this level will inevitably mean failure of the rest of the plan.

Method of alerting hospital staff will vary from hospital to hospital depending on type, size, communication facilities and location of the hospital. Public address system, coded light system, personal paging system and telephone system are usually used. In smaller places messenger may have to bc used. Some hospitals use a siren system. There rue many methods used to save time in alerting like alerting Head of the Department who in turn inform other members of the department Hospital switch hoard operators can play a key role in alerting the staff once the disaster plan activation is announced.

A hospital's ability to respond rapidly lo a disaster depends on the time of the day and the day of the week. During working days hospitals are fully staffed but condition will be very different during the night holidays and weekends. A separate staff alert and recall plan will be required by the hospitals.

2.9.3 Deployment

Experience has shown that in the circumstances of disaster there is little or no time to start thinking about how best lo deploy hospital staff. A system of action cards drawn up in advance will enable the hospital plan to put in effect with the minimum confusion and delay. An action card method incorporates written information, advice and instruction for hospital staff. Some action card may be kept on permanent display in Accident and Emergency Department while other are immediately available in easily identifiable racks and can be handed over to staff as rcyuired. Cards of different colours can be used to indicate different stages of alert procedures. The cards should be of standard format and instructions should bc simple and clear.

2.9.4 Disaster Administration

Control Centre

The aunospherc of chaos and confusion and overload of work is expected in disaster situation. An efficient execution of the disaster plan needs effective conlrol to meet the goal. A command nucleus in the form of Control Centre is essential from where the key functionaries organise, communicate and control the implementation of disaster plan.

Staff Report Board

There is a requirement of a staff report board. Whenever key members of the staff arrive in the hospital they report by telephone to the information centre and whereabouts of each individual is plotted on staff report board to facilitate easy contact in case required,

Information Centre

Combining the Information and Control Centre in conveniently sited rooms helps the senior members of the hospital to control the many facets of the hospital during a disaster, An information centre appropriately staffed has a vital role. A hospital administrator acts as a Hospital Information Officer, supervising the casualty and general status board, liaison with various authorities, medical and nursing staff report centres, relatives, reception area and other departments. It also help in drawing attention to bottlenecks or the need to make additional beds available.

Communication

Without communication Infonnation Control Centre can control nothing. A cominunication centre with dedicated facilities within the hospital and outside, based on intercom, telephone, wireless, and other system would be needed.

2.10 DISASTER MANUAL

A written disaster inanual is an essential requirement for each hospital. It serves to provide information, educate staff, helps in orienting the staff joining the hospital and serves as a reference when needed. The disaster inanual should be a working manual, action oriented with a practical and direct review of disaster response. It is important that disaster manual be in the fonn of multiple custom made manuals so that a person can easily tind pertinent information to the specific job.

All items in the plan should be presented in order of application and importance. The expression must be concise and clear. It would be ideal to have a inanual easily identifiable by a distinctive cover and its contents so arranged that information may be obtained as. rapidly as possible. It will have many appendices and annexures on various aspects. Many authors have provided details of the information to be included in the manual but generally the manual should cover the following, important aspects:

- General Hospital Policies and Procedures: It includes disaster organisation roles and responsibilities, the Hospital policies and procedures for alerting, phased response, general instructions, various facilities and procedure for stand down.
- Disaster Notification: It lists plan on working day and silent hour plan.
- Accident and Emergency Department: It covers the casualty management, deployment of staff, emergency medial care, discharge procedure and documentation etc.
- Special Duties and Responsibilities: This section deals with roles and responsibilities of various administrative staff, medical staff, nursing staff, supportive services staff etc.
- Nursing Services: The nursing services, in various areas and the role of the nursing staff in specific areas is provided in this section,
- Departmental Duties and Responsibilities: In this section various departmental duties and responsibilities of department like dietary service, linen stores, CSSD, house keeping, medical records etc. is given.
- In case of specific risk of a particular type of disaster like nuclear or chemical disaster the specific facilities, staff responsibilities etc. could be given.

2.11 DISASTER DRILL

The disaster drill is to test the hospital preparedness and response to determine whether response was effective and efficient. The disaster drill presents an opportunity for the hospital to reach out to the cold community and to coordinate and cooperate with local and state authorities in meeting community needs. There is little doubt that in the absence of a real disaster, the only way to ascertain the level of preparedness and success of response plan is lo test it, The system must be rehearsed until participants are as familiar as possible

with their role. Drill inust be well organised whether announced or unannounced. In the simple exercises the specific procedures drill alerting, staff recall arrangements are tested. Eventually a full scale disastar'exercise can be planned with realistic siinulation or mock casualties, The aim of the drill should be to train, test performance and to demonstrate weakness that requires revision.

Evaluation of the drill is an essential requirement and must be built in to disaster plan. Evaluation will be necessary both in training and following any disaster with the continuous turn over of hospital staff. It is essential that the knowledge of any plan is tested and that the individual must demonstrate knowledge of his role. Evaluation method could be internal committee or external agency evaluation. Evaluation validates and complements planning and helps arrive at a critical assessment of the performance as under:

- Whether the organisational methods provided in the plan were carried out in a timely and proper manner.
- Whether medical care in the disaster area was adequate and efficient.
- Whether the evacuation to hospital proccddcd according to plan.
- Whether intra hospital care was adequate, tiinely and speedy.

2) Describe the disaster response mechanism and essential aspect of disaster administration.

2.12 LET US SUM UP

In this unit you have learned about the basic concepts of disaster including the disnstcr process and special characteristics of disasler events which have significant management imperatives. The key issues involved in disaster management focussed on the effect for coordination of multiple agencies or multi-disciplinesinvolved in the response operations.

You also learned about the disaster management system at National, State and District levels. The principles of disaster planning described the requirement of a suitable plan and how the medical relief is organised. The medical care during disasler events where the workload exceeds the capabilities and resources available demand that the principles of mass casually management be practiced,

The hospital disaster planning process and method of development of plan is a scientific process for arriving at the objectives and appropriate disaster plan based on the response capabilities. You would have also learned about the role and responsibilities of the staff and facilities required lo care fur the disaster victims. You would have understood the response mechanism and importance of the disaster manual and disaster drill.

2.13 ANSWERS TO CHECK YOUR PROGRESS

Check Your Progress 1

1) **WHO** has defined disaster as any occurrence that causes damage, ecological disruption, loss of human life and deterioration of health and health services on a real

sufficient to warrant an extraordinary response from oulside tlie affected community.

Classification **of Disasters:** Disaster has been classified in various ways but tlie most convenient method used is the division of disasters into two distinct categories according to their causes:

- Disasters caused by the natural phenomenon
- Manmade disasters

Natural Disasters

- Meteorological disasters—Storms (Cyclones, hailstorms, hurricanes, tornadoes, typhoons and snowstorms), Cold spells, Heal waves and Droughts.
- Typological Dasters—Avalanches, Landslides and Floods.
- Telluric arid Teutonic Disasters—Earthquakes, Tsunamis and Volcanic Eruptions.
- Biological Disasters-Insect Swarms (e.g. locust) and Epidemics of communicable diseases.

Manmade Disasters

- Civil Disturbances — Riots and Demonstrations.
- Warfare — Conventional Warfare (bombardment, blockage and siege).
  — Non-conventional Warfare (Nuclear, Biological and Chemical warfare, Guerrilla Warfare including Terrorism).
- Refugees — Forced movement of large number of people usually across Frontiers.
- Accidents — Transportation calamities (land, air and sea) Collapse of Building, dams and other structures, mine disasters.
- Technological failures (e.g. a mishap at a nuclear power station, a leak at a Chemical plant causing pollution of atmosphere or the break down of a public sanitation system).

2) Disaster situation toto has been conceptualised as a process with different phases. In each phase the information, the action required, the problems encounteredand people involved may bc quite different. The interrelationship of these different phases and activities is important for its management. The time diversion of disaster phenomenon forms an important base for planning. Each type of disaster phase will vary according to tlie type of disaster event with different time element like in an air crash there may be little or no waving as against floods, which may give sufficient waving for preparedness.

3) The geographical diversion forms the basis to classify tlie arising problems it also explain the type of management activity required in the particular geographical area. There are three major divisions:

a) Impact Area

b) Filter Area

c) Community Aid Area

Convergence is a common problem in most disaster event **and** is charecterised by the spotaneous movement of large number of people and large amount of materials towards the zone of impart. This convergenceis motivated by a concern of victims, a desire to help a simple curiosity and search for information. Themovement usually outweighs the outward flow of those wishing to have,

Check Your Progress 2

1) Disaster management requires a planned and systematic approach towards understanding and solving problem to minimize the effects of disaster. The general principles of disaster planning are as under:

Principles: Disaster management means a planned and systematic approach towards understanding and solving problems in the wake of disasters. The effeds of disasters could be minimized, if there is pre-disaster planning are as under:

- It should be a continupus process.
- It should reduce the unknown in a problematic siluation by foreseeing what is likely to happen.
- Plan must evoke appropriate response.
- Plan must be based on valid knowledge.
- Elan must focus on general principles.
- Plan should serve as an educational activity.
- Plan must be tested.
- Adjust planning to people rather tlian expecting people to change their behaviour in order to conform with the planning.
- Greater the preparedness for probable or foreseeable events, more effective the relief operators will be.
- No two disasters are alike, but the problems that a certain kind of disaster is likely to create are quite foreseeable.
- There can be no tailor made plan for all situations, but as most elements of response are common to all disasters, a general preparedness plan will help in a more rational response in various emergency situations.
- Plans must be realistic and adaptable.
- Plans must use existing structure rather then create new ones.
- Plans must be clearly written.
- Plans at each level should be harmonized with those of the levels above.

2) Disasters invariably have health consequences. The health problems in disaster could be due to either or any combination of factors enumerated below:

- Directly due to impact of drowning during floods, injuries during earthquake.
- Due to delay in evacuation.
- Due to non-availability or inadequate immediate medical cue.
- Due to disorganisation or non-availability of centres for advanced medical care,
- Due to delay in transportation to medical centres.

The health hazards resulting from the disaster events depend upon a large number of factors as given below:

- Population density
- Populntion displacement
- Disruption of pre-existing facilities
- Disruption of normal health programmes
- Increased vector breeding

- Climate exposure
- Inadequacy of food and nutrition.

There is probably no event that so severely tests the adequacy of health infrastructure as the occurrence of a sudden disaster such as an earthquake and cyclone etc. To a large extent, well-planned health delivery systems is the most important preparation for a catastrophe. Planning, organising and coordinating health care in advance needs the utmost priority in order that a disaster stricken population may be attended in a more national way.

Principles of Mass Casualty Management: Disaster medicine is a mass arid multiple trauma medicine and it is not different from ordinary medicine, the distinguishing feature is its method of application and primary concern for yield and efficiency.

Some types of disasters usually result in a large number of casualties, which are beyond the routine handling capacity of the health care system. Application of principles of mass casualty management helps meet the demand of a large number of people. The principles of mass casualty management are universal and can be applied in any mass casualty situation natural or manmade.

- Doing the best for the most within the available resources.
- Triage is inescapable through out the chain of treatment.
- Graded care of casualties, first aid life saving measures, preparation for evacuation, primary surgery and definitive treatment.
- Rrst aid measures carried out at the earliest assumes life saving significance,
- First aid at the scene of disaster must be limited to monitoring and restoring vital functions.
- Simple and standard therapeutic principles.
- The casualty must be conditioned or treated so that the degree of urgency is lessened.

Management of mass casualties can be divided into four phases, rescue, first aid, transportation and definitive treatment. Rescue in large-scale disasters in inost instances must be of necessity and is performed by the survivors themselves, The rescue team supports the community rescue efforts with special equipment. A reduction in mortality in the severely injured can be achieved by early first aid. The first aid is usually limited to primary life supported measures — the main functions of which are maintaining Airway, Breathing and Circulation. The routine practice in medical care — first come first treated — is inadequate in mass emergencies. Whenever time, personnel and resources are grossly insufficient to meet all the needs sorting or triage is the only appropriate way to provide a maximum benefit to most of the injured. The process involves sorting out those of the wounded whose progress is most favourable.

The most casualty management involves categorising the casualty for priority of treatment and evacuation based on the chances of survival and most benefit from measures. There are various types of classification of casualties available worldwide but the most common categories arc as under:

- Category I : Immediate Treatment: Scvercly injured victims wlio can be saved if they receive appropriate stabilisation transportation and treatment immediately.
- Category II : Delayed Treatment: Urgent but less serious injuries who can be transported and treated after the most serious have been attended to. These victims will require surgery in 8 to 12 hours.
- Category III ; Minimal Treatment: Walking wounded wlio can often be attended in small group and if ambulances are in short supply can be transported by oher means.
- Category IV: Injuries, which are not serious, will generally be treated and sent back to their homes. In a disaster even causing very large number of casualties

this category may include moribund cases or so severely wounded then even immediate care would be inadequate to prevent death.

Tagging is a commonly used method lo indicate priority of evacuation. Various types of tags are in vogue. Each patient must be identified with tags stating their name, age, sex, place of origin, triage category, diagnosis and initial treatment given. Usually red tags indicate first priority, yellow priority two and green priority three.

Check **Your** Progress **3**

1) **Objectives and** Purpose: The purpose of a disaster plan is lo make it possible to attend, promptly and effectively, to the largest possible number of people requiring medical care, in order to reduce the number of deaths and disabilities. The principle objectives are:

- To prepare the staff and institutional resources lor optimal performance in an emergency situation of certain magnitude.

  To make the community aware of tlie importance of the disaster plan, how it is executed and the benefits it provides.

- To train tlie staff as a past of educational activity.

- To carry out periodic drills and its evaluation to update plans.

Development **of Plan for a Hospital:** Disaster management plan should be developed in a manner that the emergency system must be functioning on a routine basis. It sliould be take into account the planning process, as follows:

- Analyse the risk and hazards in the geographic location concerned with the hospital.
- Cary vulnerability analysis of tlie community exposed lo this risk and hazards.
- The probable demand and nature of work expected during disasters.
- Assess the resources available.
- Determine response capabilities.
- Determine the aim of the disaster plan based on factors enumerated above.
- Detennine organisation structure for disaster.
- Development of organisation, allocution of role and responsibilities. Authority structure sliould be made clear.
- Training of organisation.
- Testing of organisation.
- Testing of tlie plan.
- Periodic revision of both the plan and the Organisation.

The hospital disaster plan provisions sliould include the following:

- Efficient system of alert and staff assignment.
- Conversion of a usable space into clearly defined areas for triage, patient observation and immediate care.
- Removal of casualties to more appropriate and definitive medical care facilities.
- Special, medical services for disaster cases.
- Procedure for prompt transfer of patients within tlie hospital,
- Security arrangements.
- Establishment of a public information centre.

- Evaluation of hospital services and its sources of electricity, gas, water, food and medical supplies.
- Method of identifying patients who are immediately dischargable or transferable.
- Special disaster medical record and medical tag.
- Planning use of OT, X-ray, Blood Band and Laboratory.

2) **Disaster Committee:** The hospital disaster management committee operates at the decision making level and the action decided upon are executed by the medical staff supported by (lie institution's logistical and general service units. The composition of the committee should include doctors and nurses as well as administrative staff. The number, specialization and seniority of committee members should be decided according to tlic anticipated need. The membership of the committee generally includes the following:

- The Director ol' Hospital
- In-charge of Accident and Emergency Services
- Department Heads
- The Hospital Administrator
- The Nursing Superintendent
- A representative from the community/civil administration.

The functions of the Hospital Disaster Committee are:

- To develop the hospital disaster plan.
- To allocate duties lo tlic hospital staff.
- To establish standards of emergency care.
- To conduct mid supervise training programmes.
- To supervise drills to test the hospital plan.
- To renew and revise the disaster plan at regular intervals.

Check Your Progress 4

1) To meet the medical care demands of disaster victims special functional areas should be set up within the hospital, which includes the following facilities:

- Triage or Sorting Area: Located with Accident and Emergency services where triage team consisting of emergency physician, surgeon, nursing personnel handles the incoming casualties. Here rapid assessment of the injury and extent of severity of the casualty's injuries are carried out by a doctor/nurse and assigns that casualty to an appropriate treatment area.
- Primary Treatment Areas: Immediately after triage casualties are sent to appropriate treatment areas. These treatment areas would include immediate, urgent and lion-urgent care areas. Those in need of iminedialc life saving measures are sent to resuscitation room where facilities are available for establishing airway, controlling hemorrhage supporting fractures and treating shock. Casualties should remain in the resuscitation room for the shortest possible time, further investigations and treatment being carried oul in another treatment area. Urgent cases needing diagnosis, investigation and initial treatment of their injuries receive attention in an urgent treatment area. Non-urgent casualties may be investigated, diagnosed and treated in non-urgent treatment area. Special treatment areas may be needed for the management of bums, fractures and in case of chemicals or nuclear disaster victitns.
- Secondary Treatment Areas: The secondary treatment areas include all the

wounds, critical care units and operating and diagnostic deptt etc. The casualties requiring important care will be taken from primary treatment area to the Intensive Care Unit, Operating Theatres or to special receiving wards which have been evacuated to house the disaster victims.

- In-patient Evacuation Holding Area: The setting up of one or more wards to receive all the admitted victims of a disaster is essential if medical and nursing staff are not to be scattered around the hospital, Clearing of these designated wards should be carried out at an early stage in preparing the hospital to cope with a disaster, and personnel and equipment can bc diverted lo the receiving ward. Additional beds are made available in other wards by arranging for suitable patients to be discharged home or transferred to other hospitals.

- Additional Facilities: The additional facilities would be required to be created like:
  - Control and information centre
  - Volunteer reception
  - Relatives waiting area
  - Mediaroom

Support facilities play a vital role in managing the disaster victim. These support facilities like, CSSD, Pharmacy, dietary services, security services, transport etc. would require staff support.

2) **Response:** The response to disaster is heavily dependent on the disaster plan, preparedness, training and periodic rehearsals. The disaster response must be in chronological order to facilitate execution. The designated hospital staff should be responsible to activate the hospital disaster plan. The casualty Medical Oflicer, Hospital Administrator on duty or Senior Consultant on call can be designated for putting plan into action. Hospital plan often fails to start when disaster strikes because they are designed on an all or none response. Graded response or phased response has been suggested to overcome these problems. The graded response systems in vogue are as under:

- **Green Alert:** I should there be a sudden influx of casualties it mobilize on duty medical, nursing and other paramedical staff to support the accident and emergency department, It is used at frequent intervals with minimal interference with hospital activity.

- **Amber Alert:** Prepares the hospital to admit a large number of casualties. It is an extension of green alert, which must be completed first. Receiving wards are cleared, staffed and prepared together with ICU and OT.

- Red **Alert:** It prepares hospitals lor a major community disaster. An extension of the green and mnber alert mainly in time scale involved.

Disaster administration: To work in a cohesive and systematic manner without chaos and confusion it is of paramount importance that every individual in the hierarchy knows his job and the work for each individual is well defined. Control monitoring centres at different level should be established as follows:

- **Control Centre:** The atmosphere of chaos and confusion and overload of work is expected in disaster situation. An efficient execution of the disaster plan needs effective control to meet the goal. A command nucleus in the form of Control Centre is essential from where the key functionaries organise, communicate and control the implementation of disaster plan.

- **Staff Report Board:** There is a requirement of a staff report board. Whenever key members of the staff arrive in the hospital they report by telephone to the information centre and whereabouts of each individual is plotted on staff report board to facilitate easy contact required.

UNIT 3 SECURITY ORGANISATION AND MANAGEMENT

Structure

3.0 OBJECTIVES

After going through this unit, you should be able to:

- enumerate the goals and objectives of the security management;
- describe role and functions of security as a service in hospitals;
- familiarise with the various aspects of protection, loss prevention and security organisation of hospital administration;
- explain the legal aspects of security;
- discuss strategic security plan and standing security policies and procedures; and
- describe security related disaster management in hospitals.

3.1 INTRODUCTION

Hospitals are institutions, similar to any other business organisation, engaged in providing Quality Healthcare. They, however, possess certain unique characteristics, given below:

- They provide free access to just about anyone and are "open for business" 24 hours a day, 365 days in a year. They are one of the most "people_intensive" places, where everyday functions are filled with life and death, sorrow and triumph. The Out Patient Department (OPD) patients and visitors and attendants of patients contribute significantly to the floating population of the hospital.
- The entire hospital operates under continual stress and periodically experiences periods of extreme stress, which may cause irrational, confrontationist behaviour, giving rise to conflicts or even aggression.

- The people in or near a hospital generally fall into three categories -– patients, visitors or staff. The Hospital Security Organisation must understand this grouping, since security will have a different and distinct relationship with each group.

- The hospital security staff, duly authorised by management, present a visible image of a "service" to the patients, visitors and staff, carefully combining it with the fundamental objective of security, which is protection of people and the assets. The security functionary may he tlie first or last hospital employee, a patient or visitor may see. A sccurily staff simply saying "Welcome to ABC Hospital" or wishing 'Jaihind' can reduce anxiety of a visitor/patient. Whatever tasks are performed, whether it is helping someone find a laboratory or a bathroom or taking a theft or accident report, these functions should be performed with energy, enthusiasm and in a civil and polite manner.

- Regrettably, the out-moded system of 'Chowkidars' at the entry points continues to be the main constituent of security in most hospitals in India. Even the government and most private hospitals lack an efficient security system.

- Hospital Security Staff members need to be tactful, sensitive, patient and diplomatic, while dealing with situations in a stressful environment.

It has to be realized that hospitals in India are no longer sheltered or isolated from the strifes and anxieties of onr society. The hospitals too have to face up to the growing challenges. While no database is available of losses in the Indian hospitals, a study carried out in the USA indicates that the hospitals lose around 10% of their purchase inventory due to preventable securily lapses/mis-management. The basic causes are primarily attributable to Security in Hospitals, being treated as a peripheral function, rather than a vital objective of top managements for protection of tlie facility's total assets—property, staff, patients, image and information and of course to establish a system of safeguards "designed to achieve relative safety for all persons inter-acting within tlie hospital and its environment".

While operational aspect of Security Management is the responsibility of the security executive and their staffs, the lop management ol'a hospital is responsible to lay-down the policy frame-work to integrate "Comprehensive Security" in organisational culture of a hospital, to achieve Loss Prevention. Well-organised hospital security department and well-trained security staff should pro-actively assist in creating an atmosphere of safety, goodwill, service and human concern so that the 'Patient-Care' can continue undisturbed.

Check Your Progress 1

Fill in the blanks:

1) The security functionary may be the ..... or ..... hospital employee a patient or visitor may see.

2) The top management of a hospital is responsible to lay clown the .... to integrate "Comprehensive Security" in organisational culture of a hospital to achieve ..... .

3.2 SECURITY THREATS AND VULNERABILITIES OF HOSPITALS

3.2.1 Threats and Vulnerabilities of Hospitals

All hospitals are liable to 'seen' and 'unseen' vulnerabilities. A vulnerability in tlie context of hospitals can be defined as, "something that could lead to injury, harm, or threat to persons, property, ideals or image". As hospital administrators, you should familiarize yourself with the specific vulnerabilities that your institution may face, as no two circumstances or locations or alike. By understanding these, you would be better equipped to direct and monitor the security department Common threats and vulnerabilities that a hospital may face are:

- Thefts — External or Internal
- Patients property losses
- Employees property losses
- Destruction or damage of property including vehicle accidents, attributable to negligence, lack of training or out of sheer malice or external and natural causes
- Information losses, pertaining to confidential or privileged information, medical records of patients, research material and computer security
- . Assaults or robbery upon employees, staff or visitors (workplace violence)
- Fire and arson
- Violation of work-safety norms, including environment pollution, hazards to safety, health and hygiene .
- Anti-national activities, e.g., bomb-threats, sabotage and subversion of employees
- Threats to medical and nun-medical executives or their family members
- Drug theft and drug abuse
- Internal or external disasters
- Medical imposters
- White-collar crimes, like corrupt practices by unethical employees, in collusion with outsiders or independently
- Cases of sexual assault/molestation on the premises
- Strikes or civil disturbances
- Infant abduction

3.2.2 Threat Groups

The above threats may emanate from any of the following sources:

- Criminals
- Disgruntled patients/former patients/relatives/employees/former employees or their friends
- Members of the public with real or imagined grievances
- Terrorists/sympathizers

3.2.3 Security Sensitive Areas/Functions of Hospitals

There are a number of places and functions, in a hospital, that can be considered security-sensitive. Listed below are some of the more sensitive areas/functions of a hospital:

- Pharmacy
- Cash handling areas (cashier, cafeteria, retail shops)
- Medical Records Office
- Emergency Department
- Computer Centre
- Infant and Pediatric Units
- Parking Areas

3.2.4 Strategic Security System

A pragmatic assessment by the hospital administrator of security vulnerabilities and visualization of threats must form basis for formulation of an efficient iuid cost-effective security management plan of a hospital. This will help in providing **'Total Security'** for pro-active Assets **Protection,** security of staff awl patients and **prevention / minimization** of loss of **materials and information.**

3.2.5 Conclusion

Hospitals have become increasingly attractive targets to crime, because of valuable equipment, materials, and drugs. **A hospital** administrator performs **an** anchor's role in **the** hospital security **system in assessing and constantly** updating **the threats and vulnerabilities, laying** down policies **and** directing **and** monitoring **the Security Organisation.**

Check Your **Progress** 2

1) All hospitals face the same types of threat and vulnerabilities. True/False

2) Security of hospital's assets is responsibility of the Security Staff alone. True/False

3) Understanding the security risks would equip a hospital administrator to direct and monitor the security department. True/False

4) Destruction or damage to hospital property can be attributable to:

   a) .....

   b) .....

   c) .....

   d) .....

5) List five of the more security-sensitive areas/functions of a hospital.

.....

.....

.....

.....

.....

3.3 ROLE AND FUNCTIONS OF SECURITY AS A SERVICE IN HOSPITALS

3.3.1 Role of Hospital Security

The role of hospital security **department** is, "to provide security services to **all staff,** patients and visitors **and for protection** of **hospital** property on **the** premises, through **use** of **well-trained** personnel, technology, prevention activities and **timely response** to requests". It involves treating people equally and with total care and respect, regardless of their gender, religion, age, handicap or any other factor which may put them in a minority category.

3.3.2 Functions of Hospital Security Department

- Analysis of security threats and vulnerabilities in conjunction with the management, civil police and others.
- Preparation of strategic security plan, security standing instructions and security operational deployment plan and their periodic updating, based on directions of the management.

- Organisation and monitoring of security operations and implementation of Security Plans to achieve elimination/reduction of incidence of theft/pilferage of property/ information and crime on premises.
- Advising hospital management on all security matters.
- Conduct of enquiries/investigations as directed by the management, in a professional, efficient and confidential manner.

  Conduct of initial, 'on-the job' and refresher Security Training, as relevant, for all segments of the hospital staff.
- Surveillance and patrolling of the premises

  Access control, issue and record-keeping of identity documents for the employees, contract and casual staff and visitors.
- Control of movement of vehicular traffic within the premises and in its immediate vicinity, falling under limits of external control of the management.
- Reception and conduct of visitors and attendants.
- Assistance with pooled manpower for Fire Control and Emergency Plan
- Assistance in monitoring implementation of Fire and Safety instructions and accident prevention.
- Represent management in mutual aid deliberations, as directed.
- To keep aware of potential threats of criminal activity, through liaison with civil police and other appropriate agencies.
- Vigilance and intelligence duties, as assigned.
- Performance of any other tasks and functions, as may be assigned by the management.

3.3.3 Non-traditional "Service" Functions

In some hospitals, the security staff may be required to perform some other non-traditional 'service' functions too. They may deliver mail, assist and coordinate vehicle parking, provide assistance to victims of crimes or harassment, supervise maintenance and upkeep of lawns and horticulture or taking people to court. All these "peripheral" functions add value to the security functions and make other hospital employees and visitors/patients feel good about security's cooperation. However, such functions should not be at the cost of primary responsibility of security, which is to safeguard the hospital property and the people interacting therein.

3.3.4 Conclusion

A proactive, professional, well-trained security department, which focuses on crime - prevention as well as public service can make significant contribution to a hospital's mission.

3.4 SECURITY ORGANISATION AND PHYSICAL SECURITY MEASURES

3.4.1 Security Organisation

The overall organisation of a hospital would vary depending on whether it is a government, private or charitable institution. No matter what the structure, the medical superintendent (by whatever designation he/she may be called) is normally responsible, besides his other functions, for ensuring efficient loss prevention and organisation of the security functions. It is important that the Security's control is kept under a single agency. Depending on the size of the hospital, the medical superintendent would have directly accountable to him through the head of security department, a complement of security staff comprising a mix of;

a) Chief/assistant security officer

b) Security supervisors

c) Security guards — departmental/contract

3.4.2 The Staff Complement

The security staff may be proprietory/departmental, contracted through an agency or a mix of all. Weighing pros and cons of each system, a mix of departmental and contract security staff, functioning under departmental security officer and supervisory staff provides all ideal mix to ensure efficiency and to achieve cost-effectiveness.

3.4.3 Physical Security Measures

Physical security measures are a vital element of any hospital's security system. **These measures should be planned in depth,** as **a single barrier system fails to provide 'total security'**. These measures, it must be understood, can only be expected to act as physical deterrents, "to discourage the undetermined and delay the determined" and need to be backed up by a series of other contributory measures.

3.4.4 Perimeter Protection System

It comprises:

a) Outer Protective Ring: Fencing or tvalls to define the ownership and to channelize movement.

b) **Middle Protective Ring:** Exteriors of the buildings comprise the middle ring.

c) **Inner Protective Ring:** Within the hospital, a number of protective rings should be established to safeguard vulnerable/sensitive areas, e.g. pharmacy, offices, medical records, computer room/telephone exchange, cashier's locations, infant security, laundry, kitchen/stores etc.

3.4.5 Implementing Physical Controls

I-Iospital administrators are often reluctant to implement such physical control that they feel, may detract from open and friendly atmosphere of the hospital or inhibit free flow of patients, visitors and staff. This attitude has to be balanced with a judicious mix of physical controls to ensure elimination/minimization of losses and to enable the 'patient-care' activities to proceed un-hindered. **Traditionally, the administrators respond to security problems by increasing the** security mall-power. **This** philosophy **needs** to **be** reviewed in the **light** of **available** and effective Security **Technology devices, which are becoming** available indigenously in **a** cost-effective **manner. This aspect** well **be elaborated** upon, **subsequently,** as your **study** progresses.

3.4.6 Conclusion

The hospital management and administrator must constantly review the Security Organisation and its composition, based on the ever changing threats and vulnerabilities. Physical Security Controls are only one component of a hospital's security system and cannot be the sole means of protection. They are to bc complemented by correct policy delineation, security procedures, staffing and operational control, reinforced by security technology devices. **It has** to **be recognized that security** controls **are as efficient** as the people **who** operate them.

3.5 ACCESS CONTROL CONCEPTS

3.5.1 Defining Access Control

We need to understand the concept of Access Control. Simply put, Access Control is "Controlling **the movement** of **people (including vehicles)".** It means permission or

denial of entrance to a given premises/location or within a defined place against unauthorized observation or removal and to prevent injury Io persons or damage to things.

3.5.2 Means and Components

The commonest Access Control System is the manual system, still having almost universal application in India. In the hospitals, checking people entering or leaving a building is a form of Access Control. Essential components of an Access Control System are:

Identification System for Staff: Hospital management should make it mandatory for all staff members to display identification badges at all times, Io allow them access lo the premises/specified segments therein, while on hospital premises on duly. Failure to display the identity badge, regardless **of** designation or seniority, will subject individuals to being challenged and reported for possible disciplinary action. An identification badge should include the following details:

- Logo of the hospital and serial number to prevent forgery.
- A photograph (preferably colour), placed in a manner, that it cannot be replaced.
- Name of the individual, in bold type, which can be read at a istance of three feet.
- Individual's job title and area of work (an employee from laundry would need to explain his presence in OT or pharmacy).
- Optional capability to be used in card-access environments.

Temporary Identification Badges: These should be used as a form of Access Control for contractors, visitors and casual workers. Currently, some temporary badges are designed to "self-destruct", after lapse of the given time period, by becoming discoloured *or* revealing the word "expired"

Card Access System: **A** card access system requires a plastic rectangular card, which needs to be passed through a wall-mounted reader. A variety of card technologies are in use. Explanation of each type, however, is beyond the scope of this lesson. Some systems, which permit proximity identification, by the card being held close to the 'reader', are suitable for senior management/doctors/staff members. The cards should be safe-guarded at all times,

Locks and **Keys:** As part of a hospital's access control system, locks restrict movement of people into or within certain areas e.g. computer room, stores, pharmacy etc. A centralized 'key cabinet' at a control point, controls this system. Masler-keys may be provided to the Security Officer, to have access in case of emergency like fire etc.

3.5.3 Conclusion

Access control system must be installed in each hospital-taking into account, detailed analysis of specific threats/vulnerabilities and requirements. **The** identification **system** should he periodically reviewed and replaced to prevent forgeries.

Check Your Progress **3**

1) Fill in the blanks:

   a) The physical security measures should be planned in ....., as a single barrier system fails to provide Total Security.

   b) The identification system should be periodically ..... and replaced to prevent .....

2) Name the three components of a perimeter protection system.

   a) .....

   b) .....

   c) .....

3) Assessment of security threats and vulnerabilities of a hospital is the sole responsibility of security officer/manager. True/False

3.6 INTEGRATION OF SECURITY TECHNOLOGY

3.6.1 Need for Security Technology

Crime prevention system, based purely on human element, is not only expeinive in the long run, its efficacy too to counter the current or potential types of crimes, is restricted. Equally, it is contingent on quality of security man-power, their training and supervision, which may not always be of the requisite standards. It is desirable, therefore, to augment man-power based security organisations, with security technology devices. Besides making the total security management plan more effective, it may reduce the expenditure in the long run, make security less obtrusive and may even assist in monitoring alertness of the security staff. What is **needed** is a **balanced mix of technology** nnd **man-power.**

3.6.2 Security Technology Plan

A Security Technology Plan needs to be implemented for integration of securily equipment, which would strengthen the manned security operations and would improve quality of monitoring and supervision. The following types of equipment should be considered:

a) CCTV for surveillance at selected locations.

b) Access Control Equipments.

c) Intrusion Detection Devices.

d) Guard Watch Equipment to monitor regularity of search patrols and alertness of guards.

e) Alarms.

f) Augmentation of Security Lighting along the perimeter and key locations.

g) Security Communications in tlie form of dedicated tele-communications lines and walkie-talkiesets.

h) Metal and Explosives Detectors.

i) Metal Detector for screening of incoming mail,

3.6.3 Computer and Information Security

a) Key assignments on EDP Staff should be identified and their verification system be instituted.

b) Simultaneous updates for all Common data/programmes.

c) Regular back-ups of data and programmes. It should be duly indexed and catalogued.

d) **Annual** Maintenance Contract (AMC) by contractual personnel should be carried out **under** supervision of regular EDP staff.

e) Formal training for new entrants and regular refresher programmes for all users should be institutionalized.

f) Anti-Virus precautions.

g) Allocation of computers for security operations.

h) Formal Computer Security Policy and Security Instructions should be implemented.

Check Your Progress 4

b) .....

c) .....

d) .....

3.7 SELECTION AND MANAGEMENT OF DEPARTMENTAL SECURITY STAFF/CONTRACT SECURITY AGENCY AND SECURITY TRAINING

3.7.1 System Choice

Out of various modes for provisioning security manpower, i.e., departmental or proprietary, contracted or a mix of the two, the hospital management needs to evaluate advantages and disadvantages at each pattern. For optimum results, the management and supervisory elements should be fully departmental, whereas security guards may be a mix of departmental and contracted security staff.

3.7.2 Selection of Contract Security Agency

The following aspects require careful consideration by the hospital administration, while selecting a contract security agency:

a) Short-listing and selection of an Agency should he done through a Board of Officers, preferably comprising of one executive each from Personnel & Administration, Finance Fire and Security Departments of the hospital. This Board should put up their recommendations showing Inter se gradations for approval of the Board of Management/Trustees or Director of the hospital (whosoever is the final approving authority) Following arc the recommended stages in the selection of a contract agency:

a Short-listing ol' Agency.

Establishing Bid Specifications.

- Visit to Site by the bidders (where required).

Submission or' Bids.

- Final Selection of the Agency.

b) Once the tenders have been received, these should he vetted by the Board of Officers. Deliberations should be transparent. **While selecting the Agency, the Board should keep in mind that the lowest rates may not necessarily ensure quality of service. A system of weightage in the proportion of 60:40 for Professional or Technical merit and 40% for comparative rstcs should be implemented, while considering the man-power contract,**

3.7.3 Verification of Security Personnel

All security staff, including ex-servicemen who have been retired for more than one year, should he duly vetted by the hospital management and verified hy the civil police authorities, prior to employment. Photographs and finger-prints records of staff of all categories must be maintained.

3.7.4 Security Staff Discipline

Maintaining a high degree of discipline amongst security staff is a priority task for the hospital management who should be on the look-out constantly for dereliction of duty or incompetence and deal with it swiftly and decisively. The following types of instances should invite quick action:

a) Absence without notice.

b) Alcoholism and drug addiction/dependence

c) False reporting or failure to report incidents

d) Sleeping while on duty.

e) Un-necessary harashness/violent ways.

f) . Wilful disobedience of orders.

g) Dishonest or corrupt practices

3.7.5 Security Training

a) Training, particularly of the following types needs to be ensured through a professional body or under the Chief Security Manager.

	Minimum Duration
i) Mandatory Induction Training	
– Ex-Servicemen	15 hours
– Fresh Inductees	30 hours
ii) On-the-Job Training	15 hours
iii) Refresher Training	10 hours/2 working days/ 4 half days once every six months
iv) **Security Awareness Programme for all Non-security Executives and Staff Members**	10 hours

b) Security training for non-security staff should be carried out in convenienthatches, for about 10 hrs duration. Induction level training for the contracted security staff should be built in the contractual provisions and standards ensured prior to dctailinent of security guards on duty.

3.7.6 Conclusion

In the foreseeable future security manpower would continue to be the primary basis for security organisation in hospitals in India. It is imperative, therefore that the security staff is appointed/selected, keeping in view the overall organisation structure, environment and mission of a hospital.

3.8 SECURITY AND LAW

3.8.1 Introduction

The hospital security staff, by the nature of their work, have to interact daily with large number of people. Most of these interactions are cordial. However, some of these exchanges may turn out to be stressful and even hostile. **The security officers and their staff mny confront suspicions trespassers, unhappy family members of patients, intoxicated visitors, at times violent or mentally imbalanced patients and angry employees/outsiders or criminals suspected of theft or illegal use of drugs,** In handling such cases, the security staff and in turn the hospital administrators, will face some very

difficult decisions, having to decide within seconds, whether to detain, use force, search, interrogate or initiate prosecution of possible offenders. At times, they must also decide whether to tell other parties about such incidents. **Each of such situations has legal implications. Violation of legal provisions may not only place the security staff in the wrong but the institution too, being the principal employer, may become liable for the acts of violation of the law.** It is, therefore, necessary that you, as the hospital administrators, as also the security staff, should be well-informed on provisions of law regarding the more common legal risks, both civil and criminal, which hospital security staff may have to face, in daily discharge of their functions.

3.8.2 Some Basic Provisions of the Indian Penal Code (IPC) – Concerning Security

While this lesson, for obvious reasons, cannot be all-encompassing, some of the basic provisions of the IPC, having an impact on discharge of security functions arc outlined below. In all cases, however, when in doubt, the security staff must consult with the hospital administration, who should act under advise of the legal counsel. It should be realized that the Industrial Security staff, as of now, in our country, derive their authority, to act from provisions in the IPC regarding Right of Private Defence.

- **Right of Private Defence:** (P C Section 96 & 97): "Nothing is an offence, which is done in the exercise of private defence." There are some restrictions in Section 99. Every person has a right to defend:
  - Firstly, his own body and the hody of iuiy other person, against any offence against the human body,
  - Secondly, the property, whether moveable or immovable of himself or of any other person against an act, which is an offence falling under the definition of theft, robbery, mischief or criminal trespass.
- **Theft** (IPC Section **378):** A theft is always committed in relation lo moveable property.
- **Pilferage:** Is removal of small items due to temptation of daily needs like pencils, pens, cooked food, etc.
- **Robbery** (Section **390):** Robbery is an aggravated form of theft. The most important element ofrobbery is the presence of imminent force or violence.
- **Dacoity** (Section 391): When live or more persons jointly commit a robbery, it will amount to dacoity.
- **Mischief** (Section **425):** Whoever causes or intends to cause or knows that he is likely to cause'loss or damage to the security of the property, commits on offence of mischief.
- **Criminal Trespass** (Section 441): Whoever enters into the property of another with an intention to commit the offence or to intimidate, to insult or to annoy the owner of that property, commits the offence of criminal trespass, Further, whoever has lawfully entered into the property of another and unlawfully remains there with an intention to intimidate, insult or annoy the owner of the property, commits the offence of criminal trespass,

3.8.3 Authority to Arrest, Use Force, Conduct Searches, Frisk, Inspect, Interrogate and Interview

The industrial security officials in our country, do not enjoy the authority normally vested in the civil police authorities. They may detain, temporarily (till earliest handing over to the civil police), in the execution of right of self-defence. **The authority to conduct searches, frisking or inspections, even on the premises, must be with specific authorization of hospital administration, who too must stipulate such possibilities in the conditions of service of their employees.**

3.8.4 Reporting Procedure

All major incidents, accidents, thefts and offences should normally be reported to the civil police in the form of a First Information Report (FIR). **However, invariably prior permission of the hospital management must be obtained by the security staff or departmental heads before any report is lodged with the civil police.** Tlie **FIR.** depending on the situation, may be oral (on telephone) or written; the important points are that it must be lodged without any unexplainable delay and with as much relevant information as is available.

3.8.5 Conclusion

Security function in a hospital, is sensitive, challenging and a responsible task. The hospital administrators and the security staff must be thoroughly conversant with their rights and limitations, when enforcing various directions, in order to avoid the risk of violating laws of the land.

Check Your Progress 5

3.9 STRATEGIC SECURITY PLAN AND STANDING SECURITY POLICIES AND PROCEDURES

3.9.1 Introduction

Security lapses occur in hospitals, primarily due to one or more of the following factors:

- Absence or inadequacy of well-analyzed security policies, directives and guidelines by the hospital management for tlie security department and other staff.
- Inadequate involvement of hospital's top management in securily organisation, in threat assessment, monitoring, review and periodic updating of security orders and instructions.
- Faulty selection of security staff and lack of appropriate training of security personnel and other staff,
- Virtual absence ol' integrated security technology devices.

3.9.2 Effective Security Management in Hospitals

Some of the important counter-measures for ensuring efficient security management in hospitals are as under:

- Preparation of Strategic Security Plan, based on a professional Security Audit. This should be carried out under directions of the top management and must have their continuous involvement.
- Stipulation of security policies, procedures and standing orders and instructions for security department and other non-security staff.
- Effective screening of all employees, especially security staff and contract security agencies.
- Initial/On-the-job/Refresher training lor all security and non-security staff in Loss Prevention.
- Effective organisation of security operations, based on 'site' and 'post' instructions and system of regular supervision.
- Immediate incident reporting/response.
- Mutual Aid Plan and effective liaison with civil police and other agencies.
- Contingency Plans for security-related Crisis/Disaster Management.
- Periodic review and updating of security plans, instructions and procedures.

3.9.3 Central Security Control Room

A Central Security Control Room (CSCR) should be established to execute the following tasks:

a) Act as the Security Office.

b) Be fully equipped to detect explosives, lire arms and conduct electronic and physical searches.

c) Monitor performance of the Security Staff.

d) Monitor the Security of Vital/Sensitive areas within the installation.

e) Be able to communicate in case of urgency, immediately with the Medical Superintendent and Chief Security Officer even after Office 1Iours and Security Posts and Mobile Patrols at all times.

f) Carry out verification, hold records, issue passes for all sections of employees, contracted staff and visitors.

g) Generate MIS reports for the Management on Security aspects.

11) Keep computer based records of incoming and outgoing movement including personnel, vehicles and materials.

3.9.4 Patrols and Post Procedures/Techniques

Effective patrolling is the hack-bone of any good security and safety programme. It affords opportunity to monitor the entire environment, prevent problems from occurring, by instituting timely remedial measures and generating a feeling of 'Security' on the part of staff, patients and visitors alike. Patrols can be on foot (most common type) or a vehicle patrol (including bicycle or moped), 'conspicuous', 'inconspicuous' or selective (concentrating on high-risk/sensitive areas).

3.9.5 Control of Visitors/OPD Patients/Attendants

a) Well-formulated and comprehensive guidelines and instructions for the visitors need to be created to reduce congestion,

b) While anxiety factor of the relatives/well-wishers and the so-callctl, "Indian Culture" of displaying 'visible' sympathy can be appreciated, these must be balanced against the totality of enhanced Security threat, administrative problems of accommodating larger number and the risk of greater infection.

3.10 SECURITY-RELATED CRISIS/DISASTER MANAGEMENT IN HOSPITALS

3.10.1 Introduction

At no time has crisis/disaster management been more critical to the literal survival of hospitals and health-care facilities. The hostage taking of 500 persons, in the year early 2000, in a large hospital in Thailand, by 10 terrorists belonging to a Mynnamar-based so called "God's Army" is an example of the unforeseeablekind of threats. In times of crisis/ disaster, everyone turns to "Security", who may be ineffective, in the absence of a well-thought out, rehearsed and practised disaster-management plan. Traffic control, prevention of crowds and theft, communications, assistance to police and fire crews and handling of press and VIP visitors become critical responsibilities for security staff during emergencies.

3.10.2 Types of Disasters

Basically, there are two broad categories of concern to a security organisation—external or internal. Major disasters can be:

a) External Disasters: Influx of multiple casualties at short notice due to:

- Rail/Road/Air accidents
- Radiation release (like Bhopal gas tragedy)
- Earthquakes (like Latur, Joshimath)
- Severe weather floods or cyclones (Orissa, Andhra Pradesh)
- Civil disturbances/terrorist/militancy situations
- Structural failures
- Fire
- Hot war or war like situations

b) Internal Disasters: These relate to conditions, within the hospital, which disrupt normal operations. These may be:

- Bomb-threats
- Fire incidents
- Radiation release or chemical spill
- 'Hostage-taking or violeiit situation
- Power/water/sewerage disruption
- Staff strikes or patients/visitors agitations

3.10.3 Preparing for a Disaster

The hospital management needs lo formulate a comprehensive disaster response plan, establishment of a control centre and assigning specific responsibilities, in order to deal with the emergency, ensuring that the health-care aspects continue with as little disruption as possible. It is beyond the scope of the brief lesson to go into any greater details of disaster management aspects of hospitals.

3.10.4 Bomb Threat/Response

Bomb threats are becoming a reality for hospitals too. Whether bomb incident involves a hoax threat or a threat that leads to discovery of a bomb or a detonation without warning, proper planning and training will ensure that your hospital is ready to react when an incident occurs. One of the many challenges that face, the decision-makers is the guessing game. Is the threat a hoax or real? Do we commence a hospital-wide search? Do

we evacuate the hospital? Fully or partially'?The organisational plan for dealing with bombs and bomb-threats will ensure laying down guidelines for dealing with the situation, based on available information. It must be realized that in our urban conglomerates, the police bomb detection and defusion squads, may take quite some time to reach. **A hospital's 'Bomb-Threat' plan should cater for creating a protective system without creating panic, till the specialist bomb squads get activated.**

3.10.5 Conclusion

The foregoing points provide only a basic outline of functions, that the hospital security organisation may be required to perform to pro-actively prepare for crisis/disaster situations'. A detailed plan needs to be prepared, disseminated, rehearsed and kept updated.

Check Your Progress 6

1) Hospitals. being vital to the community, can totally depend for security, on police and fire services. True/False

2) During an emergency, penplc will recognize the security uniform and obey all instructions. True/False

3) Most bomb-threats are hoaxes and need to be ignored. True/False

4) Responsibility for the overall threat assessment and for formulation of strategic security management plan in a hospital is of:

   A) Hospital's Top Management

   OR

   B) Chief Security Manager

5) List seven important counter-measures for ensuring efficient Loss-Prevention and Security Management in hospitals

.....

.....

.....

.....

.....

.....

.....

.....

.....

.....

3.11 GOALS AND OBJECTIVES OF SECURITY MANAGEMENT

3.11.1 Goals

The goal of hospital security department is to "provide security services to all those who are interacting within the hospital premises and to ensure protection of hospital property, through use of well-trained personnel, technology, prevention activities and timely response to emergencies and requests." It involves treating people equally and with total care and respect, regardless of their gender, religion, age, handicap or any other factor which may put them in a minority category.

3.11.2 Objectives

Your major objectives, as hospital administrators are:

- Preparation of strategic security plan, based on threat and vulnerabilities analysis, and formulation of security standing instructions.
- Monitoring implementation of the security operational deployment plan, through well-selected and trained security staff/contracted security agency.
- Guide security department to pro-actively contribute to achievement of your hospital's mission of providing the best treatment and patient-care, allowing people to have peace of mind, while interacting in the hospital premises.

3.11.3 Conclusion

If the hospital's security department can detect or catch 100 thefts/losses per year by their efforts, even at only Rs. 1000 per incident, they would have saved the hospital Rs. 100,000. If the security organisation identifies security and safety hazards before incidents or prevents assaults; it can significantly reduce the material losses and damage to the hospital's image. The above does not take into account security's efforts to help diminish the pain, suffering and inconvenience to patients, visitors and hospital staff, thereby contributing *to* the hospital's overall mission and its image in the public.

3.12 LET US SUM UP

In this unit, yon have learnt the basic essentials of the role of hospital administrators in planning, organisation, review and direction of security administration in hospitals in India — whether in public, private or government sectors. You have learnt of the prevailing security threats and vulnerabilities of hospitals and how to effectively and pro-actively counter these by implementing physical security measures, access control concepts, integration of security technology deices, selection and management of security organisation and security training. Currently, in most organisations, security is considered by the hospital administrators as a peripheral function, relegated to performance by tlic subordinate security staff, without any direction or guidelines. Effective or Comprehensive Security involves all executives and departments and not merely the security staff. Hopefully, at :he conclusion of this unit, you have realized that hospitals in India are no longer sheltered or secluded from the strifes and anxieties, facing the rest of the society. The hospitals too have to face up to the growing challenges and sophistication of die criminals. "A proactive, professional and well-trained security department, which focuses on crime prevention as well as public service will make significant contribution to your hospital's mission and function as an integral, well-respected and essential part of your bigger organisation.

- enumerate the basic principles of Hospital planning consideration in relation to fire emergency plan;
- describe the causes and source of hospital fire and various types of fire fighting devices and equipment; and
- explain various structure planning and design consideration for fire detection systans and fire precaution.

4.1 INTRODUCTION

Fire is a potential hazard in all hospital premises. In this unit, you will learn

systematically how the consequences of fire in hospitals and health units can be especialy serious because of the difficulties and dangers associated with the emergency evacuation of patients. You will also learn about the aim of management of medical and health services, how outbreaks of fire should not occur in hospitals and if they do occur, how it should be rapidly detected, effectively contained and promptly controlled. In order to achieve this, the role of hospital management and the overall Are-safety policies, fire prevention and fire protection measures in hospital premises are also explamed. In subsequent paragraphs, you will learn about the physical Qctors like building design and construction, together with equipment and furnishings, installation and maintenance of detection and alarm systems, and the local policies for handling emergencies and the need for staff training in all these matters. At the end, you will learn about risk evaluation for your building so that you can lake extra-precautionary measures based on your assessment.

4.2 ELEMENTS OF FIRE

Fire takes a heavy toll of human life throughout the world. As per recent slatistics fire has been ranked as the third largest accident killer nexl to motor vehicles accidents and accidental fhlls.

Given below are eome of the major lire accidents in Health Care Centres

i) October, 1971: Nursing Home Honesdale, 15 persons were killed due to lack of automatic fire protection systems.

ii) December, 1978: Institution for Mentally Retarded, Ellis Ville, I-IS, Lack of automatic detection and suppression and for want of smoke stop partitions — 15 persons were reported killed.

iii) October, 1981: James Ward of Warlingham Park Hospital — 7 patients died by inhalation of smoke and toxic gases.

iv) December, 1984: JP Hospital, New Delhi

v) April, 1994: AIIMS, New Delhi – No loss of life

Health care centres comprising of hospitals and sanatoria fall under the sub-division C-1 under the main head Group C – "Institutional Buildings" in accordance with the classification of buildings based on occupancy as incorporated in the National Building Code, Part IV. The Sub-Division C-1 obviously includes any building or a group of buildings under one management which is used for housing persons suffering from physical limitations because of health or age, e.g., hospital infirmities, sanatoria and nursing home. Therefore, hospital buildings fall within the purview of institutional buildings where a large number of visitors could bc expected at the peak hours besides patients and hospital staff.

The three elemenls essential to start a fire anywhere can best to illustrated as a fire triangle (Fig. 4.1). In the absence of any of the three elements, fire cannot start and this fact is to be borne in mind while designing fire safety plans. Since **oxygen** cannot be eliminated, planners should concentrate on restricting the fuel, i.e. inflammable **materials**/substances, interior finish materials of the building, etc., and **heat,** i.e. electric sparks, open unguarded flames, static electricity, etc., so that the lire does not start/ spread.

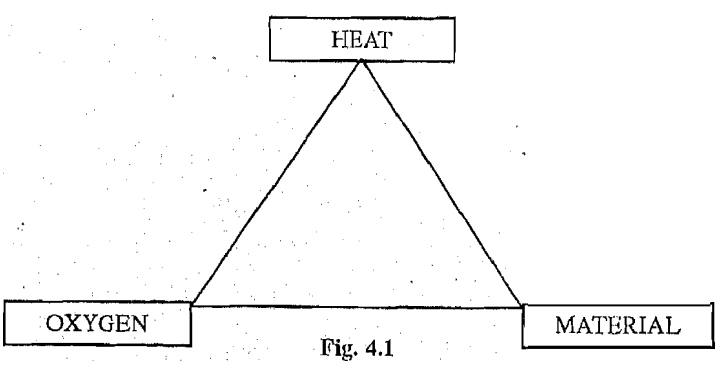

Fig. 4.1

4.3 FIRE HAZARD TRIANGLE

Fire hazard triangle (Fig. 4.2) demonstrates that three factors work, in isolation or in combination, lo pose the hazard. An effective plan for fire safety should, therefore, address itself lo these three factors, i.e. cause (policies and procedure on smoking, maintenance of electrical system, defective equipment, storage of hazardous materials, etc.), spread (types of furniture, fabrics, doors, internal finish material, ctc.), and lack of response (poor training of hospital staff, inadequate alarm system etc.).

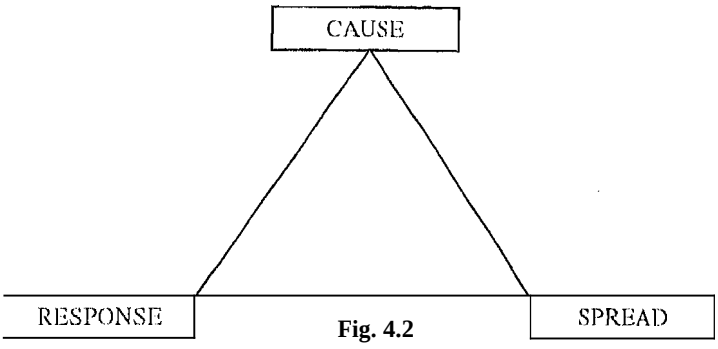

Fig. 4.2

4.4 CAUSES OF HOSPITAL FIRE

Analysis of the most frequent causes of hospital fires (Table 4.1) indicates that human carelessness is the major factor in starting fires in a hospital and therefore, a major effort for combating fire should be directed towards education/motivation of various users of this community facility.

Table 4.1 : Most **Frequent** Causes of **Hospital** Fires

Sl.No.	Cause	%
1.	Smoking	33
2.	Contractors carelessness	18
3.	Carelessness of hospital staff	16
4.	Defective equipment	14
5.	Visitors carelessness	13
6.	Defective wiring	3
7.	Lighting and unknown causes	3
	Total	100

4.5 FIRE PROGRESSION CURVE AND SMOKE DANGER

Before learning to curb fire, it is essential to know how fire progresses or spreads. Studies conducted to see the effects of fire progression have highlighted a very important aspect, i.e. fire grows exponentially, its growth rate increases as long as air and combustible malerials arc around.

The point which you should remember as a designers is that the smoke is much more lethal than flame or heat, as is proved by mortality statistics due to fire, in which 75% victims die due to smoke. What do you understand by term smoke'? Smoke is un-burnt liquid or solid matter suspended in the combustible gases. Smoke attacks the mucous membranes and, worst of all, it impedes visibility, thus contributing lo loss of orientation and eventually leading to panic. Common gases emitted from fires, with their effects, are listed in Table 4.2.

Table 4.2: Common Gases from Fires

Gas	Result
CO_2	Over stimulated breathing
CO	Asphyxiation
H_2S	Respirator and nervous system damage
SO_2	Irritation
NH_3	Irritation
HCN	Cyanosis
NO_2	Anesthesia

4.6 CLASSIFICATION OF FIRES

Fire can bc classified into four grades depending upon the cause and required type of extinguisher to control it:

'A' grade fire is caused by ordinary combustible material like wood, coal, paper, etc. It can be extinguished by using fire extinguishers like soda ash, water, dry chemical power, etc.

'B' grade fire is caused by inflammable liquids, especially those which are lighter than water. Fire extinguishers like Halon 1211 and dry chemical powder type should be used to tackle this type of fire.

'C' grade fire is caused by electrical faults, mostly due to over-loading of the Aluminum wiring. Dry chemical powder fire extinguisher should be used in this case.

'D' grade fire is due to combustible metals like magnesium, sodium, etc.

4.7 FIRE PROTECTION

Fire protection measures for multi-storied and high rise buildings have in general been discussed in Part IV of the National Building Code and ISS 3844. Hospitals housed in the multi-storeyed buildings though not exactly falling in the category of 'high-rise building' need to be provided with fixed installation facilities and adequate means of escape for certain special reasons. In hospitals, majority of patients are incapable even to sit or walk, by their own efforts, therefore in a major fire, intensive approach is necessary for large scale rescue operations and orderly evacuation. It is for these extra protective requirements, internal hydrant installations envisaging wet riser installation etc. is recommended for multi-storcycd hospital buildings irrespective of their heights etc.

4.8 STRUCTURE PLANNING AND DESIGN CONSIDERATION

This aspect is single most important part where if due can is taken during planning and design period the accident rate and its gravity can be reduced significantly,therefore you should learn this component in more details. It is not necessary to remember all this but it will serve a handy ready reference when required.

You will appreciate that the degree of hazard in any structure bears direct relationship with the design of the building, type of occupancy, facilities provided for effective discharge of functional obligation, electrical installation provided in pursuant to the functional facilities, means of escape, compartmentation to keep the premises free from smoke-logging and effects of radiated heat. To some extent it also depends on use of treated and untreated vegetable and synthetic fiber and plastics commonly used for upholstery, mattresses, beds and bedding. Identification of risk and quantification of fire protection facilities directly varies with tlic gravity of hazard in relation to the factors enumerated above. The gravity of potential risk generally encountered in hospitals are given below:

a) Building-structure, design, quality of building material and workmanship.

b) Building services.

c) Central air conditioning facilities.

d) Electrical installation, transformers etc.

e) Functional facilities or special hazards like the provisioning of kitchen, laundry, boiler room, operation theatre, storage for gas cylinders, storage of radioactive material, laboratories and sensitive electrical installations. The fire protection/fire prevention facilities in relation Io the above are discussed in tlie succeeding paragraphs.

4.8.1 Buildings: Harness Communication Zone

i) Hospital planners are absorbed in a process of standardization for new premises based on a modular horizontal development in which standard hospital departments are linked together by a main common passageway/corridor/gallery at each level, together with standardized forms of vertical access, provided by lifts and stairways.

The whole communication system is referred to as the 'harness communication zone', and the main backbone of this on eacli floor is known as the 'harness street'. The whole buildirig form, which is limited lo 4 floors in height, is designed with in a master grid, each square being 16.2 meters in length. Within this grid series of modules (units) are designed, each becoming a standard department, with alternate units becoming courtyards to provide natural lighting and ventilation. The maximum depth will be equal to 4 modules on eacli side of a harness zone. The structure proposed is made to offerone hour's fire resistance to both the structural frame and compartment walls between departments. The harness zone which is designed for the flow of people and the distribution of supplies and services is 10 metres wide, consisting of two main elements: (1) the harness street, and (2) vertical linking, services, plant rooms and miscellaneous accommodation. The vertical linking part of the harness zone contains staircase lilts, ramps, escalators, chutes, ducts, plant rooms and some oflices. All these, either individually or in a group, will form separate fire compartments apart from the Harness Street.

ii) As a thumb rule, structural member of building should be able lo offer a lire resistance for 2 hours. To keep the area free from smoke logging, lobby approach to lift and stair- cases should be protected by a sell closing door of at least ½ an hour fire resistance. Self-close door opening in the direclion of escape should be provided. Two hours fire resistance can bc easily achieved with brick work walls of 22 cms thickness or reinforced concrete of 10 cms floors, Protection to steel columns and beams is achieved with concrete of 4 cms thickness; gypsum concrete for equal thickness also provides fire resistance of 2 hours duration. Paneled door of minimum finished thickness of 44 mm provides half an hour fire resistance. To achieve one-hour fireresistance minimum finished thickness of the door should be of the order of 54 mm.

iii) Compartmentation: A very small percentage of causalities in fire are as a result of direct burning and most people die due to sever exposure to heat and smoke, which mostly contain toxic gases. Human body can endeavor this punishment only to a limited degree and only for very short duration. Taking heat first, the medical authorities believe that a skin temperature of 44°C will result in second degree bums and the temperature is unbearable if skin remains at that point for long enough. However, if the temperature is raised to 55°C similar burns will result in 20 seconds exposure, time is reduced to one second at 65.5°C. Similarly the air inhaled at higher temperature has serious effects on lungs etc. According to medical authorities, 149°C is the maximum survival temperature and that also for.a very short time and not at all in very humid conditions. Compartmentation in relation to fire safety means dividing the building or portion of buildirig into number of parts ensuring that resultant heal and smoke are confined to (he place of origin for as long a period as possible until either fire is extinguished oi safe evacuation is carried out. Compartmentation, properly designed and installed has been successful in limiting fires to the unit of origin, Smoke stop-doors are also interposed between galleries and lobbies and between ward and ward and compartment and compartment to stop ingress of smoke. The smoke stop-doors usually have a fire resistance of half an hour and shall be a single swing type opening in the direction of escape, placed across the corridor to give access to the staircases in either direction. It shall be fitted in a wall or screen having a fire resistance of not less than half an hour. Walls or screen may be incorporated with fixed glazing fire resistance rating of not less than half an hour.

4.8.2 . Building Services

We will lake up each component of building services separately, viz.

i) **Electricity and Gas** are the principal sources of energy lor power, light, heat in any building be it industrial, commercial or residential. Both of these are major sources of ignition wherever they are installed. Tlie passage of an electric current generates heat, which may be used inlentionally for functional facilities and space heating. The heat is also generated in electrical illumination and anywhere electricity is transmitted along a cable. All electrical equipment must be carefully rated according to the work it is expected to do. If it is overloaded, excessive heat will be generated leading to the appearance of spark or fire. Fires are also caused by defects in electrical equipment and through damage to electric wiring insulation. They are also

caused by defects in allowing dry combustible materials to come in close contact with electrical circuit. A high standard of installation and maintenance, therefore, is necessary to ensure safety from fire, which may be caused by the use of electrical equipment.

ii) **Lifts** are the main communication and evacuation system and should confirm with following norms:

a) Walls of lift enclosure shall have a fire rating of 2 hours, and lift car door shall have a iire resistance rating of one hour.

b) Lift motor room should be located preferably on top of the shaft, and following extinguisliess should be provided to deal with any electrical risk. Generally automatic extinguishing system is not recommended as it is manned during working hours, however, heat sensitive detectors operating on rate of rise of temperature and also incorporating fixed temperature mechanism are provided duly coupled to warning system. Lifts should be provided with:

1) BCF Extinguisher 1.25 kg capacity - One

2) CO, Extinguisher 4.5 kg capacity One

c) One lift bank should not accommodate more than four lilts, each separated by a wall of at least two liours lire resistance. Landing doors in lift enclosure should have a lire resistance of not less than half an hour, whereas lift car doors should have fire resistance rating of one hour.

d) **Fire Lifts should be worked with** an **independent source of power other than the source feeding the building. Cables should be laid within the lift shaft to ensure no damage from tire. Lights and fans in the elevators having waoden paneling or sheet steel construction would be operated an 24 volts supply.**

e) Arrangement should exist that in case of failure of normal supply, it should get automatically switched over to alternate supply, failing which it should come down to ground level and be stand still with door open.

iii) **Basement:** Each basement shall he separately ventilated. The staircase of basement shall be enclosed type having fire resistance of not less than two hours and shall be situated at the periphery o l the basement and shall communicate with basement through a lobby provided with fire resisting self closing doors of half hour fire resistance. IF the travel distance exceeds 18.50 m additional staircase at proper place shall bc provided. Storage of corrosive chemicals, flammable liquids, gases or hazardous substances, which liberate toxic vapour on heating is not permitted in the basement.

iv) **L.P.G. Cylinders:** Liquefied Petroleum Gases consisting of mixture of Propane and Butane are generally used in the laboratory, kitclicn and cafeteria as a source of energy. In kitchen a battery of cylinders is used at a time for supply of gas to the gas stove. To overcome shortage, about 25 to 30 charged cylinders are always kept in storage shed. The following points are worth consideration from fire prevention angle:

a) A common manifold connecting a series of cylinders must be equipped with an individual cylinder valve and should also carry a main control valve at the pipe leading to stoves.

h) The cylinder should be kept at a place separated by brick wall of 34 cm thick or by reinforced concrete wall of 15 cm thick, so that the flame/heat generated from the stove could he trapped. Piping of rccornrnended metal should be used for all gas connections.

c) The storage shed for the spare cylinder should be located at an isolated place and no naked flame or spark should be permitted up to a distance of 30 metres in the vicinity of the shed. Ventilation at the floor and roof arid roof levels should be adequately provided.

d) To obviate the chance of any sparlc by friction, a sand bed of 5 cm thick should be provided.

e) No electrical conductors as far as possible should be installed inside the storage shed. In case the necessity exists then all electrical installation should be flame/ spark proof and be in conformity with the BIS regulations. All switches should be spark proof and be installed outside the shed.

f) Filled cylinder should be stacked vertically occupying not more than 3 tiers and empty cylinders could be stacked horizontally in tiers not exceeding five.

g) A fire point should be erected near the shed and two points should bc sited not nearer to 30 m from tlie shed.

h) A "NO SMOKING" board should be displayed at a conspicuous place near the storage shed.

4.8.3 Central Air-Conditioning Facilities

i) **Air Conditioning Ducts:** It has been reported that air-conditioning ducts are the major cause for the spread of fire engulfing tlie entire building. A few buildings in the hospital complex are provided with central air conditioning system. Inlets and outlets ducts originate and finally terminate in the AC Plant room. To eliminate the chance of spread of fire through AC ducts, the following measures are recommended:

a) Insulation and lining including vapour barriers and coatings used in conjunction with ducts should be of non-combustible material. All filters for use in air-conditioning system shall be such that will not burn freely or emit large volume of smoke or other noxious products of combustible when attacked by flames.

b) The air-conditioning ducts should he provided with dampers /stoppers preferably of fusible link type actuating at pre-determined temperature thereby emitting audio-visual alarm. Arrangement should exist lo get the plant switched off automatically on sounding of the alarm and also manually from the place of working. The dampers are installed to stop or to restrict tlie flow of hot gases/ flames from one compartment to another.

c) Damper should be installed in tlie inlet duct at the point of originating from the air-conditioning plant room and in tlie outlet duct at all points where it passes from floor to floor or from compartment to compartment.

d) All the electrical installations arid other electrical fitments must be vapour-proof/flame proof .

e) It is again stressed that switch gears to the hazardous store/flammable liquid storage room, as far as possible should bc located outside the room to avoid the chance of occurrence of my spark.

ii) **Air-conditioning Plant Room:** Heat sensitive detectors, preferably electro-pneumatic type incorporating fixed temperature as well as rate of rise mechanism are considered suitable for AC Plant room. These should be coupled with the automatic warning system emitting audio-visual alarm. **Automatic extinguishing system is not recommended, however, minor fire fighting equipment comprising of two BCF extinguishers of 1.25 kg capacity and one CO_2 extinguisher of 4.5 kg capacity may be installed to tackle any electrical fire. In** addition, one CO_2 extinguisher trolley mounled single cylinder having a capacity of 22.5 kg coupled with adequate length of high pressure flexible rubber hose duly connected with discharge horn may be catered for, to tackle abnormal situation.

4.8.4 Electrical Installation

i) Electrical services in general sliould conform to the following provisions:'

a) Conductors/wiring should be laid in separate duct which should be sealed at every alternative floor with non-combustible material having the same fie resistance as that of duct. Low and medium voltage conductors drawn in shaft and in voids above false ceiling should be laid in separate conduits.

b) Telephone lines, gas pipes and water main etc., should never be laid in the duct used for electric cables.

c) Separate circuits laid in separate conduit pipes shall bc provided for operation of water pumps, lifts. staircases and corridor lighting and blowers for pressurizing system, and be drawn from the main. Switches controlling essential services should bc labelled.

d) Emergency lighting shall bc provided in the staircases/corridors.

e) As an alternative source of supply, a stand by generator should be installed to supply power to emergency lighting circuits, fire lifts standby fire-pumps, pressurization system and smoke to extraction dcviccs. The generator should be capable to feed and operate all the above emergency devices simultaneously. In occupancies where alternate sources of energy is available to feed the above systems in emergent situations? the installation of generator may not be insisted upon provided powers is drawn direct from the Sub Station.

) **Power House:** Power House should be equipped with 2 BCF extinguisher of 1.25 kg capacity and CO_2 extinguisher of 4.5 kg capacity to tackle any electrical risk and the same quantum of extinguishers may be provided in other electrical installations.

iii) **Transformers:** Transformers are installed in the buildings below the ground level, in the first basement in separate fire resisting room of 5 hours fire resistance, to meet load of A/C Plant among other electric installations. The High Power Capacity transformer should be well protected and it is suggested that Bund wall (a dike of adequate dimensions) should be erected around the transformer to arrest the total quantity of coolant (heavy oil) plus 10 percent. In case of transformers installed at ground level, a drainage pipe should be laid from the transformer to soak pit constructed outside the building at a safe place. A fire point with following extinguishers should bc crectcd near larger capacity transformers:

a) BCF Extinguisher 1.25 kg capacity - 2

b) CO_2 Extinguisher 4.5 kg capacity - 2

c) Dry Powder 10 kg capacity - 2

d) A single cylinder trolley mounted CO_2 extinguisher of 2.5 capacity with sufficient length of pressurized flexible rubber hose duly connected with discharge horn may be catered for to tackle abnormal situation.

e) Large capacity transformers housed in basement should be protected hy an automatic high velocity water spray projection system.

4.8.5 Special Hazards

There are certain other areas. also in the hospital buildings. which need to be given special attention from fire fighting point of view. These provisions are discussed in the following paragraphs:

i) a) **Operation Theatre:** Besides the operation theatre, there are other locations where flammable anesthetics are or may hc administered to patients. Anaesthetics such as chloroform, cycloropanc. divinylether, ethylene and nitrous oxide arc stored for emergency use. The operation theatre is always having flammable liquids/vapours and gases, it is. therefore, necessary that electrical installation and other electrical fitments musty be vapour proof/flame proof and should conform to IEE /BIS regulations. Switch gears to the individual rooms as far as possible should be located outside the room to avoid chances of occurrence of any spark. In view of the potential risk associated with such locations, it is recommended that all electrical installations must be intrinsically safe or flame proof so that no spark emerges out in the open atmosphere from the electrical fitments.

h) Operation Theatre should be equipped with early detection cum warning system. Smoke detectors preferably combination of ionization and photo electric cell type, be coupled to a warning system, capable to transmit audio-visual signals to the centrally located control panel sited at a suitable place to be

manned round the clock. Besides the above, manual call points duly linked with the warning system should also be installed outside such premises.

c) Extinguishing system employing CO, as extinguishant is recommended. Manually operated extinguishing system should be actuated subsequent to the sounding of alarm. A battery of CO_2 cylinders connected to a common manifold, each cylinder having a capability of 22.5 kg, should be provided in the corridor or at a place adjacent to the room. Pipe lines connected with common manifold on one side and extended to provide coverage to the entire room should terminate with discharge horn projected to cover all the vulnerable points. On detection of fire as a result of manual actuation CO, would be released in the particular zone thereby extinguishing the fire in the affected compartment. However, evacuation of all personnel must be ensured before the systein is operated. Small fires of electrical origin should be tackled with the first aid extinguishers bracketed against the wall.

ii) Presence of radio-active materials require the need for exercise of every precaution in the storage/handling of materials which are hazardous being in a slate of disintegration emitting continuously radiations, the excessive doze in case of accident could be lethal to the workers. Hence it is imperative that the rooms in which radio active materials are stored/handles shall be provided with the water sprinklers with manually operated remote controlled valve installed at a safe place outside the room.

iii) Laundry rooms, large storage houses and kitchens with abnormal dimensions would be provided with heat detectors preferably electro-pneumatic type incorporating fixed temperature as well as rate of rise mechanism coupled with early warning service. First aid fire extinguishers be provided to tackle fire in the incipient stages in these areas.

4.8.6 Fixed Installation

Protection to Air-conditioned Portion of the Building

The air-conditioned premises housing sophisticated electronic equipments and computers of laboratories accommodating sensitive instruments should bc provided adequate lire coverage envisaging automatic early detection-cum-warning-cum-extinguishing systems, The details of such system is dealt separately at Appendix 1 to this unit.

Here we will confine ourselves to learn, what to do in case of lire in such premices:

i) In case of small fire of electrical origin, on sounding of the alarm efforts should be made to fight the lire with the portable extinguishers installed in the room but if f i e develops into serious proportion and goes out of control, then the system should be actuated by operating the overriding switch provided with in the room. Arrangement should exist to operate the system after closing hours from a remote control device installed inside the gallery/verandah/corridor at a conspicuous and accessible location.

ii) The warning system coupled with the siren should emit two consecutive notes, At the premises should be completely evacuated and the last man should ensure that none is left in the room. At the second warning which I'ollows 30-40 seconds alter the first warning, the system if automatic gets commissioned by its own, but in case of manually operated system, the system should be brought into actuation by the last person by operating the switch provided in the corridor.

iii) Warning should be displayed at conspicuous place inside the room that complete evacuation should e ensured in all circumstances before causing the system to operate. This is necessary to obviate the chance of any casualty as a result of asphyxia due to over flooding of the room with extinguishant discharged.

Fire Protection to Non-air-conditioned Premises

i) Heat sensitive detectors preferable electro-pneumatic type functioning on the rate of rise of temperature and also incorporating iixed temperature mechanism are recommended for installation is non-air conditioning blocks accommodating various types of hazardous stores and costlier plant and machinery. The detectors would be coupled to the warning system, comprising hooters, siren, response indicators. On actuation of the detectors the signals will bc transmitted to the control panel, repeat panel and to the siren installed at the top of the building. One BCF/CO_2 extinguisher single cylinder trolley mounted fitted with high pressure flexible rubber hose and discharge nozzled/horn having a capacity of 25 kg /22.5 kg respectively should be placed near the risk to be protected. However, one BCF fire extinguisher 1.25 kg

capacity and one CO_2 extinguisher 4.5 kg capacity should invariably be installed inside each room/compartment to tackle minor fires in Ilie incipient stages.

ii) ***Protection to General Wards*** : Wards like Intensive Care Units and Emergency wards which have been provided with central air conditioning facilities or with package air conditioners would he covered by the installations of smoke detector mid manual call points as stated above. However, General Wards comprising a part of tlie non-air conditioned portion of tlic hospital would be covered by the sprinkler installation, the salient features of which are as follows:

a) **Detection System**: Quartzoid type detector consisting of a small cylindrical barrel made of special glass is used to hold tlic water valve intact. This bulb is hermetically scaled and contains a quantity of a liquid entrapping a small air bubble. As the temperature rises tlic liquid expands and the size of the bubble decreases until it disappears. A further rise in temperature shatters the bulb breaking it into small pieces thus allowing the water to flow thereby drenching the area. The strength of' Ilie bulb is compatible to withstand any pressure applied to the pipes. By adjusting the composition of the liquid and to a restricted extent, the size of the bubble the bulb type head can be set to operate at any temperature. For normal occupancy situations the recommended rating is 68°C.

b) Quartzoid build detector would perform Ilie function both of a detector as well as of a sprinkler. For light hazard a detector covers an area of 20 m square and these are positioned at 4.5 m apart to meet tlic stipulated requirements of water discharge rate.

c) The detector will be suitably coupled to a network of pipes of adequate size and the entire sprinkler installation should have an in-exhaustive supply of one hour duration.

d) The sprinkler installation should be fed from two independent sources of water supply one of which must be inexhaustible in nature. As per norms, sprinkler installation should be fed from an independent source of water supply, therefore, it is imperative that a sump of adequate capacity with a suitable pump having duty points matching with aggregate requirements of sprinklers heads should be provided and installed at the sump. The feeder will remain charged under prcssurc and with the fall of pressure due to actuation of sprinkler's, the pumps would get automatically commissioned into operalion.

4.8.7 Hazards Associated with Furnishing Material, Curtains Upholstery, Dresses, Bed and Bedding Materials

Some cases of Grc got initiated from a burning discarded cigarette butt accidentally dropped on a bed. There have been a number of cases reported relating to fire in clothing and textiles to which such attention was not paid earlier to reduce such hazards. Apart from the type of dress, material of tlie fabric plays an important role .It is estimated that in India around 10,000 deaths occur annually due to burns and it seems that incidents of fire on account of textiles and clothing is approximately 5- percent. Generally victims are mostly children and women.. Though knowledge of flammability of textile fabrics helps in selecting right type of material which is generally done on aesthetic value of the textile rather then flammability aspect, however it may riot be necessary for you to learn these details at this stage, hence it is given separately at appendix B to this unit.

4.8.8 Water Supply

i) **Static Water Tanks**: Open Static water tanks are not generally recommended in the vicinity of hospital buildings, As hospitals are generally visited by patients along with their relatives, often accompanied by children as outdoor patients and also to visit their ailing relatives, so there could be chances of accidental fall. Hence to avoid mishaps open static water tanks are not to be provided, however, covered static tanks are suggested for giving adequate fire coverage to all the blocks. Underground static tanks covered with a reinforced concrete slab should be provided. The storage tanks should be linked with an approach road 3.6 m in width. The tanks should be

recouped within 18 hours and each tank should have a capacity of at 110 KLs. Adequate opening should be provided for inserting the suction hose.

ii) **Wet Riser Systems:** Wet riser system which is kept permanently charged consists of riser (Pipe) 150 mm in diameter locatcd within lobby approach stair case or within staircase where there is no lobby. Generally one riser is provided to cover a floor area of 1000 sq m. Number of wet riser could bc computed at this scale and be located preferably near to staircase. As per IS 3844, the diameter of the wet riser could be 100 mm if the building is less than 34 in in height wet riser system forms part of basic engineering planning componant,you should ensure that it is functional all the time specially during mock fire drill. You need not remember it, however in case you want to know more about it you can consult Appendix 3.

iii) **Hydrant Installation:** Besides the above arrangement, the entire complex should be encircled by a network of hydrant installation which is a positive source of watcr supply, it is, therefore, suggested that hydrant should bc sited all around the entire premises preferably by the side of the approach road spacing each hydrant at a distance of 45 metres apart. It is advised that the ground installation should also be coupled to the main feeder originating from the sump where two pumps have been installed for pumping watcr into the riser system. Details of hydrant installation system is given at Appendix **3.**

4.9 FIRE POINTS AND ESCAPE ROUTES

i) Adequate number of fire points should be provided outside as well as inside the building at conspicuous places so that these are accessible from all directions. As per stipulated requirements one fire point should be erected on each floor near the staircase and it should be equipped with tlie following first aid extinguishers:

Stored Pressure type water extinguisher 9 ltr capacity	2
Dry powder extinguisher 10 kg capacity	1
CO_2 extinguisher 4.5 kg capacity	1
Ceiling hook	1
Water buckets	2

ii) Requisite number of CO_2 extinguishers of 2.0 kg capacity and BCF extinguisher of 1.25 kg capacity should be provided in the corridors duly bracketed against tlie wall at tlie equi-distance in a manner the person bas not to run more than 15 meters to pick up the extinguisher.

iii) An Internal Board of officers may be constituted to pin-point the locations for erections of fire points considering the gravity of the risk. In brief, tlie location shóuld bc conspicuous and accessible usually from all directions and further should restrict normal functional requirements of the Hospitals.

Notes: 1) Before the use of water is resorted to on elcctricnl appliances, switch gears and fitments, switching off power supply should be ensured in all circumstances.

2) As far as possible, dry powder extinguisher should not be used in the room occupied by tlie patients and in cases where CO_2 or BDICF extinguishers of higher capacity have to be actuated, caution should be exercised to evacuate the patients before operating the extinguisher.

4.9.1 Fuel Store

One fire point may be sited near the POL storage/motor transport section consisting of the following lire fighting equipment:

a) Mechanical foam extinguisher 9 ltrs capacity preferably AFFR 2

b) Dry powder extinguisher 10 kg capacity 2

c) CO_2 extinguisher 4.5 kg capacity 1

d) Sand buckets 4

One BCF extinguisher 1.25 kg capacity and one CO, extinguisher 4.5 kg capacity may bc bracketed inside the POL room as an additional fire fighting equipment.

4.9.2 Manual Call Points

Manual cull stations generally known as the manual call points have been recommended for all the buildings located in tlie complex which would also be connected to the siren/ hooter of adequate range through the waning system. The call boxes should be installed at a distance of 22.5 meters apart especially in the corridors/verandah/galleries of the wards in a manner that dead ends and comers are adequately covered Manual call points are enclosed in a sturdy robust box which is installed on the wall at a distance of one meter above the floor level. The box is equipped with the device which is linked with the main warning system and to protect the device from the dust particles it is covered with a glass plate. A hammer is provided which is to be struck for breaking the glass plate the knob pulls out actuating the system emitting audio-visual alarm with spot indicators and simultaneously transmitting impulses to tlie siren which emits loud repeated notes of sharp pitch compatible with audibility, quite distinct lo alert the emergency services.

4.9.3 Means of Escape

In view of mass evacuation of patients, visitors and staff, Means of Escape in Health Care Centers bears significant importance. In this connection, reference is invited to the contents of IS 3844 and Part IV of the National Building Code which are the main guidelines followed by all concerned within the country. Fire authorities in whose jurisdiction the building is to be located, may, if considered appropriate, be consulted in assessing means of escape for the hospital buildings. It may be appreciated that Municipal Bye-Laws or By-laws is to be discussed with the competent fire authority before implementation. Following points may bc given due consideration in determining the category and quantum of means of escape:

i) The size of the doors provided in the ward should not bc less than 3 units in width i.e. 1500 mm.

ii) Each Ward must be provided with escape route in the ward which should not be less than 2.5 meters in breadth, although provisioning of escape exit on b o h the sides of ward is an advantageous factor, as it would enable the authorities in emergent situations to pull the patients while lying on cot through the exits to the corridor.

iii) Ramp:

a) It is pertinent to note that lifts are never construed as authorized means of escape as per standard practice observed by die authorities in this field. Hence it is felt that Ramps are essential ingredients for hospitals buildings.

b) One stair case in tlie shape of Ramp having inclined plane configuration with a breadth of not less than 2,5 metres should be provided to enable tlie patients to evacuate with their own efforts.

c) Ramps are built in the form of inclined plane free from steps rendering the facilities to the patients to climb down without exerting much efforts. It would also facilitate movements for wheeled stretchers and trolleys ctc, with speed without restriction in case of ambulatory patients.

d) Depending only on the staircases as the means of escape would increase the gravity of efforts as the patient has to come down by staircases step by step which may not be practicable in most of the cases. Obviously more labour is exercised while coming through staircases as com1 red to ramps.

iv) Although lifts are not considered as authorized means of escape yet one lift specially allocated to be used by the patients in emergent situations should be catered for in addition. The dimension of the lift platfonn should such as to accommodate wheeled carriage/stretchers.

v) Lobby Approach Staircase and Lifts : In hospitals over 24 metres in height there shall be provision of a lobby approach staircase provided with firelifts (exclusively for fire brigade use). These fire lifts are capable of carrying at least 6 persons and fully automatic with emergency switch at ground floor to facilitate fire fighting operations. Arrangements should also exist in the lift to cut off all switches installed on each floor so that lift can move non-slop and should stop only at the desired floor. In general, there should be a lobby approach staircases to every 1000 sq meters of floor area of each storey.

Pressurization of staircase: General practice in this regard is that staircases should be pressurized to the extent to slop entry of smoke and toxic gases. This aspect is taken care of in fully air-conditioned buildings,

vi) There shall be sufficient open spaces available on the sides of building so that in case of an eventuality the fire fighting/rescue vehicles have access to the farthest part across the building for carrying out rescue operations.

vii) In addition to the above, all the means of escape — staircases or ramps — must bear directional sign which should be illuminated from an independent source of power supply. The exit sign wherever fixed should be indicated by arrow reflecting green colour instead of red.

viii) Horizontal Exit and Rescue/Fire Tower: To ensure safe evacuation some celebrated authorities recommended the provisioning of a horizontal exit to from the main building, where it is not effected by smoke or radiated heat. The rescue tower is connected with all the floors of the main building through corridors/galleries.

4.10 RISK EVALUATION

Generally Hospitals are located in old pre-existing buildings and it may not be possible now to change the architecture design, however it will be worth an exercise to do risk evaluation of the the hospital building. The risk evaluation for m y building is calculated from the product of the following five factors after assigning weighing factors to each of them depending upon the nature and type of the facility (Table **4.3).**

1) Patient's mobility: It represents the degree to which patients musl be assisted for their safety.

2) Patient's density: It refers lo the number of people at risk in a given Fire zone.

3) Fire zone location: It reflects the accessibility of the zone to the lire Sighting facility, for suppression of fire and rescue operation.

4) Ratio of patients to attendant: It takes into account the impact on the safety of the patients of the number of staff available to respond in an emergency.

5) Patient average age: It reflects the age of the patients. The rating takes into account the susceptibility to harm by smoke, etc.

The total occupancy risk is therefore the product of the fire factors and this calculated risk should be assessed, by the designer in terms of the risk-factor values available in the relevant codes. There may be some limitations to the system which are required to be considered in the planning stage.

As regards structural fire precautions and means of escape, the Bureau of Indian Standards has also formulated some parameters as contained in the Nations Building Code (Part N). It is essential that hospital buildings incorporate structural fire precaution measures in their design taking into account the latest fire-resistant materials, compartmentation and methods of construction including means of escape and active fire protection system.

Table 4.3: Occupancy Risk Parameter Factors

Risk Parameters		Risk Factor Value				
1. Patient Mobility (M)	Mobility Status	Mobile	Limited Mobility	Not Mobile	Not Movable	
	Risk Factor	1.0	1.6	3.2	45	
2. Patient Density	Patient	1.5	6.10	11.30	>30	
	Risk Factor	1.0	1.2	1.5	2.0	
3. Fire Zone Location (L)	Floor	1st	2nd or 3rd	4th or 5th	6th and Above	
	Risk Factor	1.1	1.2	1.4	1.6	
4. Ratio of Patient to Attendants (T)	Patient Attendant	1.2 1	3.5 1	6.10 1	>11 1	One or more None
	Risk Factor	1.0	1.1	1.2	1.5	4.0
5. Patient Average Age (A)	Age	Under 65 Years and over 1 Yenr		65 Years and over Yeas and Younger		
	Risk Factor	1.0		1.2		

* Risk Factor of 4.0 is charged to any fire zone that houses patients without any staff in immediate attendance

4.11 LET US SUM UP

In this unit, you have learnt about various aspects of fire accidents in a health case set up. You have also acquired the knowledge of importance of keeping these factors in mind while planning and designing a hospital building. Depending upon the tire hazard present in different parts of hospital premises, now you can assess the need of first aid fire fighting appliances including hose reels, portable extinguishers and fixed fire protection system to cater for any special risk. Based on these factors you can draw a fire plan of the hospital building indicating escape routes, compartmentation and other fire protection facilities and incorporate all these in routine fire evacuation mock drill.

4.12 SELF ASSESSMENT ACTIVITY

The following question to help you to test yourself whether you have grasped all that has been explained in this section. Separate sheets arc to be used for writing out answers to these questions, You may refer to the text of the unit to sharpen your understanding of the subject matter. After attempting these questions you may act as your own evaluator.

i) Study the design and construction of your hospital building, does it conform to the norms of fire safety?

ii) Draw an Improved design observing ideal fire norms.

iii) Can you relocate some wards and make some fire escape route in the existing building?

iv) See where all fire-extinguishers are placed, are these adequate? Discuss your plan with district fire authorities.

4.13 ANSWERS TO CHECK YOUR PROGRESS

Check Your Progress 1

1) Sub-division C-1 under the main head Group C — Institutional Building

2) • Heat
   • Oxygen
   • Material

3) • Smoking
   • Contractors carelesness
   • Carelessness of hospitasl staff
   • Defective equipment

   Visilors carelessness

4) Grade of lire helps in determining the type of fire extinguishers.

Check Your Progress 2

1) Compartmentation by dividing the building into number of parts ensures that the health and smoke generated as a result of lire remains confined lo place of origin as long period as possible.

2) Fire rating of walls of life should be two hours.

3) No, fire lift should have independent source of power supply.

4) In air conditioning plan room heat sensitive detectors, preferable electro-pneumatic type incorporating fixed temperature as well as rate of rise mechanism should be installed.

5) Recommended:

   BCF extinguisher 1.24 kg. Capacity 2

   CO_2 extinguisher 4.5 kg. Capacity 2

   Dry power 10 kg. Capacity 2

   Extra precaution:

   Trolley mounted Co, extinguisher of 2.5 capacity with long pressurized flexible rubber hose connected with discharge horn.

6) CO, extinguishing syslem.

Prasad, M., "Fire Protection facilities for Health Care Centers", In *Hospital Planning and Designing in Developing Countries,* Academy of Hospital Administration, New Delhi.

Protection to Air-conditioned Portion of the Building

The air- conditioned premises housing sophisticated electronic equipments and computers of laboratories accommodating sensitive instruments should be provided adequate tire coverage envisaging automatic early detection-cum-warning-cum-extinguishing systems

a) **Automatic early detection device:** A combination of detectors comprising of a smoke detector working on ionization principle along with a detector equipped with photo electric cell is considered a suitable device for detection. The detectors would be suitably connected into circuits and zones and further would be coupled lo the warning system. Combination and cross zoning of the detectors to eliminate the chance of false alarm simultaneously to ensure the actuation irrespective of the type of smoke liberated is recommended.

b) **Warning system:**

i) Detection devices, call points, etc. would be coupled to the warning system in a manner that on actuation of a detector, a visual indication would appear near the detector wherever it is installed.

ii) Further in relation to the detector which are installed inside the compartment, a response indicator would be visible being fixed outside the room thereby indicating tlie particular room in which detector has actuated.

iii) A hooter would be coupled in each circuit or each zone, which will indicate the actuation of a particular zone or a circuit in tlie part of the building.

iv) The impulses from the warning system would be fed to zonal panel/central control panel installed at the entry i.e. on the ground floor of each building. In fire conditions it would emit audio-visual alarm depicting the particular circuit or zone which has been actuated.

v) The central panel/zonal panel would be installed at a place which is being manned round the clock.

vi) The signals from the warning system would also be fed lo a repeat panel installed at the fire station so that the Fire Brigade can respond to the scene of fire without loss of time. The repeat panel on receiving the impulses would also cinit audiovisual signals.

vii) Circuit and zone would be coupled to an independent siren installed at top of the building In case of actuation of any detector or manual call point in any of the zone/circuit of a particular building the siren would be of adequate range of at least from 1 to ½ kilo-meter and should emit a sharp note/pitch which should be audible irrespective of noise produced by the general functioning of hospital.

viii) The audio-visual indication given at the repeat panel which is further being supplemented by the sharp note emitted by the siren installed at tiie building is essential to guide the services to the point of occurrence hence no mechanism should be provided at the Fire station lo silence the siren which could only he switched off at the zonal panel.

ix) A smoke detector generally provide coverage to an area or 80 to 90 sq m but in actual practice is restricted to 50 sq m depending upon the situation.

x) Call boxes, manual call stations should also be provided in each room and in the corridors, verandah at a distance of not more than 22.5 m apart. These too would be connected with the warning system through siren/hooter of adequate range, as stated above.

c) **Extinguishing system:** The extinguishing system is generally installed for the rooms accommodating highly sensitive instrumentation. The main features of the system are as follows:

i) A batlery of CO_2 cylinders each of 22.5 kg or 50 kg capacity or equivalent quantum of Halon 1301 should be located at a suitable place outside the room. A pipe should originate from a common main fold connecting the cylinders, and should cover all tlie strategic point of the room. Depending upon the lype of extinguishant used, the discharge horns or nozzles are to be coupled at the terminus of each pipe branched off from the main feeder, so as to cover the entire room. The quantum of extinguishant for total flooding system could be computed at the scale of 33 kg of Halon 1301 for 100 Cu M of volume or. 36 kg of BCF or 51 kg of CO_2 for equal volume. While computing the total quantum of extinguishants due consideration should be given for openings if any within the room.

ii) As the occurrence of false alarm cannot be completely ruled out: hence the automatic flooding system duly coupled with the warning system may not he insisted upon, rather the system should be coupled with a remote control device so that it can be actuated by anyone on sounding of the alarm in case there is a fire or manifestation of flame.

UNIT 1 CASE STUDY/GUIDELINES – NOSOCOMIAL INFECTION

Structure

1.0 OBJECTIVES

After reading this units, you should be able to:

- define nosocomial infection and differentiate it from other types of infection;
- establish the association of nosocomial infection with hospital environment;
- distinguish between hygienic and unhygienic particles in the hospital or your work area;
- explain the potential hazards to patients and health care providers;
- identify the faults and correct them to prevent the infection; and
- explain the role of sound practices in preventing the infection.

1.1 INTRODUCTION

Micro-organisms (microbes) are present everywhere. They are found in air we breathe, water we drink, and the earth we walk on. Similarly the microbes are present in hospital environment. Most of these are harmless and some are harmful. In normal condition the harmful micro-organisms do not effect the patients but due to low body resistance and faulty practices the patients admitted in the hospital may get infection. Thus, hospital in addition to treating the patients also give certain inborn infection to hospitalised patients. The infection occurs due to contamination of air in the ward, the contaminated fomites such as tray, linen and equipment used for patient care such as suction apparatus, endoscope, IV set, oxygen mask, feeding bottles, operation instruments, etc. Nosocomial

(hospital acquired) infection occurs in every hospital beyond doubt but many times it is overlooked. It comes into picture only when it has caused damage out of proportion to the magnitude of relatively minor therapeutic procedure carried out on the patients. Nosocomial infection (hospital acquired infection) is perhaps the single most important factor productivity and performance. It increases'average length of stay and increases total cost of treatment.

1.2 NOSOCOMIAL INFECTION

1.2.1 Definition

Nosocomial infection (hospital acquired infection) can be defined as infection acquired by the patients in the hospital, manifestation of which may occur during hospitalisation (usually after 48 hrs) or after his discharge.' It should not be compared/confused with the infection with which he may have come to the hospital for his treatment. These infections not only effect the hospitalised patients but hospital personnel (health care providers) also. These infections are difficult to treat than the community acquired infection because hospital stains of bacteria are resistant to anti-microbial agents. The common nosocomial infections are post operative wound infection, respiratory tract infection, urinary tract infection and septicemia.

1.2.2 Aetiology and Types

Nosocomial infections occur due to microbes known as Bacteria. These bacteria are present everywhere such as air we breathe, soil we walk on and water we drink, in the hospital environment. In normal condition usually they do not manifest but they manifest quickly when the body resistance is low like admitted patients. The common bacteria responsible for nosocomial infections are:

1)	Post operative wound	–	Stephylococcus aureus
2)	Urinary tract infection	–	E. coli
3)	Septicaemia	–	Pseudomonas
4)	Respiratory tract infection	–	K. pneumonae

1.2.3 Mode of Spread

The nosocomial infections are acquired through "contact". The contact may be due to inhalation of contaminated air or direct,contact with contaminated object.

1.3 DEMONSTRATION OF CASES AND ENVIRONMENTAL CONTAMINATION

1.3.1 Types of Infected Cases

Purpose

In this exercise you will:

a) see the different types of nosocomial infected cases,

b) demonstrate how these infections are developed.

Case 1

A patient of acute dysentery with pain in abdomen was admitted in medical ward. He developed sore throat, pain and fever on fourth day of admission.

Demonstration: The patient developed upper respiratory tract infection (URTI) on fourth day of admission and this was the reason for pain in throat and fever. Throat swab culture shows K. Pneumonae growth. The problem was not at the time of admission but developed after **48** hrs of admission. The problem developed due to contaminated air inhalation in the ward, therefore, it is a nosocomial infection.

Case 2

A patient was admitted for appendicitis and operated on same day. Operation (appendicectomy) was successful and after this he was shifted to' surgical ward. After **48** hours of operation, patient complained of pain at the site of stitches were made and having mild fever.

Demonstration: The operated wound stitched after operation was inspected and found that pus is coming out from stitched area. The area was red and tender. The problem was not at the time of admission as there was no wound. The problem developed in the surgical ward. On culture of pus it shows growth of stephylococcus aureous growth. It shows that either the air of the ward was contaminated or some contaminated object (hand, forceps, scissors) was applied on the wound. Therefore,. it is a nosocomial infection.

Case 3

A patient was admitted in a ward with acute retention of urine. Urinary catheterisation was performed to relief the patient. The patient was relieved from the problem and hospital. But after third day of discharge from hospital he developed fever and burning in micturition and reported back to the same doctor.

'***Demonstration:*** The patient developed fever and burning in micturition after **48** hrs of urinary catheterisation. The problem was due to urinary tract infection. The urine culture shows growth of E. coli. This problem was not at the time of previous admission but developed after **48** hrs of procedure. It shows that the catheterisation was the reason and catheter was contaminated. It is a nosocomial infection.

Demonstration of Environmental Sources of Contamination

Purposes

In this exercise, you will see

- how bacteria spread from your body and surroundings by droplets, hands, air and fomites,
- demonstrate how this can be reduced or prevented by simple hygienic practices e.g., hand washing, disinfection, use of antiseptic agents and sterilization.

Equipment

- Culture plates – blood agar (BA)
- Sterile swab sticks
- Antiseptic agent (70% alcohol)
- Disinfectant solution glutaraldehyde – 2% (Cidex)
- Gloves (sterile)
- Incubator adjusted to 37°C.

Activitiy : Peform the following activities and record your observations

i) Checking *Air Contamination*

Expose sterile BA plates for 1 hr in different parts of a room, incubate for 24-48 hrs at 37 °C, do colony counts and describe the different types of bacteria grown on the plate.

ii) *Spread by Cough*

Cough on a BA plate with lid open kept at a distance of 1 feet, incubate and examine as in (i).

iii) *Use of **Hand** Washing*

Culture hands before and after washing with antiseptic agent, incubate plates and examine as in (i).

iv) *Spread of Infection by Dust*

Collect dust with help of a swab from a patient's bed and culture on BA plate, incubate and examine as in (i).

v) *Use of Disinfectants to **Reduce** Contaminants*

Culture a thermometer after taking temperature in a patient's mouth, dip in disinfectant for 10 mts. Reculture on BA plate, compare results on two plates as in (i).

From the above observations you can conclude that:

- Microbes are present inside and outside the human body.

  They can be transmitted to the patient by oral, respiratory routes or by direct contact.

  Prevention of spread of infection involves hygienic practices.

  Sterilization and disinfection reduce contamination.

1.3.2 Mode of Spread

The nosocomial infections are acquired through "contact". The process of contact can be:

A patient inhales contaminated air. The air comes into the contact of body. URTI is developed,

- A contaminated catheter (unsterile) is used in patient. The urethra comes into contact with contaminated catheter and gets UTI.
- **A** sterile post operative wound comes into contact with hand, forceps or any other contaminated object. The wound is infected.
- **A** patient was injected drug through a contaminated/unsterile needle with syringe. The body comes into contact of contaminated needle and gets infected.
- A contaminated/unsterile endotracheal tube is applied on patient. The lungs come into contact with contaminated tube and get infected.

Above experiments show that the mode of spread of nosocomial infection is **"contact"**. Therefore, if the contact is avoided, the infection can be prevented.

1.4 CONTROL OF INFECTION

Practices **of universal** precaution: Principle of universal precaution is based on the fact that any type of fluid coming out from the body of patient is considered to be infected. Therefore, precautions to be taken in every case whether infected or non-infected.

1.4.1 Hand Washing

Avoid contact by hand washing. Frequent contact with patient body fluid, blood, tissue by hand of the health care provider provide a means of transmission of infection from patient to patient and patient to personnel.

- Hand washing with soap and water under running tap washes the most of the microbes and prevents the spread of pathogen to non-contaminated area.
- Hand washing is the most effective and most economical method of infection control.
- Running water inhibits the growth of microbes (bacteria).
- Hand washing can also be done with anti-microbial agents (e.g. chlorhexidine i.e. savlon and habitant, alcohol). Friction from a brush or vigorously rubbing the hands together removes direct micro-organism.
- Always dry your hands with clean dry towel or air dry.

Fig. 1.1: Hand Washing

1.4.2 Use of Barrier Precautions

Barrier precaution such as gloves, mask, gown should be used by the health care provider while dealing with infected patient. This will further help in preventing the nosocomial infection to other patient.

1.4.3 Waste Disposal

Waste generated from diagnosis, treatment or immunization to be treated first then disposed finally. Detail you will find in Unit 2 of this block.

1.4.4 Use of Disposable Items

Use of disposable (sterilize) to be encouraged so that chances of spreading the infections are minimized.

You should visit the ward and observe that how many hospital employees are really applying the method.

Fig. 1.2: Barrier precaution'

Activities

- Wash the hand with soap and running water before and after examining the patient and generating the waste.
- Put on gloves in hand, face mask before you go for dressing the patient, examining the infected patient.
- Throw the blood/pus soaked cotton, gauze in separate container identified for it i.e. yellow plastic bag.
- After examination generating the waste throw the gloves in identified container (blue/white plastic bag).
- Use the sterile consumables on patients.
- Discard the needle immediately after use by needle destroyer and then put the needle and syringe inside disinfectant for one hour.
- Segregate the waste at source collected in covered container for further disposal.

1.4.5 Disinfection/Aseptic Practices

Many of the substances are used in various procedure carried out on the patient. To prevent the nosocomial infection, these substances should be disinfected or sterilized. Therefore, it is very essential to confirm the sterility of the material. Many of the times same substance/appliance/equipment is used on many patients. Therefore, here we have to confirm that the substance/appliance/equipment is properly sterilized before used for second patient. The common sterilization methods are:

a) Chemical Method

Chemical agents destroy only pathogenic organism on or in an object. The process of destroying the pathogen is called "disinfection" and the object is said to be disinfected. The chemical used for lifeless objects is called disinfectant (formaline, chlorine, carbolic acid, gluteral dehyde) and if the same is used for living object (tissue of human body) the chemical is called antiseptic (ethyl alcohol, iodine, gention violet)..

Common Chemicals Used for Disinfection

Class	Example
I) Phenol and cresol	Lyson, settel
2) Alcohol	Ethyl alcohol (spirit)
3) Halogen	Iodine, chlorine compound
4) Aldehyde	Formaline
5) Dye	Gention violet
6) Acid	Boric acid, carbolic acid
7) Gas	Ethyline oxide
8) Oxidising agent	Hydrogen peroxide
9) Surface active agents	Soap

The effectiveness of these chemical disinfectants depends upon:

i) Concentration of the disinfectant

ii) The number – type and location of organism

iii) The temperature and pH of treatment

iv) Time of contact with chemical

Some of the substances used are exposed to disinfection. These are laringoscope, endoscope, colonoscope, urinary catheters, nasogastric tubes, endotracheal tube etc. Different chemicals are used for different substances.

- Ethylene oxide a volatile and explosive chemical is rarely used for disinfection/sterilization for the substances which melts at temperature greater than 100°C. The examples are plastic materials i.e. catheter gloves, syringe, etc.
- To disinfect sharp instruments, endoscope, cystoscope, use gluteraldehyde (2%) or carbolic acid (5%).
- To disinfect cheattle forceps we use chlorhexamide (5%) + citramide (savlon)

You should visit the Operation Theatre, Intensive Care Unit, Ward, OPD and observe that how these chemicals are used for disinfection of various items and record your findings.

Activities: Peform the following activities.

Take large covered container depending upon size, flexibility of the equipment,

Equipment to be sterilized : Endoscope; Urinary catheter; Nasogastric tube; Endotracheal tube; PCNL endoscope.

- Wash the equipment thoroughly.
- Fill up the container with chemical (gluteraldehyde 2% – cidex) to the level that the equipment is completely merged in the chemical.
- Cover the container and leave for 2 hours.
- Take out the equipment after 2 hours and wash with sterile water or saline.
- Now it is sterilized and you can use it.

b) **Sterilization**

Heat (Dry and Moist)

- **Dry** heat such as hot air oven on incineration denatures enzymes, dehydrates microbes, and kills by oxidation effect. A standard application of dry heat in a hot air oven is 170°C for 2 hours. It is used for dry sterilization of glass wares such as.glass syringe, pipette, test tube, blunt instruments.
- Incineration is used in hospitals for destroying infected swabs dressing, operated materials, laboratory materials, bedding, etc.
- Direct flaming is used to sterilize inoculating loop in microbiology laboratory. In emergency direct flaming is used to sterilize needle and blades.
- Moist heat is used in pasturization, boiling and autoclaving.
- "Autoclaving" is most effective method of moist heat sterilization using steam under pressure. Increased pressure raises the boiling point of water and produces steam with higher temperature., The standard conditions for autoclaving are 15 pounds per square inch, 121°C for 15 minutes. The process also kills the endospore and makes material sterile. In modem hospital, autoclaver (sterilizers) are available in operation theatre (TSSU) and Central Sterile Supplies Department (CSSD). Autoclave is preferred for material made of cotton (gauze, sandoge, drops, linen, etc.) and blunt instrument. It is not ideal for material made of plastic and rubber.

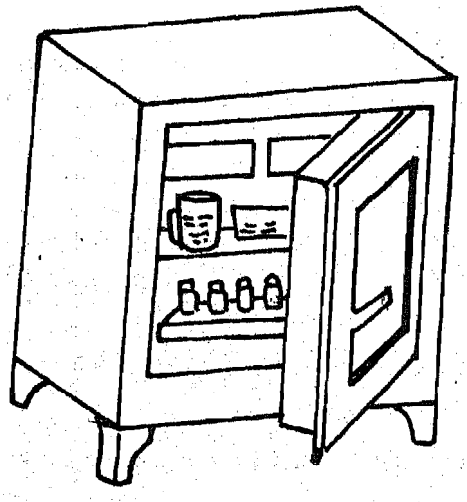

Fig. 1.3: Hot Air Oven

Activities: Perform the following activities.

Materials to be sterilized : Gauze, cotton, linen, glass syringe, blunt instrument, etc.

Clean and wash the material to be sterilized.

- Wrap the cotton/gauze piece in a perforated drum. **A** chemical indicator of sterilization is sticked on the top of material.
- Place the material on perforated stand or diaphragm after adjusting water level the autoclave is switched on.
- The lid is kept in position and is closed tightly by means of screw clamps. .
- The steam valve is kept open until all air is expelled out and only steam comes out.
- Steam valve is then closed so that pressure begins to rise. As the pressure rises, temperature also rises accordingly. When the pressure is 15 lbslsq. inch i.e. temperature is 121^{0}C, the time is noted as zero time. Automatic steam release valve maintains the pressure at pre-adjusted valve. In this case 15 lbs/sq. inch.
- After 20 minutes the autoclave is switched off and is allowed to cool down. When pressure gauge indicates zero pressure, the steam valve is opened and the autoclave can be opened and all sterilized materials are removed and dried.
- The efficiency of the sterilization can be checked by temperature, pressure and time taken, change in colour in chemical sticker and incubating the media at 37^{0}C in an incubator for 24 hours. If growth is observed then autoclaving has not been carried out properly. Repeat the same process.

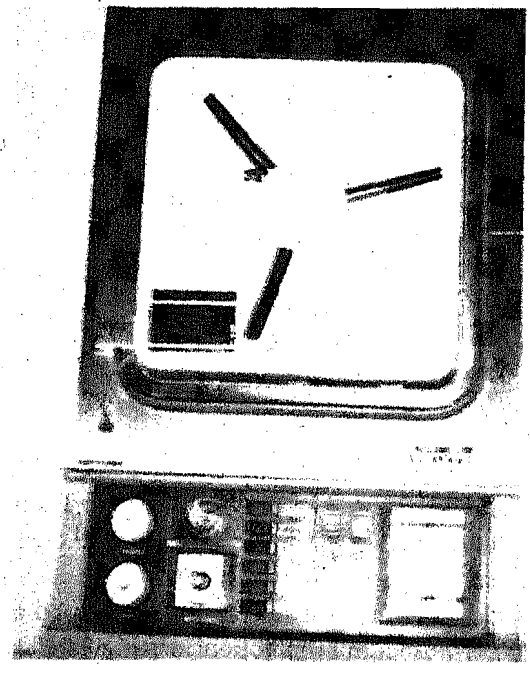

Fig. 1.4: Autoclaving Machine

1.4.6 Waste Disposal Practices

All waste generated in the hospital is not infective. It is only 10% of the waste generated is infective. Sound practices for infected waste disposal minimizes the chances of nosocomial infection. Infected waste is potential hazard to patients,

health care providers and public. The proper disposal of waste can be achieved by applying Biomedical Waste (Management and Handling) Rules, 1998, Ministry of Forest and Environment, Govt. of India. Rules say segregation is the essence of effective waste management. Based on above the biohazardous (biomedical waste) has been categorized into ten categories. Accordingly they have identified five types of coloured heavy-duty polythene for collection of waste. The treatment and final disposal of waste is also done based on the category. You will learn more about Hospital waste disposal in Unit 2 of this block,

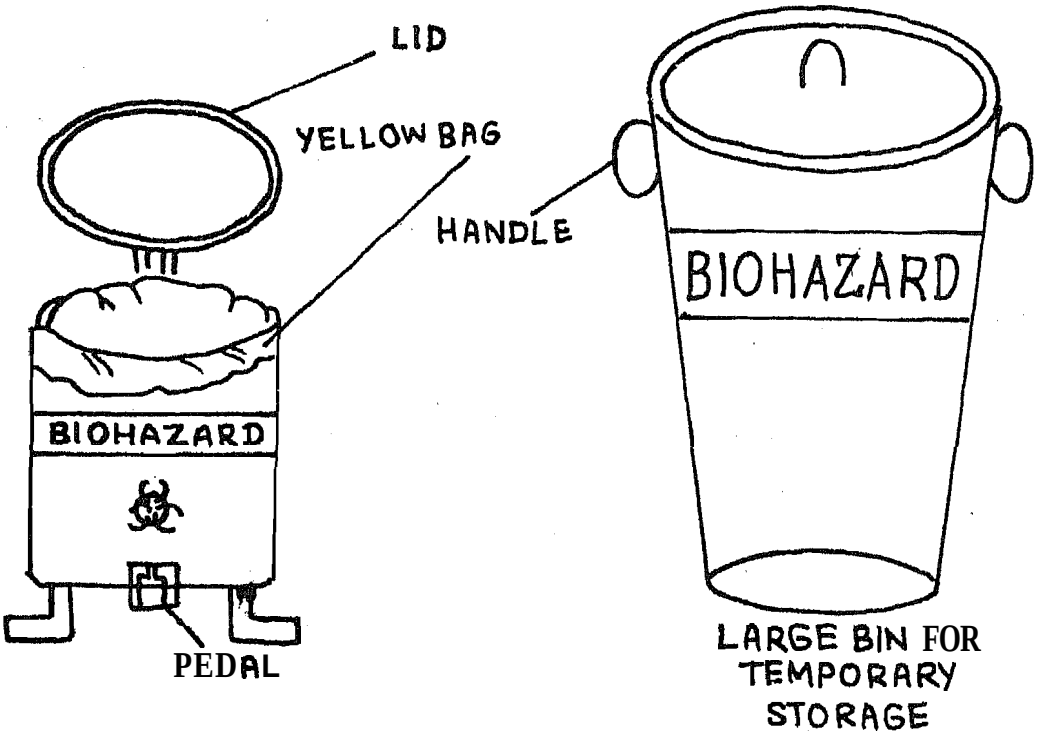

Fig. 1.5: Container for Infectious Waste

1.4.7 Health Education and Training for Health Care Providers

As you have learnt that the health care providers are responsible for nosocomial infection. The mode of spread of infection is contact. The contact can be in many ways as illustrated in sub-section 1.2.3 & **2.3.2** of this block. It is imperative to educate the health care providers about the infection, its spread, complication. The health care providers must be trained to follow the proper sterilization and hospital waste disposal practices.

1.4.8 Hospital Infection Control Committee (HICC)

The administrative control of nosocomial infection can be achieved by the Hospital Infection Control Committee. Every hospital should have HICC. The HICC includes various disciplines such as administrator (Medical Superintendent) Surgical, Medical, Laboratory, Sanitation, Sterilization, etc. The infection control nurse coordinates and monitors the patients, environment and laboratory function. **A** constant surveillance of nosocomial infection in patients should be done. Drug policy should be laid down on antimicrobial susceptibility patterns of pathogenic bacteria encountered in infection diseases in the hospital patient from time to time. Standardization of disinfection and cleaning procedure and continuous implementation and training of personnel is very important to minimize the infection rate. You as an administrator have a very important role to play in prevention of nosocomial infection.

1.5 LET US SUM UP

In this unit of practical manual you have learnt that nosocomial infections are acquired infections in the hospital and, therefore, hospital is responsible for its prevention and control.

You have also learnt that nosocomial infection increases average length of stay and at the same time also increases the cost of treatment. Moreover, nosocomial infections are difficult to treat as most of them have resistant strain. Health education and training programme of Health care providers have paramount role in prevention of these infections.

Further you have learnt that the only mode of spread of infections' is contact and therefore, avoiding the contaminated object in the patient's body is the essence of prevention of infection. The control of micro-organism by disinfection and sterilization is an essential factor in maintaining good health of patients.

Autoclave and chemical disinfections are commonly used practices for disinfection. At the same time sound hospital waste management also plays role in control of infection.

Towards the end you learnt that Hospital Infection Control Committee is responsible for prevention and control of nosocomial infection.

In this unit, Practical Manual you have also performed various activities to gain proficiency in prevention and control of nosocomial infections.

UNIT 2 GUIDELINES FOR WASTE DISPOSAL IN HOSPITAL

Structure

2.0 OBJECTIVES

After completing this unit, you should be able to:

- identify the types of waste generated in the hospital and segregate the biomedical waste from rest of the waste;
- make understand for rationale for hospital waste disposal and potential hazards involved in improper waste disposal;
- explain the process of generation, segregation, transportation, treatment and final disposal of waste and technology involved in the process; and
- based on above to develop the sound practices of hospital waste disposal.

2.1 INTRODUCTION

Since beginning, the hospitals are known for the treatment of sick persons but the secret of these places which throw the adverse effect on human body and environment remained hidden till now. Now it is a well established fact that there

are many adverse harmful effects to the environment including human being which are caused by the hospitals. The secret of cause is the "Hospital Waste" generated while delivering the patient care. Hospital waste is a potential health hazard to the health care worker, public, and flora and fauna of the area. Disposal off hospital waste was witnessed by the health care providers and the common public but merely taken as a filthy and unwanted product. Discovery of hospital acquired infection, transfusion transmitted diseases, rising incidence of Hepatitis B and HIV, increasing land and water pollution leading to increase the possibility of many diseases, air pollution due to emission of hazardous gases by incinerator such as furan, dioxin, hydrochloric, etc. have compelled the authorities to think seriously about hospital waste and the diseases transmitted through improper disposal off hospital waste. The thrust area has now become a threat for the public health and ultimately the Central Government had to intervene for proper handling and disposal off hospital waste and passed an act in July, 1996 and made Biomedical Waste (Handling and Management) Rule in 1998.

A modern hospital is a complex, multidisciplinary systein which consumes thousands of items for delivery of medical care and is a part of physical environment. All these products consumed in the hospital leave some unusable leftover i.e. hospital waste. The last century witnessed the rapid mushrooming of hospital in the public and private sector, dictated by the needs of expanding population and advent and acceptance of "disposable" has made the generation of hospital waste a significant factor in today's hospitals.

2.2 HOSPITAL WASTE

2.2.1 What is Hospital Waste

Hospital waste refers to all waste generated, discarded and not intended for further use in the hospital.

2.2.2 Types of Hospital Waste

a) **General waste:** It is. like household waste, e.g. paper, plastic, rappers etc.

b) **Pathological waste:** It contains tissue, organ, body part, blood etc.

c) **Infectious waste** which could cause tlie infection, e.g. culture stock, waste from laboratory, surgery and infectious patient.

d) **Sharps** which could cause cut or puncture e.g. needle, scalpel, saw, glass, blade etc.

e) **Pharmacological waste:** Example, unused or discarded drug, chemical etc.

f) **Chemical waste:** Solid, liquid and gaseous chemical, e.g. cleaning, house keeping disinfecting product.

g) **Radio active waste:** Solid, liquid and gaseous waste that is contaminated with radio nuclides.

2.2.3 Amount and Composition

In India the amount of hospital waste generated ranges between 1.5 kg–2 kg/ bed/day.

Composition

a) Non Hazardous 85%

b) Hazardous 15%

1) Hazardous but not infective 5%

2) Hazardous and infective 10%

2.2.4 Biomedical Waste

Any solid, fluid and liquid waste including it's container and any intermediate product which is generated during the diagnosis, treatment or immunization of human being or animal in research pertaining thereto, or in the production or testing of biological and the animal waste from slaughter houses or any other like establishments. All biomedical waste is hazardous.

Classification of Biomedical Waste (as per Biomedical Waste Management and Handling Rules, 1998)

Categories of Blotnedical Wastes

Option	Waste Category Waste Class	Treatment and Disposal
Category 1	Human Anatomy Wastes (Human tissues, body parts)	Incineration deep burial*
Category 2	Animal Wastes (Animal tissues, organs, body parts, carcasses, bleeding parts, fluid, blood and experimental animals used in research, waste generated by veterinary hospitals, discharge from hospitals, animals houses)	Incineration deep burial*
Category 3	Microbiology and Biotechnology Waste (Waste from laboratory culture, stocks or specimens of micro-organisms live or attenuated vaccines, human and animal cell culture used in research and infectious agents from research and industrial laboratories, wastes from production of biologicals, toxins, dishes and devices used for transfer of cultures)	Local autoclaving/micro-waving/incineration
Category 4	Waste Sharps (Needles, syringes, scalpels, blades, glass etc. that may cause puncture and cuts. This includes both used and unused sharps)	Disinfection (chemical treatment autoclaving/ micro-waving and mutilation/ shredding

Option	Waste Category Waste Class	Treatment and Disposal
Category 5	Discarded Medicines and Cytotoxic drugs (Wastes comprising outdated, contaminated and discarded medicines)	Incineration/destruction and drugs disposal in secured landfills.
Category 6	Solid Waste (Items contaminated blood and body fluids including cotton, dressing, soiled plaster casts, lines bedding, other material contaminated with blood)	Incineration Autoclaving/microwaving
Category 7	Solid Waste (Waste generated from disposable items other than the waste sharps such as tubing, catheters, IV sets etc.)	Disinfection by chemical treatment and autoclaving/ microwaving/shredding
Category 8	Liquid Waste (Waste generated from laboratory and washing, cleaning, house-keeping and disinfecting activities)	Disinfection by chemical treatment and discharged into drain
Category 9	Incineration Ash (Ash from incineration of any biomedical waste)	Disposal in municipal landfill.
Category 10	Chemical Waste (Chemical used in production of biologicals, chemicals used in disinfection, as insecticides etc.)	Chemical treatment and discharge into drains for liquid and secured landfill for solids.

Colour Coding and Type of Container for Disposal of Biomedical Wastes

Colour Coding	Type of Container	Waste Cntqory	Treatment Option
Yellow	Plastic bag	Cat. 1, Cat. 2, Cat. 3 and Cat. 6	Incineration/deep burial
Red	Disinfected container/plastic bag	Cat. 3, Cat. 6, Cat. 7	Autoclaving/Microwaving/ chemical treatment
Blue/White	Plastic bag/ puncture proof container	Cat. 4, Cat. 7	Autoclaving/Microwaving/ chemical treatment and destruction/shredding
Black	Plastic bag	Cat. 5 and Cat. 9 and Cat. 10 (solid)	Disposal in secured landfill

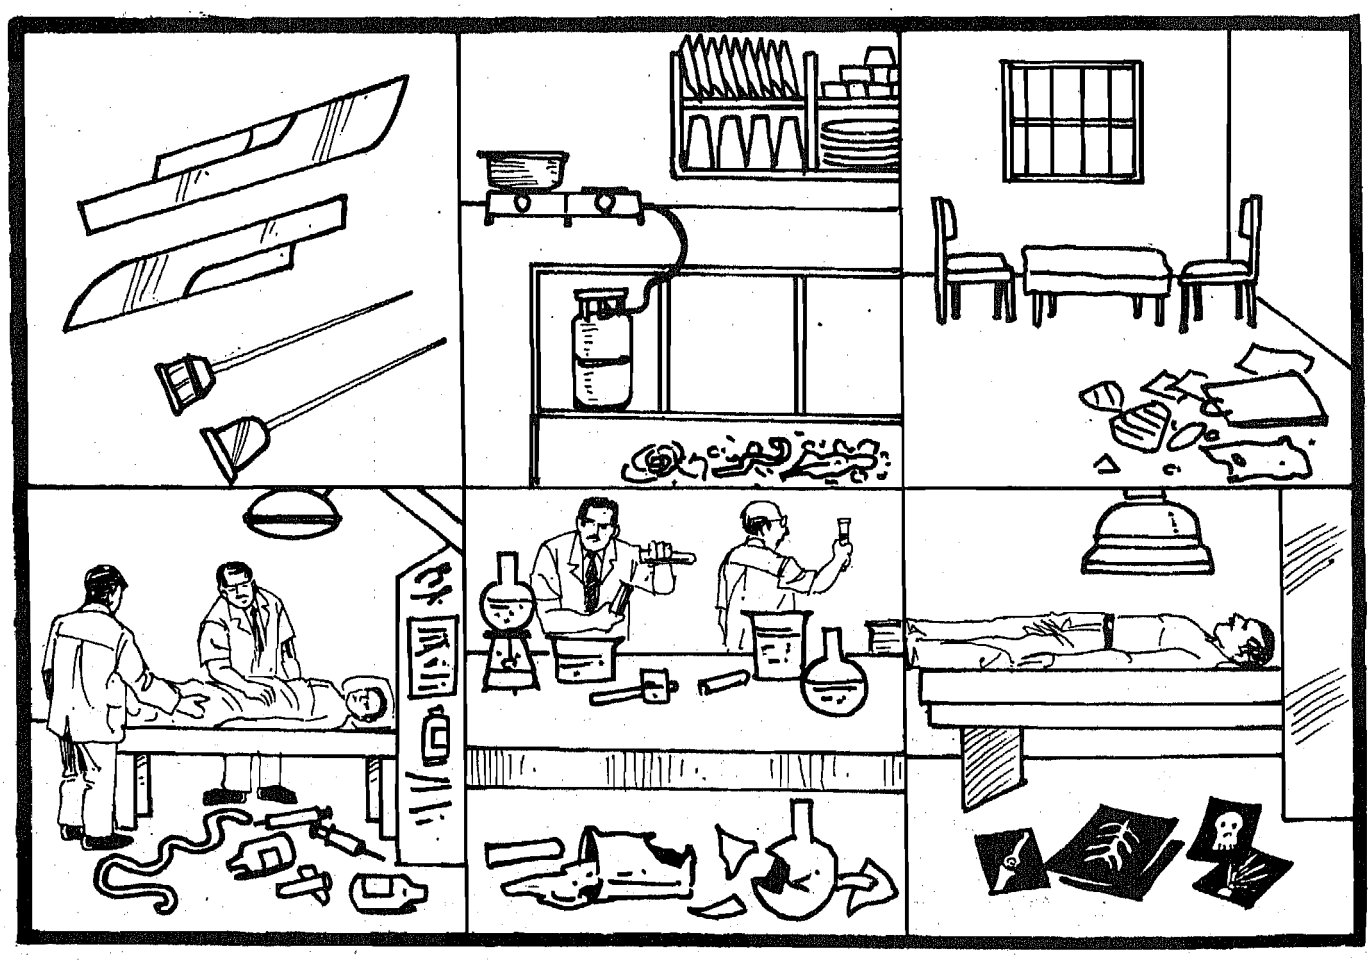

Fig. 2.1: Hospital Waste and Source of Generation

2.3 RATIONALE FOR WASTE DISPOSAL

2.3.1 Patients and Hospital Acquired Infections (Nosocomial Infection)

In last unit you have already learnt that nosocomial infections are developed in some of the patients due to hospitalisation. Infectious waste is one of the reasons for. it. In addition to post operative wound infection, URI, UTI, there are more and more chances of developing HIV, Hepatitis B, etc. diseases. The hazardous waste is a potential reservoir of the infection and diseases in patients are transmitted through it.

2.3.2 Health Care Providers at Risk

In addition to patients, health care providers such as doctor, nurse, patient helper, technician, and sweepers are also exposed to develop many diseases including nosocomial infection if the waste is not properly handled and disposed. The other hazards are body injury, chemical burn, etc.

2.3.3 Population at Risk

Hospital waste without proper treatment if thrown in open area is also hazardous for the population in the vicinity. Ragpickers are mostly exposed to the diseases such as HIV and Hepatitis B.

2.3.4 Environmental Pollution and Hazards

Now it is well-established fact that there are many adverse harmful effects to the environment including human being which can be caused by hospital waste. It causes environmental pollution and'effect man, animal, flora and fauna of the area. Air pollution due to emission of hazardous gases by incinerator, e.g. dioxin, furan, hydrochloric acid are very common. Environmental pollution includes air, water and soil contamination.

2.4 DEMONSTRATION OF WASTE GENERATION

A hospital consumes thousands of items for delivery of medical care. All those items leave some unusable leftovers. During the health care delivery, some products of the body such as blood, tissue, organ, pus, etc. are released which also become part of waste. Different types of waste are generated from different types of treatment and procedure. Here we will see that how the waste is generated in different areas of the hospital,

2.4.1 Visit to Ward

The following are the waste generated in ward:

- Leftover food
- Leftover drug
- Rappers of drug, syringe and edible items
- Bark of fruits—such as orange, banana etc.
- Needle and plastic syringe after use
- Dressing material after use (pus or blood soaked)
- IV canula, IV set and IV bottle pack
- Blood bottle pack and BT set

- Plaster material removed
- Chemical such as savlon, spirit, betadine used during dressing
- Disposable gloves, catheter and other tubes
- Used paper

2.4.2 Visit to Intensive Care Unit (ICU) and Operation Theatres (OTs)

During your visit to ICU and OT, you will observe that following wastes are generated.

- Leftover drugs and chemicals
- Rappers of drug, syringe and other consumable items:
- Needle and syringe and other types of consumable after use.
- Blood, tissue, body organ taken out during operation.
- Sponge and other items used for soaking.
- IV canula, IV set and IV bottle.
- Blood bottle and BT set.
- Chemical such as savlon, spirit, betadine, iodine used during dressing.
- Disposable syringe, gloves, face mask, cap, catheter and other items.
- Broken vials, ampule, blades, scalpels etc.

2.4.3 Visit to Laboratory

In the laboratory set-up following wastes are generated.

- Chemical, reagent, culture media used during experiment.
- Gloves, face mask used.
- Syringe, needle after use.
- Rappers of vials, ampule, bottles.
- Container used for sample collection.

2.4.4 Visit to Areas where Radioactive Material is Used

You will notice following waste material where you visit to areas radioactive material.

- Vials, bottles, syringes used for keeping and using the radioactive material.
- Gloves, syringe, needle, face mask etc.

2.4.5 Visit to Other Areas

In other areas you will find following wastes materials.

a) Kitchen
   - Leftover food

b) Blood bank
   - Syringe and needle after use
   - Blood used for testing
   - Gloves, face mask
   - Rappers of disposables
   - Paper

c) Sample collection centre
   - Needle, syringe after use
   - Rappers of the consumables
   - Cotton swab after use
   - Drop out blood, CSF etc.

d) Medical store
   - Drug and chemical rapper
   - Carton, used bottles

e) Laundry
   - Unusable linen

f) Animal house
   - Used animal
   - Blood
   - Gloves, syringe, chemical used
   - Sharps.

2.5 DEMONSTRATION OF SAFE DISPOSAL

2.5.1 Segregation and Container

Biomedical waste (hazardous) consists of approximately 15% of total waste generated in the hospital. Rest 85% waste is non-hazardous. But infact, usually the segregation of the waste is not done at the source of generation and all waste is mixed up. Therefore, the complete waste becomes Hazardous. Segregation is the essence of waste management. Biomedical Waste (Management and handling) Rules, 1998 has described 10 types of biomedical waste and different types of containers for segregation, collection and transportation of biomedical waste.

Demonstration – Biomedical waste

1) **Surgical Ward**

In surgical ward you will find many post operative patients. The dressing of the wound is done periodically. During the dressing of the patient following waste is generated:

a) Removed gauze and cotton soaked with discharge or blood or both.

b) While cleaning the wound some of the chemical/antiseptic solution used.

c) Gauze and cotton used for cleaning the wound.

d) Gloves used during cleaning the wound.

e) Wound debridement was also done and tissue taken out.

Analysis

As per Biomedical Waste Management and Handling Rule following category of waste is generdted and to be segregated and collected in different coloured containers.

Waste	Category	Container
Blood/pus soaked cotton gauze	Solid waste (Biomedical)	Yellow/Red plastic bag
Chemical/antiseptic solution	Chemical waste	Diluted and drained
Gauze/cotton used for cleaning the wound	Solid waste (Biomedical)	Yellow/red plastic bag
Gloves used for dressing	Solid waste (Plastic)	Blue/white
Tissue	Human Anatomical waste	Yellow plastic bag
Scalpel used	Sharp	Puncture proof container

Opinion

a) Yellow, red, blue and white coloured plastic bags are required for collection of different types of waste.

b) Waste should be segregated in different types of bags at the time of generation.

2) Blood Collection Centre and Laboratory.

You will find following types of waste generated in this area:

a) Gauzelcotton used for applying the antiseptic on body.

b) Syringe and needle used for drawing the blood.

c) Blood drops fall down on table etc.

d) Chemical discarded after testing the blood.

e) Gloves used in drawing and processing the blood.

f) Rapper of the syringe/needle.

Analysis

As per Biomedical Waste (Management and Handling) Rules, 1998, following types of waste is generated and to be segregated and collected in different types of containers.

Waste	Category	Container
Cotton/Gauze applied	Solid waste	Black Plastic bag
Needle used	Sharps	Puncture proof container
Syringe and gloves used	Solid waste (Plastic)	Blue/white bags
Blood and tissue–Human	Anatomical waste	Yellow plastic bag
Chemical discarded	Liquid waste	Diluted and drained
Rappers of syringe/needle	General waste	Black

Opinion

a) Yellow, red, blue, white, black plastic bags and puncture proof container are required for segregation and collection of different types of waste.

b) Before collecting the waste it should be segregated in different types of containers at the time of generation.

3) Operation Theatre

When you visit the operation theatre, you will find the following types of waste:

a) Gauzelcotton and chemical/antiseptic used for part preparation

b) Fresh blood and blood soaked sponges

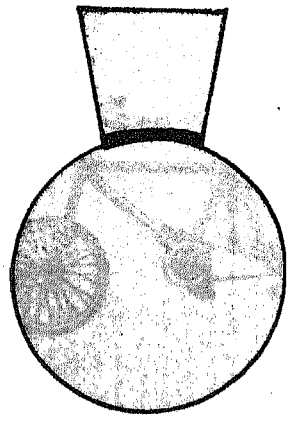
c) Body part/tissue removed during operation

d) Gloves, face mask, cap (disposable)
e) **Needle,** syringe, blades, scalpel, broken ampule used
f) Rappers of needle, syringe, drugs and other consumables
g) IV canula, IV* and BT set and bottles.

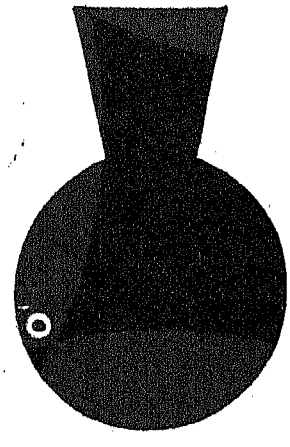
Analysis

As per Biomedical Waste (Management and Handling) Rules, 1998 you will find following category of waste generated and to be segregated and collected in different types of containers.

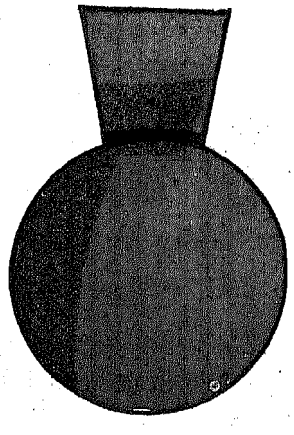
Waste	Category	Container
Gauze/cotton used	Solid waste	Black plastic bag
Blood, body part/Tissue	Human Anatomical waste	Yellow plastic bag
Gloves, syringe, Canula, IV and BT set and bottle	Solid waste (Plastic)	Blue/white bag
Needle, blade, scalpel, broken ampoule	Sharp waste	Puncture proof container
Rappers of needle, Syringe, drugs	Domestic waste	Black.



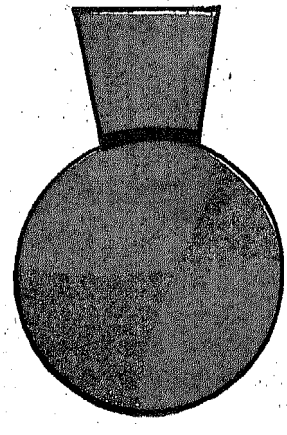
infectious Non-Sharp?Waste **(Incineration)***



Incineration Ash, Solid Chemical Waste (Secured **Landfill)**



Plastic & Sharps **(Autoclave/Chemical/** hlicrowave, Shred, Recycle or Landfill



Infectious Non-Sharp Waste (Autoclave/Chemlcal/Mlcrowave, Landfill)

Fig. 22: **Colour** Coding of Waste Bags

a) Yellow, red, blue, white and black plastic bags and puncture proof containers are required for segregation and collection of different types of waste.

b) Waste should be segregated at the time of generation.

2.5.2 Transportation

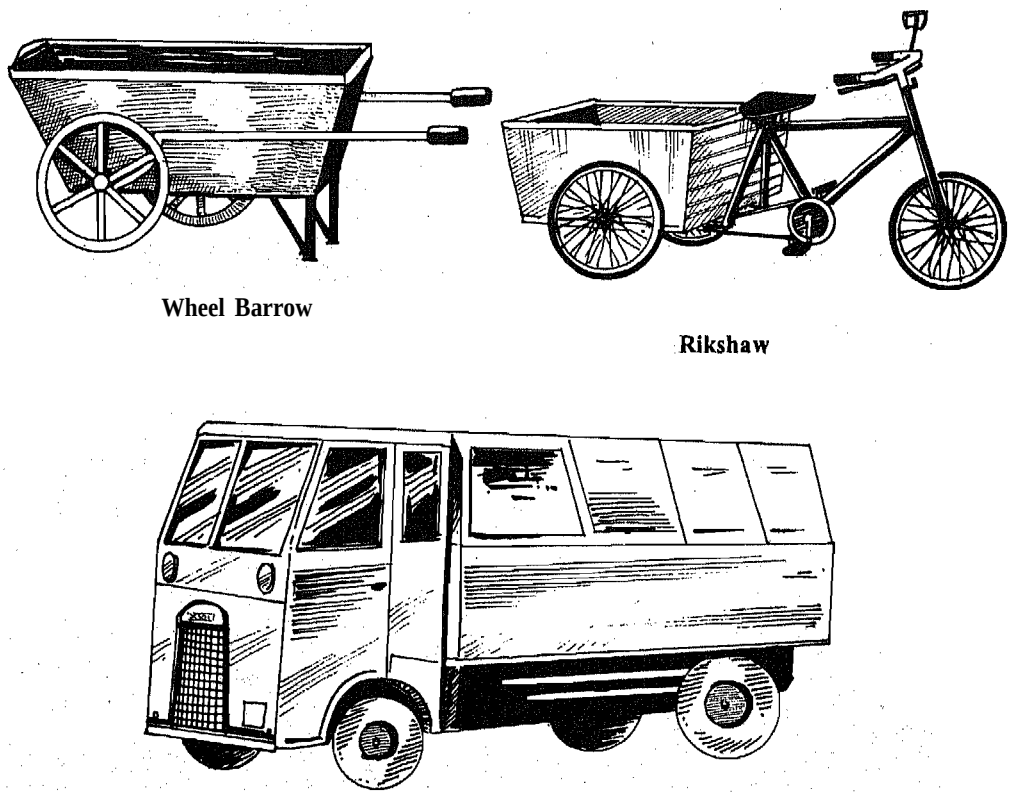
You have observed that how the different types of biomedical waste is generated, segregated at the source. The segregated waste in different plastic bags/puncture proof container is now collected by the person identified in same coloured large container. Each container is thoroughly closed and levelled for cytotoxic and bio-hazardous identification.

The transportation of the collected waste will now be transported by a central team of identified. Following are the pre-requisite for transportation:

a) The waste transportation route must be designated and avoid the passage of waste through patient care area.

b) Biomedical waste and general waste should be collected and transported separately.

c) Dedicated wheeled container trolley or cart should be used and these should be cleaned and disinfected after use.



Wheel Barrow

Rikshaw

Fig. 2.3: Transportation

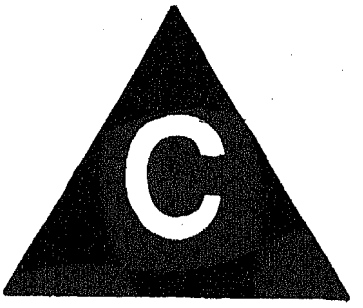
d) Transportation of waste for longer distance should be done in dedicated vehicle.

e) All efforts to be done to prevent pilferage, spilage and transmission of infection.

Biohazard Symbol

Biohazard

Cytotoxic Hazard Symbol



Cytotoxic

Fig. 2.4: Handle with Care

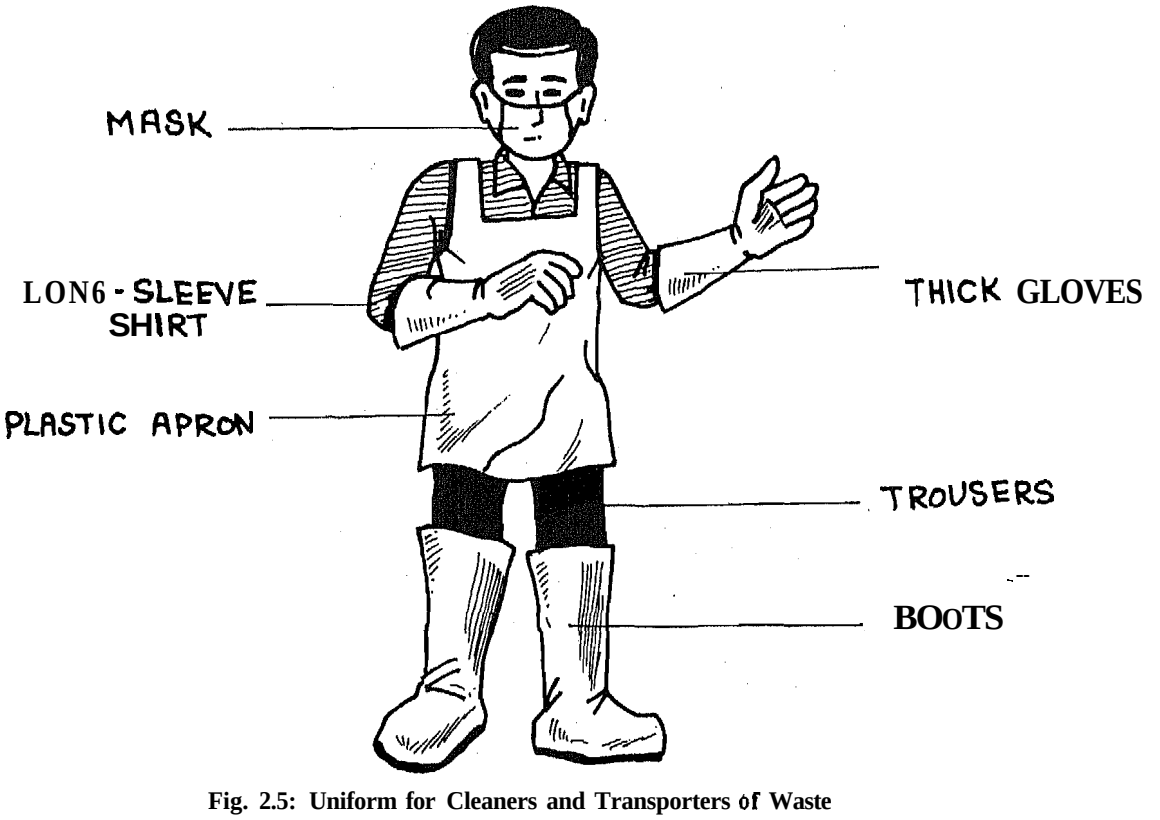


Fig. 2.5: Uniform for Cleaners and Transporters of Waste

2.5.3 Treatment and Disposal

You should know, before the final disposal of hospital waste, the treatment required for biomedical waste. The general waste (85%) does not require any treatment. This can be taken away by the local authority, rest 15% of hospital waste (biomedical) requires treatment. The objectives of treatment are:

a) to disinfect the waste so that it is no longer the source of infection

b) to reduce the volume of the waste for aesthetic reason.

c) to make recycle items usable.

You have learnt that there are 10 categories of biomedical waste. Among all, the sharp category is very important. You must have observed that needle prick is very common to staff nurse or technician while they recap the used syringe.

Similarly broken ampoule, scalpel, blades are also likely to harm the body if not properly disposed. In view of potential hazard to doctor, nurses, technician etc., it will be safe if these sharps are disinfected and destroyed at the time of generation, of waste (immediately after use). Watch how this can be possible.

a) Take the syringe and needle for injection purpose or drawing the blood.

b) Use the gloves and face mask before procedure is started.

c) Once work is over, do not detach the needle from syringe and do not try to recap the needle.

d) Put the needle inside needle destroyer and cut the sharpened end and thereafter put the complete structure in disinfectant.

e) If needle destroyer is not available put the needle with syringe in the container of disinfectant.

f) Leave the needle and syringe for 30-45 minutes and collect.

g) Now the complete structure is disinfected and is no longer a biological hazard.

h) The disinfectant used for disinfecting can be of any following types because most of the bacteria and virus including HIV are killed.

1) 2% Gluteraldehyde solution
2) 1% solution of hypochlorite solution
3) 95% solution of ethyl alcohol
4) 3% solution of hydrogen per oxide
5) 5% solution of formaldehyde
6) 0.5% solution of lysol
7) Bioling

The rest of the biomedical waste is treated with following ways.

1) Autoclave and Microwave Treatment

In previous unit you have learnt that how the autoclave functions. The same principle is applied here. The principle is that some category of the waste should be autoclaved first and make it disinfected then send for final disposal. Waste category 1, 2, 3, 4, 6, 7 should be treated by this method.

Microwaving and hydroclaving are advance methods of sterilization of the waste.

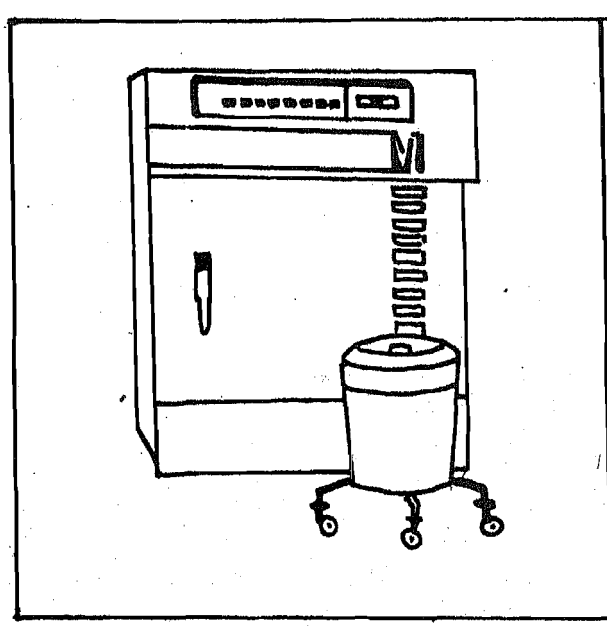

Fig. 2,6 (a): Microwave

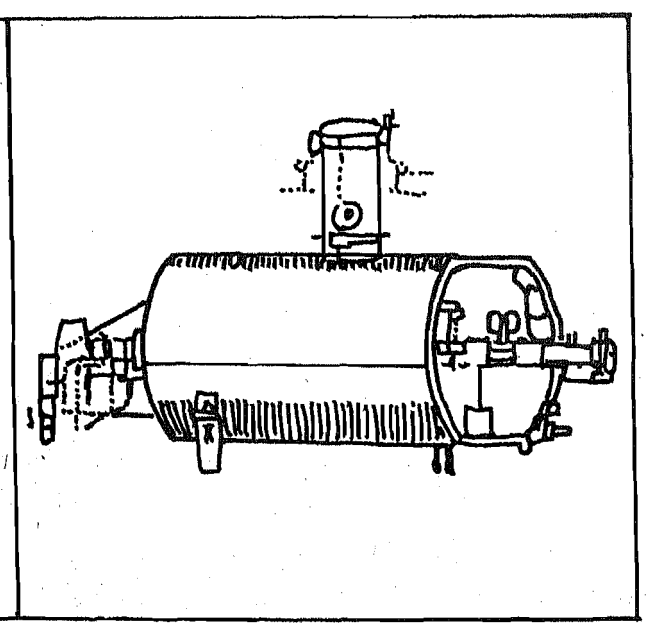

Fig. 2.6 (b): Hydroclave

2) Deep Burial

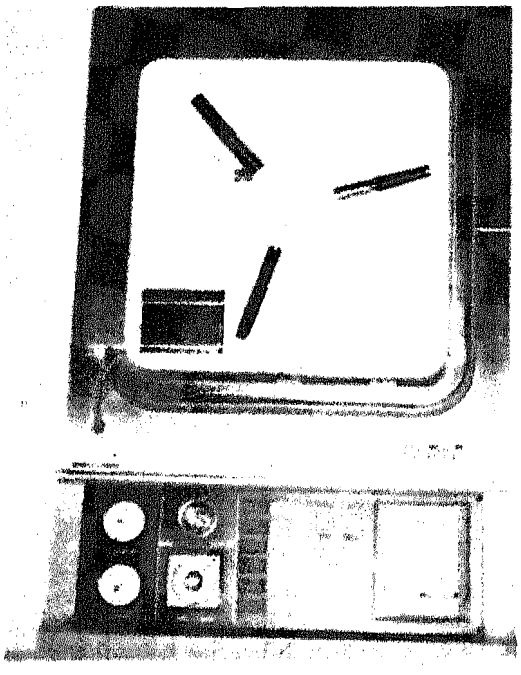
Certain waste like category 1, 2 after autoclaving should be disposed by deep burial to avoid the access of man and animal. Similarly waste sharp,should be disposed. This process can be applied in the cities where population is less than 5 lakh.

3) Land Filling

Waste like category 3, 4, 6, 7 after autoclaving can be used for land filling of low lying area. General waste can also be used for this purpose. Secured land filling is required for incinerator ash, discarded medicine, cytotoxic substances of solid chemical waste.

4) Shredding

The plastic materials such as IV canula, IV/BT set, bottle and other types of plastic can be shredded after disinfection or autoclaving. The plastic can be sold for reuse because now it is safe (non-infected),



Pig. 2.6(c): Autoclaving Machine

5) Incineration

The waste category 1, 2, 3, 5 can be incinerated. It is very often seen that all category waste is just thrown inside the incinerator but it is not correct. Incinerators are of many kind but diesel operated (oil fired) is the best one. They generate the desired temperature for combustion and also are cost effective

The incinerator should meet the standards for combustion efficiency, emission and ash as laid down by pollution control board. The desired temperature of primary and secondary chamber are 800°C (± 50°C) and 1050°C (± 50°C) respectively.

The incinerator is very harmful if it does not meet the criterias. Gases like furan, dioxin, hydrogen chloride are emitted and are very harmful to the human population. They are carcinogenic and effect the lungs. The environmental pollution is very common.

Demonstration

- Identify the waste to be incinerated i.e. category 1, 2, 3, 5, 6
- Put all together in cart, wheel barrow, trolley and bring to the incinerator.
- Put all waste inside the incinerator depending upon capacity and close the door.
- Start the burners of primary chamber.

  Measure and monitor the temperature of primary and secondary chamber.
- Watch the smoke coming out of stake, if it is thick black, it shows that the combustion is incomplete.
- After desired hours take out the incinerator ash.

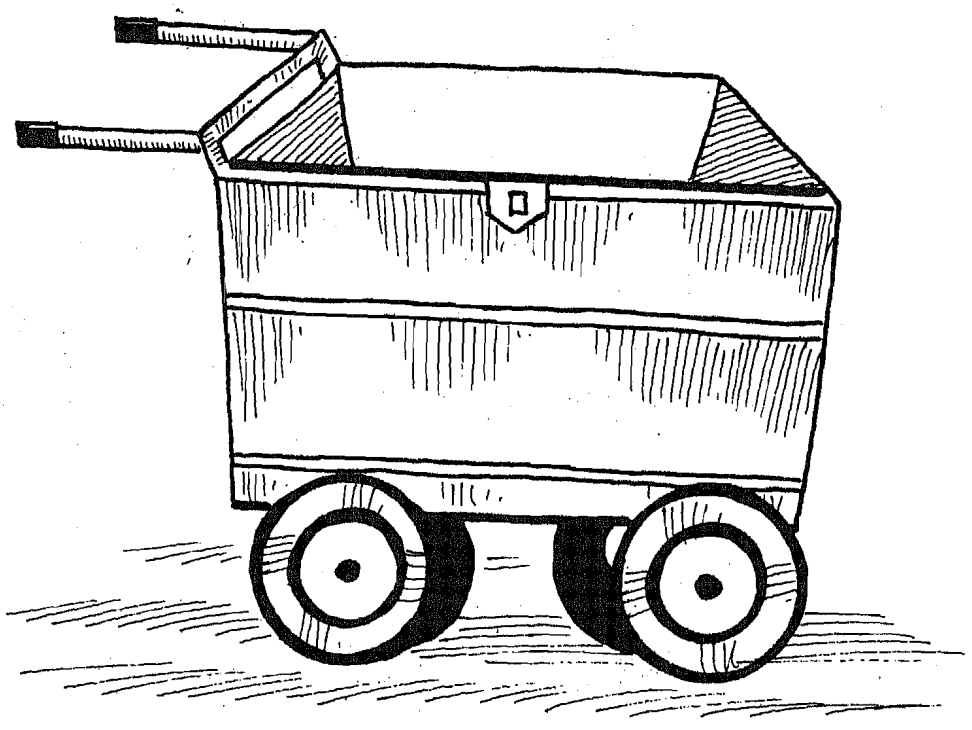


Fig. 2.8: Troiley for Transporting Hospital Waste

- Periodical inspection of the incinerator should be done for the following:
  a) Incineration ash
  b) Gases coming out from stake
  c) Material to be incinerated.
- The ash is to be land filled properly. Now you can understand that the incineration is quite different from the burning. Incineration process kills all bacteria and reduces the volume to negligible quantity (ash).

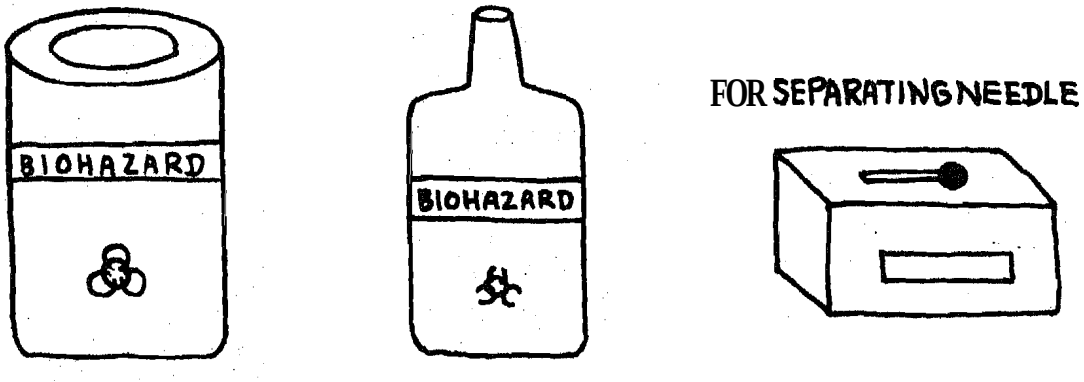

Fig. 2.9: Containers for Needles, Surgical Blades

2.6 EDUCATION, TWINING AND SAFETY MEASURES

Each and every hospital must have well planned awareness and training programme for all category of personnel including administrator. Practice of universal precautions should be followed by all categories of hospital employee coming in contact of hospital waste, They should also be immunized for disease like Hepatitis B.

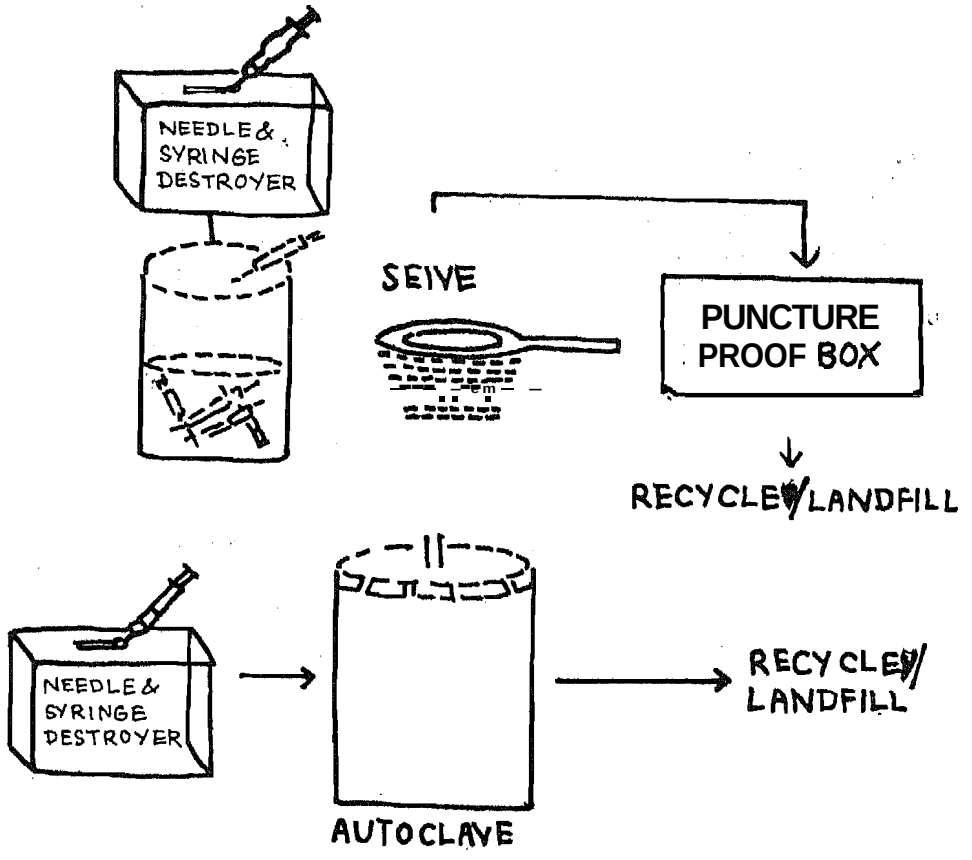

Fig. 2.10: Needle and Syringe

Demonstration – Universal precaution and waste

- Wash the hand with soap and running water before and after examining the patient and generating the waste.

Fig. 2.11: Hand Washing

- Put on gloves on hand, face mask before you go for dressing the patient, examining the infected patient.

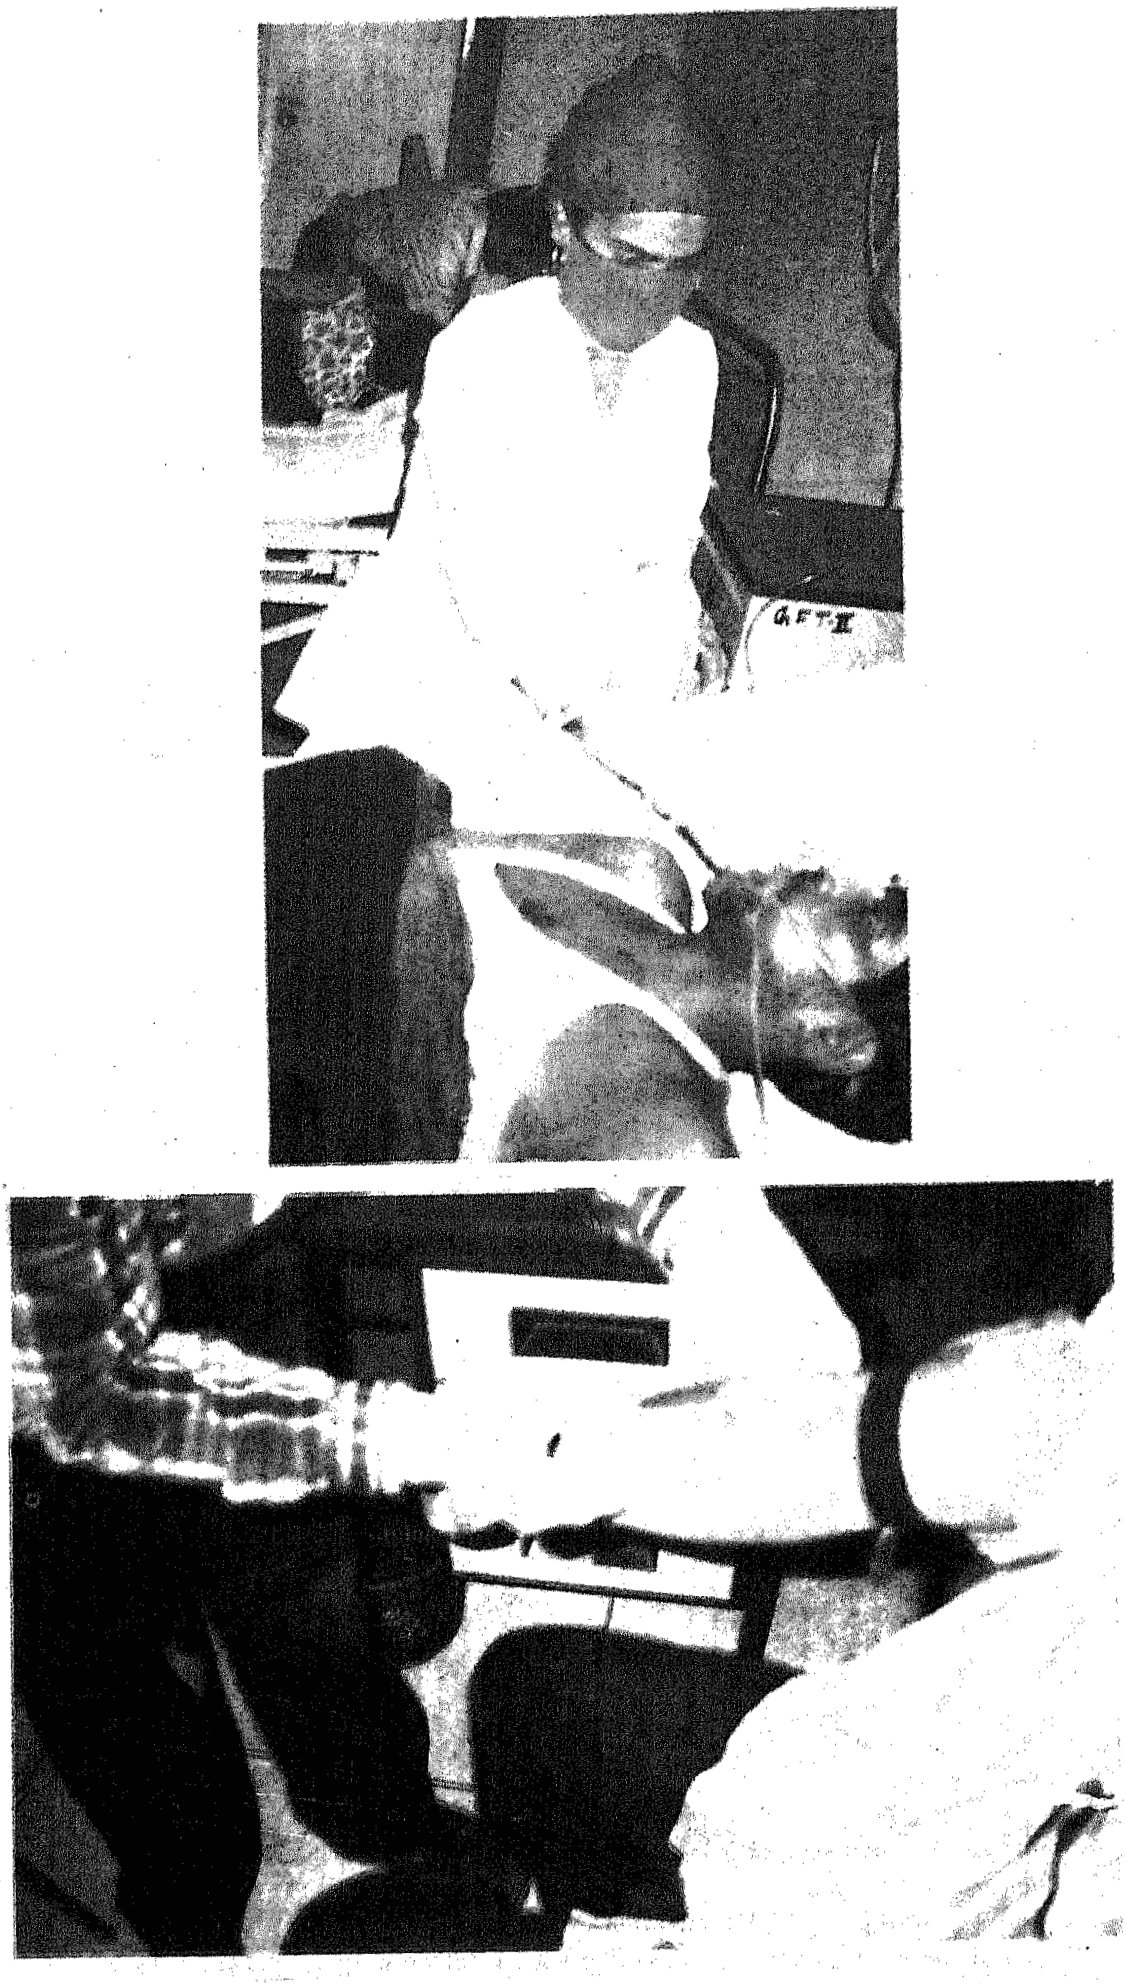

Fig. 2.12: Measures for Universal Precautions

- Throw the blood/pus soaked cotton, gauze in separate container identified for it i.e. yellow plastic bag.
- After examination generate the waste, throw the gloves in identified container (blue/white plastic bag).
- Use the sterile consumables on patients.
- Discard the needle immediately after use by needle destroyer and then put the needle and syringe inside disinfectant for one hour.
- Segregated waste at source should be collected in covered container for further disposal.
- Wash the hands after process.

2.7 · LET US SUM UP

In this unit of practical manual you have learnt that only 15% of waste is biohazardous. The average production of hospital waste is approximately 1.5-2.0 kg/bed/day. The waste should be segregated at source of generation to avoid complete waste hazardous. Therefore, segregation is essence for hospital waste management.

You have also learnt that Government of India, Ministry of Forest and Environment has passed the rules for safe hospital waste disposal known as Hospital Waste (Management and Handling) Rules, 1998 and as these rules, the waste has been classified into ten categories.

You have also learnt that waste collection is to be done in prescribed coloured bags and containers. Hazardous and non-hazardous waste to be collected and transported separately.

You have learnt the need to treat the biomedical waste to be treated before final disposal. Distinfecting the sharps at point of generation and autoclaving, incineration are the effective methods of treatment. Incinerator causes environmental pollution if it does not meet the standards laid down by Ministry of Forest and environment.

Practices of universal precautions to be adopted while dealing with biomedical waste have also been discussed and the need for educating/training all the categories of employees in the hospital for safe disposal of waste has also been emphasised.

UNIT 3 GUIDELINES FOR DISASTER MANAGEMENT MANUAL

Structure

3.0 OBJECTIVES

After going through this unit, you should be able to:

- enlist the various stages of the disaster;
- enumerate the points which a Hospital/Health Manager should keep in mind while developing a disaster manual;.
- outline the layout of a disaster manual; and
- analyse the disaster manual of a hospital.

3.1 INTRODUCTION

In Unit 2 of Block 3 on disaster management of this course, you have learnt about the definition of disaster, types of disaster and underlying principles for management of various medical and health problems during a disaster. In this unit, you will learn how to apply the concept and principles of disaster management into practice. This unit contains the various stages of disaster, the need for preparing a disaster management manual and its essentials components.

It is expected that after going through this unit, you should be able to apply the concepts and principles of disaster management learnt in theory.

3.2 STAGES OF DISASTER

You will agree to that a good state of preparedness before the striking of a disaster can reduce its impact and the greatest number of lives can also be saved during the first few hours after the disaster has occurred. If the lives have to be saved, local health authorities need to prepare an efficient disaster preparedness plan well in advance laying special emphasis on commonly occumng disasters. Before you go for learning the steps of developing a disaster manual you need to understand the following stages of the disaster:

1) Warning Stage

The first stage is the period of time when meteorological, seismological and other forecast related departments could predict the occurrence of a disaster before it strikes. It can be a few hours to forty-eight hours before in case of a cyclone and a week before in case of floods.

2) Stage of Impact

The second stage is the time period during which the disaster actually strikes, It may be just a few minutes in case of earthquakes, hours in cyclones and days in floods.

3) Stage of Rescue Operations

The third stage is the time when the actual rescue of the victims and their evacuation is being done. This requires active interventions and need to be completed at the earliest in the most efficient possible manner. It should not take more than two to three days even for a worst of the disasters. It requires good disaster preparedness.

4) Stage of Health and Medical Relief

You will agree to that from the health and medical point of view, this is the most crucial stage of the disaster management. The mortality, morbidity and the loss of property are inevitable when the disaster strikes. It shall however be a further disaster if survivors of the disaster succumb and suffer due to relief work being not up to the mark. It requires a lot of foresight, planning, coordination and management. An efficient relief phase is in fact the hallmark of a competent Hospital/Health Manager.

5) Rehabilitation Stage

The last.stage is that of rehabilitation. The displaced persons are then to be rehabilitated in their original settings. This depends on the resources of the stage and its commitment. Healthy rehabilitation is possible only if there is good political support. A poor rehabilitation phase results in an exodus as large number of refugees and the people migrating to nearby urban areas resulting in slums, unemployment and deprivation.

3.3 DISASTER MANUAL

The disaster manual is an important written document of disaster plan, which is to be activated during disasters. As stated earlier, for disaster relief, the health/hospital authorities need to develop a plan in the form of a disaster manual, While preparing disaster manual following points should be kept in mind:

- The plan should be 'simple' to be understood by everyone, so that it can be put into action immediately,
- The plan should be 'flexible' to fit in different types of disasters.
- It should be 'clear and concise', so that even in panic and confusion, staff should be able to act upon it instantaneously.
- It should be adaptable for all hours i.e., day and night including holidays, when most of the staff is not available.
- It should be an 'extension of normal hospital and public health working', so that people can act on it immediately in a routine manner.
- It should be rehearsed before implementation and updated according to experience gained.
- The concept of triage, basic life support and advance life support should be understood well and followed to determine priority in order to manage emergency and mass casualties. The terms triage and basic life support in this context have already been explained in the theory unit on disaster management.

Since this disaster manual is an important written document of disaster plan, it should include as many types of disasters as possible after thorough planning and deliberations. It should be clear and concise and vital information should be presented first. The suggested layout of the disaster manual is described below. However, each hospital/health institution has to modify it as per its requirements.

The disaster manual can be divided into following sections:

Introduction

- Distribution of responsibilities
- Chronological action plan
- Checklist of personnel and items
- Rehearsal and conclusion

3.3.1 Introduction

The first section of a disaster manual is the introduction, which enumerates all aspects of disaster management. The introduction should include:

- Disaster alert code
- General principles of conduct
- Brief synopsis of total plan

The disaster alert code word is given for activation of disaster plan. The message carrying this word when received by staff, they should immediately report for duty. This saves valuable time where every second counts.

3.3.2 Distribution of Responsibilities

The second section of disaster manual contains the duties and responsibilities of different individuals involved in disaster relief work. This should include in detail the responsibilities of individuals and concerned departments. The action cards describing in detail the responsibility and action to be taken by each member and key hospital staff involved in disaster management such as Medical Superintendent, Medical Officer in charge of casualty department, matron, nursing officer, public health supervisors and workers, telephone operators, clerks, messengers and stretcher pullers etc. These cards are issued to these people as soon as they are assigned the disaster duty. These action cards would serve a more useful purpose if hospital/health authorities get timely warning about likely disaster and type of casualties anticipated.

3.3.3 Chronological Action Plan

The action plan should be listed in chronological order and should include:

- The Medical Superintendent/Chief Medical Officer may get alerted by casualty itself, if accident is too near the hospital or by getting information on telephone or through a person. The person receiving information should gather details regarding casualties, regarding place, time of accident, the estimated number and type of casualties and source of communication. The reaction time for hospital will depend upon place and time of accident, while type of casualty will determine the type of preparation required by the hospital.
- The designated hospital staff should be responsible to activate the hospital disaster plan. The casualty medical officer, hospital controller and hospital administrator and senior specialist can be designated. The switchboard operator, duty clerk or casualty department in-charge should notify key personnel, activate emergency departments like Radiology Department, OT, Blood Bank, Laboratory Services, Medical Stores and supportive services like dietary services, security staff and ambulances. The complete detail of resources mobilisation should be given. The maximum number of staff should be available within 10 minutes of disaster notification. The matron or senior nursing officer on duty, should prepare pre-arranged ward(s) for receiving the casualties.
- In any disaster, it is likely to get large number of injured persons at short interval for treatment. In order to accommodate them there must be a plan for immediate expansion of beds and following action may be helpful if taken in advance:
  - Expansion of existing hospital beds by utilising all available space such as comdors and conference hall etc.
  - Discharging minor cases
  - Transfer cases to other hospitals

- The possibility of occupying buildings in close proximity of the hospitals such as schools and colleges etc. may be considered.

- The command nucleus should be fonnulated immediately and it should be near the casualty department. This nucleus includes hospital superintendent, matron or senior nursing officer and hospital casualty officer.

3.3.4 Checklist of Manpower Equipments and Drugs

The next section of the manual should contain the checklist of manpower involved in relief work, as well as checklist of equipment and drugs required for the reliefwork.

For managing the disaster effectively an elaborate checklist of various categories of medical and health personnel should be included in the disaster manual. Similarly the disaster manual should contain a detailed list of equipment/instruments and medicines.

The hospital should have adequate buffer stock of essential medicines like I.V. fluids, dressing materials, splints, oxygen cylinder and suction apparatus etc. District Chief Medical Officer and Hospital Superintendent should prepare an exhaustive list of medicines and hospital equipment. The quantity of these medicines and location should also be decided and known to all medical officers.

3.3.5 Rehearsal and Conclusion

The last section of manual should contain testing mechanisms/procedures for the plan. It should have provision for conducting periodical rehearsals or mock exercises to ensure the effective implementation of the plan.

The periodicity and type of rehearsal should be explained to all concerned. The rehearsal could be of many types like pre-announced, mini-drill without moving patients or simulating disaster. The rehearsal will test the plan and will bring lacunae, which will help to improve the plan accordingly.

The conclusion section should contain specific instructions or vital information, which can be useful in effective implementation of the plan. It may also contain the inventory of available health institutions/hospitals in the catchment area; resources available at these institutions and the mechanisms for coordination with these institutions.

You will agree to that there can be no tailor made disaster plan for all the hospitals. Each hospital has to evolve its own plan, based on the above considerations and it has to be revised from time to time, as each experience brings new perspectives.

3.4 ACTIVITY

After going through this unit, you visit a hospital and obtain a copy of the disaster pladmanual, compare the hospital disaster plan/manual with the checklist given below and record your observations/findings/comments and discuss the same with your academic counsellor.

Checklist of Disaster Management Plan

General Considerations

Have appropriate portions of the hospital disaster plan been officially incorporated in the disaster plan?

- Does the plan take into account all the possible disaster situations'of the community in which the hospital is located?

Is there an awareness in hospital personnel of the specific phases of the area-wide plan disaster operation applicable to the community in which the hospital is located?

Does the plan meet the requirements imposed by geographical location?

- Does the plan include provision for handling of increased patient loads through a variety of routines designed to meet different situations?

Organisation **for** Disaster

Are all key personnel included in the plan?

Is the plan for each department individually published, in the hands of each responsible department head, and known to all personnel of each specific department?

Is the assignment of key responsibilities fixed within each department?

- Is the organisation for evening, night, weekend, and holiday routines established so that the disaster plan may be activated as promptly as during day shifts?
- Is a designated area established for command nucleus?

Initial Alert

- Does the plan provide for prompt activation of the hospital on the occurrent of a disaster?
- Is the administrator or his representative on duty or available immediately by telephone at all times?
- Is there an organised procedure for reporting internal failures?
- Is there a procedure for alerting the hospital switchboard?

Activation of Plan

- Does the plan authorise and direct a designated individual or his alternate to make the necessary judgment promptly?
- Is authority to activate any phase of the disaster programme assigned to an individual who is backed up by several responsible officers?

Receipt and Control of Casualties

- Is the receiving and sorting area accessible and in close proximity to the areas of the hospital in which definitive care will be given?
- Is the sorting staff organised and directed by an experienced physician?
- Are sufficient equipment, supplies, and apparatus available in an organised manner to permit prompt and efficient patient movement?
- Is there a traffic control chart showing patient movement to and from special treatment areas, i.e. operating room, delivery room, urology, radiology and from these to bed areas or to the discharge areas?
- Will all entrances and exits be controlled?
- Is there an organised discharge routine sufficiently streamlined to handle large numbers of patients upon short notices?
- Have provisions been made for evacuation of the patients by utilising all available transport?
- Is there a predetermined schedule signifying which wards, room arrangements, classrooms, etc., will be used for housing emergency casualties?
- Are reserve supplies of linen, bedding and emergency clothing included in the plan?

Expansion of Patient Areas

- Are there emergency stores of equipment and supplies located adjacent to each ancillary department?
- Is there a plan by which personnel will be assigned to activate expanded ancillary units?

Internal **Communication** Systems

- Is there an organised communication system to substitute for telephone or other electrical systems in the event of a complete power failure?
- Will key communication personnel be provided with schematic area layout maps showing key areas for disaster operations?
- Does the plan provide the expansion of the hospital by using nearby building such as churches, schools, halls etc. for use as auxiliary hospitals or wards?
- Does the plan call for coordinating the hospital activities with the Police, Fire Brigade, Engineering department, Telephone and Transport departments.
- Does the plan provide for coordination with other hospitals and health facilities in the event of a disaster?

Evaluation **of** Existing Disaster Plan

- Is the plan reviewed by a permanently assigned planning committee at least annually?
- Are test exercises or drills conducted periodically?
- Are critiques held after each test exercise?

3.5 LET *US SUM UP*

In this unit you have learnt about the various stages of disaster viz. warning stage, stage of impact, stage of rescue operations, stage of health and medical relief, and rehabilitation stage. You have also learnt about the need for development of a disaster manual, its essential characteristics and layout, The disaster manual contains five sections i.e. introduction, distribution of responsibilities, chronological action plan, checklist of personnel and items, rehearsal and conclusion. You have also learnt that the manual should be concise and simple and should include all possible types of disaster in that particular area. You have also carried out the analysis of a disaster manual of a hospital, which will help you to develop an effective and viable disaster plan for your own set up.

UNIT 4 FIRE MANUAL GUIDELINES

Structure

4.0 OBJECTIVES

After going through this unit, you should be able to:

- appreciate the importance of having a manual for fire fighting;
- develop emergency fire order for all the staff of your hospital;
- ensure smooth fire fighting drill for all the employees of your hospital; and
- help the authorities to minimize the loss of life and property in case of fire in a hospital.

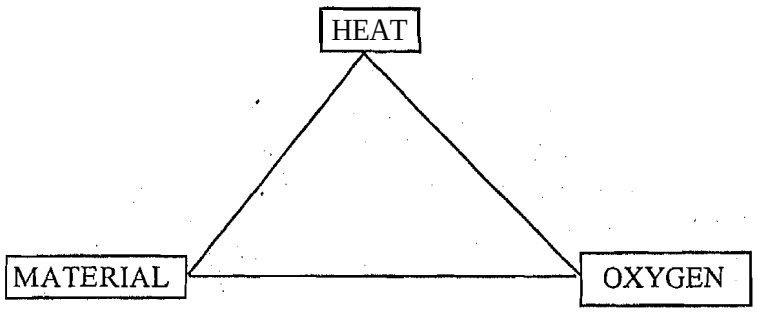
4.1 INTRODUCTION

Fires pose a continual threat to hospitals and nursing homes. Year after year fire claims their victims and cause property damage, fire keeps breaking out despite whatever precaution taken. The ,statistics of Swiss Hospitals have recorded following sources of origin of fire: 47 per cent in patient wards, 21 percent in kitchen, laundry and store-room, and the balance in many small unobstructive places where it is apparently impossible to stamp out fire. Thus, fire has a very special place among all the potential hazards, this becomes all the more special when it involves sick and dependent human beings as in hospital scenario. The safety of lives of patients of a hospital should be the primary concern, interest and responsibility of hospital authorities and personnel i.e. doctors, nurses, para-medical and technical staff and non-medical staff. Personnel of all categories working at the hospital and other buildings (non patient areas) should have a basic elementary knowledge about fire safety, fire fighting and rescue operation.

To implement fire fighting procedure efficiently and effectively, all the staff working in the respective departments should be aware of the hazards of fire and their responsibilities, if eventuality so very arises. The procedure laid down should be disseminated to all the staff and should also be practice periodically.

4.2 TUBES OF GRADES OF FIRE

The name fire is given to a process whereby any substance combined chemically with oxygen in the air produces heat and light. Fire is thus a combination of three things i.e., (i) Heat, (ii) Material, and (iii) Oxygen. If any one out of these three things is eliminated from the fire, the fire is automatically extinguished. Fire is, /therefore, fought or extinguished always on these principles.



Grades **of** Fires

Fire has been classified as A-grade, B-grade and C-grade fire.

A-Grade Fire

A-gradc fire is caused by all ordinary combustible material like wood, coal, paper, etc. This type of fire is extinguished by using fire extinguishers like soda acid, CO_2, dry chemical powder, water, etc.

B-Grade Fire

B-grade fires are caused by **inflammable** liquids specially those which are lighter than water. For this purpose fire extinguishers like Halons and dry chemical powder should be used.

C-Grade Fire

C-grade fires are caused by electrical faults, either in fittings or in distribution points. The causes of such fires are generally because of the over and excessive loading on the aluminium wiring. Most of the fires at the hospital have occurred because of the electrical faults or due to unauthorized excessive loading of the electrical circuits.

4.3 ELEMENTS OF FIRE SAFETY

The basic approach of any institution should be to have well laid down fire-manual and practiced fire policy. The fire safety programme consists of following elements in chronological orders:

a) Prevention

Prevention encompasses those activities of fire safety programme which occur before actual fire. This will include:

i) Detection and correction of the hazards

ii) Fire control pre-planning

iii) Employee and occupant education

iv) Design and specifications considerations

v) Periodic equipment testing

vi) Well rehearsed drills and liaison with fire department.

These measures are essential to prevent and also organize the system to take appropriate action in case of any contingencies. It is difficult to attain all these prevention absolutely, therefore, pragmatic approach should replace idealism, the organisation may compromise and should chalk out and reheare what is reasonable within economic and operating limitations.

Though all components of fire safety are so closely integrated that it's difficult to separate them, all fire elements mentioned above play a prevention role at some stage or other. It is also important that a regular periodic inspection of fire fighting appliances, any obstruction to fire-escape route, careless use of oxygen cylinders, flammable liquids and any other fire programme violation.

b) **Detection**

The application of **automatic early warning fire detection system** has helped a great deal in early detection of fire. The fire detectors require a sensing unit which measures the presence and/or changes in the products of fire, which are basically flame, heat, smoke, and gases. The functioning of detectors are based on these senses, and they are activated when the standards are exceeded, and once detector senses an abnormal condition, it must transmit a signal to an annunciator. This signal can activate any predetermined message or alarm on which an appropriate action can be taken by the ear-marked staff. Fire detection system in most of the hospital services, are combination of sensors due to the varied application presented by the medical care environment. Automatic fire detection has following components:

i) Sensors

ii) Response detectors

iii) Manual call buttons

iv) Wiring system

v) Electronic hooters

vi) Local control panel

vii) Main control panel

The various types of fire sensors are enumerated as:

i) Fixed temperature sensors activate when a pre-selected temperature is reached. These sensors are quite in-expensive and have good reliability. They also require very little maintenance.

ii) Rate of rise sensors activate when the temperature accelerates rapidly. The rate of temperature rise to be exceeded is generally in the range of 15^0 F to 20^0 F per minute.

iii) Combination of fixed temperature and rate of rise of temperature: While the temperature rising devices are reliable and maintenance free but they are rather slow to respond to slow burning and smouldering fire.

iv) Photocell detection units sense the mashing of light beam by smoke particles or the reflection of smoke particle into the cell. They are reliable but require considerable maintenance compared to heat sensor. They are also slow to respond to hot clean fire.

v) Flame sensors are not widely used but do provide fast response to the quick developing fire. They are fairly expensive and require a fair amount of maintenance activity.

vi) Products of combustion sensors are quick to respond and to detect either visible or invisible gases. They provide a means for early warning and are used quite extensively despite a relatively high degree of false alarms.

c) **Containment**

The third element of the fire safety programme is that of containing smoke and fire. The objective is to contain the fire in the area of origin, when this is not possible the concept is one of providing successive level of defence or areas of refuge from fire. There are fire of these basic areas defined in the "line safety code", they are also referred to as the unit concept, which are - room, a compartment, a floor, a building and exits, all these units have distinct function in the fire protection system.

i) **Unit one:** The room is the smallest unit and is the first line of defence. The function of unit one is to provide the first barrier against the passage of smoke.

ii) **Unit two:** The compartment is the second level of defence with the intent of providing two areas of refuge on any given horizontal plane of the hospital. If an area must be evacuated the initial movement will be horizontal as opposed to a vertical movement. The compartment is created by smoke and fire resistive partitions.

iii) **Unit three:** The floor, or floor assembly, is the next level of containment. The function of the floor assembly is to prevent the spread of fire and smoke from one floor to another, either above or below, the floor involved. These assemblies are penetrated by stairways, shafts and chutes, which require spread protection.

iv) **Unit four:** The building is the fourth unit or level of fire protection. It must remain structurally intact for a period of time.

v) **Unit five:** The exit is the final unit in the unit concept of fire protection, The basic requirement is that at least two remote exits be provided on each floor or fire section of the building. This means that two separate means of exit should be visible from any location in corridor.

Note: The containment of the fire can also limit the air needed to sustain combustion. A fire will generally rise to seek ventilation. If it cannot continue to rise, the smoke and heat build up will work back downward, looking for a lateral opening. If there is any air in the room that is breathable it will be found closest to the floor. When a fire is contained extreme caution must be taken when entering the area as the opening of the door may provide the exit the fire is seeking.

d) **Evacuation**

The fourth and very important component of the hospital fire safety plan is evacuation of patients, visitors and staff. The employees of hospital are responsible to see that every patient is evacuated to safety.

Evacuation can be whole or partial and it can follow vertical or horizontal flow. The total evacuation of patient from a hospital is however a last contingency. The concept of evacuation plan will be to move the patient horizontally to the safe area (compartment) on the same floor and required than only to shift vertically by two or three floors up and down. Wheel chairs and stretchers are useful and often necessary for evacuation, but they may not be available at the time and place of emergency. The blankets and sheets are most important piece of equipment on hand for evacuation purpose, the blanket/sheets can be handled by one person to drag a patient, and where two carriers are available the blanket can be used as impoverished stretcher.

A vertical evacuation plan is mandatory for a high rise building, a building with seven or more stories. The exit routes should be well maintained, the elevators need special consideration for fire evacuation.

e) **Extinguishment**

The last element of the hospital fire safety programme is extinguishment of the fire itself. The suppression of fire is achieved either manually or by automatic extinguishing system.

Know Your Fire Extinguishers

Pressurized Water

2 1/2 Gallons

Range: 3035 feet

To be used on Class A Fires (Wood, Paper, Trash, Bedding, etc.)

.....

Carbon Dioxide (CO_2)

5-15 lbs.

Range: 4-6 feet.

To be used on Class B Fires (Flammable Liquids) and on Class C Fires (Electrical)

.....

Dry Chemical (ABC)

5-10 lbs.

Range: 12-20 Feet

Can be used on Class A, B or C Fires

.....

Halon (ABC)

5-10 lbs.

Range 10-15 feet

Can be used on Class A, B or C Fires

.....

For proper and effective use of Fire Extinguisher you can remember the word

PASS

P Pull the pin

A Aim low (at the base of the fire)

S Squeeze the handle

S Sweep from side to side

Remember to keep an exit path between you and fire if you choose to use an extinguisher,

The stand pipe and hose located in the hospital building are used to provide quick and convenient water streams on upper/lower stories of high rise buildings. This system of water hose is basically installed to be used by fire department or trained Fire Brigade personnel.

The automatic extinguishing system comprises automatic water sprinkle system, which also acts as an alarfn device. The operation of the sprinkler is generally activated by a holding link, which melts at a given temperature. The sprinkler systems utilized in hospital are almost always of wet system type as opposed to a dry system. Other piped extinguishing methods are steam, water spray, foam, carbon dioxide, dry chemicals and halon agents.

Employees Reaction: Proper employee reaction to the fire situation is one of the fundamental factors in saving lives and property. The safety is a race against time, and the action taken and lack of action in few minutes can make the difference between a minor fire threat and a tragic disaster. Since the employees must react instinctively when fire breaks out, detailed instructions are seldom remembered and hence acronyms expressing essential steps are suggested.

A) **S** Save patients or person if in immediate danger.
A Alarm –.Sound the alarm.
V Vent – Close doors and windows to keep fire contained.
E Evacuate – use evacuation routes and first-aid
E Extinguish – fire extinguishers equipment.

B) **R** Rescue those **in** danger,
A Activate the nearest alarm, dial security, give location.
C Close doors, contain the smoke and fire. ,
E Evacuate and zxtinguish.

It is essential that to execute these steps properly, all staff members irrespective of their jobs and status must receive continuous in-service training. Unless the personnel have been through the actual experience, a very few persons are able to imagine the swiftness with which the fire danger can spread and the panic that can ensue. Hence, larger the staff members have received the training, the better the chances that they will react correctly under extreme stress.

4.4 FIRE SAFETY TRAINING

Planning for a fire emergency requires cooperation and understanding from every employee in the hospital. Each employee is potentially the one who may discover a fire or be the first to arrive at the scene of an alarm. The degree of personnel turnover and their effective involvement in carrying out fire preventive measures largely depends upon their continuous in-service and new employees training.

Robert Palmer of North Memorial Hospital in Minneapolis, a national recognized authority on Hospital fire safety, has emphasized the importance of following functions:

a) Rescuing those in immediate danger
b) Properly reporting the fire
c) Confining the fire
d) Securing the fire
e) Using the proper extinguisher
f) Controlling employees, visitors and patients, and
g) Meeting and guiding fire department personnel to the scene.

The Hospital Administration should earmark a staff member responsible for imparting regular in-service and to new employees fire safety training. The methods for training may include:

a) Training session, where employees are actually handling fire extinguishers and patients requiring evacuation.
b) Posters of fire prevention and safety.
c) Organising fire drills.
d) Assessing the knowledge of employees by random stopping and questioning them about their role in case of hospital fire, the person who answers the question correctly should be suitably rewarded.
e) Audio-visual aids are very effective means of imparting training as it leaves a clear image in mind, which is easy to recollect.

4.5 GENERAL INSTRUCTIONS

1) All the fire escape routes (staircases and corridors) which have been encroached upon or blocked, must be got cleared for providing emergency exit.

   (Sister in charge of the wards to ensure that fire escape staircases and corridors are not encroached upon. Fire safety officer to carry out periodic checks of all the fire escape routes and staircases).

2) All the gas pipelines, particularly the oxygen lines and their regulators, must be thoroughly checked periodically and a proper record of its checking be maintained by manifold room in charge. Any problem of leakage of gas should be immediately intimated to manifold room as well as to the Medical Superintendent Officer/Duty Fire Officer and-action to be taken to avoid fire hazard.

3) All heating appliances must be used with a plug and socket of proper ampere and use of excessive load from a particular point. Sister in charge ward to

ensure that over loading of electrical points is avoided. All electric appliances should conform to BIS specifications.

4) Monitoring system in every department and section should be introduced to ensure that person leaving last, satisfies himself that all the unwanted heating appliances are switched off.

5) Proper type of fire extinguishers and other fire fighting equipment should be readily available for use in the event of fire. Special safety and fire preventive measures should be ensured where very costly and sensitive electronic equipment has been installed. Fire safety officer to ensure provisions of fire extinguishers and other fire fighting equipment in all wards/ departments and sections. Sister in charge ward to ensure that fire extinguishers and fire fighting equipment issued to the ward is kept in readiness for use in case of fire.

6) "No Smoking" instructions and other safety precautions must be enforced in all Stores, Lecture Theatres and Auditorium, Manifold Room, X-Ray Department and Laundry etc.

7) Good housekeeping: Attention to matters commonly referred to as "good housekeeping" can reduce the likelihood of fire incidences. The basic practices, therefore, to be observed is to avoid the accumulation of rubbish particularly in "out of sight" spaces e.g. lift shafts, behind radiators, basements, dead-end of corridors and keep cleaning rags and materials in a non-combustible container after use.

8) Sister and officer in charges of respective areas should ensure that wall fire hydrants are functional in each area. They are one CO, cylinder and one Soda Acid/Water, CO, Fire extinguishers and one water drum with 9 buckets full of water is available at all times.

9) Fire safety officer to detail one person by name for checking that fire equipment held in the departments are available physically accordingly to the list available in the fire control room and they are serviceable. Establishing a fire control room with all communication facilities.

10) Electrical checking for overloading and state of wire specially in sensitive areas, should be carried out periodically.

11) Fire resistant materials must be used on renovation and construction work.

12) Whenever inflammable fluid is there it must be labeled.

13) Each area must have'a plan as per, type of fire.

14) Fire escapes:

a) All fire escape routes and emergency exit doors should be clearly marked with illuminated paints and electrical sign posts with clear directions in Hindi and English.

b) Keys of all emergency exit doors snould be kept in the box near the door. Sister in charge ward must frequently check the key box so that in the event of emergency, the emergency doors' are quickly opened. Staff of each ward and department should be made conversant about these matters.

c) The locks of the emergency doors should be such that they can be opened by one master key, which will be kept in central fire control room. The key should be kept in the box near the door and one key be with sister on duty.

4.6 DO'S AND DON'TS FOR ELECTRICAL FIRE PREVENTION

1) Lights and fans should be switched off when not required or rooms are to be locked.

2) Flexible leads to portable appliances should be well-protected to avoid damage to the insulation of wires.

3) Defective heaters and appliances should be removed immediately from service until these are repaired and tested for satisfactory performance.

4) The capacities of connecting leads; wires and switches must match the load requirements of equipment.

5) All heaters, table and pedestal fans etc. should be fitted with proper guards.

6) Proper and secure earth connections to the heating appliance and other electrical equipment must be ensured.

7) In case any excessive heating, burning smell or sparking in wiring or connections is noticed, control switch should be put off immediately.

8) Do not connect portable electrical appliances to the electrical outlet points through bare and loose ends, proper plug tops be used always.

9) Do not use more than one portable electrical appliance to a single outlet point at the same time.

10) Do not use heaters and high rated equipment on light (5 ampere) socket outlets.

11) No multipurpose plug tops should be used for connecting more than one appliance on a socket outlet point.

12) Extension Boards should be normally used, if unavoidable, the extension boards should not have more than a set of 15 ampere 2 Nos. of socket outlets.

13) Do not add or connect any new electrical equipment unless proper wiring and outlet point of matching capacities are provided,

14) Heaters and hot plates must not be left unattended while these are on.

15) Passages and approaches to main switches, distribution boards and riser-rooms should not be blocked or locked.

16) Do not pile or stock office-records and other stores near socket outlet points or in riser rooms.

17) Do not block or close the heat dissipation system and arrangements of electrical machines and equipment.

18) Do not use stabilizers or emergency light topes, as racks.

19) Use of heaters must be avoided in entire basement storing spaces particularly stationery, linen and medical stores.

20) Do not keep heaters and heat producing appliances too close to the overhanging curtains, combustible and other flammable items and chemicals.

21) All the electricians to pay extra attention for using proper insulation after repairs.

4.7 ACTION TO BE TAKEN IN CASE OF FIRE IN A HOSPITAL

1) Action by employee or worker on the spot

i) To verify the extent of fire outbreak.

ii) To intimate at once to immediate superior present on duty in that area.

iii) Worker in the area will take immediate action to put off the fire.

iv) Sister in charge/Doctors on duty/Sr. worker on duty to inform M.S., Security Officer-cum-Fire Officer and fire guard located in the Building.

2) Action to be taken by sister in charge present on the floor, who acts as a Controlling Authority

A) *If Small Fire*

1) Organise few personnel available to extinguish the fire using fire extinguisher or by improvisation.

2) Get all inflammable material removed e.g., spirit, oxygen cylinders, cotton, bandage, rags and mattresses etc. from the site of fire.

3) Put off main switch if there is an electric short circuit.

4) Organise shifting of patients, specially, lying cases, with help of available staff and attendants of patients to places of safety.

5) Get the fire escape route opened.

6) Close the oxygen supply from manifold room and change over to portable oxygen cylinder supply.

7) Ambulant patients to be guided to go to other floors by using staircases.

8) Ask Medical Superintendent Officer/Fire Officer for trained manpower.

9) Do not attempt to evacuate the patients (except from immediate danger) unless ordered to do so by Medical Superintendent, Fire Department.

10) While evacuating organise the shifting of non-ambulatory cases first horizontally and then by lifts/ramps/staircase, patient charts should accompany the patients unless it is impractical given the emergency.

B) *In Case of Big Fire*

1) Raise fire alarm

2) Fire escape routes to be opened by the key kept in the box, fixed near fire escape route. If key is not available the lock can be broken and open.

3) Walking patients will go out horizontally to rescue area and then by using the staircase.

4) Lying cases will be shifted away from the site of fire to rescue area, then their rescue will be organised by staff immediately available with guidance from Doctors/Sisters/Senior workers present on the spot, and with the extra manpower which will be sent by M.S./Fire Officer

5) Doctors/Senior Sisters/Seniormost workers present on the spot will assist sister in charge on duty in operations till Fire Officer or any other officer deputed by M.S./Fire Officer.

4.8 PROCEDURE AFTER FIRE ALARM

Security: Security will meet and direct the City Fire Department to the fire location. They will also maintain communications at the fire and direct those not involved in the emergency to evacuate the area. They are authorised to stop others from entering the building in jeopardy. They will call the fire department and give street address and floor number where the incident is occurring. They will also communicate with Maintenance and Plant Operations to assure that everyone is aware of the alarm.

Telephone operators: Immediately upon being notified of a fire or visible smoke, telephone operators will immediately initiate rehearsed fire drill.

Operating rooms: If surgery is in progress, all decisions affecting the patient's welfare will be made by the surgeon in charge. Operating room personnel must be familiar with the locations of medical gas shut-offs.

Maintenance control room: Upon receipt of an alarm, Control Room personnel will despatch via mobile radio all maintenance employees assigned to the Emergency Response Team to the fire location. They will also notify security to assure that everyone has received the alarm.

Emergency response team: Employees from the Maintenance, Security and Environmental Health and Safety Departments staff are the Emergency Response Team. They shall immediately upon notification of a fire alarm proceed to the area of alarm. They should pick up fire extinguishers as they approach the area in jeopardy,

Elevators: During the period of alarm, elevators will be returned to the ground floor level and remain inoperative. Security will take the Emergency Response Team and Fire Department to the floor below the fire, via elevator if necessary.

The emergency Response Team is directed by Hospital Medical Superintendent1 Fire Officer, Director of Maintenance and Plant Operations or the senior team member present.

4.9 WHAT TO DO IN CASE OF FIRE IN NON-PATIENT BUILDINGS

1) Pull the nearest fire alarm box. Dial designated telephone, give the location of the fire.

2) Be familiar with fire exits, fire alarm boxes and fire extinguishers in the building where you work or live.

3) When the fire alarm sounds, evacuate your area and go to the nearest fire exit stairway; close doors behind you.

   In building with a PA (Public Address) system, there will be an announcement of "Fire Alarm, All Clear" following the silencing of the bells. In buildings without a PA, the silencing of the bells will serve as "All Clear".

4) If you have been trained in the use of portable fire extinguishers and you decide to fight the fire, always position yourself between the fire and a path of escape. Never try to extinguish a fire until everyone has been evacuated from danger

a) While giving information to aforesaid authorities speak clearly without creating "PANIC" to the patients, staff and to the informer.

b) Specify the exact location of the fire indicating its severity.

c) While intimating the Local Fire Brigade tell them the route they should adopt for an early and easy excess to fire location.

Use of Fire Extinguishers

See Section 4.2 (e) of Unit 4 of this block.

For Fires Other than Electrical or Oil Fires

Water, CO, fire extinguishers, water in 'D' shape water drums containing 9 buckets, should be used. In case fire is on bigger magnitude, then water hoses connected to wall fire hydrant should be used till arrival of the Delhi Fire Brigade.

4.10 EVACUATION PLAN IN THE EVENT OF FIRE

There are two approaches, which can be implemented for evacuation.

Evacuation Types

Partial: The severity of the incident dictates the degree of evacuation. Always begin with persons in the most immediate area of danger.

Keep the doors of patient rooms closed until they can **be** moved to safety.

Total: If fire or smoke conditions warrant, a total floor evacuation will be called for. The decision to totally evacuate will be determined by the Medical Superintendent/Chief Executive Officer, the Director of Environmental Health and Safety.

General principles of evacuation in Multistorey Building:

1) Horizontal evacuation is easier than vertical 'evacuation.

2) Evacuate lying cases horizontally first and than evacuate vertically down.

3) Evacuate patient to three floors down depending on the site of fire as the floor immediately above and below has potential risk of fire if it is not brought under control.

4) Evacuate able bodied and ambulant patients preferably by stairs.

5) Evacuate lying cases by lift if possible.

Patient Care Areas Requiring Special Attention

There are many problems in evacuation of following type of patients from patient care areas, These are:

1) Disabled patient or lying cases needs support.

2) Life support measures like oxygen etc; may be required for patient even during evacuation. Evacuation with ventilatory support.

3) Paediatric cases and babies in nursery will need assistance from attendants.

4) Unconscious cases required to be evacuated as lying cases.

5) Some of the psychiatric cases will require embroil support during evacuation for their safety. One has to avoid panic amongst such cases.

6) Orthopaedic cases rendered immobile due to disease or plaster will need total assistance in evacuation.

7) Cases under immediate post operative care will need extra attention specially those with ventillatory support.

8) Patients under going operation.

The decision for evacuation of the patients from the site of fire will have to be taken by doctor/sister present on the spot depending on the extent and severity of fire. This decision should be taken in due course without creating any undue panic, The doctor/nurse on the spot will have to take charge of situation till arrival of Fire Safety Officer/Medical Superintendent.

Assessment of total number of patients needing assistance in evacuation should be made by doctorlnurse on the spot and project additional requirements of manpower, wheel chair, stretchers/trolleys to the Medical Superintendent/Hospital Administration/Fire Officer. Till arrival of additional help mobilize all available manpower in the ward and utilize available wheel chairs, trolleys and stretchers.

4.1 CHECKLIST FOR FIRE PREPAREDNESS

To implement the fire fighting programme effectively every hospital must draw and rehearse the fire preparedness and document the checklist:

Sl. No.	Subject	Yes	No
1)	Water hydrant located strategically		
2)	Water hydrant connections are standardised/ compatible with local fire department loose lines		
3)	Sprinker system provided where indicated		
4)	Fire Alarm system working effectively		
5)	Adequate Fire Extinguisher available		
6)	Following are available and in working condition in each working area:		
	a) Wall Fire Hydrant		
	b) One Soda Acid/Water, CO, Extinguisher		
	c) One CO, Extinguisher		
	d) One Water drum D shaped with 9 buckets of water		
	e) Adequate availability of water	/	
7)	Presence of any Electric loose connection/ defective improper Electronic points (if yes – location)		
8)	Any combustible/inflammable matcrial near potential fire point (if yes – material and its location)		
9)	Fire escape routes arc free (if no location of any obstruction)		
10)	Fire escape routes door lock keys available		

Sl. No.	Subject	Yes	No
11)	Emergency fire lights and directional sign adequate		
12)	LPG is stored in a cool and non fire area		
13)	LPG inspected for linkage on receipt		
14)	Kitchen exhaust working		
15)	Fire lift connected with generator is working		
16)	Fire safety regulation training programme imparted to Hospital staff satisfactorily		
17)	Up-to-date list of training record maintained		
18)	Periodic/surprise check carried out		
19)	Record for periodic check maintained		
20)	Last periodic/surprise check carried	Date	Time

This checklist will help you in assessment of fire fighting preparedness in your own set-up and take necessary steps for an effective and efficient implementation of fire fighting programme.

4.12 LET US SUM UP

In this unit of practical manual, you have learnt about the importance of having a manual for fire fighting in a hospital. You have learnt about the grades of fire elements of fire safety and various types of fire extinguishers. You have also learnt about the fire preparedness, plan and action to be taken in case of fire in a hospital. It is expected that after going through this unit of practical manual, you will be able to analyse the safety needs of your hospital and draw up a safety plan to protect your hospital from fire hazards.

BLOCK INTRODUCTION

The first block of this course on Community Health contains five units.

Unit 1 deals with the Concepts in Community Health and in this unit you will leam about the natural history of diseases, factors determining health and of interventions to prevent the occurrence of diseases: Important indicatiorslindices to measure health status of the community have also Been discussed in addition to the stages for epidemiological surveillance.

Unit 2 deals with Hospital and Primary Health Care. In this unit you will learn the concepts of primary health care. The very important aspect of the role of hospitals in primary health care is discussed in detail in this unit. You will also get to know some of the important norms with respect to targets and achievements in the field.

Unit 3 of the block deals with the Principles and Concepts of Epidemiology and Biostatistics. In this unit you will learn epidemiological methods and types of epidemiological studies. You will also leam epidemiological forecasting and about management of epidemics.

Unit 4 of this block is on Occupational Health. In this unit you will learn about the definition, scope and application of occupational health in industries. You will also learn how the occupational health has come to occupy the front stage in the scheme of health, ensurement and management specially so as in the most vulnerable segment of our society is affected. The workers in factories and establishment are very much exposed to such diseases: You will also learn the role of international agencies on the subject.

The last unit of the block is on Health Insurance, It gives you an overview of the evolution of the subject in our country. The two largest ongoing schemes i.e. ESIS and CGHS have been discussed in detail. You will also learn about the emerging scenario in the field due to the recent decision of union Government to open up the subject of insurance to private sector including joint set-up with foreign companies.

UNIT 1 CONCEPTS IN COMMUNITY HEALTH

Structure

1.0 OBJECTIVES

After going through this unit, you should be able to:

- describe the natural history of disease;
- describe the important factors determining the health of the individuals and the community;
- describe the interventions which can prevent the occurrence of disease during its various stages;

  list the important indicators and indices which measure the health status of the community;
- list the steps for developing an epidemiological surveillance system; and
- apply the concepts of community health particulary epidemiological surveillance in the prevention and control of diseases in the community.

1.1 INTRODUCTION

The normal course of the disease in man along with the knowledge of the factors governing a person to stay healthy or fall ill are of immense help to an administrator. It assists him in deciding the interventions he has to implement along with the stage of the disease at which they are to be implemented.

The pooled information about the health status of the community along with the various factors affecting health coming at regular intervals gives him the feedback about the efficacy of the interventions. It may also suggest the changes or the modifications that may have to be made in the programme intervention.

These basic concepts of community health along with the use of epidemiological surveillance as a managerial tool have been described briefly in this unit.

1.2 NATURAL HISTORY OF DISEASE

You would be wondering why should administrators be reading about natural history of disease. It should be read by historians and kept in the archives. The strange thing is that the more the administrators know about the natural history of disease the more effectively they will be able to control disease. So the next question is how do we know about the natural history of disease. It is not knowing the disease from antiquity but knowing the course of the disease in the population.

In fact, the natural history of disease is best studied in a virgin population in which there are no health interventions. But, it does not mean that it cannot be studied wherever health interventions have been applied. By comparing the nautral history of disease in both of these groups, we determine the effectiveness of these interventions and get clues for better prevention and control.

Disease originates via independent processes before man is involved. Hepatitis A virus needs to survive in the environment and find adequate measures for propagation before causing disease in man. These factors in the environment create a disease stimulus long before its interaction with man to produce disease. This preliminary interaction of agent, host and environment is tenned the period of 'prepathogenesis.'

The course of disease in man starting from the first interaction between agent, host and environment, through the full-blown disease to its final outcome is known as the period of 'pathogenesis'.

The combination of the processes of both these phases, prepathogenesis (process in the environment) and pathogenesis (process in man), is termed the natural history of disease.

Agent is the primary cause without which a specific disease cannot occur. Disease agents can be classified broadly into the following groups:

1) Biological Agents

These are the living agents of disease like viruses, rickettsiae, fungi, bacteria, protozoa and metazoa. Examples are streptococci,, candida, plasmodiums etc.

2) Nutrient Agents

Any excess or deficiency of the intake of nutritive elements may result in nutritional disorders. Examples of such disorders are protein, energy malnutrition, anaemia, goitre.

3) Physical Agents

Exposure to excessive heat, cold, humidity, pressure, altitude may result in illness.

4) Chemical Agents

These disease may be endogenous or exogenous. Endogenous chemicals are those which are produced in the body as a result of some derangement of function e.g. uric acid (gout),

calcium carbonate (kidney stones). Exogenous agents are those which arise outside the human host e.g. allergens, fumes, insecticides.

5) **Mechanical Agents**

Mechanical agents are chronic friction and other mechanical forces resulting in injuries and death.

6) Hereditary Factors

Hereditary factors are part of the genetic makeup of humans which are inherited e.g. the trait for thallessemia, polycystic disease, Down's syndrome.

7) Social Agents

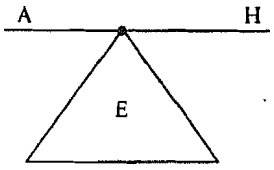
Like poverty, smoking, drugs, alcohol are known to aid causation of disease.

The term **'Host'** refers to **'man'** and more specifically, this particular man is group of men of immediate concern. Host factors may be biologic (age, sex, race, specific immunity) or behavioural (as governed by habits and customs).

"Environment" embraces all that is external to the agent and the human host(s) immediately in question. These factors are numerous and are subdivided into three classes, which relate respectively to the physical, biologic and socio-economic segments of the environment.

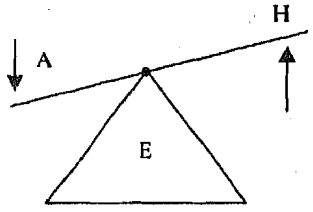
1.2.1 Interaction of Agent, Host and Environmental Factors

To illustrate graphically the interaction of agent, host and environmental factors, Dr. John Gordon has employed the analogy of a lever balanced over a fulcrum (represented by environment) and each weight at either end represented by agent and host.



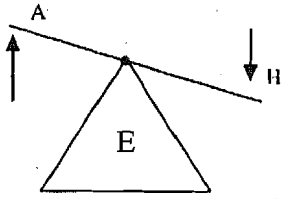
A = Agent
H = Host
E = Environment

Fig. 1.1



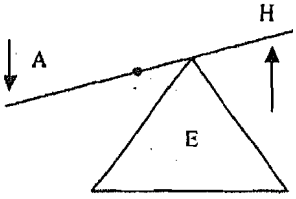
Increase in the ability of an agent to infect and cause disease in man

Fig. 1.2



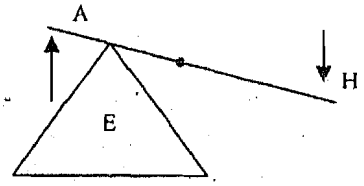
The proportion of susceptible in the human host population is increased

Fig. 1.3



Environmental change facilitates agent spread

Fig. 1.4



Environmental change after host susceptibility

Fig. 1.5

Interaction of Agent, Host and Environmental Factors

Source: J.P.; Hall C. E and Elveback *L. R., Epidemiology Man and Diseases*. The Macmillan Company, New York.

The agent and host exist in equilibrium in the environment. The host thus stays healthy (Fig. 1.1).

Any increase in the ability of an agent to infect and cause disease in man can be seen in the case of HIV which was able to infect and cause disease in man within the past two decades, and also in the increased resistance of microbes to commonly used a antibiotics (Fig. 1.2).

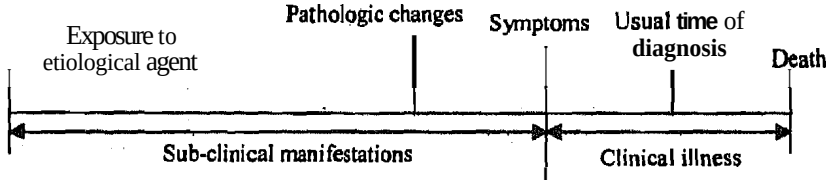
In Fig. 1.3, the population may fall ill due to its increased susceptibility. In Russia, there have been a few cases of diphtheria reported in the recent past. This had followed the suspension of the immunization against diphteria thinking that the population was not at risk against diphtheria any more. This had reduced the immunity of the community and placed them at a higher risk of contracting the disease.

In Fig. 1.4, the change in the environment facilitates the spread of the agent, like in the Bhopal Gas Tragedy in 1984, the sudden leakage of the toxic gas in the environment killed the people or made them seriously ill.

The epithelial lining of the respiratory tract is effected in the people constantly inhaling polluted air in the urban areas. This predisposes them to frequent respiratory infections. (Fig. 1.5).

122 Spectrum of Disease

But the presence of varying balances of these three factors does not simply lend itself to the mere causation of disease. The severity and extent of disease in the individual passes through various stages, is signified by the "spectrum of disease". It is the sequence of events that occur in the human organism from the time of exposure to the aetiological agent till death. It is composed of sub-clinical and clinical components. Whether an individual with the disease progresses through the entire spectrum depends on the availability and efficacy of preventive and therapeutic measures, which if introduced at a particular point of the spectrum, will completely prevent or retard any further development of the disease. For example, in cancer of the cervix, the spectrum consists of dysplasis, carcinoma in situ and invasive carcinoma.



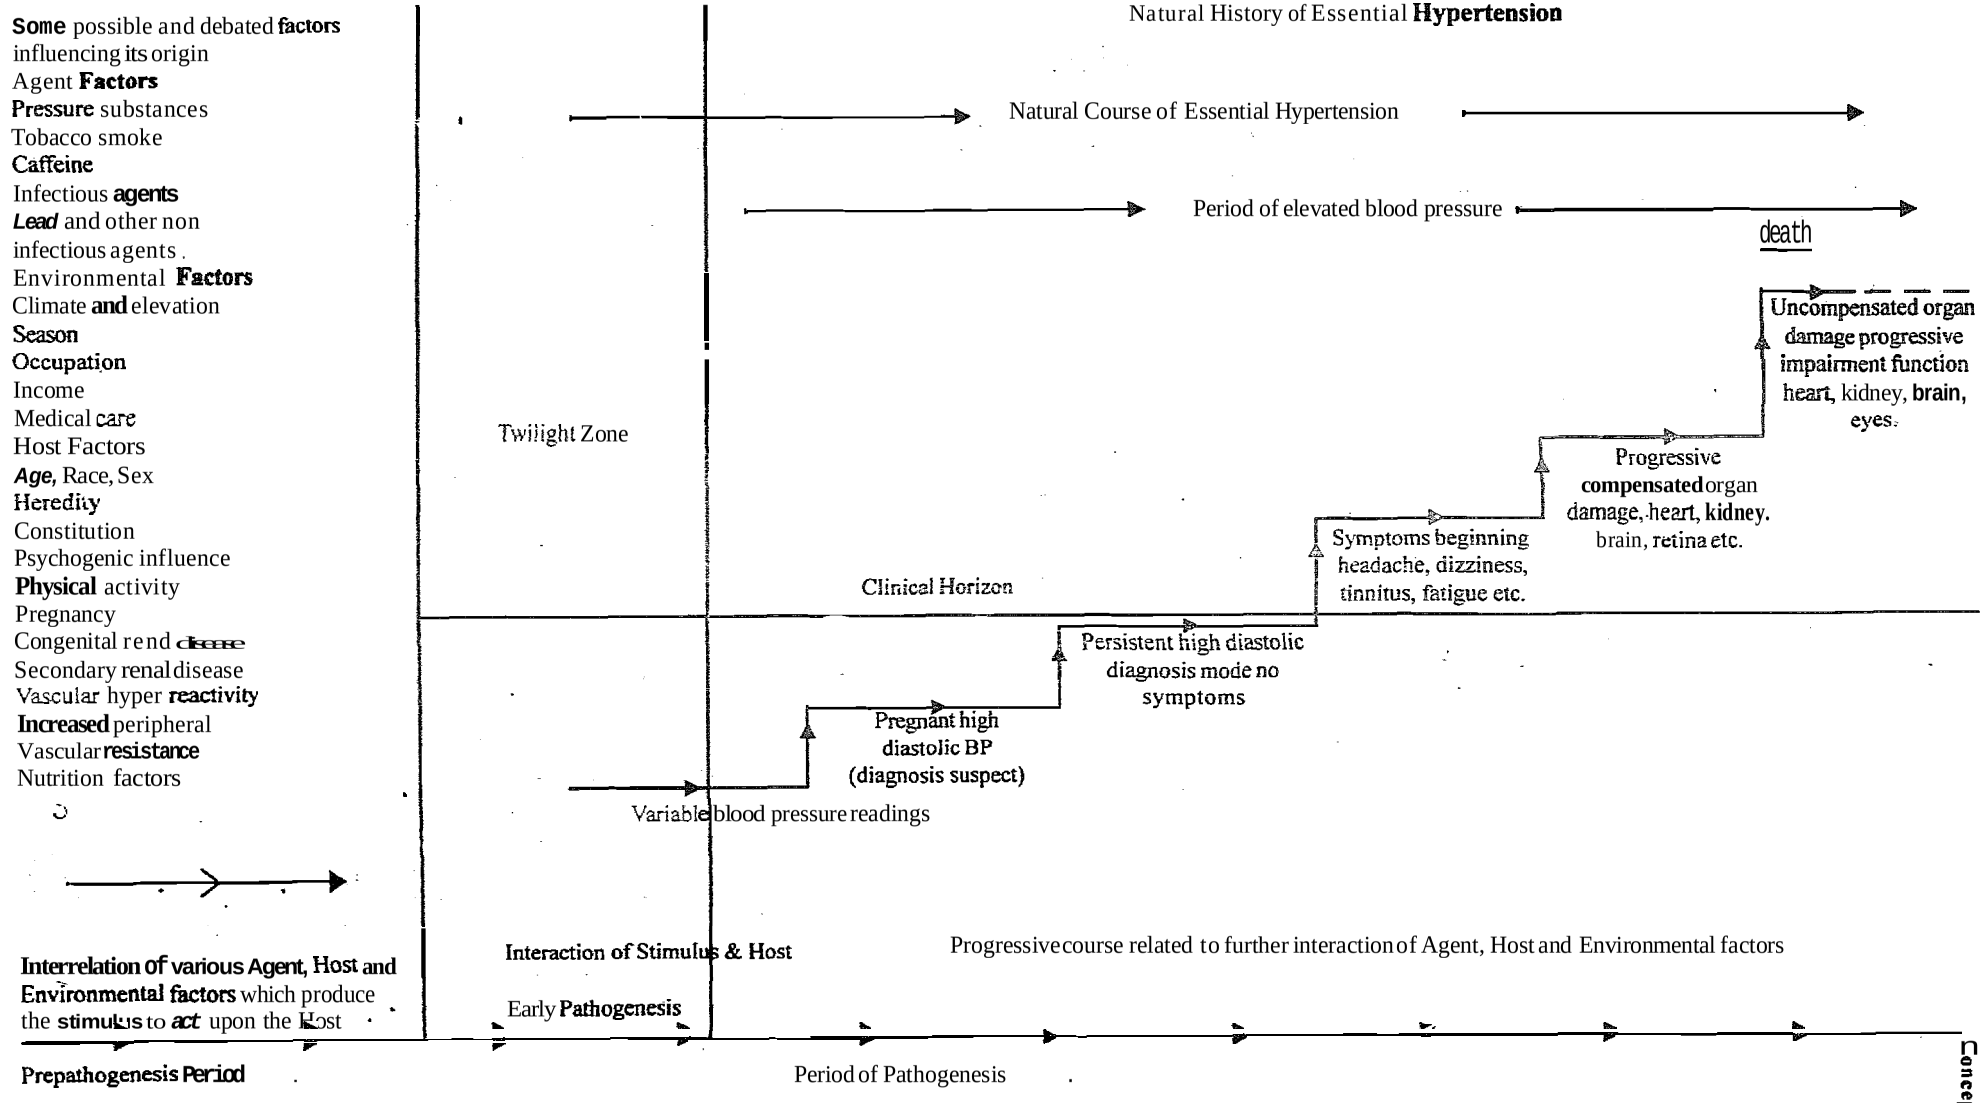
Foundntlons of epidemiology: Lilieufield

In infectious diseases, this spectrum is usually known as the "gradient of infection" which refers to the sequence of manifestations of illness in the host reflecting his response to the infections agent. Extremes of this spectrum extend from inapparent infection to death. In poliomyelitis, over 90 percent of the infections are not clinically apparent whereas in measles, over 90 percent of infected persons exhibit clinical illness.

Doctors are usually aware of a small part of the spectrum of disease (usually clinically apparent) and this part is proverbially known as the tip of the Iceberg.

1.3 DETERMINANTS OF HEALTH

We all know that a child born in a developing country is ten to fifteen times more likely to die before reaching his first birthday than a child born in a developed country. Similarly, he may expect to live upto fifty years as compared to eighty years in some developed countries. We have also observed that during the World War II fighting in the same area in similar conditions more European soldiers developed jaundice (Hepatitis A) as compared to Indian soldiers. So what determines whether a person will fall ill or die? Is it just being born or living in a particular geographic area or more than that? Obviously it's more than that. Health is a multifactorial amalgamation of various determinants. Some of the important ones are:



Source: Leavell and Clark, *Preventive Medicine for the Doctor in his Community*, Mc Graw Hill, USA.

i) Genetic

The positive health advocated by WHO implies that a person should be able to express as completely as possible the potentialities of his genetic heritage. The genetic make up of each individual is unique and connot bê altered after conception. The genetic constitution determines the health status to a great extent. It predisposes individuals to various diseases like thalassemia, cancer.

ii) Environment

Environment may be internal or external. Internal environment is dealt with by internal medicine. The external environment involves all that is external to the individual. The environmental factors range from housing, water supply, psychosocial stress and family structure and occupation.

iii) Socio-cultural

Social interaction with parents, peer groups, friends and siblings and through school and mass inedia affects the life-style of individuals. Personal habits like smoking, alcohol intake, drug abuse are developed through social interaction. Obesity, drug addiction, cirrhosis are a few examples of medical problems resulting from social causes.

Life-style can have a positive effect also on health. Reduction of smoking, avoiding red meat, regular exercise all contribute to a healthy life-style.

'iv) Economic

Economic performance is the major factor in reducing morbidity, increasing and improving life expectancy. Economic status determines the purchasing power, standard of living, quality of life, family size, disease pattern and deviant pattern. It is one of the crucial factors which determine health Seeking behaviour,

However, affluence leads to habits like increased alcohol intake, drug abuse, excess consumption of junk foods. Hence, economic affluence can act as a double edged sword in affecting health status.

v) Health **Services**

Provision of maternal and child health services to the population at large determines the status of health of the community. Health services must be equitably distributed, affordable and socially acceptable.

vi) Political System

The percentage of GNP spent on health is a quantitative indicator ofpolitical commitment. To achieve the'goal of health for all, WHO has set the target of at least 5 percent expenditure of each country's GNP on health care. India spends 3 percent of it's GNP on health care.

Let's review the status of tuberculosis in the last two centuries in U.K. Tuberculosis was a major public health problem in the eighteen century. However, with the industrial revolution the economic status of the people started improving. They started living in bigger houses and hence there was less overcrowding, The nutritional status and the literacy levels improved. Surprisingly the deaths due to tuberculosis started going down despite the fact that there was no effective treatment or immunization In fact, the prevalence of tuberculosis started literally halving itself every twenty five years from1850 A.D. onwards.

The number of people suffering from tuberculosis had come down to a large extent till streptomycin was discovered in the thirties. However, almost all of them were dying of it. After the discovery of streptomycin the deaths in the people suffering from tuberculosis came down drastically. So, we saw that socio-cultural, economic and environmental factors resulted in a drastic decrease in the prevalence of the disease but health services reduced the death rates in the persons suffering from the disease,

In the second half of the twentieth century efforts were made to eradicate the disease, Though U.K had not reached the eradication level set by WHO, the disease ceased to be a public health problem. However, with the epidemic of HIV/AIDS the immunity of these

patients went down and they started presenting with the disease and tuberculosis once again became a public health problem. So, we see how a person falling ill is governed by so many factors.

1.4 LEVELS OF PREVENTION (INTERVENTIONS)

What would any individual want regarding an illness. First of all he/she should not contract an illness. If unfortunately he/she does contact an illness, it should be treated at the earliest. It should have no sequalea and if some sequalae have to be there, they should be minimized. He should be able to carry out his normal activities or at least the basic minimum physical and social activities. These actions form the world of preventive medicine and the precise level at which the intervention takes place determines the level of prevention.

Needless to say the best way to prevent a disease would be by initiating intervention before the illness occurs. This is known as 'Primary Prevention'. Treating the illness as early as possible is called 'Secondary Prevention', Trying to limit the disability and rehabilitate the person in his own environment is known as "Tertiary Prevention".

1.4.1 Primary Prevention

Primary prevention thus is preventing man from developing overt disease. In other words, it is preventing the disease in the "prepathogenesis" phase of the natural history of disease. It may be achieved by 'health promotion' and 'specific protection'. Health promotion in the case of communicable diseases is to try to prevent if not eliminate the interaction between the agent and the host, so that the illness is not caused. Efforts may be directed towards destroying the agent (in communicable diseases) by spraying with DDT or by chlorination of drinking water, Interventions may be made in the environment by the elimination of the breeding sites or by proper storage and transmission of the drinking water.

The host may be educated and motivated to lead a life-style whereby protection from the disease may be possible. In the case of above mentioned diseases it may be by using mosquito nets or repellants creams and washing hands before eating food.

Health promotional activities may include promoting proper nutrition, housing, recreation, exercise and good home and working environment along with leading healthy life-style. Counselling and periodic health examinations arc other health promotional activities.

Health promotional activity for a non-communicable disease like myocardial infarction could be directed towards reduction of cholesterol in diet (agent), reducing passive smoking and stress at work place (environment) and promoting optimum weight, physical exercise and periodic health examination (host).

Specific Protection

Specific protection as the name suggests is by introducing interventions which specifically protects the host e.g. by giving vaccinations or by giving specific nutrients like fluorides, iodized salt etc. It may also be protection from carcinogens, ultra-violet rays or from accidents like wearing of helmets, seat belts etc.

1.4.2 Secondary Prevention

Early Diagnosis and **Prompt Treatment**

Secondary prevention is initiating intervention during the pathogenesis phase i.e. the disease process has started in man. The purpose is to diagnose the cases as early as possible and treat them. This may be by case detection, screening to cite a few examples. The aim is to cure the patient of the disease and prevent its spread along with preventing the complications and sequalae and limiting the disability as much as possible.

1.4.3 Tertiary Prevention

Disability Limitation

Very often people come for treatment at a very advanced stage of the disease. This is generally due to medical care not being provided at the appropriate time either due to non-

availability of medical care facilities or due to non-utilization of the services. Sometimes, it may be due to the incomplete knowledge of the disease. Disability limitation is either preventing or delaying the consequences of a clinically advanced disease.

Rehabilitation

This level of prevention is more than looking at the disease from the medical or surgical point of view. The aim is to return the person to a useful place in society and make maximum use of, his remaining capabilities. The person after his treatment should not only be physically but mentally, socially and economically adjusted or rehabilitated in the society.

Now let's look at some examples of the levels of prevention:

Communicable Disease: Poliomyelitis

Primary Prevention	
i) Health Promotion	Health education, provision of safe drinking water and proper sanitation.
ii) Specific Protection	Immunization against polio, increasing herd immunity and elitnination of wild polio virus by "pulse polio" immunization.
Secondary **Prevention**	
Early diagnosis and prompt treatment	Identification of AFP cases and diagnosing ifparalysis due to polio (AFP surveillance)
Tertiary **Prevention**	
i) Disability limitation	Physiotherapy
ii) Rehabilitation	Physical – by providing artificial artificial limbs, social by counselling for improving social esteem, vocational by teaching skills to get gainful employment.

Non-communicable **Disease:** Diabetes

Primary Prevention	
i) Health Promotion	Health education regarding the disease and leading life style by which the diseases can be avoided/delayed.
ii) Specific Protection	There is no specific protection in a disease like diabetes.
Secondary Prevention	
i) Early diagnosis and prompt treatment	Regular screening for early diagnosis of the disease prompt treatment and its prompt management by diet, exercise or drugs.
Tertiary Prevention	
i) Disability Limitation	Given top priority while treating the diseases at every stage.
ii) Rehabilitation	A perfect example ofrehabilitating the patient to live with the diseases.

Check Your **Progress** 1

Name the level ofprevention (intervention) in the following examples:

a) The male health worker giving chloroquin to the persons having fever in a high malaria zone.

.....

.....

.....

b) A child being given Vitamin 'A' solution six monthly.

.....

.....

.....

c) Artificial limb being provided to a person whose foot has been amputated.

.....

.....

.....

d) Screening by pap smear for cervical cancer.

.....

.....

.....

1.5 INDICATORS OF HEALTH

The question that immediately comes to mind is that why should we spend time developing indicators and then measuring them. Indicators arc variables which help us to measure changes. They measure the health status of a conimunity and also compares the health status between two or more communities or geographic regions. Health care needs are also assessed which are important for the allocation of scarce resources. Finally, they can be used for monitoring and evaluation purposes whereby we arc educated about how well (or poorly) are health care programmes progressing and perhaps why.

The commonly used indicators are:

1) Mortality indicators
2) Morbidity indicators
3) Disability rates
4) Nutritional status indicators
5) Health care delivery indicators
6) Utilisation rates; fertility rates
7) Indicators of social and mental liealtli
8) Environmental indicators
9) Social-economic indicators
10) Health policy indicators
11) Indicators of quality of life
12) Other indicator series
   - HFA indicators
   - Social indicators
   - Basic needs indicators

1.5.1 Mortality Indicators

Mortality indicators as the name suggests measures to death. Representing the traditional measures of Health, these are the most often used indicators even today. In fact, they are the starting point in most health status evaluation. For instance, the deaths due to communicable diseases have gone down in recent years.

It is a fair indicator of the comparative health of a community because in many countries it is the only available indicator. The disadvantage is that it gives no indication as to the cause of death.

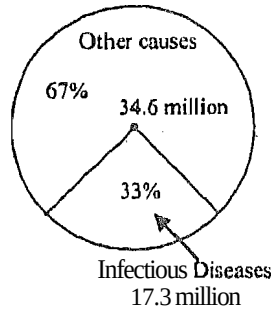


Fig. 1.6: Deaths from Infectious Diseases (1995)

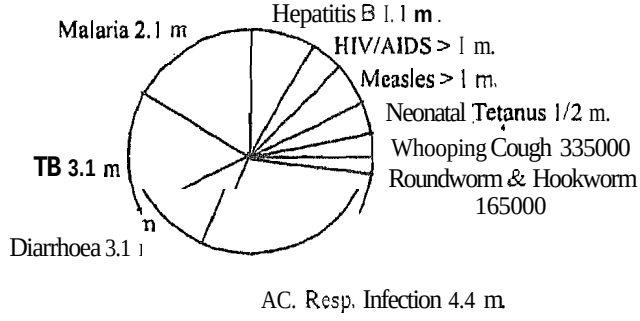

Fig. 1.7: *Ten* Biggest Killers

3 Infant Mortality Rate (IMR)

It is the number of deaths under one year of age in a given year to the total number of live births in the same year, usually expressed as a rate per thousand live births. It is a very sensitive indicator of the standard of living of the population. It is one of the most

universally accepted and sensitive indicators because IMR *is* the largest single age category of mortality, affected quickly by health programmes. Decline in IMR is attributed to-

a) Improved standard of living
b) Better control of communicable diseases
c) Advances in medicine
d) Improved nutrition
e) Better health care services

ii) Neonatal Mortality Rate

$$\frac{\text{Number of deaths of children under 28 days in a year}}{\text{Total live births in same year}} \times 1000$$

iii) Post Neonatal Mortality Rate

$$\frac{\text{Number of deaths of children between 28 days and 1 year}}{\text{Total live births in same year}} \times 1000$$

The reason for dividing IMR in two is that etiology and cause of death for the two groups is very different. Neonatal mortality especially early neonatal mortality (i.e. before 1 week or before 48 hours of birth) is mainly due to prematurity, congenital malformations, low birth weight, hypothermia etc. whereas as post neonatal mortality is mainly due to infection and malnutrition.

The importance of the division of IMR in post neonatal, neonatal (early and late) is of great help in deciding programme management. When the IMR is high and infrastructure and services poor, focus is laid on bringing down post neonatal mortality. In India, post neonatal mortality formed around two thirds of IMR about a quarter of century back and today it forms about 40% of the IMR. In the developed countries early neonatal mortality forms around two thirds of IMR.

iv) Perinatal Mortality Rate

$$\frac{\text{Late fetal and early neonatal deaths} > 1000 \text{ gm.}}{\text{Total low births} > 1000 \text{ gm.}} \times 1000$$

This ratio gives us an idea of the extent of pregnancy wastage and quality and quantity of health care services provided.

(When the numerator does not form a part of the denominator, it is called a ratio).

v) 1-4 year Mortality

$$\frac{\text{Number of deaths 1-4 years}}{\text{Number of children 1-4 years}} \times 1000$$

This is a more sensitive indicator than IMR of social situation in a country.

vi) Maternal Mortality Rate

Total number of female deaths due to conplications of pregnancy, child birth or within 42 days of delivery from puerperal causes in an area in a given year per 1000 live births in the area.

This also is a ratio generally written as a rate.

vii) Disease Specific Mortality Rate

It is the mortality rate due to specific diseases

viii) Proportion Mortality Rate

It is the proportional mortality rate due to a disease or a group of diseases.

1.5.2 Morbidity Indicators

3 Incidence Rate

It is the number of new cases of the disease reported during the year per thousand mid-year population. It is a way to measure the rate at which the population becomes recognisably ill.

ii) Prevalence Rate

It is the number of cases of the disease known to exist on a given day per thousand population on that day. Prevalence rate is normally calculated for chronic diseases as it is easier to measure. In the chronic diseases the prevalence rate is more than the incidence rate. However, in acute illness of short duration viz. episodes'of diarrhoea, ARI, malaria, the incidence rate will be more than the prevalence rate as the number of people ill on a particular day would be less.

iii) Notification Rates

This is the notification and diseases like polio, cholera and plague.

Other morbidity indicators include attendance rates; admission, readmission and discharge rates; duration ofhospital stay; and spells of sickness/absence from work/school.

1.5.3 Disability Indicators

i) Event Type

- Number of days of decreased activity
- Bed disability days, workloss days

ii) Person Type

- Limitation of mobility, activity
- DALY
- Sullivan's index

1.5.4 Nutritional Status Indicators

i) Direct

- Clinical Assessment
- Dietary Intake
- Anthropometry

Age Known		Height for age Weight for age Head and chest circumference
Age unknown	:	Weight for height Midarm circumference
School Entry	:	Weight for age Weight for height
Weight of Newborn	:	Average LBW (<2.5 kg).

Skin Fold Thickness
Stem Stature Index
Body Mass Index
Biochemical and Biophysical Test

ii) Indirect

Mortality and Morbidity Data.
Food Consumption Data

1.5.5 Utilisation Rates

i) Actual coverage
ii) Availability, accessibility, attitude
iii) Proportion of infants immunized under UIP (Universal Immunization Programme)
iv) Proportion of pregnant wome receiving

- antenatal care
- intra natal care
- post natal care

1.5.6 Indicators of Social and Mental Health

i) Suicides
ii) Homicides
iii) Rapes
iv) Alcohol and Drug Abuse
v) Battered Bady Syndrome

1.5.7 Environmental Indicators

i) Air
ii) Water
iii) Solid wastes
iv) Noise

Water: Microbiological, toxic substances, specific substances, radioactive substances

Air Pollution: Sulphur dioxide, smoke index, suspended particles, carbon monoxide, oxidants, nitrogen dioxide, lead.

1.5.8 Socio-economic Indicators

i) Rate of population above poverty line

ii) GNP per capita

iii) Food availability

iv) Literacy

v) Unemployment rate

vi) Working conditions

vii) Housing.

viii) Health care provision: availability, accessibility, quality, utilization

ix) Health status: LBW (Low Birth Weight), nutritional status, disability prevalence, morbidity

Other Indicators

i) ***Social Indicators***

Learning and educational services, housing, public order and safety, time used in leisure and cultural activities, social stratification.

u) ***Basic Needs***

a) Calorie consumption

b) Access to water

c) Life expectancy

1.5.9 Health Care Delivery Indicators

i) Provision of health care

ii) Equity of distribution

iii) Doctor population ratio

iv) Doctor Nurse ratio

v) Population bed ratio

vi) Population per centre

vii) Population per TBA

1.5.10 HFA Indicators

i) **Health Policy**

- Political commitment

  Resource allocation
- Equity of distribution
- Community involvement
- Organised framework

ii) **Socio-economic Indicators**

- Rate of population growth
- GNP
- Working conditions
- Literacy
- Housing

- Food availability

Health care provision : availability, accessibility, quality, utilization

iii) Health Status

- Low birth weight
- Nutritional status
- IMR
- MCH indicators
- Disability prevalence
- Morbidity

Indicator	Goal HFA 2000	All India
IMR	<60	74
Perinatal Mortality (93)	≤30	49.1

5.	Perinatal and Neonatal	1	9.1
6.	Meternal Causes	0	1.5
7.	Others and Unknown causes	23.1	7.7

1.5.11 Indices

Indices are prepared by considering a few indicators after giving weightage to each of them. Clubbing of a few indicators helps in producing a more holistic and realistic picture. For Instance two countries may have the same MMR but their TFRs may be different. The woman on an average will have more children and thus has an increased chance of dying to pregnancy or related causes than a woman from the area where the TFR is lower (despite the fact that MMR is the same). Thus lifetime risk gives a better picture and is a more useful index for international comparison.

Human Development Index

Human Development Index was released for the first time by the **UNDP** for 30 countries of the world in 1990. The UNDP has defined human development as the process of enlarging people's choices. Income is one of those choices but it does not cover the totality of human life. Health, education, a good physical environment and freedom of action and expression are just as important. The Human Development Index (HDI), therefore, combines indicators of national income, life expectancy and educational attainment to give a composite measure of human progress.

Human Development Index for Selected Developed and SAARC Countries

HDI Rank	Name of the Country	Life Expectancy nt Birth 1995	Adult Literacy Rate (%) 1995	Life Expectancy Index	Education Index	GDP Index	Human Develop- Index (HDI) Value
	Developed Countries						
1	Canada	79.1	99	0.90	0.99	0.99	0.960
4	USA	76.4	99	0.86	0.98	0.99	0.943
8	Japan	79.9	99	0.91	0.92	0.99	0.940
14	UK	76.8	99	0.86	0.95	0.99	0,932
15	Australia	78.2	99	0.89	0.92	0.99	0.932
19	Germany	76.4	99	0.86	0.93	0.99	0.925
72	Russian Federation	65.5	99 F	0.68	0.92	0.99	0.769
	SAARC Countries						
139	India	61.6	52.0	0.61	0.53	0.21	0.451
147	Bangladesh	56.9	38.1	0.53	0.38	0.21	0.371

90	Sri Lanka	72.5	90.2	0.79	0.83	0.53	0.716
	World	63.6	77.6	0.64	0.72	0.95	0.772

Gender Related Development Index'

The Genderrelated Development Index (GDI) measures achievements in the same dimensions and'variables as the HDI, but captures inequalities in achievement between women and men. It is simply the HDI adjusted downward for gender inequality. The greater the gender disparity in basic human development, the lower a country's GDI compared with its HDI.

Gender Empowerment Measure

The Gender Empowerment Measure (GEM) reveals whether women can take active part in economic and political life. It focuses on participation, measuring gender inequality in key areas of economic and political participation and decision making. It tracks the percentages of women in Parliament, among administrators and managers and among professional and technical workers and women's earned income as a percentage of men's. Differing from the GDI, it exposes inequality in opportunities in selected areas.

HDI Rank	Developed Country	Gender Empower- ment (GEM) Rank	Seat in Parliament Held by Women (%)	Female Administ- rators and Managers (%)	Female Professio- nai and Technical Workers (%)	Women's Share of Earned Income (%)	GEM Value
	Developed Countries						
1	Canada	7	21.2	42.2	56.1	38	0.72

– Not Available

Human **Poverty Index**

Human poverty is denial of choices and opportunities for living a tolerable life. Around a third of the world's population lives on less that $1 a day. The human poverty index increases deprivation in basic human development in the same dimensions as HDI. The variables used are the percentage of people expected to die before age 40, the percentage of adults who are illiterate, and overall economic provisioning in terms of the percentage of people without access to health services and safe water and the percentage of underweight children and lack of maternal means. Graphic representation of HPI is as given below:

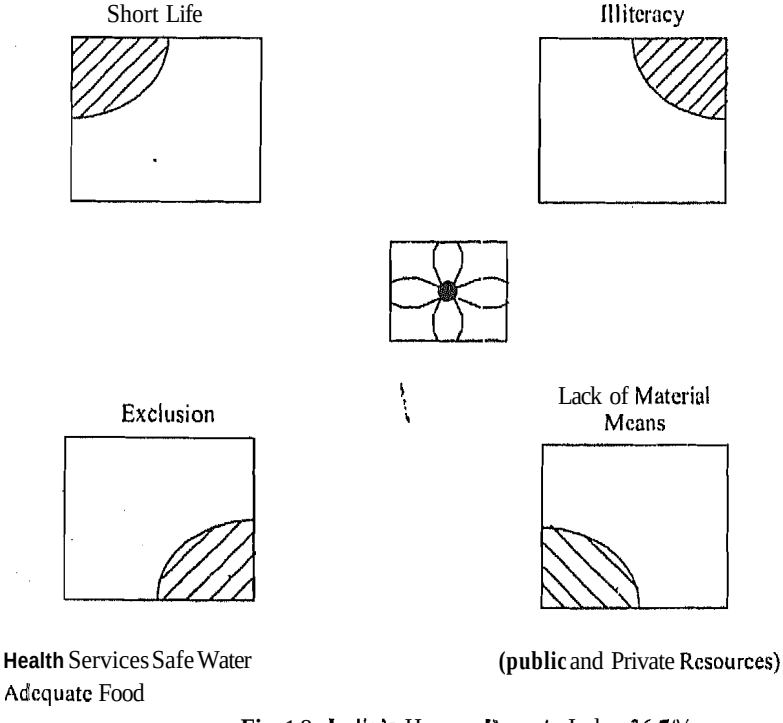

Fig. 1.8: **India's** Hurnan **Poverty** Index 36.7%

Life Time Risk (LTR)

The risk of a woman dying from pregnancy or child birth during her lifetime based on maternal mortality and fertility, (Total Fertility Rate)

The LTR in,

South Asia	–	1 in35
Bangladesh	–	1 and21
India	–	1 in37
Nepal	–	1 in 10
Pakistan	–	1 in38

Disability **Adjusted Life Year (DALY)**

The UNDP, jointly with the World Health Organisation, in 1993, brought out the concept of measuring the global burden of disease (GBD) by combining – (a) Losses from premature death which is defined as the difference between actual age at death and life expectancy at that age in a low mortality population and (b) loss of healthy life resulting from disability. The GBD is measured in units of disability adjusted life year (DALY). World-wide 1.3 billion DALY were lost in 1990. Premature deaths were responsible for 66% of all DALY lost and disabilities for 34%. In the developing world 67% of all DALY loss was a result of premature death; in the developed world this figure was 55%. The three categories of disease used are the group of communicable disease, non-communicable diseases and injuries.

The results of research on GBD challenge the belief that the war against infections and parasitic diseases has been won. The burden of these diseases is substantial in India (28%). It is contributed to mainly by tuberculosis. STDs and HIV, diarrhoea vaccine preventable childhood infections, malaria, worm infections, respiratory infections, maternal and perinatal causes.

Cost effectiveness of interventions are also measured in terms $ per DALY gained.

DALY gained for:

1)	The universal immunizationprogramme	–	$8
2)	Treatment for RTIs/STIs	–	$10–15
3)	Early cure of cervical cancer	–	$150–250
4)	Provision of referral care for complicated pregnancies	–	$2
5)	Urban pregnancies with little complication	–	$18
6)	Neonatal care for perinatal condition	–	$60
7)	Rural pregnancies with little complication	–	$100

1.6 EPIDEMIOLOGICAL SURVEILLANCE

Surveillance is an important epidemiological activity in the field of public health. This term may be used in two ways:

In the broader sense, surveillance has been equated with the routine health information system which gives idea about the total health situation.

In the narrower sense, it is used to refer to specific information system pertaining to specific disease or any other health related event.

1.6.1 Definition of Surveillance

So how do we define surveillance?

The simplest definition could be "Surveillance is data collection for action". It is however defined as:

- the systematic collection and use of epidemiological information for planning, implementation and assessment of disease control (World Health Assembly, 1968).
- the ongoing and systematic collection, analysis and interpretation of health data in the process of describing and monitoring a health event. This information is used for planning, implementing and evaluating public health interventions and programmes. Surveillance data are used to both determine the "need" for public health action and to assess the "effectiveness" of programmes (CDC, 1988).

So what do these definitions suggest? The key characteristics of epidemiological surveillance could be listed as:

i) It is a systematic, regular, ongoing and continuous activity.

ii) It involves collection, consolidation/analysis, interpretation and timely dissemination of information.

iii) The information should be used for different types of action,

So surveillance may be quite simply defined as "Ongoing scrutiny, generally using methods distinguished by their practicability, uniformity and rapidity rather than by complete accuracy. Main purpose is to detect changes in trend or distribution of diseases in order to initiate investigative or control measure.

Surveillance is an essential prerequisite to the rational design and evaluation of any disease control programme.

The ultimate objective of surveillance is prevention.

1.6.2 Purpose/Use of Surveillance

The purpose of the surveillance is:

- assessing magnitude of problem
- monitoring implementation of health programmes
- understanding local epidemiology of the problem
- assessing changes in the trend of diseases or its distribution
- identifying specific population groups at risk
- enabling predictions about the pattern of occurrence of disease
- assessing the impact of the programme intervention for control of diseases.

Effectiveness of surveillance system depends to a great extent on the quality, completeness and regularity of the reporting.

1.6.3 Methods of Surveillance

Different methods are adopted for collection of data for surveillance as no single method of surveillance can be used with equal reliability for all diseases or events. The commonly used methods are:

a) **Passive Surveillance**

It is the routine reporting of the cases of diseases reaching dispensaries/hospitals/ institutions for treatment or service.

b) Active Surveillance

This special search is done for finding cases in the community mainly through door to door surveys, e.g. malaria.

c) Sentinel Surveillance

It is a reporting system based on selected institutions or individual that provide regular, complete reports on one or more diseases occurring ideally in a defined attachment. It also provides additional data on cases.

d) Criteria for Selection of Institutions for Sentinel Surveillance

i) Large attendance of patients with target disease

ii) Capability for reasonably accurate diagnosis

iii) Availability of good recording and reporting facilities

iv) Easy accessibility to population (especially rural)

v) Treatment facility not too expensive or specialized as to exclude some people

vi) Willingness of staff to provide reports

vii) Availability of reasonably developed control programme in the area to enable follow up action on reports.

e) **Case/Outbreak Investigation**

Epidemiological investigation of diseases during outbreaks that even though are adhoc in terms of frequency can provide detailed epidemiological data on the disease. In-depth investigation of epidemic also helps in determining the factors responsible for the occurrence of the epidemic which can help in taking control and preventing action

f) **Case/Events** Investigation

In-depth investigation of specific events/cases, e.g. investigation of each maternal death or each case of Acute Flaccid Paralysis, each infant death, each case of neonatal tetanus etc. The pupose is to identify the situations and circumstances that led to the occurrence of the event under question so that appropriate action can be initiated. Verbal autopsy is the term used for such investigation of deaths.

g) Surveys and Special Studies

Sample surveys for specific disease when periodically repeated at regular intervals can provide more accurate community based epidemiological information about the disease in terms of magnitude and contributory factors in the non-epidemic situation for any particular disease.

h) Vital Registration System

Herein public and, private health care providers report births and deaths etc.

i) Census

It is a count of persons including question about health habits, diseases etc.

1.6.4 Epidemiological SurveillanceSystexn

The steps for the development of an epidemiological surveillance system are as described below:

i) Decide the disease/condition on which surveillance is to be undertaken

ii) Specify the objective/purpose of surveillance

iii) Use standard case definition as well as inclusion criteria

iv) Decide what information need to be collected

v) Select method of surveillance

vi) Develop data collection proceduresltoolslformats

vii) Prepare list of reporting units.

viii) Obtain the data on the condition/disease as to suspected/probable/diagnosed or confirmed cases regularly from the reporting units along with the line listing as required.

Suspect: Diagnosis made on the basis of history by paramedical personnel or tlie members of the community, e.g. rice water stools in cholera.

Probable/Presumption: Diagnosis made on typical history and clinical examination by medical officers e.g. shooting stars under dark field microscopy in cholera.

Confirmed: Clinical diagnosis by a medical officer and/or positive laboratory identification.

ix) Collect and transport laboratory specimens if necessary for diagnosis.

x) Compile accumulated data for the reporting person.

xi) Decide how often and to whom to report as well as channel of flow of report.

xii) Monitor receipts of report for its timeliness and completeness as well as correctness.

xiii) Analyse data to determine the magnitude/changes in frequency and distribution pattern.

xiv) Interpret data ana take action accordingly.

1.6.5 Limitations of Surveillance

The following are the limitations of surveillance:

- Labour intensive activity
- Tabulation and analysis are time consuming
- Limited to a few key indicators
- Several years of data collection necessary to identify trends
- .Difficult to assess impact if no control group or if population is small
- Reporting of surveillance data is often incomplete

1.7 LET US SUM UP

In this unit you have learnt that the preliminary interaction of the disease process starts in the environment (pre pathogenesis). The course of the disease in man is called as the period of pathogenesis and together they form the natural history of disease.

You have also learnt that the health, its maintenance and falling ill is governed by a multifactorial amalgamation of various determinants. Some of the important determinants are genetic, environment, socio-cultural, economic, provision of health services and political commitment.

Further you have learnt that prudent interventions may prevent the occurrence of the disease or limit its grave course. Preventing the disease before it occurs in man is known as 'Primary Prevention'. Early treatment of the patient is 'Secondary Prevention' while limiting the disability and rehabilitating the person in 'Tertiary Prevention'.

In this unit you have also learnt that the order to assess the scale of burden of disease and the need for intervention, indicators are needed that capture the important components contributing to it.

Towards the end you have learnt that surveillance of diseases helps in detecting changes in trends or distribution of diseases in order to initiate investigative or control measures. It is essential for the rational design and evaluation of any disease control programme. The effectiveness of a surveillance system depends to a great extent on the quality, completeness and regularity of the reporting. The common methods of surveillance are passive surveillance, active surveillance, sentinel surveillance, investigation of outbreaks, events, surveys and special studies, vital registration system and census. The steps for the development of a surveillance system along with its limitations have been discussed.

1.8 ANSWERS TO CHECK YOUR PROGRESS

Check Your Progress 1

a) Secondary Prevention – Early diagnosis and prompt treatment

b). Primary Prevention – Specific protection

c) Tertiary Prevention– Rehabilitation

d) Secondary Prevention – Early diaagnosis and prompt treatment

Check Your Progress 2

1) Indicators of MCH Care are:

- Maternal Mortality Rate
- Infant Mortality Rate
- Neonatal Mortality Rate
- Postnatal Mortality Rate
- Perinatal Mortality Rate
- 1-4 Years Mortality Rate

2) Indices are arrived at by combining a few indicators and by comparing the figures of the index we are in fact comparing those indicators together.

By comparing the HDI we can compare the relative development between different countries. In fact, we are comparing the combined effect of national income, life expectancy and educational attainment – the three, key indicators of development in a multidimensional approach.

Check Your Progress 3

1) No, the medical check up of the school going children will not be considered as surveillance because it is not a regular, ongoing and continuous activity, However, if the medical check ups are done regularly say yearly, the findings analysed and the information used for action, it will constitute surveillance.

2) Census is a method of surveillance because:

   i) It is a systematic, regular, ongoing and continuous activity.

   ii) It involves collection, consolidation/analysis, interpretation and timely dissemination of information.

   iii) The information is used for different types of action.

UNIT 2 HEALTH FOR ALL AND PRIMARY HEALTH CARE

Structure

2.0 OBJECTIVES

After going through this unit, you should be able to:

- discuss the background of the development of the concept of Health For All By The Year 2000AD;
- define and discuss the components of the Primary Health Care;
- discuss the role of hospitals in Primary Health Care;
- identify your role in delivery of Primary Health Care.

2.1 INTRODUCTION

In this unit you will learn about the infrastructure for health care delivery in the country. You will also learn about the concept of 'Health For All', its vision and definition. Further you will learn about primary health care, its definition, components and principles. Towards the end you will learn about the role which hospitals can play in primary health care delivery. After going through this unit yau should be able to identify your role in delivery of primary health care.

2.2 CONCEPT, SCOPE AND VISION OF HFA

India is the largest democracy in the world. It presents a unique case in terms of sheer size of its population characterized by heterogeneity in respect of physical, economic, social and cultural conditions. India's population rose from 361.1 million in 1951 to 864.3 million in 1991 and to 96.9 million in 2000. On 2.4% of the land area only India supports more than 16 per cent of the population of the world. 74.2 per cent of India's population lives in villages.

The Republic of India has a federal structure consisting of 25 States and 7 Union Territories. The Constitution of India envisages the establishment of new social order based on equality, freedom, justice and the dignity of the individual. It aims at elimination of poverty, ignorance and ill-health and directs the States with regards to raising the level of nutrition and the standard of living of the people, securing the health and strength of workers, men and women, and especially ensuring that children are given opportunities to develop in a healthy manner. Constitutionally while public health, sanitation, hospitals and dispensaries are the responsibilities of the States, population control and Family Planning, drugs, prevention of food adulteration are concurrent subjects.

The delivery of Primary Health Care is the foundation of rural health care system and forms an integral part of the national health care system. For developing vast human resources of the country, accelerating the socio-economic development and attaining improved quality of life, Primary Health Care is accepted as one of the main instruments of action.

The program of establishing Primary Health Centres in each Community Development Block having a population of 60,000 to 80,000 was launched as an integral part of the Community Development Program on October 2,1952. Each Primary Health Centre Complex consisted of the main center with 6 beds located at the Block Head Quarters, and 4 subcentres. The staff consisted of 1 Medical Officer, 1 Sanitary Inspector, 4 Midwives (ANMs) and 2 Anciliary personnel. The Centre was to bc supported by district organization for referral consultation, laboratory, medical, surgical nursing and administrative services.

Health for All

During the Thirtieth World Health Assembly meeting in 1977 it was decided that the main social goal of all the countries and WHO should be the attainment by all the people of the world of a level of health that would permit them to lead a socially and economically productive life. Subsequently, WHO and UNICEF jointly organized an international conference on Primarily Health Care at Alma Ata, USSR, from 6-12 September, 1978. A momentous decision was taken in this conference:

- That health is a fundamental human right
- And that the attainment of the highest level of health is a most important social goal, whose realization requires the action of many other social and economic sectors in addition to health.
- "International Conference on Primary Health Care Alma-Ata 1978" – The Conference was attended by delegations from 134 governments and by representatives of 67 UN organisations and non-government organisations (NGOs).

This in nutshell means that HFA (2000 AD) should be achieved through a multi-pronged strategy mobilizing the support of other socio-economic sectors as well, or we can say All for Health (AFH) approach.

The goal of Health for All by the year 2000 still continues to be a Vision founded on social equity, on the urgent need to reduce the gross inequality in the health status of people in the world, in development and developing countries and within countries. It is a vision based on the principles that health and development are closely interlinked. It is a vision whose range of view encompasses fundamental change in the way health is perceived, promoted, projected and delivered.

And these changes, which represent a fundamental shift in values, include:

- Change in how people, individually, take greater responsibility for the protection and promotion of their health;
- Change in the way people participate collectively in health, organizing themselves into action groups and enhancing self-reliance;
- Change in the perception and value system of the health providers – in which the health professionals have to be socially concerned, de-mystify health, involve people, empower

them so that they may assume greater responsibility for their own health. They also have to broaden their understanding of health, no longer confined mainly to medical care or traditionally defined preventive health care services;

- Change in the organization administration of the health system, going beyond the physical design involving redefinition of objectives of the principal institutions, reallocation of responsibilities and even of the pawer structure; getting health closer to the people by decentralizing and delegating authority, by revolutionizing the health care delivery system, emphasizing bottom-up planning and forging linkages, and by bringing other health-related sectors into closer alliance;

- Finally, change in the attitudes and perception of policy makers in which health has to be seen and pursued as an integral part of development emphasizing a greater concern for social equity, bolstered by the courage to choose healthcare systems which are affordable, which give preferential attention to the under-privileged and vulnerable, and which provide rational means for deploying resources,

The perspective of Health for All assigns new values to health. "Health" is no longer just the availability or the access to health services but rather a state of personal well being going beyond the absence of medical problems. It means promoting healthy life-styles and ameliorating the environment in which we live; preventing illness, accidents and disability with all the means at our disposal; and providing care and cure to all using relevant technology. "For All" means that health is to be brought within reach of everyone. It emphasizes equity, social justice and cooperation.

Central to these new values is that health is a fundamental human right and a worldwide social goal, it is an integral part of development; and, people have a right and the duty to participate individually and collectively in the planning and implementation of their health care and thus they must be encouraged and prepared to become self-reliant.

Definition: Health for All is defined as the enjoyment of health as one of the fundamental rights of every human being. The vision incorporates the value of health as human right, equity, solidarity and ethics.

The basis for organization of health services in India was laid by the recommendations and guidance provided by the "Health Survey and Development Committee" (Bhore Committee) in 1946. Bhore Committee recommended basic health care approach which subsequently changed to primary health care approach. Over the last five decades, the health services organizations and infrastructures have undergone extensive changes and expansion in stages following review by a number of expert committees (Mudaliar 1961, Chadha 1963, Mukherjee 1966, Jain 1967, Kartar Singh 1973, Srivastava 1975, Alma Ata Declaration, 1978, National Health Policy 1983 and various five year plans). You will learn in detail about the recommendations of various committees and National Health Policy in Block 2 of this course.

Government of India subsequently announced a "new and restructured 20-point program" for national development in August 1986. This included "Health For All" and "Two Child Norm" as two separate points in the 20-point program. It further stated the sub-objectives of each of these two important points.

Health for All	Two Child Norm
3 Improving quality of primary health care.	i) To bring about voluntary acceptance of two child norm.
ii) Fighting leprosy, tuberculosis, malaria, goiter, blindness and other major diseases.	ii) To promote responsible pnrenthood.
iii) Providing immunization for all infants and children.	iii) To reduce infant mortality.
iv) Improving sanitation facilities in rural areas specially for the females.	iv) To expand maternity and child care facilities.
v) Paying special attention to program of rehabilitation of the handicapped.	

It will be worthwhile to emphasize that the quality of both the primary health care and the reproductive and child health are crucial to the success of both Health for All and the Two Child Norm. The quality of these services from the rural health infrastructure has come under repeated criticism and question mark.

2.3 PRIMARY HEALTH CARE AND COMPONENTS

In the previous section you learnt that Alma Ata Declaration identified Primary Health Care as the key to attain health for all.

Primary health care is defined as essential health care, which is based on practical scientifically sound, socially acceptable methods and technology, made universally accessible to people through their full participation and at a cost, which the community and country can afford to maintain in a spirit of self-reliance.

This essentially means a holistic approach, which is low cost and appropriate to local people and conditions.

The Alma Ata Declaration states that the primary health care should at least have the following eight-components:

i) Education of people regarding prevailing health problems and methods of preventing and controlling the same.

ii) Promotion of food supply and proper nutrition.

iii) Adequate supply of safe water and basic sanitation.

iv) Maternal and child health and family planning.

v) Immunization against major infectious diseases.

vi) Prevention and control of locally endemic diseases.

vii) Appropriate treatment of common diseases and injuries.

viii) Supply of essential drugs.

2.4 PRINCIPLES OF PRIMARY HEALTH CARE

The conference on Primary Health care in Alma Ata gave the PHC philosophy a political dimension with five underlying principles:

- Equitable distribution
- Community involvement
- Focus on Prevention
- Appropriate technology .
- Multi-sectoral approach

This political philosophy has dominated discussions about primary health care since the late 1970s, and it is distinguished from the original narrow definition of PHC by being referred to as the primary health care approach.

The meaning of the five principles, which provide the framework of the primary health care approach, can be summarized as:

Equitable Distribution

Health services must be more equally acces'sible, not neglecting rural and isolated population or peri-urban dwellers.

Community Involvement

Active participation by the community in their own health decisions is essential.

Focus on Prevention

Preventive and promotive services rather than curative services should be the central focus of health care.

.Appropriate Technology

The methods and materials used in the health system should be socially acceptable and relevant.

Multi-sectoral Approach

Health must be seen as only part of total care; nutrition, education, water supplies and shelter are also essential minimum requirements to well-being.

2.4.1 A New Course of Action for Health

The Primary Health Care (PHC) approach thus constitutes a qualitative break with the past, a new course of action for health. Far from being just the addition of yet another layer to the health service – at the bottom, in the communities, using community resources – PHC implies a reordering of priorities that should permeate all levels of sectors concerned with the promotion of health. Such a reordering has, above all, three main applications.

2.4.2 Implications of the Primary Health Care Approach

First, in terms of understanding health problems, the PHC approach stresses that health promotion involves a set of issues much wider than those, which health services have conventionally tried to tackle. Therefore, the PHC approach is qualitatively different. It involves political action and the efforts of many sectors other than health.

Second, the PHC approach emphasizes the use of certain policies to translate that understending into practice. These policies include other relevant socio-economic issues which develop a framework for inter-sectoral action; they emphasize the need for an integrated approach to health care within the health service itself; they encourage a progressive shift from centralized planning and decision making to decentralization and active involvement of people in health matters.

Thirdly, the PHC approach calls for shifts in the allocation of resources to give greater emphasis to the preventive and promotive health activities and to the underserved and disadvantaged population groups.

It should be clearly understood that it is the primary health care approach, which is being promoted internationally as the key to attaining the goal of health for all by the year 2000. The approach advocates that health care be brought as close as possible to where people live and work. It stresses that primary health care be an integral part both of the country's health system, of which it is the central function and main focus, and of the overall social and economic development of the community. It therefore requires a strong political will and support at both national and community levels reinforced by a firm national strategy.

2.4.3 Distribution of Primary Health Care Centres

The Comprehensive National Health Policy created a model of health care service, with the objective of providing Health for All by 2000 AD. A working Group of the Ministry of Health of the Government of India recommended integration of the promotive, preventive and curative aspects at all levels of primary health care. Keeping in view the local topography, density of population, transport system etc., the following model of health services structure was recommended. Each state/union territory was expected to undertake careful exercises to review the available structure and to adopt the recommended model with local variations as required, to adequately meet the requirements. The health facilities will be fully utilized and equipped to implement the national programs.

Each district: A District health centre with specialized curative services and public health experts.

Each **sub-division:** (approximately 5 lakh population). A sub-divisional health centre with epidemiological wing attached to it.

Each block: (one lakh population). A Community health centre – having specialists offering medical care services in Gynaecolgy, Paediatrics, Surgery and Medicine. There will be four non-specialists doctors (general duty). One of these may be drawn from any of the locally accepted 5 traditional systems of medicine, and one should be frons the public health stream. Community health center will have 30 beds. It serves as a referral centre for four PHCs.

***For* 30,000 population** (or 15,000-20,000 in the case of hilly, tribal, sparsely populated or desert areas). ***Primary* Health Centre (PHC)** is the first contact point between village community and the medical officer. A PHC is manned hy a medical officer supported by 15 paramedical and other staff. It acts as a referral unit of six stah-centres. It has 4-6 beds. A PHC will be fully equipped to render preventive, promotive and curative services. Existing rural dispensaries will be upgraded with additional funds, equipment and expansion of staff building,

Staff *for New* Primary Health Centre

1)	Medical Officer	1
2)	Pharmacist	1
3)	Nurse midwife	1
4)	Female Health worker (ANM)	1
5)	Health educator	1
6)	Male health assistant	1
7)	Female health assistant (LHV)	1
8)	Upper Division Clerk	1
9)	Lower Division Clerk	1
10)	Lab technician	1
11)	Driver	1
12)	Class IV	4
	Total	**15**

For *5,000* population (or 3,000 population in the case of hilly, tribal, sparsely populated or desert areas) **Sub-Centre** is the most peripheral contact point between the primary health care system and community. One sub-centre, will have one MPW (Female), MPW (Male) and one part time attendant. It will provide antenatal, natal and post-natal care for pregnant women.

For each **village/1000 *population*** (or 500 population in the case of hilly nnd tribal areas or sparsely populated or desert areas). A decentralized, participatory approach involving the community intimately in the planning, implementation and maintenance of the health services was recommended.

A village health guide was appointed for population of 1000 peoples. She was trained for a period of three months and was equipped with a manual of instructions and a medicine kit. A stipend of Rs. 2001- was given during training and thereafter a stipend of Rs. 50/- p.m. was given. It was started as a 100 per cent centrally sponsored program in 1977 but in 1979, states

were requested to pay for 50 per cent of the expenses. In 1981, the scheme was again made 100 per cent centrally sponsored, with the provision that only female health guides will be appointed. If female workers not available male health guides may be appointed with preference given to ex-servicemen, freedom fighters and persons known for social service. The village health guide was meant to be a link between the community and health functionaries to ensure community participation. The scheme is under review at present.

2.5 ROLE OF HOSPITALS IN PRIMARY HEALTH CARE

According to Dr. H. Mahlar (former Director-General WHO), there are those who believe that hospitals and Primary Health Care are incompatible subject, arguing that every dollor spent on a hospital is one less for primary health care. According to this school of thought, we enhance the position of primary health care at the direct expense of hospitals. There are still others who see hospitals'as the repository of the best that medical care has to offer and, as such see it as a waste of time and energy for hospitals to deal with other aspects of health care. They would keep primary health care as separate and not allow it to interfere with the life of a hospital.

Commenting on the managerial implications of the role of hospitals in primary health care, Dr. Kawaye Kamanga, Head and Social Secretary, Lusakaa, Zambia said, "almost immediately acceptance of primary health care approach – universally – was largely d e to the impression that it offered a chance for the fulfillment of same political promises, dreams aspirations by means not demancling extra resources".

But, primary health care concept challenged the status quo, required new money and resources and demanded new management outlook in health services.

Many of the difficulties with the establishment of primary health care are concerning the management and the reorientation of the already existing services. In many ways, the hospitals and the primary health care were seen as either/or – mutually exclusive alternatives. What is needed is a management exercise to improve this relationship.

The WHO Expert Conunittee on the Role of Hospitals at the First Referral Level met in Geneva from 9 to 17 December 1985. The meeting was opened by Dr. T A Lambo, Deputy Director-General, on behalf of the Director-General. Dr. Lambo emphasized the timeliness and importance of the task before the Expert Committee and reminded the Committee that it was, in fact, the first WHO Expert Committee on hospitals since 1968, and the first since 1959 to review the role of the hospital in the broader context of a health system.

2.5.1 Hospitals Versus Primary Health Care: A False Antithesis

Hospitals represent, throughout the world, the main concentration of health resources, professional skills, and medical equipment. How can they give more help to the' field of primaryhealth care? That question is being asked increasingly by hospital policy makers who want to contribute to the health care revolution that is now taking place. It is also being voiced with equal urgency by those involved in organizing and promoting community health care who recognize the need for the kind of support (technical skills, scale and depth of resources, etc.) that only hospitals can provide.

Hospitals and community health services have often been seen as separate entities, and as rivals, The apparent antithesis is a false one, it is common and of long standing. Moreover, it has enough semblance of the truth to be thoroughly dangerous. However, as the demand for universal health care coverage intensifies, and constraints on resources increase in almost all health-care systems, it is clear that what is done within hospitals must be closely interrelated with health activities going on outside in the community.

Successful cooperation between hospitals and other local health services has often been hindered by differences in tradition, principles, and skills. These differences are real and in many respects valid, but both types of services are needed for a comprehensive approach to health care.

The hospital is traditionally concerned with individual patients, and with acute curative care. Such care is resource intensive, and requires modern techniques and well-trained professional manpower. The hospitals tend to define performance in terms of the quality of individual care for those who are seriously ill, and of the use of sophisticated methods. The main problems encountered are those arising from doctor-patient relationships and the interaction of treatment methods and individuals.

By contrast, the primary health care approach (which is just as relevant to hospitals as to other local health services) advocates promotive and preventive activities as well as treatment, and is oriented to the needs of entire populations. It seeks to maximize the impact of available resources in relation to all health needs by the use of appropriate technology and a broad range of health personnel including community health workers. The success of such an approach is defined not only by the quality of individual care but also by improvements in the health status of populations, and in terms of more equitable use of available health resources, wider coverage of the population, and greater personal responsibility for health. The main problems encountered are those arising from the interaction of health systems and populations, and resource allocution.

The philosophies behind these two different approaches also differ. In the hospital approach, the improvement of health is often viewed as being beyond the power of the individual, it being regarded as the realm of the specialized providers of medical care; the service is thus professionally oriented. The trained professional, who has invested substantial amounts of time and money in developing technical skills, is seen as the most valuable instrument in a system that focuses on nurture and development. The health provider's role is more that of a "facilitator".

Differences in the underlying philosophies of the two approaches may result in conflict when they are brought together. However, health professionals both within and outside hospitals can and should find common ground in a comprehensive view of primary health care, despite their differences in tradition and orientation.

2.5.2 The Need for Hospital Involvement

No local health system based on the primary health care approach can work without the involvement and support of a hospital, and an efficient system of referring patients who need more specialized care than can be given outside the hospital. However, it is equally important that the hospital does not offer treatment that can be provided by other levels of the health service, if it does it will become overloaded and unable to provide proper support to the community.

In many countries there is a deep-rooted impression that the higher levels of the health service, provide the bebt care. Therefore, strong links are essential between the hospital and the community in order to reassure people that they will receive specialized hospital treatment if it is truly needed.

Primary health care does not simply mean community health services or primary medical care in a'conventional sense. It can be looked at in several different ways:

As a range of programs adapted to the patterns of health and disease of people living in a particular setting;

- As a level of care (the exact definition depending upon the country concerned) backed up by a well-organized referral system;
- As a stsategy for reorienting the health system in order to provide the whole population with effective essential care, and to promote individual and community involvement and intersectoral collaboration; and
- As a philosophy, based on the principles of social equity, self-reliance, and community development.

Whichever way primary health care is looked at, hospital involvement is essential. If primary health care is regarded as a range of programs, it requires the back up of hospitals in promotive and preventive activities, as well as curative and rehabilitative services. If it is regarded as a level of care, primary health care will not work unless there is effective hospital support to deal with referred patient, and to refer patients who do not require hospital attention back to one of the other primary health care services. If it is regarded as a strategy, it will not work without an adequate investment of skills and finance, which, at present, are mainly in the hospital sector. Moreover, the philosophy of primary health care is just relevant to what goes on within hospitals, as to what happens outside them.

2.5.3 Role and Functions of the Hospital at the First Referral Level

Typically, hospitals are extsemely busy places, doing the best they can for individual patients, whether they present for emergency treatment, an outpatient consultation, or inpatient care. Rarely can staff stand back from their work and consider the hospital's role in conceptual terms.

One way to analyze the hospital's role in the model of primary health care illustrated in Fig. No. 1 is as part of a dynamic system with inward and outward flows of people, materials, requests, reports, ideas, etc., from the home, the community, or the health center to the hospital, or vice versa. Some examples of these flows are given below:

Inward Flow: Patients, problems, requiring resolution, people for training, reports, data for evaluation, requests for consultations, equipment needing repair and maintenance, and requisitions for supplies.

Outward **Plow:** Patients, instructions, analyses of reports, training and supervisory activities, consultation reports, requests for information about the periphery, new ideas and techniques, equipment, and supplies.

Such intersactions (which differ according to local circumstances) do not take place in a vacuum; the hospital at the first referral level must relate to all the other levels of the health service, including secondary and tertiary referral levels. Moreover, the hospital's relations with other public services (intersectoral collaboration) are vital, as is the social and political context of the community, which it serves. The inward and outward flows are thus moulded in a particular setting by such forces as population density, economic development, the attitude of the medical profession, and the degree of decentralization and integration of the political system.

Another way to address the question of the hospital's role is by considering its contribution, in terms of clinical care and functional support (for example, manpower development and management activities), to specific primary health care programs (for example, immunization) in relation to the contributions made by other levels of the health service. In effect, this approach is the same as extracting a series of program "slices" from the multidimensional model shown in Fig. 2.1 in order to review who does what, and where the gaps or overlaps may be?

Both approaches can lead to a definition of the hospital's role in terms of patient referral, health program coordination, education and training, and management and administrative support. The Committee discussed each of these subjects in turn, and then considered their organization implications.

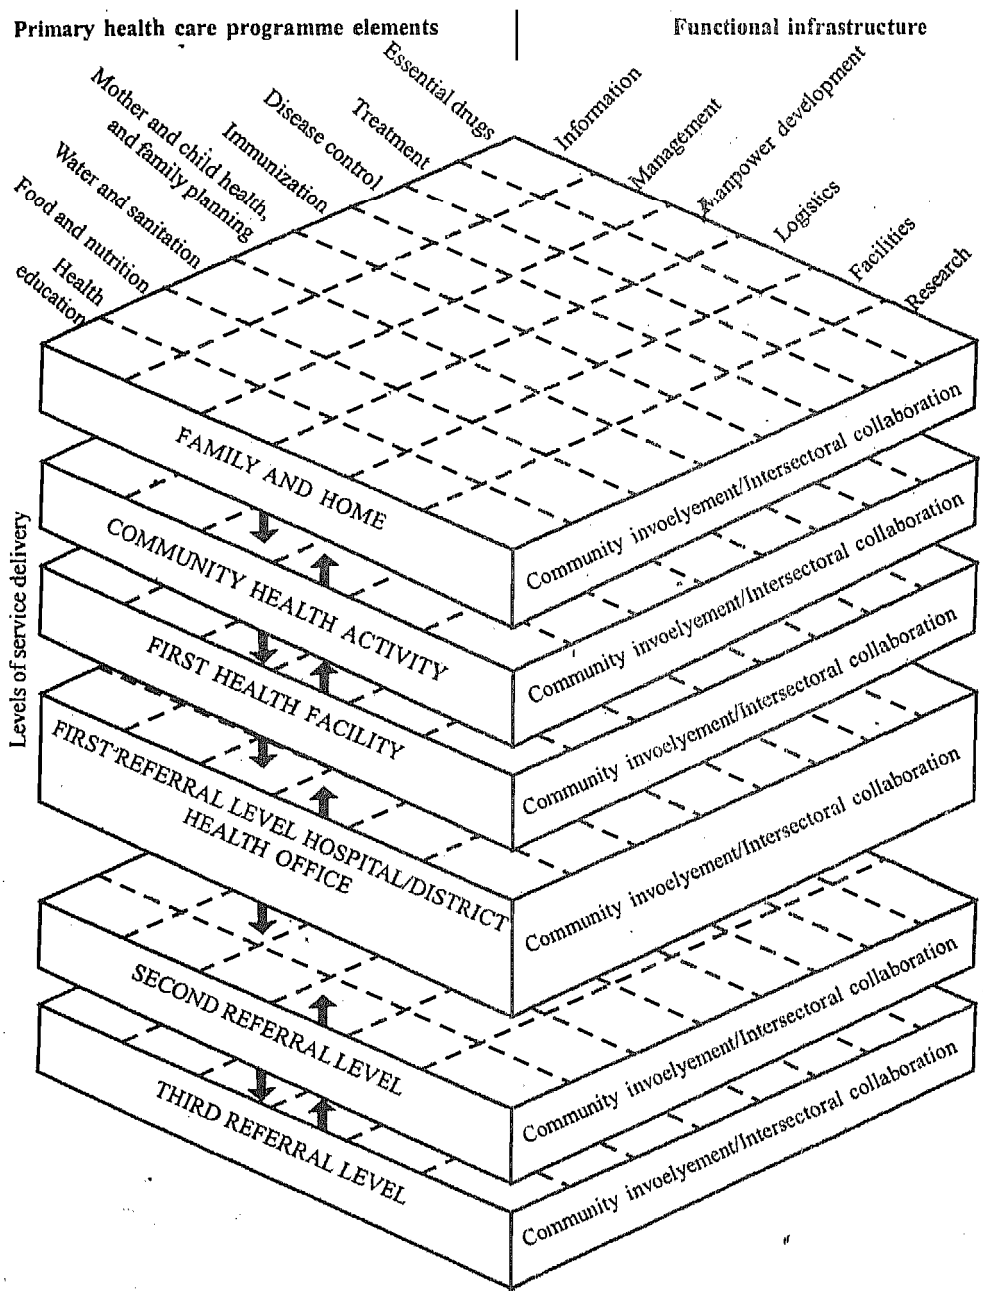

Fig. 2.1: A Conceptual Model of a Comprehensive Health System Based on the Principles of Primary Health Care

Patient Referral

Some patients present direct to the hospital, through emergencies and self-referral, while others are referred by a physician, nurse, or the health care worker. In any of these instances the hospital's job is to treat the patient as best it can, discharge him or her as soon as it is consistent with appropriate care, and explain to the referring practitioner or health care worker its findings and the further care required.

In theory this sounds simple, but it is not always so in practice. For example:

- The hospital may be almost overwhelmed with patients (through self-referral and through poorly judged referral), so that adequate care is difficult to achieve;
- Referred patients often do not arrive at the hospital or arrive only after an undesirable delay because the journey to the hospital is too long, or because of lack of transport or of financial problems;
- People may have very little confidence (sometimes justifiably) in the care that they would receive outside the hospital, and therefore go directly to the hospital; and

- The flow of information to and from the hospital is generally inadequate. Evidence presented to the Expert Committee (based on one, not untypical, study) suggested that at least half the letters of referral to hospitals were inadequate, and that most discharge reports and summaries were either defective or late, or both.

2.5.4 Issues in Role of Hospital i-n Primary Health Care

The WHO Expert Committee has raised the following issues which the hospitals should consider with regard to their role towards primary health care:

- defined coverage of population by the hospital.
- service to the population outside its walls.
- identification of problems, resources and needs of the covered population.
- liaison with other health agencies.
- defining the prevalence and distribution of specific health problems and planning the type of services (Indoor/Outdoor).
- development and maintenance of an information system for evaluation.
- participation in health manpower development.
- provision of logistic support to PHC.
- development of effective referral system.
- review & increased resources allocation to PHC proportionately.
- quality wise evaluation of hospital services and extension of same to PHC.
- consideration of essential functional and organizational changes to accommodate PHC.
- evaluation PHC activities (supported by the hospital) as a component of total evaluation of the hospital performance.
- changed its role to join with community representatives to generate support for PHC.

The Expert Committee emphasized the fact that a general hospital cannot work in isolation and it must be a part of a social and medical system that provides complete health care. While accepting that curative medicine is the principle function of hospitals, the Committee agreed that preventive activities should be developed, and that the training of health personnel and research (both biomedical and social) were other indispensable functions of any general hospital. The organization of a regional system of hospitals, and the development of extra-mural activites for a defined population, were strongly recommended as a way to achieve integration of preventive and curative medicine.

It can be said that the hospitals should support and encourage the Primary Health Care and establish sound linkages with the rural health infrastructure.

2.6 HEALTH FOR ALL IN THE TWENTY-FIRST CENTURY

At the end of the 20th Century, it is beconling clear that the goal of Health for all by the year 2000 has not been achieved. Two major factors are held responsible for this failure.

These include:

a) biased and poor socio-econonlic development in the regions where it was needed most, and

h) discriminatory policies due to age, gender and ethnicity thus preventing access to health care surveillance.

In order to realize the goal of HFA in the 21st Century, WHO has come forward with a outline of visions, goals and objectives and targets to achieve it in the very near future. Health has to be made central to hunian developments and this presupposes, a commitment to developmental policies and economic strategies, so well outlined in the HFA 21st century document.

The implementation of new global health policy "Health for All in 21st Century" will be guided by global targets. Specific indicators will bc developed to assess progress at all levels.

2.6.1 Targets

Ten global targets are identified to guide the implementation of HFA policy in the 21st century. These can be broadly classified into three groups. However, regions and countries should sets their own targets based on local conditions and priorities.

i) Those related directly to health outcomes and are quantifiable directly (1–4)

ii) Those requiring intersectional action and enhancement of intervention in the field of health promotion (5–6)

iii) Those reflecting the significance of building sustainable health systems (7–10)

Target 1: Improve health equity By 2005, health equity indices will be used within and between countries as a basis for promoting and monitoring equity in health. Child growth will be initially used as a quantitative target for equity as follows. "The percentage of children under five years who are stunted should be less that 20 per cent in all countries and in all specific subgroups within countries by the year 2020". Height for age is considered a good indicator for monitoring child growth because it can measure the long-ten11cuniulative deficiencies in growtli. Presently 38% children in developing countries and 34% worldwide are stunted.

Target 2: Increase survival By 2020, the target agreed at World Conference for maternal mortality Rate, under five mortality rate and life expectancy would be met.

Maternal Mortality Rate < 100 per 1,00,000 live births

Child Mortality Rate < 45 per 1000 live births

Life Expectancy at birth > 70 years for all countries

Target 3: Reverse Global trends for five major pandemics: By 2020, the worldwideburden of disease will be substantially decreased, This will be achieved by implementation of sound disease control programs aimed at reversing the current trends of increasing incidence and disability caused by tuberculosis. HIV/AIDS, malária, tobacco related diseases and violence1 traume.

Target 4: Eradicate and eliminate certain diseases. The following table presents a clear picture:

Disease	Target	Strategy
Measles	Eradication by 2020	Immunization, surveillance, training
Lymphatic filariasis	Elimination by 2020	Vector control, community treatment

Disease	Target	Strategy
Chagas's disease	Interrupt transmission by 2010	Vector control, blood screening
Leprosy	Elimination by 2010	Multi-drug therapy, surveillance, research, awareness
Trachoma	Elimination by 2020	SAFE strategy Surgery, antibiotics, facial cleanliness and environmental improvement
Vitamin A and Iodine deficiency	Elimination by 2020	Dietary improvement, fortification of fats or sugar or salt, supplementation program

Target 5: Improve access to water, sanitation, food and shelter By 2020, all countries should make major progress in providing safe drinking water, adequate sanitation, food and shelter in sufficient quality and quantity. This can be achieved by

- Targeting the high risk population first
- Emphasizing on community participation and management of facilities, and

  Increasing the awareness of politicians and decision–makers concerning the health risks of insufficient water and sanitation facilities.

Target 6: Promote health enhancing life styles By 2002, all countries will have introduced and be actively managing and monitoring strategies that strengthen health-enhancing life-styles and weaken health damaging ones through a combination of regulations and economic, educational , organizational and community based programs. The target advocates a healthier public policy, and support environment, community action, personal skills und health services. For achieving the goal, indicators related to both health enhancing (for example, physical activities, nutrition, personnel relationship) as well as health damaging (substance use, violence, unsafe sex etc.) life-style needs to be developed.

Monitoring will be focused on changes in (i) health behavior (ii) health determinants, (iii) regulatory, fiscal, economical and environmental policies, and (iv) capacity building programs and participation of individuals communities, schools, work places, media and other sectors.

Target 7: Develop, implement and monitor national HFA policies By 2005, all member states will have operational mechanisms for devetoping, implementing and monitoring policies that are consistent with these HFA policies. Each country should select the best mix of policies to achieve HFA depending on its needs, capacities and priorities. Policies should then be translated into action with the help of a strong strategic management expertise and local framework.

Target 8: Improve access to comprehend essential quality health care By 2010, all people will have access throughout their lives to comprehensive, essential, quality healthcare, supported by essential public health functions. This target incorporates the concept of a life span approach to health promotion, prevention and care.

Target 9: Enhance health information and surveillance system By 2010, appropriate global and national health information, surveillance and alert system will be established with best use of resources.

Target 10: Support research for health By 2010, research policies and institutional mechanism will be operational at global, regional and countiy level. All countries need to define their research priority, ensure that research is funded, managed, ethical principles applied and capacity development is support.

The current mismatch between the burden of diseases and resources allocated for research on these diseases should be eliminated. Research efforts should be directed towards areas where substantial health gain is needed.

2.6.2 Primary Health Care Infrastructure

The Primary Health Care infrastructure has been developed as a three-tier system and is based on the following population norms:

Centre	Population Norms	
	Plain Area	Hilly/Tribal Area
Sub Centre	5000	3000
PHC	30000	20000
CHC	120000	80000

Sub-centres

It is the most peripheral contact point between the Primary Health Care system and the community, It is manned by one Multi-purpose Worker (Male) and one Multi-purpose Worker (Female)/ANM. Only 97,757 Sub Centres are funded by Department of Family Welfare, out of a total number of 1,37,271 Sub Centres functioning in the country as on30.06.1999. The rest are being funded under the State Minimum Needs Program/Basic Minimum Services Program.

It has been decided during 1997 that the states will have the choice of opening new sub-centres out of the funds provided to them under the BMS Program.

Primary Health Centres (PHC's)

PHC is the first contact pomt between village community and the Medical Officer. These are established and maintained by the State Government under the Minimum Needs Program (MNP)/Basic Minimum Services Program. A PHC is manned by a Medical Officer supported by 14 paramedical and other staff. It acts as a referral unit for 6 Sub-ccntrcs. It has 4-6 beds for patients. The activities of PHC involve curative, preventive, prornotivc and Family Welfare Services. As on 30.06.1999, 22,975 PHCs arc functioning in the country.

Community Health Centres (CHCs)

CHCs are being established and maintained by the State Government under MNP/BMS. It is manned by four medical specialists i.e. Surgeon, Physician, Gynaecologist and Paediatrician supported by 21 paramedical and other staff: It has 30 in-door beds with one OT, X-ray, Labour Room and Laboratory facilities. It serves as a referral center for 6 PHCs. As on 30.06.99, there were 2935 CHCs functioning in the country.

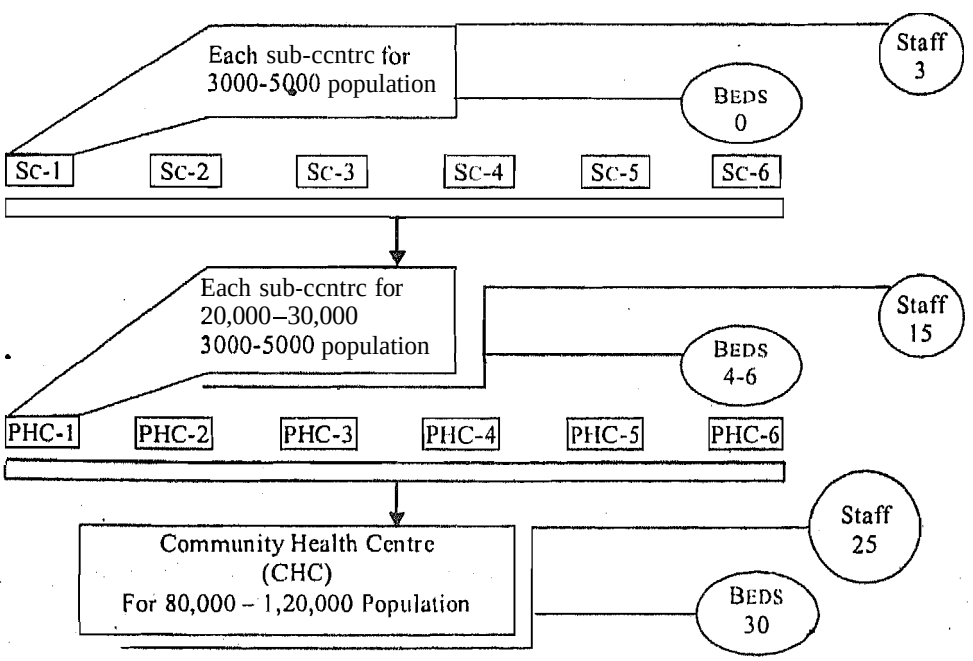

Fig. 2.2: Population Norms of Community Health Centre, PHC and Sub-centre

Primary Health Care Infrastructure

The number of health centres in India and other levels of achievement are shown below: (as on 30.6.1999, Bulletin on Rural Health Statistics in India, Ministry of Health & Family Welfare, New Delhi)

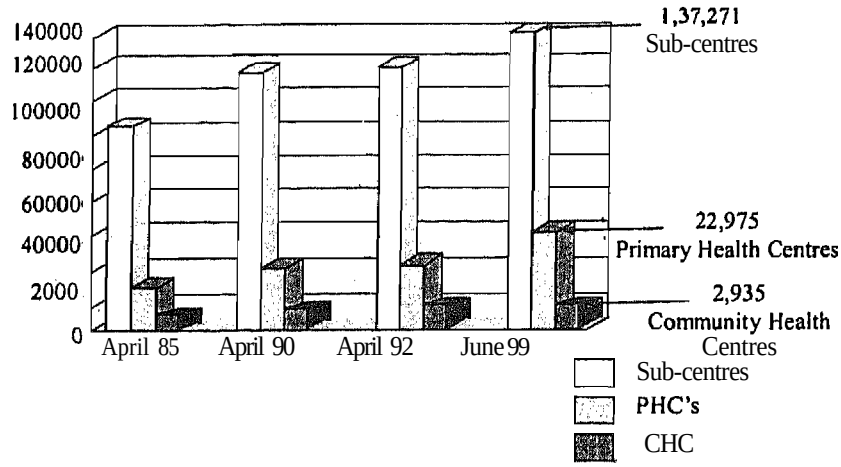

Fig. 2.3: **Existing** Health Centre Facilities in **India** as on 30.6.1999

This by no means is a small health infrastructure that the country has, but the quality of services from them or their utilization in general is rather poor. Therefore, the existing health infrastructure needs to be consolidated and made vibrant so as to address to the felt needs of the rural/tribal community, specially the disadvantaged group of the society. In fact, the success of health and family planning programs depends on (a) good teamwork among the various categories of health workers. The leader of this team is normally a doctor. Today, all studies suggest that the leadership role played by these doctors, particularly in the mral health infrastructure is disturbing. They need to be given serious management training especially in the behavioral/attitudinal aspects.

We should not forget that HFA is the destination, and leadership is the cutting edge of change and the driving process to get to the destination.

2.7 LET US SUM UP

In this unit you have learnt that nearly all health systems, hospitals are too dominant and consequently too little attention is paid to the links between the hospital and Primary Health Care and workers in the field.

You have also learnt about the concept, scope and vision of Health for All. Further you learnt the definition and components of primary health care. Subsequently you learnt the role of hospital in primary health care and achieving the targets of health for all.

Towards the end of the unit you learnt about the availability of primary health care infrastructure in the country. Today's health planners and adminstrators must take a note of this disturbing trend and make all efforts to correct this kind of enforces.

2.8 ANSWERS TO CHECK YOUR PROGRESS

Check Your Progress 1

1) Health Survey and Development Committee, 1946. (Bhore Committee, 1946)

2) Primary health care is essential health care, which is based on practical scientifically sound, socially acceptable methods and technology, made universally accessible to people through their full participation and at a cost, which the community and country can afford to maintain in a spirit of self-reliance.

Check Your Progress 2

1)
- Equitable distribution
- Community involvement
- Focus on Prevention
- Appropriate technology
- Multi–sectoral approach

2) Staffing pattern of a PHC:

Medical Officer	1

   The implementation of new global health policy "Health for All in 21st Century" will be guided by global targets.

UNIT 3 BASICS OF EPIDEMIOLOGY AND BIOSTATISTICS

Structure

3.0 OBJECTIVES

After going through this unit, the students should be able to:

- comprehend the significance and describe the concepts of epidemiology;
- apply the principles of epidemiology to logical reasoning about the causes of health problems and derive practical solutions to them;
- conduct various epidemiological studies;
- forecast an epidemic and manage it if it occurs;
- use the knowledge of screening in prevention and management of diseases; and
- understand and apply common biostatistical tests.

3.1 INTRODUCTION

In this unit you will learn about the epidemiological principles and concepts. You will also learn about various epidemiological methods including descriptive and analytical epidemiological studies. Further you will learn about the various pattern of epidemics, forecasting of epidemics and its management. This unit also covers that concept of screening

UNIT 3 BASICS OF EPIDEMIOLOGY AND BIOSTATISTICS

Structure

3.0 OBJECTIVES

After going through this unit, the students should be able to:

- comprehend the significance and describe the concepts of epidemiology;
- apply the principles of epidemiology to logical reasoning about the causes of health problems and derive practical solutions to them;
- conduct various epidemiological studies;
- forecast an epidemic and manage it if it occurs;
- . use the knowledge of screening in prevention and management of diseases; and
- understand and apply common biostatistical tests.

3.1 INTRODUCTION

In this unit you will learn about the epidemiological principles and concepts. You will also learn about various epidemiological methods including descriptive and analytical epidemiological studies. Further you will learn about the various pattern of epidemics, forecasting of epidemics and its management. This unit also covers that concept of screening

of diseases. Towards the end of the unit you will learn about basic concepts of biostatistics including the tests of significance.

Epidemiology is primarily based on two assumptions, i.e. human disease does not occur at random and that human disease has casual and preventive factors that can be identified through systematic investigation of different population or sub-groups of individuals within a population in different places or at different times.

Epidemiology has not evolved as a science recently. In fact, it is as old as medicine itself. As early as the 5th century BC, Hippocrates considered that the development of human disease might be related to the external as well as the personal environment of an individual.

Recognition by John Graunt in London in 1662 about the value of routinely collected data on births and deaths in providing information about human illness forms the basis of modern epidemiology. William Farr, later in 1839, in England and Wales established a tradition of careful application of vital statistical data to the evaluation of health problem of the general public.

John Snow during 1849-1854, used his clinical knowledge as well as observations to formulate and test the causal hypothesis for cholera epidemics, This approach was applied primarily to outbreak of infectious diseases throughout the 19th and early 20th centuries. Thus, the term epidemiology was originally used almost exclusive to mean the study of epidemics of infectious diseases. The patterns of mortality in developed countries and to a large extent in developing countries have changed markedly with chronic diseases assuming increasing importance. Accordingly, the concept of an epidemic has become much broader and more complete, thus necessitating more advanced methods of investigation.

Control of infectious diseases characterised by relatively short latency periods between exposure and onset of illnesses, by improvement in nutrition, housing, water supply and sanitation coupled with methods of treatment, immunisation etc., in developed countries has led to emergence of chronic-diseases, characterised by long latency periods of 10-22 years or more as a major cause of mortality. This change in mortality pattern for developed countries had far reaching implications for epidemiology. First, the priority population group on which public health activities were focussed got shifted from infants and young children to middle aged people with the aim of preventing premature death from chronic conditions like **CHD** and cancer. Second, the term epidemic is broadened to include any disease-infectious or chronic occurring at a greater frequency than usually expected. Third, the increased importance of chronic diseases has necessitated the development of new methodologies because while investigating etiologies, the exposure of interest in case of chronic diseases might have occurred many years prior to the onset of illness (as compared to an investigation of a disease like measles or diphtheria). The major development are the design of studies and-techniques for collecting and analysing data to facilitate evaluation of risk factors for chronic diseases through case control and cohort studies. More recent development has the application of epidemiologic principles and methods to the design, conduct and analysis of intervention studies like clinical trials wherein the investigators manipulate the human environment like the basic researchers control conditions in the laboratory.

Contribution of Epidemiology

The results of basic laboratory and animal research may differ from those that apply to human beings and may become irrelevant to humans i.e. applicability of findings from a particular species of animals to humans cannot be predicted. Similarly, there are variation in dosages as well as routes of administration of agents in animal and human experiments and hence reliable quantitative estimates of risks in humans is difficult. Thus, while basic research may add to our biologic understanding of why an exposure causes or prevents disease, only epidemiology allows the quantification of magnitude of the exposure disease relationship in humans and offers the possibility of altering the risk through intervention. Therefore, epidemiological studies (i.e. on human population) can provide strong and reliable evidence on which the base policy and ultimately decisions affecting the health of the general public.

3.2 CONCEPT OF EPIDEMIOLOGY

Definition of Epidemiology

A modem definition, internationally accep ted is: Study of the distribution and determinants of health-related states and events in populations, and the application of this study to control health problems. The phrase "health-related" – relates to phenomena like physical fitness, pregnancy, eating habits etc., which are not diseases. The final clause in the definition is there because there is no sense in studying the distribution and determinants of problems without doing something to control at and evaluate the control measures (John. M Last, 1988, Journal of Public Health Policy, Vol. 9, No. 2).

Epidemiology is the most powerful tool for the diagnosis, monitoring and evaluation of a community's health.

Basic purpose of epidemiology is to obtain, analyse, interpret and use health information to promote health and reduce disease.

Epidemiology does not represent a body ofknowledge like 'anatoniy' but it represents a philosophical method of studying a health problem.

Epidemiology is actually logical reasoning about causes of health problems based on information gathered through observations and measurements.

Epidemiology is an applied discipline which is concerned with practical solutions to problems, and it depends on other disciplines like clinical medicine, biostatistics, microbiology, pathology, demography, behavioural sciences, etc.

Information for epidemiological studies are derived from the following questions:

What?	What is the problem,. disease condition? What are its manifestations and characteristics?
Who?	Who is affected with reference to age, sex, social class, occupation, heredity, personal habits, etc?
Where?	Does the problem occur in relation to place of residence, geographical distribution?
When?	When does it happen in terms of days, months, season or years?
How?	How does it occur and what is its association with specific conditions, agents, vectors, sources of infection, susceptible groups, and other contributing factors?
Why?	Why does it occur in terms of reasons for its persistence or occurrence?
So What?	What interventions have been implemented as a result of the information gained and what was their effectiveness'? Have there been any improvement in health status?

Epidemiological skills are crucial for health managers to obtain and interpret health information for preparing plans, for guiding allocation of resources, for monitoring the implementation of different health programmes, for assessing their access and coverage as well as effectiveness by measuring changes in the health status. Thus, the main function of epidemiology is to handle/manage various types of data either already generated by health and other service facilities routinely as a part of the health service procedure or newly generated through specific survey procedures, for the purpose of enabling technical and managerial decision making for improving health service delivery and thereby tlie health of community. The important feature of epidemiology is that the bulk of data which are available are analysed and converted into meaningful indicators of measurement of different aspects of health problems and services and interpret them to relate to the community from where the data are generated so that appropriate decision are taken to benefit the community.

3.3 IMPORTANT EPIDEMIOLOGICAL PRINCIPLES AND CONCEPTS

3.3.1 Natural History of Disease

In this carlier unit you have already learnt that every disease will follow a natural course. It includes a pre-pathogenic phase, where the interaction of agent, host and environment takes place and once the balance is in favour of the agent the disease process starts i.e. the pathogenic phase begins. In this phase there is the incubation period followed by the emergence of clinical manifestation of signs and symptoms, development of progressive disease process including complications, disabilities and the ultimate outcome of either recovery, with or without sequel or death. In some cases in some diseases where the host nearly overcomes the disease processes initiated by the agent there is a sub-clinical phase which is most diseases are missed by the clinicians.

3.3.2 Epidemiological Triad

The agent alongwith the secondary factors determine the occurrence of the disease i.e. theory of multiple causation. These causal factors may thus relate to the etiological agent itself, to the host and to the environment in which both agent and host exist. The interaction among these three i.e. the agent, host, and environment is the epidemiological triad. The tilt of the equilibrium in favour of either the agent or the host will ultimately decide if the disease occurs or not.

3.3.3 Levels of Prevention/Intervention

Depending upon the knowledge about the stages of the natural history of the disease and availability of technological inputs/strategies, different levels of prevention/interventions can be applied as follows:

Prepathogenic phase: Primary prevention i.e. health promotion and specific protection.

Pathogenic phase: Secondary prevention i.e. early diagnosis and prompt treatment and tertiary prevention i.e. disability limitation and rehabilitation.

For details of these you may refer to unit on Concepts in Community Health (Unit 1 in this Block).

3.3.4 Risk Approach in Health Care

Risk approach in health care is an effective management tool to ensure rational and more efficient use of resources. Important assumption underlying this approach is that risk factors which predispose persons to higher chances of suffering from undesirable outcomes of diseases or death, are known and that individuals can be grouped under high, moderate, low risk categories as well as specialised care can be provided to those who need them by directing the allocation of Iimited resources particularly for this purpose. Prior knowledge1 ascertainment of risk factors through epidemiological studies (with analytical studies which have proved the hypothesis establishing the association between the risk factor under question with the disease) is an essential prerequisite in this regard.

Application of risk approach in health care are evident in case of MCH services, Coronary Heart Diseases (CHD), Cancer etc.

3.3.5 Measurement

A prerequisite for any epidemiological investigation is the ability to quantify the occurrence of disease. The most basic measure is the simple count of affected individuals. This will give the actual load of disease in a community which would enable proper allocation of resources to tackle that problem. However, conclusion in epidemiology are generally based on comparisons. Such comparisons are based onstudying the relative frequency of the event in a population against the frequency of the same event in another population. The basic tools of measurement in epidemiology are rates, ratios, and proportion. Rates are a way of comparing the frequency of an event in population.

Measures of disease frequency used in epidemiology fall into two broad categories i.e. Prevalence and Incidence.

Prevalence quantifies the proportion of individuals in a population who have the disease at a specific instant;

$$P = \frac{\text{Number of existing cases for a disease}}{\text{Total population at a given point of time}}$$

In contrast to prevalence, incidence quantifies the number of new events or cases of disease that develop in a population of individuals at risk during a specified time interval.

$$I = \frac{\text{Number of new cases of a disease during a given period of time}}{\text{Total population at risk}}$$

Check Your Progress 1

List the uses of epidemiology?

.....

.....

.....

3.4 EPIDEMIOLOGICAL METHODS

Knowing that human disease does not occur at random, the next step is to try to find the causal factors for human disease through systematic investigation. Statistical association is then determined between the causal factor suspected and the disease before drawing inferences for its use in the prevention and control of diseases.

3.4.1 Descriptive Epidemiological Studies

They describe the general characteristics of the distribution of disease in relation to person, place, and time.

Indices of person include:

- demographic factors like age, sex, occupation, marital status, race, life-style variables like food habits, drug use etc.
- characteristics of place refer to geographic distribution of diseases including variation among countries or within countries such as urban and rural areas etc.
- time characteristics refer to seasonal patterns of disease, onset, trend of disease over years etc.

Sources of data for descriptive studies may be:

- case reports kept by clinicians.
- routine disease surveillance reports.
- cross-sectional surveys,

Cross-sectional surveys on any disease would help in quantifying the disease for that time of survey, prevalence, and also in describing the disease in relation to various parameters.which might include some risk factors also. However, since data on the disease and the risk factor is obtained at the same point in time, it is difficult to distinguish whether the risk factor proceeded the development of the disease or not (which is important in establishing a causal association).

The information obtained from these studies can lead to formulation of epidemiological hypothesis regarding causation or prevention of disease. It also helps planners to allocate resources and to plan effective prevention and education programmes.

3.4.2 Analytical Epidemiological Studies

Since analytic studies aim at testing hypothesis related to the exposure factor and disease, the investigator assembles groups of individuals for systematically determining whether or not the risk of the disease is different for individuals exposed or not exposed to the factor of interest. Comparison between two groups is explicit in such studies.

There are two types of analytical studies i.e.

a) Observational, and b) Interventional

Observational studies can be: Case control and Cohort

Decision to use a particular study is determined by:

- the features of exposure,
- the features of disease,
- the current state of knowledge, and
- logistic considerations like time available, resource availability.

Case Control Study

In this, subjects are selected on the basis of whether they do (cases) or do not (controls) have a particular disease under study. The groups are then compared with respect to the proportion having history of exposure or characteristic of interest.

Selection of Cases (affected individuals)

- First define the disease or the outcome of interest
- Establish diagnostic criteria to ensure inclusion of homogenous entity of disease.
- Selection of cases from different courses i.e. from medical care institution is from the general population.

Selection of Control

Controls are necessary to allow the evaluation of whether the frequency of an exposure observed in the case group is different from that which would have been expected among those who do not have the disease. Controls could be from medical care institutions (suffering from some other diseases), general population controls, special groups like friends, relatives, etc.

Information about Exposure: To be obtained from the study subjects, both cases and controls, either by interview or questionnaire and if available, from records.

Analysis: Basically a comparison between cases and control with respect to the frequency of an exposure whose aetiologic role is being evaluated. Comparison is made by estimating the relative risk/odds ratio, e.g.

Cigarette Smoking	Lung Cancer		Total
	Cases	Controls	
Yes	70 (a)	300 (b)	370
No	30 (c)	700 (d)	730
Total	100	1000	1100

$$\text{Odds Ratio} = \frac{ad}{be} = \frac{70 \times 700}{30 \times 300} = 5.4$$

$$\text{Relative Risk} = \frac{a/(a+b)}{C/(c+d)} = \frac{701370}{301730} = 4.6$$

RR = 1.0 indicates that the incidence rates of disease in the exposed and non-exposed groups are identical and thus that there is no association observed between exposure and disease. In a case control study, since participants are selected on the basis of disease status, it is difficult to calculate the rate of development of disease incidence. Yence, the relative risk

- can be estimated by calculating the ratio of the odds of exposure among cases to that of control, i.e. Odds Ratio.

A value of RR more than 1 indicates a positive association or an increased risk among those exposed to the risk factor.

Strengths and **Limitations** of Case **Control** Studies

Strengths

Relatively quick and inexpensive compared to other analytic designs. Particularly well suited to the evaluation of diseases with long latent periods. Optimal for evaluation of rare diseases can examine multiple etiological factors for a single disease.

Limitations

Inefficient for the evaluation of rare exposures, unless the a'ttributable risk percent is high.

Cannot directly compute incidence rates of disease in exposed and non-exposed individuals, unless study is population based.

In some situations, the temporal relationship between exposure and disease may be difficult to establish.

Particularly prone to bias compared with other analytic designs, in particular selection and recall bias.

Cohort Studies

Here groups of individuals are defined on the basis of presence or absence of exposure to suspected risk factor for a disease. At the time of defining **the** exposure status, subjects must be free from the disease under investigation. Participants are then followed over a period of time to assess the occurrence of that outcome/disease.

Selection of Exposed Population/Cohort

For life-styles like smoking, alcoholism etc, individuals with that particular life-styles can be included in the cohort, or for environmental factors, people from specific geographic locations or if the exposure is related to a particular occupation, people engaged in that-occupation can be included as "exposed cohort".

Selection of **Comparison** Group

Appropriate comparison group of non exposed individuals are to be selected. This group should be as similar to tlie exposed group with respect to all factors related to the disease except the determinant factor under investigation.

During follow up, complete, comparable, unbiased information on tlie health experience of every individual in both groups will have to be collected. The basic analysis of data from' cohort studies involve the calculation of rates of the incidence of a specified outcome among tlie cohort under investigation which will be compared between the exposed and the non exposed. Both relative and attributable risks can be estimated from this type of study.

If the frequency of occurrence of the disease/outcome is significantly higher in the exposed group, then the association is said to be established i.e. tlie hypothesis indicating the association between a disease and its causal factor will be accepted.

Strengths **and** Limitations of **Cohort** Studies

Strengths

Of particular value when the exposure is rare

Can examine multiple effects of a singie exposure

Can elucidate temporal relationship between exposure and disease.

If prospective, minimises the bias in the ascertainment of exposure.

Allows direct measurement of incidence of disease in exposed and non exposed group

Limitations

Inefficient for evaluation of rare diseases, unless the attributable risk percent is high.

If prospective can be extremely expensive and time consuming.

If retrospective, requires the availability of adequate records.

Validity of results can be seriously affected by loss of follow up.

Intervention Studies

In intervention studies the individuals are included on the basis of exposure to a factor, which invariably should be some beneficial factor, and aie followed over a period of time for the occurrence of the outcome. The investigator allocates the exposure. Common examples for epidemiological intervention studies are clinical trials for new treatment procedures, or vaccine trials, or introduction of some service package like provision of iodised salt., It may also be the introduction of a preventive safety device like helmets or car belts while driving or wearing of lead aprons while conducting radiological procedures.

The first step in conducting intervention study is the selection of the study population where tbere should be an experimental group and a control group. This allocation in the, experimental and control group should be through randomisation of avoid bias. Randomisation is the hallmark of an honest trial.

The investigator may be aware of the groups being experimental or control, but the recipients will not know if they are receiving the drug or the placebo. These are single blind trials. In double blind trials neither the investigator nor the recipient will come to know the experimental and control groups.

In triple blind studies not only the investigator and the participant but also the data analyser do not know the experimental and the control groups,

The second step is the allocation of the treatment regimens intervention. The next step is the maintenance and assessment of compliance. This could be by ensuring the availability of iodised salt or good quality helmets and assessing the population actually consuming iodised salt and wearing helmets while driving in the experimental groups. The last step is the ascertainment of outcome. The results are statistically tested using the tests of significance. If the results are significantly better in the experimental group, the drug or the vaccine may be recommended for use. The process of enacting legislation may be initiated like in case of iodised salt and wearing of helmets.

Check Your Progress **2**

You are a paediatrician in a district hospital. You observe that over the past few years the incidence of bronchial asthma has increased specially amongst the children coming from the district headquarters. You feel that it is because of pollution both vehicular as well as from generators. How will you test your hypothesis'?

3.5 EPIDEMIC MANAGEMENT

The very mention of the word 'epidemic' brings to the mind a scenario, seen in a movie or read in a book, of a town affected by a dreaded disease like plague with the people fleeing in panic leaving their loved ones dying unattended. A brave young niissionary with a heart of gold and a true Christian spirit rolls up his sleeves and literally snatches the people back from Yama's hands. Situations have changed with time but epidemics still do occur though in a milder form.

Now what is this epidemic? Epidemic is a derivation of two Greek words epi (upon/among) and demos (people). It is the unusual occurrence in a comniunity or region of a disease or specific health related events "clearly in excess" of the "expected occurrence". Thus any disease, which occurs in numbers more than the expected occurrence constitutes an epidemic. It includes not only the communicable diseases but also the non-communicable diseases like coronary heart diseases or even the psychosomatic disorders. Health-related behaviours like smoking, drug addiction and health-related events like accidents also fall into the category of epidemics. Then to determine an epidemic the major question is how to define the "expected occurrence" so as to call the disease frequency as an epidemic one.

There is no constant number for the expected occurrence of a disease. It varies from place to place, region to region. A few hundred cases of yellow fever in a district of a country like Nigeria or Ethopia, where the disease is endemic, shall be called as the expected occurrence of the disease in that area. On the contrary in a district of an equal population in India, where the disease is non-existent, tlie expected occurrence shall be zero. So the basis of defining an epidemic is the defining of an endemic.

An endenlic is defined as the constant presenceof a disease or infections agent within a population in given geographical area without importation from outside. It may also refer to tlie usual prevalence of a given disease within an area.

The incidence clearly in excess of this expected occurrence or the endemic frequency shall constitute an epidemic. A few cases of yellow fever in a district in India shall constitute an epidemic whereas a few hundred cases of yellow fever in a district in Nigeria shall not become an epidemic. Now let us take tlie example of sniall pox. Forty years from today small pox was rife in the country. It was thus an endemic disease. Now it has been eradicated from the world. It is no more an endemic disease. The expected occurrence of sniall pox is zero. A single case of small pox will, therefore, be clearly in excess of the expected occurrence and have would be now considered as an epidemic of small pox. So a disease, which was endemic once, may cease to be so and a single case may be taken as an epidenlic.

A disease may be both endemic and epidemic depending on the frequency. In some districts of Rajasthan water becomes scarce in summers and may result in getting polluted. Therefore, water-borne diseases like infectious hepatitis and typhoid may be common. To illustrate, in a hospital with a relatively fixed catchment area eight to ten cases of typhoid and infectious hepatitis occur in the month of June and in November, when the situation of water eases the number of cases drops down to two or three. Now in a given year, nine cases of typhoid in June will constitute an endemic but nine cases in November shall constitute an epidemic.

The difficulty generally arises as to when to label the disease to have assumed epidemic proportion in a region where it is normally endemic. In an area where malaria is endenlic when do we say that epidemic of malaria has broken out. For instance, a disease like hepatitis 'A' is endemic in district X. When shall we say that an epidemic of Hepatitis 'A' has broken out in the district. The decision is slightly arbitrary. If tlie number of cases are more than two standard errors from the endemic frequency it will be called an epidemic, Keeping a track and diagnosing a disease taking an epidemic dimension at the earliest is the hallmark of an efficient health adniinistrator.

3.5.1 Patterns of Epidemics

The epidemics generally follow a pattern depending on the geographical and environmental conditions, the distribution and characteristics of the host population and their socio-cultural behaviour. If there is no intervention or change in these conditions, those epidemics tend to repeat themselves. Therefore, knowing about the various kinds of epidemics and the conditions in which they occur can thus be of immense help in managing them.

The various types of epidemics normally occur are described below:

a) **Common** Source Epidemics

These epidemics originate from a single source of infection or the disease producing agent - the two common source epidemics are:

i) ***Point Source or Single Exposure Epidemic***

The agent responsible for the causation of disease is exposed to the agent population at risk atone point of time and only once. For instance, a marriage party may experience an epidemic of food poisoning due to eating of contaminated food, the point source of the epidemic. The cases will occur within one incubation period. It normally has one spurt which rises abruptly and declines equally fast (Fig. 3.1). The time after which half the number of cases occur is known as the median incubation period. A single exposure epidemic may also be caused by a chemical (Bhopal Gas Tragedy) or a pollutant (Chernobyl nuclear holocaust).

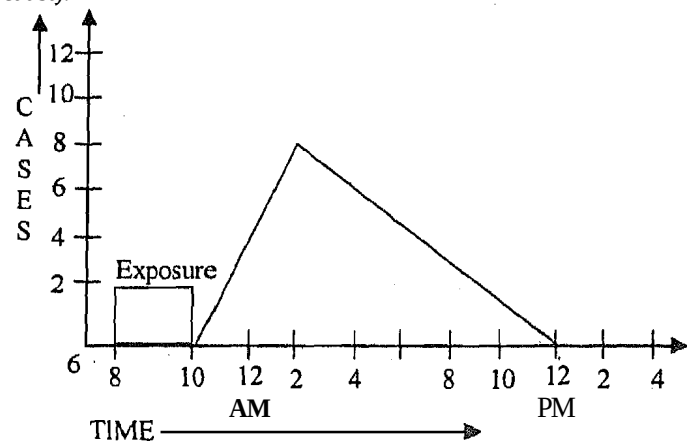

Fig. 3.1: **Epidemic Curve** of Exposure to Staphylococcal Contaminated Food'

ii) ***Continuous or Multiple Exposure Epidemic***

The source of infection for the causation of an epidemic may be continuous. In such a case the epidemic shall not cease to exist till the source is removed. A well with contaminated water becomes a regular source of infection to the people using it and the epidemic may continue till the time the water is treated and made potable. Similarly a cook who is a typhoid carrier may keep on infecting the diners in the restaurant till he is treated and made non-infectious.

b) **Propagated** Epidemics

The propagated epidemics are generally of infectious origin and the transmission of infection is from person to person. Vector or vehicle transmission may also be there in diseases like malaria, cholera, gastroenteritis, etc. The speed of spread depends on herd immunity, secondary attack rate and opportunities for contact.

c) Seasonal Epidemics

Infectious diseases and some non-infectious diseases tend to have a,. increased incidence during certain seasons or months. Gastrointestinal infections have an increased incideace during the summer month and respiratory infectious during the winter months. Road traffic accidents are more frequent in rainy months and asthma in spring.

d) Cyclic Epidemics

Some epidemics tend to occur in cycles which repeat itself in weeks, months or years. Measles tend to present in epidemics in a cycle of 2-3 years (in an unimmunized population). Certain behaviour related events like road traffic accidents occur in cycle form during the weekends due to a spurt in drunken driving.

e) Epidemics of Non-Communicable Diseases

The sedentary and affluent life-style has resulted in a marked rise in diseases like ischaemic heart diseases and diabetes mellitus. The slow growth of the numbers has perhaps concealed the size and the gravity of the epidemic.

3.5.2 Epidemic Forecasting and Management

An able hospital administrator using the knowledge of epidemiology can anticipate or forecast an epidemic, make preparations to handle the epidemic in advance and manage it if the epidemic unfortunately occurs.

Early forecasting of an epidemic may be possible by methodical surveillance. Prompt intervention on the basis of the surveillance reports may even abort or at least contain the epidemic before it reaches its peak. Surveillance has already been discussed in the uni: on. Concepts in Community Health (Unit 1 of this Block). The best of administrators may not be able to 'forecast' an epidemic and may start action only after it has occurred. It shall however be a crisis if the administrator becomes aware of the epidemic after it is in full swing. Surveillance, thus, is of paramount importance in epidenuc forecasting and its management,

Techniques of Forecasting

The major techniques of forecasting of epidemics is based on the trend analysis of the particular disease over a period of time. In order to have a correct trend analysis you will have to undertake the following measures.

a) Tabulation of the data on monthly basis and yearly basis for at least three years on the following parameters for immediate cornparison and identifying the deviations.
   - Disease
   - Sex
   - Age group
   - Incidence/prevalence rate of the disease for the same months of the past three years.
   - Regional, state and national incidence/prevalence rates or ratios of past years.

b) Comparison of monthly and yearwise data based on available rates/ratios.

c) Plotting different graphs for total, sex-wise, age group-wise incidence and prevalence for the past few vears.

d) Preparing spot maps to detect regional variations.

e) Comparing for seasonal and cyclic variations with respect to specific disease.

Preparedness to Meet the Epidemic

There is a saying in the army 'the more you sweat in peace, the less you bleed in war'. The same holds true for epidemics. The more the organisational preparedness for an epidemic the less is the mortality and morbidity during an epidenuc. A contingency plan must be prepared in collaboration with the administrative structure of the catchment area. The contingency plan consists of two parts, the first concerning logistics regarding the inventory or resources both existing and required and the second being the technical consisting of the preparations of investigation and control plans for the most probable epidemics in the region.

Managing the Epidemic

The investigation and management for the epidemic will be the prime responsibility of the district authorities. As an hospital administrator you can help them by:

i) Verifying the diagnosis i.e. confirming the cases. ***Suspect*** is a case with clinical signs and symptoms compatible with the disease but no laboratory evidence e.g. passing rice water stools (cholera).

Presumptive Case is one when the laboratory evidence is suggestive of infection but does not prove it conclusively e.g. shooting starts seen in dark field microscopy (cholera).

Confirmed Case is based on lab'oratory evidence conclusive of current infection e.g. stool specimens on culture showing vibrio cholera (cholera).

ii) Informing the district epidemiologist and helping him in the' investigation of the epidemic.

iii) Advising the line of management for the patients

iv) Providing specialist services

This support provided by the hospital is of immense help to the district.epidemiologist in managing an epidemic.

Check Your Progress 3

You are reviewing the statistics of the diseases for the month of January 2000 of a dispensary which are as follows:

a)	-ARI	–	56
b)	Scabies	–	14
c)	Gastroenteritis	-	10
d)	Hyper emesis gravid arum	–	6
e)	Injuries	–	6
f)	Viral Hepatitis	-	4

i) Was any disease reaching a s epidemic proportion?

You further review the previous records. They are as follows:

Disease	January 1997	July 1998	January 1999	July 1999
ARI	52	22	50	20
Scabies	13	14	12	18
G.E.	3	32	2	34
Hyperemesis	4	4	5	3
injuries	5	7	5	4
Viral Hepatitis	3	9	0	10

ii) Did any disease reach epidemic proportions?

iii) If yes, why?

.....

.....

.....

.....

.....

.....

.....

3.6 SCREENING

Screening as you must be knowing is the presumptive identification of unrecognized disease or disability by the application of tests, examinations or other procedures. A screening test is not intended to be diagnostic.

It serves to sieve out population which has certain known risk factors for particular diseases and thus helps to be able to make a diagnosis during the early stages of disease. A decrease in the disease specific mortality will be a direct benefit. Any change in morbidity of the disease due to the application of screening tests is difficult to assess.

Screening in public health is an epidemiological tool when applied to population at large.

Mass **Screening**

A knowledge of the natural history of the condition is essential in order to evaluate the benefit obtained from a screening test, since the test is designed for early diagnosis and prevention. It should be possible to apply the test rapidly to differentiate between those who are well and those probably affected by the disease or disability. It should be fairly specific and should be inexpensive, as it is to be applied on a large scale. The test must not require great expertise.

Screening will therefore be useful wherever an improvement in prognosis by early detection is clearly established e.g. in early detection of breast cancer. It is also needed to make decisions about undertaking certain lines of action such as abortion in prenatal screening for some congenital abnormalities.

The WHO states that the development of screening tests has been the most important recent contribution in preventive medicine.

The criteria for assessment of a screening test are:

i) Sensitivity Validity
ii) Specificity
iii) Repeatability
iv) Predictive value

Validity

It is the ability of a screening test to correctly identify those individuals who actually have the disease and those who do not. It has two components:

Sensitivity

This is the ability of the test to identify correctly those who *have* the disease. The more sensitive the test, the less number of false negatives.

Specificity

This is the ability of the test to identify correctly those *who do not have* the disease, leading to as few false positives as possible.

This is best illustrated by a 2 × 2 contingency table:

Screening Test	Reference Test		Total
	Positive	Negative	
Positive	True positive (a)	False negative (c)	(a+b)
Negative	False positive (b)	True negative (d)	(c+d)
Total	(a+c)	(b+d)	(a+b+c+d)

$$\text{Sensitivity} = \frac{\text{True positives}}{\text{True positives} + \text{False negatives}} = \frac{a}{a+c}$$

$$\text{Specificity} = \frac{\text{True negatives}}{\text{True negatives} + \text{false positives}}$$

$$= \frac{d}{b+d}$$

True positives are cases identified as positive by both the screening and reference tests. True negatives are persons declared negative by both tests.

Predictive Value

The positive predictive value is the likelihood that a person with a positive test has the diseases. A negative predictive value is the likelihood that a person with a negative test has not got the disease.

$$\text{Positive predictive value} = \frac{\text{True positives by screening}}{\text{Total positives by screening}} \times 100$$

$$= \frac{a}{c+b} \times 100$$

$$\text{Negative predictive value} = \frac{\text{True negatives by screening}}{\text{Total negatives by screening}} \times 100$$

$$= \frac{d}{c+d} \times 100$$

Predictive value helps us to compare the various screening tests which have been developed for a specific condition.

As the prevalence of a disease increases, so does the predictive value of the screening test. The incidence of any condition is directly proportional to the predictive value of a test till a certain limit. Beyond this limit there is little gain in predictive value from a higher prevalence.

Repeatability

Once a screening test has been proved to be of value, it will be put into practice as a routine measure in many health institutions all over the world. That means that it will be repeated many times over. The greater the accuracy on repeating the test, the more reliable it is.

The factors affecting repeatability are:

a) subject variation
b) observer variation
c) technique variation
d) circumstances of the test
e) manufacturers' variation

Cost Benefit **of** Screening

The proceedings of the technical discussion of the World Health Assembly in 1971 hold well even today. It was stated that indiscriminate mass health screening is not a useful preventive tool as it often results in counter productive health effects, is costly and it is wiser to limit it to high risk groups and high risk periods of life based on epidemiological knowledge.

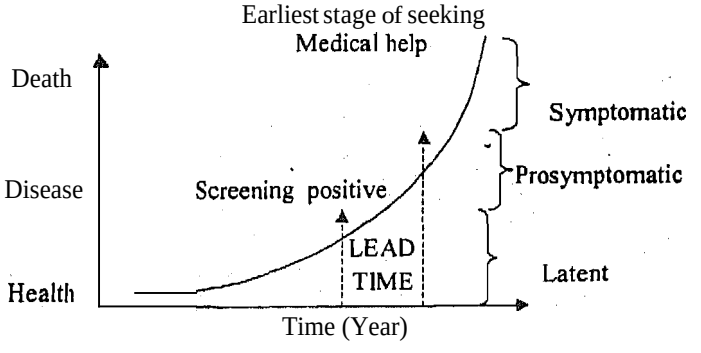

Fig. 3.2: Progression of a Disease from Onset to Death, Assuming No Medical Intervention

If no screening programme is in place for a condition, then tlie symptomatic stage is the earliest stage of seeking medical help. If screening is available and made use of, a condition can be detected much earlier before it reaches the symptomatic stage. This tinie gained by early diagnosis is the lead time and would make available more time for treatment, thus improving prognosis.

To be able to lead to effective economics of health manpower, critical evaluation of the yield of screening is essential. Yield is the amount of previously unrecognised disease which can be diagnosed as a result of screening, It is very useful in determining whether screening for a particular health condition should be undertaken in the community, when it ought to be started and when stopped. Yield depends on:

a) sensitivity of the screening test.
b) prevalence of unrecognised disease.
c) prevalence of recognised disease.
d) expert to which screcning has seen.previously undertaken.
e) acceptance of the screcning programme by tlie population.

The yield and cost effectiveness of screening tests can be improved by restricting them to high risk group.

Whenever screening is undertaken at a single point in time for various conditions it is known as multiphase screening.

For screening programmes to bc successful, the condition for which screening is undertaken should be an important health problem. There should be an accepted treatment for those with tlie recognised disease. Facilities for diagnosis and treatment sliould be readily available and accessible. There sliould be recognisable latent and early symptomatic stage of the disease. There should be a suitable screening test at hand and it must be acceptable to the population. The natural history of the condition should be adequately known. Screening for the condition must be cost effective.

Check Your Progress 4

Sou observe that in a particular slum in the age group 35-40 there are a large number of persons are diabetics and many are HIV positive. For which disease would you start a screening programme and why'?

3.7 BIOSTATISTICS

There was a joke that those students who didn't like mathematics took up medicine. Now when you have finished medicine and taken up a job you have to study statistics. But now you'll appreciate how the basic knowledge of bio statistics will help you in planning and monitoring your job as an administrator better,

Statistics may be defined as the collection, presentation, analysis and interpretation of numerical data (Croxt and Conden). To the above stages organisation (classification) and forecasting may be added. Biostatistics is that branch of statistics that studies biological events.

3.7.1 Sampling

A drop of blood after testing suggests us the haemoglobin status of the whole blood. Sampling aims at learning about the universe on the basis of the sample chosen from it to

make generalization. The process of sampling involves the following elements viz. (a) the selection of process, (b) collection of information, and (c) drawing of conclusion about the population.

All the three elements should be studied as one and not in isolation from one another because each one has an impact upon another. The entire theory of sampling is based upon two important laws namely – (i) law of statistical regularity, (ii) law of inertia of large numbers.

What are the essentials which a sample must possess if the study or survey has to have a worthwhile meaning'? The sample should be:

a) Adequate

b) Representative

c) Independent of selection i.e. selection of one item does not effect the probability of selection of another.

d) Homogeneous i.e. all the units of the universe are of a similar nature.

Methods of Sampling

There are several methods of samples which are depicted in the following line diagram and discussed below in brief.

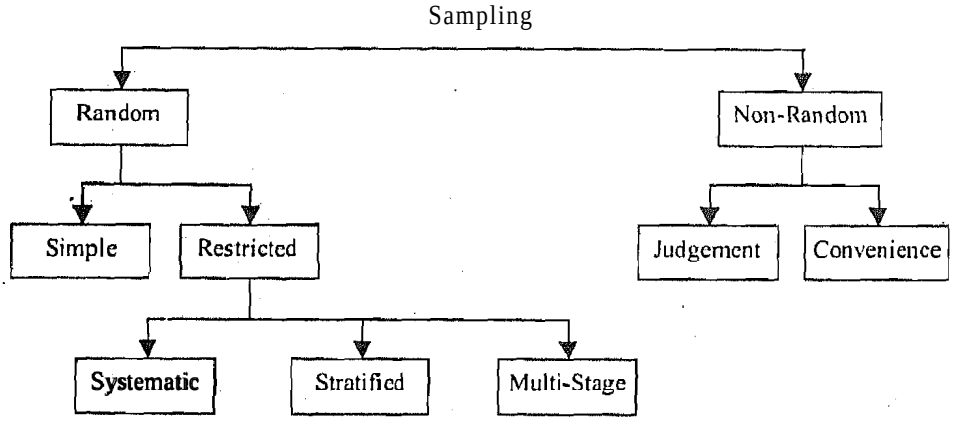

Fig. 3.3: Sampling Methods

a) ***Random Sampling***

1) *Simple Random Sampling*

It,is a technique in which the sample is so drawn that each and every unit in the population has an equal and independent chance of being included in the sample. It may be done by the drawing of lots or using the table of random numbers.

2) *Restricted Random Sampling*

This technique of sampling suits more where the population is of heterogeneous nature with respect of the characteristic under study. More efficient results can be obtained here because the population is divided into groups or sub-groups possessing similar characteristics.

Systematic Sampling: All the terms are arranged in a systematic order – alphabetic, chronological, geographical or arithmetic. The sampling interval is then determined by dividing the size of the universe with the sample size. The first sample unit is selected at random and the remaining items in a definite sequence ai equal spacing by adding the sampling interval.

Stratified Random Sampling: Stratification is done in units which are homogenous as far as possible with no over-lapping. It is normally done on the basis of sex, occupation, income, educational qualifications, geographical distribution etc. Simple random sampling is then done in each strata. Stratified random sampling is highly effective when the distribution is of highly skewed nature.

Multi-stage Sampling: Sampling is done in more than one stage. Suppose 1000 households have ta be studied in a state. The states would be divided into districts and some districts selected randomly. Some blocks would be selected randomly from the selected districts and some villages randomly from the selected blocks. Households would then be selected randomly from the selected villages.

b) ***Nun-Random Sampling Methods***

1) ***Judgement Sampling***

The basis of selection of sample is based on the judgement or discretion of the investigator. No planning is required and item selected or rejected on the criteria laid down by the investigator. Though away from the principles of sampling theory, it is useful. when the number of sampling units in the universe is small. It may in all likelihood include those important elements in the sample which might have been missed under sample random selection.

2) ***Convenience Sampling***

The criteria adopted here is that of convenience. If the dietary habits of slum dwellers have to be studied, the investigator may select the slum nearest to his hospital. Though the method is convenient the results could be alarming being prone to bias and not repiesentative enough.

Sample Size

"What is the size of the sample which one should study'?''Is the question which comes to the mind of every researcher? He wants the sample to be small enough to make the study feasible and large enough to make it scientifically or statistically valid. Then what is the "optimum" sample.

Statistics is based on a lot of presumptions and they should be considered in detail before determining the sample size.

i) What is the reasonable estimate or expected proportion or average 'p' in the study? If not known take 50% as proportion or 0.5.

ii) How far can you allow the sample estimate to deviate from the true value in the population. This has to be decided by the researcher. For high degree of accuracy with smaller the error to be tolerated, the larger is the sample size required.

iii) How confident do you want to be (Z) so that the sample estimate is as accurate as you wish. Normally for 95% confidence level Z = 1.96 and for 99% confidence level Z = 2.64.

Estimation of Sample Size (n) for proportion

$$n = \frac{Z^2 pq}{d^2}$$

Estimation of Sample Size (n) for mean

$$n = \frac{Z^2 S^2}{d^2},$$

where, p = prior estimate of percentage
q = 100 – p
Z = Standard normal variate corresponding to stated confidence level
d = error to be tolerated in the sample estimation
S^2 = measure of variation in the population (standard deviation)

3.7.2 Measures of Central Tendency

A very important objective of statistical analysis is to arrive at one numerical measure that reveals the inherent characteristics of the entire mass of unwieldy data. It is called central value or average. An average is a measure which condenses a huge unwield set of

numerical data into one numerical value which is representative of the entire distribution. An average is a gist of the entire numerical data. It is a single value which represents the group of values.

Arithmetic Mean

It is a widely used measure which represents the whole data by one value. It is known as average in layman's language. It is obtained by dividing the total of all the observations by the number of items. Computing mean in case of individuals observation (without frequency) is done as

$$8 = \frac{X_1 + X_2 + X_3 + X_4 \ldots\ldots X_n}{N}$$

or, $$8 = \frac{\Sigma N}{N}$$

8 =Arithmetic Mean

S = Sum of all the values of variables

Median

Median is a positional average, the value of which depends on the position occupied by a value in the frequency distribution, Unlike arithmetic mean it is not affected by extreme values. The term position refers to the place of a value in a series. It is the value of that item in a series which divides the series into equal parts, one part consisting of all values less and the others all values greater than it. If the values of its items are placed side by side in ascending or descending order of their magnitude, the value of the middle item is the median.

$$M = \text{Size of } \left(\frac{N+1}{2}\right) \text{item}$$

M represents the median; N represents the number of items

Partition Values

The values which divide the series into a number of equal parts are called partition values,

Quartiles: This is the value of the item which divides a series into four equal parts. When a series is arrayed and the median divides it into two halves each of the lower and the upper halves can also be divided into two equal parts. The value of the item dividing the lower half is called First Quartile and is denoted by the symbol Q, and the value of the item dividing the upper half is called the third quartile – Q3. The second quartile is median.

Mode

In case of a frequency distribution mode is the value of the variable corresponding to the maximum frequency. It is that value which occurs most often. Mode may prove representative where data is distributed unevenly. It is not suitable for further mathematical treatment and not much used in medical science.

3.7.3 Correlation

In the measures of central tendency only one variable was used for the purposes of comparison and analysis. But in real life we come across certain series where each item of the series may assume the values of two or more variables like the hsight and weight of individuals. There may exist some relationship between the ages of husband and wives, promiscuous behaviour and HIV infection. The theory by means of which qualitative connection between two sets of phenomena are determined is called the theory of correlation. In a bivariate distribution, an attempt is made to find out if there is any relationship between the two variables under study. The correlation is a statistical tool which studies and explores the relationship between two variables.

Types of Correlation

Below are given important ways of classifying correlation:

1) ***Positive atrd Negative:*** Correlation is positive (direct) or negative (inverse) would depend upon the direction of change of the variables. If the values of two variables change in the same direction i.e. increase or decrease in the values of one variable is associated with an increase or decrease in the values of the other, the correlation between them is positive. Generally correlation about heights and weights of individuals, income of families and expendihire on luxury items is positive.

When the variables deviate in the opposite direction i.e. an increase (or decrease) in the values of one variable resulting on an average in a corresponding dectease (or increase) in the values of the other variable, correlation is said to be negative or inverse.

2) ***Linear atrd Noti-Litrear:*** The basis of this division is the constancy of the ratio of change between the variables.

If corresponding to a unit change in one variable, there is constant change in the other variable over the entire range of values, the correlation is said to be linear, e.g.,

X:	2	3	4	5	6
Y:	4	5	7	9	13

Correlation would be non-linear (or curvilinear) if the degree of change in one variable does not bear a constant ratio to the amount of change in the other variable.

Methods of Studying Correlation

There are various methods of ascertaining correlation between the two variables. Some of these are discussed here:

1) *Scatter Diagram Method*

It is one of the simplest ways of diagrammatic representation of a bivariate distribution. A dot chart is prepared on a graph paper where the data are plotted. A dot is put for each pair of X and Y values, which gives us as many points as the number of observations. A look at the scatter diagram gives an idea whether the variables are related or not. Some points are given below for better interpretation of a scatter diagram.

When all the points lie on a straight line starting from O on the graph and go upwards towards the right hand top, the variables are said to be positively correlated perfectly. Conversely, if all the points lie on the straight line beginning from the left-top and falling down to the right bottom, the variables are negatively correlated perfectly. The following figures will make the point clear. All the points in Fig. 3.4 (a) rise from O upward to the right hand corner and move in the same direction. A higher degree of positive correlation is found here.

The points in Fig. 3.4 (b) show a downward trend from the upper hand corner. There is high degree of negative correlation,

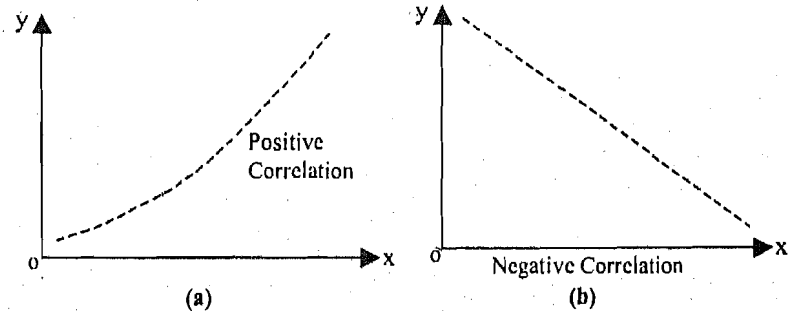

Fig. 3.4

2) *Graphic Method*

Under this method the individual value of the two variables are plotted on a graph paper. Since there are two variables there will emerge two curves, one for X variable and other for

Y variable. If both the curves move in the upward direction the correlation will be positive, and it will be negative if they move in the opposite direction.

The correlation graphs are merely suggestive of a fact of a possible relationship between two variables.

3) Karl Pearson's Coefficient of Correlation

Pearsonian method of measuring correlation was suggested by Karl Pearson (1867-1936) which is most widely used in practice all over the world. His method measures the intensity or the magnitude of linear relationships between two variable series, X and Y, denoted by r, or r (X,Y) or rxy. He defines it as the ratio of the covariance between X and Y, to the product of the standard deviations of X and Y.

3.7.4 Regression

Literally the term regression means stepping back or returning to the average value. This term was first used by Sir Francis Galton in his studies of Inheritance of Stature in 1877. He studied the heights of 1078 sons and their fatliers and published tlie results in a paper "Regression towards Mediocricity in Hereditary Stature." His studies revealed that:

i) Tall fathers tend to have tall sons and short fathers have short one.

ii) The average height of the sons of a group of tall fathers was less than that of tlie fathers and the average height of the sons of a group of short fathers was more than that of the fathers.

The line describing the tendency to regress or going back was termed by Galton as "Regression Line". This term is still used by statisticians but not in tlie old implication of "stepping back". Now the term used by them is 'Estimating Line'. Galton's conclusion was that if the average height of a certain group of fathers is 'a' cm above (below) the general average height then average height of their sons will be (a × r) cms. Above (below) the general average height where r is the Correlation Coefficient between the heights of the given group of fathers and their sons. The correlation will be positive. Below are given some definitions of regression.

I) "Regression is tlie measure of the average relationship between two or more variables in terms of the original units of the data." – M.M. Blair

2) "The term regression analysis refers to the methods by which estimates are made of the values of a variable from a knowledge of the values of one or more other variables and to the measurement of the errors involved in this estimation process." – M. Hamburg

The word regression is used in a much wider sense today. It means estimation or prediction of the unknown value of one variable from the known value of the other variable. The variable which is used to predict the variable of interest is called the independent variable and tlie variable to be predicted is called the dependent variable. The analysis used is called the simple linear regression analysis. This analysis has become synonymous with prediction or estimation which is used extensively in all social and physical sciences. Pharmaceutical companies use regression for studying the effect of new drugs on patients by way of experimentation.

Regression is not the imagination of a day-dreamer. It is a reality with which various shades of people come across in their daily life. The regression analysis confined to the study of only two variables at a time is termed as simple regression.

It cannot be said with certainty that there exists some cause and effect relationship between two dependent or the independent variables. What is meant is simply that estimates of values of the dependent variable Y may be obtained for given values of the independent variable from a mathematical function involving X and Y. It is quite likely that one variable may or may not cause changes in the other variable. They may be opposites also who knows.

Linear Regression

When the bivariate data is plotted on a graph, the points in the scatter diagram will be found concentrating around a curve which is known as the 'curve of regression'. This curve is often confusing and complicated and is difficult to understand. If this curves is in the form of a straight line, the regression between the variables under study is said to be 'linear'. In this case the values of a dependent variable changes in a constant absolute amount for a unit change in the value of the independent variable.

Non-Linear Regression

In cases where the curve of a regression is not a straight line, the regression is called ,'non-linear regression'.

Comparison of Correlation and **Regression**

Both the analyses – Correlation and Regression - are constructed under different assumptions. The experimenter is often clear regarding the selection of a measure which he should cause in a given problem situation because they furnish different type of information. The points of difference of both of these two are given below:

1) The regression analysis is studied with the objective of studying the nature of relationship between the variables so that the experimenter may be able to predict the value of one on the basis of another. Correlation Coefficient on the other hand, is a measure of degree of co-variability between X and Y.

2) Correlation is used to ascertain the degree of relationship between two variables. It. therefore, cannot be said with any amount of certainty that one variable is the cause and the other the effect. But in a regression analysis one variable is taken as dependent while the other is independent. The study of cause and effect relationship becomes possible here.

3) There can exist a meaningless or nonsense correlation between two variables which is a matter of chance but there can be no nonsense regression.

3.7.5 Standard Error of Sampling Distribution

The concept of standard error is of fundamental importance in testing hypothesis. By standard error is meant the standard deviation of the sample distribution. It emphasises that variation among sample means is clue to sampling errors. It measures the sampling variability due to random forces. To understand standard error it is necessary to explain a sampling distribution. Suppose we select a number of independent random samples of a definite size from a given population and calculate mean or standard deviation from each sample, we shall obtain a series of values of all of these statistics. These values can be arranged in the form of frequency distribution which is called sampling distribution or the probability distribution. It means that if we draw 50 random samples from a given universe and calculate their means, we shall get a series of 50 means which would form a frequency distribution. It will be known as the sampling distribution of the means.

It is quite relevant here to study the universe distribution, in the absence of which the study of sampling distribution will remain incomplete. This study is also useful in showing the relationship of universe distribution and sample distribution and showing the relationship of these two with the sampling distribution.

Universe distribution: When the statistician is out to study each and every item of universe and has full knowledge of its mean and standard deviation, there emerges universe distribution. The mean of the universe is symbolised by μ and its standard deviation by σ.

significance of **Standard Error**

1) It is an important tool in testing a given hypothesis, Ordinarily the hypothesis are tested at 5% level of significance. If the difference between observed mean and the expected mean is mofe than 1.96 S.E., it is significant and it does not support the hypothesis at 5%

level. If this difference is less than 1.96 S.E., it is not considered as significant. This result does not provide any evidence against the hypothesis.

2) Standard error gives us an idea about the unreliability of a sample. The greater the standard error the greater is the unreliability of the sample because greater is the departure of actual frequencies from the expected ones. The reciprocal of S.E., i.e., 1/S.E. is a measure of reliability of the sample.

3) The study of the standard error helps us in determining the limits within which the parameter values are expected to lie. It becomes possible because of large samples, sampling distributions tend to approximate a normal distribution. Standard error can be calculated by the formula –

$$SE = \frac{SD}{\sqrt{n}}$$

3.7.6 Significance Testing

It is natural for sample estimates to vary from sample to sample. This makes us think:

i) Is the difference between the sample value, and the population value actual or significant'?

ii) Is the difference between the mean of the two samples very much different'? These questions can be answered by significance testing. For this, it is essential to form a hypothesis and test it. A hypothesis is merely a supposition which has been made the basis for reasoning. In the words of Morris Hamburg, "A hypothesis in statistics is simply a quantitative statement about a population."

Testing **Procedures**

Steps involved in genera! hypotheses testing are given below:

1) ***Setting up a Hypothesis:*** The first step in this direction is to set up a hypothesis about a population parameter. Then the sample data is collected, sample statistics produced to use this information to decide how likely it is that our hypothesized population parameter is correct. It'is conventional to construct two different hypotheses about the parameter. Both these hypotheses must be mutually exclusive so that if one hypothesis is accepted the other one is rejected.

   The two hypotheses are:

   a) Null Hypothesis
   b) Alternative Hypothesis

   The Null hypothesis is considered as a very useful device in testing the significance of difference. The word 'Null', means invalid or void, tells that there is no true difference in the sample and the population in the matter under enquiry.

   The Alternate hypothesis specifies the values which the-researcher believes to be true. This hypothesis is a wider one which embraces the whole range of values and not a single point.

2) ***Setting up a Suitable Significance Level;*** The next step is to test the validity of both the hypotheses at a certain level of significance. The significance level is expressed as a percentage such as 5% or 1%.

3) ***Setting a Test Criterion:*** Construction of test criterion involves an appropriate probability distribution for a particular test. The investigator must employ an appropriate probability distribution. In case where only a small information is available, it would be inappropriate to use the normal distribution.

4) ***Computation:*** When a statistical list has been completely designed, the investigator proceeds to perform various computations from a random sample of size. Calculations made include the testing statistic and the standard error of the testing statistics.

5) ***Making Decisions***: As a last step, we may draw statistical conclusions and take decisions either to reject or to accept the null hypothesis. It depends on whether the calculated (computed) values of a test criterion falls in the area of rejection or that of acceptance.

Errors in Hypothesis Testing

There are two types of errors in the testing of hypothesis:

Results of the Test	H_0 true	H_0 false
Reject	Wrong	Correct
Don't reject	Cdrrect	Wrong

If the hypothesis is true and our test rejects it, it is type I error = a. If the hypothesis false and our test accepts it, it is type II error = β.

As the process of testing hypothesis goes, the investigator aims at reducing both the types of error, but it is not possible to do so because of fixed sample size. The probability of making type I error can only be reduced if we are prepared to increase the probability of making the type II error. It can be said very clearly that it is more dangerous to accept type II error (false hypothesis) than to reject type I error (correct one), at a certain level, known as the level of significance. In most cases the probability of accepting a true hypothesis is 95%.

Some Important Conclusions

The study of the significance testing reveals that:

a) Both these types of errors are inter-related. A decrease in the possibility of type I means an increase in the probability of type II.

b) Whenever a sample size increases α and β get reduced simultaneously.

c) The size of the area of rejection and the probability of committing a type I error can always be reduced by adjusting the value of type I error.

d) When the Null hypothesis is false, type II error is a maximum. The greater the distance between the true value and the hypothesised value, type 11 error will be smaller.

3.7.7 Tests of Significance

When we are comparing sample estimates (means or proportions) it is essential to rule out the possibility that the difference is due to chance. The tests of significance are statistical tests which measure the probability of chance occurrence of such differences.

Standard Error of the Difference between Two Means

If the observed difference between two means from two samples is more than twice the standard error of the difference between two means, it is said to be significant at 95% confidence limit. In other words the probability of the difference of the means of the two samples to occur by chance is less than 5%.

SE of difference between means is:

$$\sqrt{(SE_1)^2 \times (SE_2)^2} = \frac{\sqrt{(S_1)^2}}{\sqrt{n_1}} \times \frac{(S_2)^2}{\sqrt{n_2}}$$

't' test is an accurate method to test the significance of difference between two means in small samples.

Standard Error of Difference between the Proportion

If the observed difference between two proportion is more than twice the SE of difference of proportion, it is significance at 95% confidence limit. In other words the probability of difference of proportions of two samples to occur by chance is less than 5%.

SE of difference in proportion $= \frac{\sqrt{p_1 q_1}}{n_1} \times \frac{p_2 q_2}{n_2}$

Chi Square Test

It is one of the most important test of significance. It was developed by Karl Pearson. The major uses for it arc:

1) To find out if the difference between two proportions is real or by chance.
2) To find any association between 2 attributes occurring together.

The first step in the application of the test is the formulation of the null hypothesis, which is the assumption of no association between the aspects being tested:

Secondly, a contingency table is made based on the number of events and groups. For e.g. if there are only 2 events and 2 groups, it becomes a 2 × 2 contingency table. In case of 3 events and 2 groups, it is a 3 × 2 Contingency table.

	Columns ↓	↓	Total
Rows →	a r_1 c_1	b r_1 c_2	a + b
→	c r_2 c_1	d r_2 c_2	c + d
Total	a + c	b + d	a + b + c + d

a, b, c and d are the observed frequencies.

For r_1, c,, square, the number of expected frequencies is $\frac{(a+c)(a+b)}{a+b+c+d}$

For $r_1 c_2$, expected frequencies is $\frac{(a+b)(b+d)}{a+b+c+d}$

$$r_2 c_1 = \frac{(a+c)(c+d)}{a+b+c+d} \qquad r_2 c_2 = \frac{(b+d)(c+d)}{a+b+c+d}$$

Now we calculate the x^2 (chi square)

$$x^2 = \frac{(O-E)^2}{E}$$

Now we calculate the degrees of freedom (d.f)

d.f = (r – 1) (c – 1)

i.e. (no. of rows – 1) (no. of columns – 1)

To find the significance of the calculate x^2 value, we refer to the x^2 table and find the tabulated x^2 value corresponding to a given probability like 0.05 or 0.01, against the appropriate degrees of freedom.

If the calculated value of x^2 is higher than the tabulated x^2 value at the selected probability level (usually 5% or 1%), the null hypothesis is rejected. Similarly, if the calculated x^2 value is lower than the expected value, the null hypothesis is accepted,

Chi square test is applied to actual numbers and not to percentages.

3.8 LET US SUM UP

In this unit you have learnt that epidemiology is the study of the distribution and determinants of health-related states and events in population, and the application of this study to control health-related problems. The phrase 'health-related" – relate to phenomena like physical fitness, pregnancy, eating habits etc. which are not diseases. You have also learnt that epidemiology is primarily based on two assumptions that human disease does not occur at random, and that human disease has causal and preventive factors that can be identified through systematic investigation of different population or sub-groups of individual within a population in different places or at different times. The basic purpose of epidemiology is to obtain, analyse, interpret and use health information to promote health and reduce disease. Epidemiology as you mush have understood is actually logical

reasoning about causes of health problems based on information gathered through observations and measurements. It is an applied discipline which is concerned with practical solutions to problems. Therefore, epidemiological studies can provide strong and reliable evidence on which to base policy and ultimately decisions affecting the health of the general public.

You have also learnt that descriptive epidemiological studies describe the general characteristics of the distribution of disease in relation to person, place, and time. However, since data on the disease and the risk factor is obtained at the same point in time, it is difficult to distinguish whether the risk factor proceeded the development of the disease or not.

Further, in case control studies, the subjects are selected on the basis of whether they do (cases) or do not (controls) have a particular disease under study. The groups are then compared with respect to the proportion having history of exposure or characteristic of interest. Comparison is made between the cases and controls by estimating relative risk and odds ratio. In cohort studies the individuals are defined on the basis ofpresence or absence of exposure to suspected risk factor for a disease. At the time of defining the exposure status, subjects must be free from the disease under investigation. Participants are then followed over a period of time to assess the occurrence of that outcomeldisease.

You also learnt that epidemic is the unusual occurrence in a community or region of a disease or specific health related event "clearly in excess" of the "expected occurrence". The epidemics may be common source, propagated, seasonal or cyclic. Surveillance helps in forecasting an epidemic. Preparation of a contingency plan helps in being prepared to meet the epidemic.

Thereafter you learnt about screening which is the presumptive identification of unrecognized disease or disability by the'application of tests, examinations or other procedures. Screening in public health is an epidemiological tool when applied to population at large. For screening programmes to be successful, the condition for which screening is undertaken should be an important health problem. The disease should have a recognizable latent and early symptomatic stage of the disease, should have an accepted treatment and the facilities for diagnosis and treatment should be readily available and successible.

Towards the end of this unit you learnt about some of the basic concepts of biostatistics, Statistics is the collection, presentation, analysis, and interpretation of numerical data and biostatistics is that branch of statistics that studies biological events. You also learnt about sampling which aims at learning about the universe on the basis of the sample chosen from it to make generalization. The selection of an appropriate/adequate sample size makes the study scientific. Further you learnt about the measures of central tendenly, an average is a measure which condenses a huge unwilling set of numerical data into one numerical value which is representative of the entire distribution. Arithmetic mean is obtained by dividing the total of all the observations by the number of items. It is known as average in layman's language.. Median is a positional average or the value of the middle item. It is not affected by extreme values. Mode is the value of variable corresponding to the maximum frequency.

About correlation you learnt that it is the qualitative connection between two sets of phenomena, It is a statistical tool which studies and explores the relationship between two variables. Regression is the estimation or prediction of the under own value of one variable from the known value of the other variable. The variable which is used to predict the variable of interest is called the independent variable and the variable to predicted is called the dependent variable,

In the end of the unit you learnt about various tests of significance which are able to tell you whether the result obtained are scientifically or statistically significant or not,

3.9 ANSWERS TO CHECK YOUR PROGRESS

Check Your Progress 1

Epidemiology is actually logical reasoning about causes of health problems based on information gathered through observations and measurements. It is concerned with practical solutions to problems. It provides strong and reliable evidence on which to base policy and ultimately decisions affecting the health of the general public.

Diabetes: There is a treatment and hence a screening programme followed by treatment would result in the improvement in the health status of the community. Screening and diagnosis of HIV positives with the present knowledge of the disease will not help the community.

UNIT 4 OCCUPATIONAL HEALTH

Structure

4.0 OBJECTIVES

After going through this unit, you should be able to:

- define Occupational Health;
- identify the occupational hazards;
- relate the health problems due to industrialisation;
- give examples of occupational and work-related diseases;
- sunimarise the prevention of occupational diseases;
- outline the occupational health scenario in India; and
- interpret the impact of occupational health in 21st century.

UNIT 4 OCCUPATIONAL HEALTH

Structure

4.0 OBJECTIVES

After going through this **unit,,**you should be able to:

- define Occupational Health;
- identify the occupational hazards;
- relate the health problems due to industrialisation;
- give examples of occupntional and work-related diseases;
- summarise the prevention of occupational diseases;
- outline the occupational health scenario in India; and
- interpret the impact of occupational health in 21st century.

4.1 INTRODUCTION

The process of industrialisation is an important and effective means for socio-economic development of any country, particularly the resource-rich developing countries. These countries have set up their industries with indigenous technology or imported high-tech know-how within a short span of time for economic growth. But hazard control, safety and occupational health aspects have not been tackled adequately. Particularly in India, the concept of occupational health is relatively new. The industrial scenario of our country has changed during last 50 years, but the country is not prepared to cope up with the emerging situations in the field of health. Occupational health is still a far cry. In the field of occupational health, we have not been able to keep pace with the international community, due to many reasons; but we cannot afford to neglect it any further. Occupational health cannot develop in isolation and has to be integrated with total health care. Hence, while dealing with health management, occupational health management cannot be lost sight off.

In this unit you will learn about relevance of occupational health in the context of health management. Occupational health being a specialised service for the working population, the health management systein should be directed towards the industrial workforce and allied occupation. Health influences work and work influences the health of an individual, You will learn the concept, purpose, aim and scope of occupational health in this unit. Further you will learn the effect of industrialisatioiion health, occupational hazards, impact of hazards on health, occupational and work-related diseases and their prevention. Further, application of methods of occupational health management in our country during this century and beyond will also been visualised. You will appreciate that occupational health needs to be studied through an integrated approach to health particularly in relation to nature of work, work methods and work environment.

4.2 DEFINITION AND SCOPE OF OCCUPATIONAL HEALTH

4.2.1 Definition

The Joint ILO/WHO Committee on Occupational Health at its first meeting in 1950 formulated this definition.

"Occupational Health should aim at: the promotion and maintenance of the highest degree of physical, mental and social well-being of workers in all occupations; the prevention among workers of departures from health caused by their working conditions; the protection of workers in their employment from risks resulting from factors adverse to health; the placing and maintenance of the worker in an occupational environment adopted to his physiological and psychological ability, and to summarise: the adaptation of work to man and of each man to his job".

If we examine this definition closely, it becomes evident that occupational health is a multi-disciplinary activity and co-ordinated team-work to be undertaken by a health team. The definition also makes it clear to some extent that it is a preventive health care service and more health-oriented than disease-related. Other preventive health services such as public health or community health are more related to the general population or community as a whole whereas occupational health is a specific service offered to the industrial or similar workforce at their place of work. Occupational Health (previously known as industrial health; industrial hygiene, etc.) is to be practised in an organisdd manner through need-based occupational health services (OHS) as recommended by ILO, other statutory bodies and professional organisations. In American and European countries, the name is changed to "Occupational and Environmental Medicine".

4.2.2 Scope

The scope of occupational health is very wide. It is not only utilises medical sciences but also relevant aspects of many other art and science topics to bring out a synthesis of the

complex nature of health at work in a broad perspective. The functions of OHS are so designed that not only the workers are benefited alone, but also tlie management, tlie industrial community and the nation as a whole derive optimum benefit. It is not an expenditure to meet the statutory provisions, but it promotes health and welfare of tlie employees and harmony in industrial relationship. Investment on OHS gives rich dividend directly and indirectly. WHO prepared a document applicable to "Health for All by 2000" strategy. (WHO - EURO Publication No. 26). The five principles are:

i) protecting workers' health against hazards at work (the protection and prevention principle);

ii j adapting work and work environment to the capabilities of the workers (the adaptation principle);

iii) enhancing physical, mental and social well-being of workers (the health promotion principle);

iv) minimising the consequences of oocupational hazards, accidents and injuries and occupational work-related diseases (the cure and rehabilitation principle); and

v) providing total health care to the workers and their families, both curative and preventive, at the work place or from nearby facilities (the general primary health care principle).

Similarly ILO also adopted many conventions and recommendations during these years based on the above guidelines which are in the different state of implementation in developed and developing countries.

In addition to this, International Commission on Occupational Health (ICON) adopted a code of ethics for occupational health professional in 1992 for application of occupational health to three target groups – individuals, exposed groups and to all workers as a part of the population.

Today Occupational Health is widely practised in industrialised developed countries. Earlier occupational health was identified with hazards and occupational diseases – of late the total health care concept has been introduced and the scope of occupational health has been extended to the well-being of the workers and their family members, Occupational health today embraces the preventive, curative, promotive and rehabilitative medical services of the industrial and allied workforce and their family members.

4.3 HEALTH PROBLEMS DUE TO INDUSTRIALISATION

Earlier in industries and mines the hazardous/dangerous jobs were not carried out by the common men but by the slaves, prisoners or criminals. Working in industries and mining operations was considered as a punishment and hence the health of the workers was practically given no importance. Many of them were dying due to accident!, serious occupational diseases or uncared for ill health till sixteenth and seventeenth centuries. The eighteenth century brought great technological changes, inventions and new factory systems during the industrial revolution in Europe. The industrialisation became prominent all over the world during the nineteenth century raising socio-economic status of many of the developed and developing countries of today. However, the benefits of industrialisation although brought economic improvement, it posed certain problems to the working population due to profit motive of the factory owners. In absence of appropriate statutory provisions, the workers had to work for long hours for low wages, they had to work in hazardous and unclean workplaces, they had to live in poor sanitary conditions without good housing, water and environmental sanitation facilities. The health care facilities were far from satisfactory. Even then, in many countries including India, the people migrated from rural areas to the industrial cities to earn their living inspite of odd conditions because they had practically no means of livelihood in the villages. Although the process of industrialisation started in some cities in India during 19th century in a restricted manner, the industrialisation was extended and intensified during mid-fifties of this century.

India being an agricultural country and the farmers had to depend on monsoon for raising crops, in most of the years they suffered due to cyclone, flood, draught or insects which were damaging the crops for successive years. Many of them left the villages in search of employment in urban areas and industrial towns, even with low wages. They did not care for thehazards in industries and accepted the poor living conditions around their industries. They managed to stay in slums mostly away from the families. Over growing of population, scarcity of employment, low income and scarce infrastructure facilities prompted many of the migrated workers to make compromises with whatever they could earn even after hard work. Thus, the condition of the miners, textile workers, jute workers and many workers engaged in metal works, chemical plants or rubber industries during this century were really precarious. Neither the employees nor the government could do much for them. Many workers got organised in mid century through trade unions and started placing their demands for monetary benefits from the industrialists. Many new concepts like strike, dharna, gherao, work-to-rule, etc, emerged out in the industrial work culture. In the beginning, housing, education, health and recreation for the industrial workers being of low priority partly due to poor socio-economic conditions and predominantly due to attitude of the factory owners, the slums developed around the industries in-out-of proportion and civic amenities were tampered unauthorisedly to meet the day to day requirement of the slum dwellers. The outbreak of epidemics were also there in these areas from time to time. Subsequently, due to growth of many types of industries in most of the states of our country demand on urban housing, electricity, water supply, sanitary facilities; waste disposal requirements grew out of proportion causing congestion, overcrowding, traffic problem, environmental pollution and outbreak of epidemics which affected not only the industrial workforce, but also the entire urban community. The resources available for a limited population had to be shared by many under compulsion and hence there, was a scarcity everywhere, be it food, space, transport, schools, hospitals, medicines or other consumable amenities. Even today, the problem has not been solved fully although there is some improvement seen around certain industries.

Tbe indiscriminate growth of industries in this country saw another change. Due to increased awareness about the environment and ecology the older industries had to face the wrath of the community as source of pollution. Enactment of multiple laws for factories, mines and environment protection forced many industries to shift to a remote and less populous area away from the residential locations. It is a dilemma for many industries whether to shift or to close down and go for clean technologies (if available). The organised labour force, powerful trade unions, stringent statutory provisions and social-conscious group all around

are compelling the industrialists to invest on certain provisions which they were neglecting so far. The scenario is becoming more complicated day-by-day due to multi-pronged attack.

The generation of huge quantities of waste materials both hazardous and non-hazardous in nature out of various industrial operations and community waste coming out of residential area in industrial towns have posed serious problems recently. Most of the industrial effluents are discharged into the water course being untreated as many industries are located on the river banks. Similarly, solid industrial wastes are not disposed off in a sanitary manner and dumped here and there. Till recently there was no control over this. Recently, central and state pollution control boards are trying to exercise their control to prevent pollution of air, water and soil. Industries have been forced to manage their waste. Many statutes have been enacted recently to impose statutory control and compel the occupiers to recycle or sanitary disposal of the waste generated by various industries. Guidelines have been issued and monitoring is done by the statutory authorities to deal with industrial waste problems. Health hazards arising out of improper waste generation, storage, handling and disposal is posing a threat to the community health.

The impact of industrialisation thus encountered must bc solved and there is no other go. Industries will exist but their functioning has to be modified to meet the socio-political situation of the country. Therefore, health hazard arising but of industrial operations should be mutigated by adopting adequate preventive and control measures.

4.4 OCCUPATIONAL HAZARDS

A hazard is defined as a situation of risk or danger to health and safety. Occupational hazards are the outcome of the process of industrialisation. In most of the industries – new or old – the occupational hazards exist in some form or other. These hazards present in the workplace should be prevented and controlled so that the exposed workers do not have any disease or health impairment. The commonly encountered hazards are physical, chemical, biological or psycho-social in nature. These hazards produce certain impact on health causing occupational and work-related diseases.

4.4.1 Physical Hazards

A hazard is defined as a situation of risk or danger to health and safety. The physical agents like heat, noise, vibration, radiation and pressure etc, that are capable of affecting the biological mechanism of human body and producing changes on the health conditions are categorised under physical hazards. The mechanical and ergonomic hazards encountered in the work place also come under this category.

Heat

Most people function efficiently only within a very narrow range of body temperature, i.e. 37°C ± 1°C and their performance is affected in extremes of temperature: When the body temperature rises this core temperature due to work, metabolism or environment heat load, the body tries to lose heat by producing sweating to maintain a body heat balance. Therefore, sweating occurs while working in hot environment. The work environment becomes comfortable depending on air temperature, humidity and air circulation in the workplace. Comfort zone'varies widely depending on the season of the year, dry and wet bulb temperature, globe temperature, ventilation, amount of clothes worn, quantity of body water reserve and socio-cultural habits of the workers. The heat is gained or lost by the body due to conduction, convection, radiation or metabolism and lost by evaporation only. Therefore, evaporation of heat caused due to sweating is a protective phenomenon while working in hot environment. The heat balance equation of the body may be depicted as:

$$M \pm Cv \pm Cd \pm R - E = 0,$$

where,

M = metabolic heat,
Cv = convection,
Cd = conduction,
R = Radiation,
E = Evaporation.

In other words, to maintain the body heat balance, heat gain = heat lost.

An industrial worker may suffer from heat disorders while exposed to excess heat at the workplace, particularly during summer season. Heat hazard may be encountered in steel plants, cement plants, metal processing industries, textile mills, paper mills and construction work. The acute heat disorders vary from slight faintness to unconsciousness and the condition are: heat stroke, heat exhaustion, heat cramp or heat rash. Exposure to radiant heat directly may cause cancer of skin in the long run.

Cold

Hazards due to cold is not very common in our country except in areas where the environment temperature becomes very low during winter. In some industries such as freezer plants, ice factories, meat processing and packing units, cold storage, etc. the workers are exposed to excess cold. In such work places, the workers should be well protected by warm clothes/garments so that their body is not exposed to excess cold. Skin is affected first due to cold and, therefore, must be well protected. The cold disorders may be localised (frost bite or chilblain) or generalised (hypothermia). Exposure to chill wind, contact with wet surface or cold metal, inadequate clothing, extremes of age (children or old), poor health condition of the individual and associated skin disease aggravate or precipitate the cold disorders. The common diseases are: cold stress, frost bite, trench foot and chilblain.

Hypothermia: It is a generalised condition caused due to exposure to cold environment. When the air temperature falls below 10°C the symptoms like uncontrollable shivering, feeling of cold fall in body temperature rapidly, low heart rate, weak pulse and fall in blood pressure appear and hypothermia is caused. Speech disturbance, memory loss, drowsiness, irregular breathing, cold skin, tiredness and exhaustion follows when the condition is advanced.

Cold exposure may cause some vascular and neurological disorders, itching and burning sensation over the ends of fingers and toes due to abnormalities of blood circulation, blue coloration of feet or hands due to reduction of haemoglobin in the blood, blockage of arteries of the limbs particularly among diabetics and tobacco smokers and elderly persons. Emergency situation arises due to cold exposure.

Pressure

The increase or decrease in atmosphere pressure, produces immediate but transient (for a short while) effect on the human body. Some times, the consequences may be long lasting and damaging to health. The effect of pressure changes in the working environment is mostly felt by the lungs.

Raised air pressure (Hyperbaric condition) is experienced when the work is performed in a water-tight structure (Caisson chamber) as during tunnel making or bridge making under water where compressed air or gas is used under high pressure. The workers have to remain inside the chamber during the work period. Human beings can withstand large pressures provided there is free air entry into the lungs, sinuses and middle ear, If the pressure distribution is not uniform, tissue damage and sickness may be doused due to sudden pressure change. The workers suffer while entering into the chamber (compression stage) or while coming out of it (decompression stage) if there is sudden pressure change. The teeth, air sinuses, ears and lungs are affected due to decompression sickness (Caisson disease). Sudden decompression releases nitrogen gas dissolved in the blood in the form of large bubbles which get lodged in the joints and under the muscles causing severe cramps. The alveoli of lung bursts causing death. The blockage of the blood vessels by small gas bubbles may cause paralysis of the limbs, rupture of ear-drum, temporary or permanent hearing loss, swelling or bleeding into the eye ball and drowsiness. To prevent this, decompression is carried out gradually and in stages and deep-sea divers are supplied with under water breathing apparatus containing the mixture of helium and oxygen.

Noise and Vibrntion

Noise is a form of vibration conducted through solids, liquids or gases and usually termed as a sound that is unwanted by the listener and unpleasant to the ears. No instrument can

distinguish between a sound and noise, but the human reaction can. A pop music may be pleasant to somebody but may be a noise to another person. Due to industrialisation and increasing mechanisation in almost all industries and in many trades, noise is produced due to mechanical vibration. High and sustained noise levels within the workplace and even outside the works area cause noise hazard. Excess noise causes auditory and non-auditory effects in human beings. Therefore, abatement of noise by adopting appropriate preventive and control measures is essential.

The sound pressure is'measured as decibel (dB), frequency of sound as Hertz (Hz) and intensity (I) which is related both to sound pressure level and frequency. The human beings can hear sounds between 20 Hz to 20000 Hz and they are sensitive to high frequency sound. Noise is measured in decibel (dB) which is a logarithmic scale. Sound level of some common sounds are given in Table 4.1.

Table 4.1 : Levels and Source of Some Common Sounds

Sound Pressure Level (dB)	Source **of** Sound
0	Threshold of hearing
20	Whisper
30	Recording studio
35	Quiet room
40	Residential area
50	Quiet Office
60	Conversional speech
70	Outdoor traffic noise
80	Noisy office room
90	Factories
95	Machine Shop, Textile Mills
100	Motor House, Diesel Generator
110	Air Compressor House
120	Forge Shop and Revetting, Pneumatic drive
140	Jet Plane take off sound, threshold of pain

It is desirable to keep the workplace noise level at 85 to 90 dB so that hearing of the exposed workers is not affected. It should be remembered that decibel being a logarithm Scale, the loudness of sound is doubled with increase of every 5 dB.

Workplace noise is measured by using a sound level meter and the frequency of noise is measured by an octave band analyser. Integrated sound level meters contain both these instruments. The measurement should be done in dBA scale of the sound level meter. To assess the noise exposure of any individual, a noise dosimeter is used.

Noise produces temporary or permanent hearing defect (auditory) among the exposed individuals. If a person is exposed to high noise (above 90 dB) at the workplace or elsewhere, the hearing loss occurs at the level of 4 KHz frequency to start with and extends to other frequencies due to further exposure. The deafness is called as Noise Induced Hearing Loss (NIHL). The disease is not curable and does not reduce even if noise exposure is stopped. The diagnosis can be confirmed by audiometry. NIHL is reportable as well as a compensable disease in India.

Non-auditory effect of noise are such as annoyance, ringing in the ear, sleep disturbances, tension headache, lack of concentration, reduced performance, constant discomfort, raised blood pressure, etc.

The best way to prevent noise hazard at the workplace is to take steps at the design stage if excess noise is anticipated. Once the process is in operation, it becomes difficult to control noise satisfactorily, but it can be minimised to a great extent. While adopting the control measure, the source of noise, path through which it is transmitted and the receiver

(employee) have to be identified. The degree of noise reduction required to bring it to the acceptable level without causing damage to health and loss of production have to be adopted to achieve the goal to keep the noise within admissible limit. The workers should be encouraged to wear ear plug and car muffs while working in noisy area. In every industry, where noise is a hazard, hearing conservation programme to be launched for the exposed employees.

Vibration

Vibration is an oscillatory motion occurring in different occupations such as vehicle (truck, tractor, dumber, dozer) operators, workers working in ships and shipyards, construction workers(tunel, bridge making), miners (drillers, blasters, crushers, chipping hammer etc.), aircraft and helicopter maintenance engineers.

The vibrations are mainly two types:

i) ***Hand-transmitted Vibration:*** The vibration of frequency 1000 Hz or more enters the body through the hands when someone holds the vibrating tool firmly. Disorders of hands and fingers are caused due to this.

ii) ***Whole-body Vibration***: When the body is supported on a vibrating surface (vibratmg platform or floor) whole body vibration passes into the body in different directions. The frequency range of this vibration is usually low (0.5 Hz to100 Hz). Prolonged and regular exposure of the fingers or hand to vibration affects blood circulation, bones, joints, muscles and nerves. Vibration-induced white finger and hand-arm vibration syndrome are the common disorders. The vibration disorders can be prevented by isolating the person from vibration, adjusting the exposure time, proper upkeep and maintenance of vibrating equipment and preventing cold exposure of hands and fingers while working with vibrating tools. The prevalence of vibration disorders in our country is not very significant.

Radiation

The common form of radiation energy produced due to electromagnetic phenomenon are: Iight, infrared, radio and television waves, X-rays and gamma rays. The radiation may be non-ionising or ionising in nature. Radiation energy in different forms are used in many industries. The specific use depends on their frequencies starting from electro-power systems to microwave and satellite communication,

Radiation dose of above *6* Sievert (sv) is fatal. The health hazards of ionising radiation are:

- discolouration and pealing of skins and skin bum.
- acute radiation syndrome causing nausea, vomiting and weakness after 2-4 days of exposure.
- blood changes, leukaemia, sterility and cancer of other exposed organs.
- damage to the intestine and central nervous system,
- genetic changes in body cells.

Health effects of non-ionising radiation are:

- Acute due to direct exposure or chronic due to prolonged exposure.
- The effects are restricted to eyes and skin.
- Immediate skin changes such a pigmentation and damage to the epidermis, squamous cell carcinoma or ocular changes may occur.

Ergonomic **Hazards**

Ergonomics is inter-disciplinary approach to the interface between worker, the workplace and equipment. The objective of ergonomics is to fit the man to the work so that he/she can perform the assigned job comfortably without any hazard. Many of the machines and methods adopted in industrial operations in our country are not suitable for Indian workers.

Therefore, mechanical and environmental hazards exist in many industries. The height of machines, control panels, work bench, furniture and lights etc. pose some hazard for the workers which could be avoided otherwise. Repetitive strain injury and musculo-skeletal disorders may be caused due to ergonomic hazard.

4.4.2 Chemical Hazards

The chemical hazards in the workplace arises due to excessive concentration of dusts, fumes, vapours, mists and solid particulate matter in the work atmosphere. Exposure to solvents, machine oils, cleaning agent and various other organic or inorganic chemicals used in industrial processes may produce harmful effect on health. Although the number of industrial chemicals are quite large, some of them produce toxic effects on the human body and, therefore, these toxic chemicals are potential hazards, The use of chemicals is increasing. Newer and complex chemicals are being added to the list almost every day not only in industrial operations, but also in our day-to-day life. Particularly in chemical plants the hazards become prominent. In addition to this, in metal processing industries particulate material pose specific hazards.

Particulate Matter

Dusts and fumes constitute the particulate matter. Dusts are particles of variable size (0.1 m to 30 m or more) generated due to mechanical action of crushing, grinding, pulverising, sandblasting and shake out operations in industries and mines. Fumes consist of extremely fine particles, Fume is generated due to combustion, condensation and sublimation of material.

When these particulate are inhaled, they cross the respiratory barrier and get deposited in the alveoli of the lungs. Due to mechanical and fibrotic reaction and enhanced activities of the microphages the alveolar walls are damaged and fine opacities develop in the lungs. The opacities are radio-opaque and may increase in size or join together, for praducing large opacities. This disease condition of the lungs is termed as "Pneumoconiosis" or "dusty

lungs". The signs and symptoms of the disease are: shortness of breath, chest pain, feverish feeling, weakness and impaired lung function. The diagnosis of pneumoconiosis can be done by chest X-ray (large film or minimum 70 mm film and not by odelca film), lung function test and prolonged exposure to respirable dust (0.5 m to 5 m) or fumes. The'pneumoconiosis being a general term, it is specified by the causative dust such as silicosis (silica), anthrocosis (coal dust), asbestosis (asbestos fibre), bylsinosis (cotton fibre), siderosis (iron dust), bagossosis (cane sugar fibre), baritosis (barium) or stannosis (tin).

Some toxic dusts like lead, manganese, mercury, arsenic, antimony or cadmium enter into the blood stream after being ingested, inhaled or directly absorbed through the skin and produce diseases of the target organs. Manganese (affecting CNS), mercury poisoning causing mental illness and tremor, lead colic, lead palsy, chrome ulceration, arsenic poisoning and mesothelioma of the pleura due to asbestos have been well documented. Metal fume fever, occupational asthma and toxic jaundice and allergic alveolitis are some of the occupational diseases caused due to particulate matter.

Toxic Gases and Vapours

The toxic gases and vapours can be classified as irritants, asphyxiants, narcotics and anaesthetics depending on their effect on human body. The physiological response of these toxic material depend on their concentration in work atmosphere and duration of exposure. Most of these gases although produce acute effects and even death in high concentration, chronic effect due to low concentration may also be produced. Irritant gases may produce acute effect on upper respiratory tract (ammonia, sulphur dioxide, formaldehyde, acrolein) or may cause irritation of the bronchioles and alveoli (nitrogen dioxide, phosgene). Simple asphyxiant gases interfere with oxygenation of the tissues and cause suffocation. Common examples arc: carbon dioxide, ethane, methane, hydrogen, nitrogen and helium. Chemical asphyxiants like carbon monoxide, hydrogen sulphide and hydrogen cyanide, etc. cause asphyxia due to their chemical action on the blood or respiratory centre in the brain. They may cause instantaneous collapse, unconsciousness or death when inhaled in high concentration. Carbon monoxide poisoning in steel plants and coke ovens occur frequently due to leakage of the gas.

Anaesthetic and narcotic gases like ethyl and prophyl alcohol, acetone, acetylene, hydrocarbons and ethers produce anaesthetic effect, unconsciousness and accidental death in high concentration.

Cardiac sensitisation (due to volatile hydrocarbons), neurotoxicity (due to solvents, mercury and manganese vapours) and cancer (due to carcinogenic substances) also occur.

Solvents and other Toxic Chemicals

A good quality of solvents are used in industries, particularly in chemical plants. Many of these solvents are toxic in nature. When the solvents come in contact with the skin, they get absorbed and produce complex and variable effects. Some organic substances are inhaled during handling and affect the central nervous system. Depending on the degree of exposure the solvents produce effects from drowsiness to death. Exposure to solvents'not only occurs at the workplace, but also in our day to day. Their effect should be recdgnised and necessary precautions should be adopted while handling them. Safety measures should'be adopted during transport, storage and handling of these chemicals. The potential hazard of the toxic solvents may be studied in detail if used in chemical plants and other industries. Solvents which may catch fire easily or cause explosion should be handled with care. Material Safety Data Sheet in respect of each chemical should be studied to prevent accidental exposure to chemicals.

4.4.3 Biological Hazards

Biological hazards may be encountered in many industries while handling animal or plant products. The hazard may be caused by bacteria, virus, fungus, parasites or any other living organism encountered on the workplace. In paper mills, textile mills, wool works, tanneries, diaries, sugar mills, food processing industries and seed processing units where products

from plant and animal origin are used are likely to cause biological hazards. A number of occupational diseases are also transmitted from animal to man while working with animals. Veterinary surgeons, pet shop workers, butchers, farm workers and zoo workers are likely to get diseases through animal contact. The diseases may be acute or chronic in nature. A few occupational diseases caused due to biological agents are given in Table 4.2.

Table 4.2: Summary of **Occupations** and Associated **Infectious and Parasitic** Diseases

occupation	**Diseases**
Agriculture, animal husbandry, forestry, trapping and hunting	In both tropical and teniperate arcas: anthrax, anthropod-borne viral diseases (e.g. encephalitis, plague), coccidioniycosis, fungal infections, histoplasmosis, leptospirosis, Q. fever, rabies, tickborne rickcttsiosis, tuberculosis and tularaemia. In tropical areas only: anthropod-borne viral discascs (e.g. yellow fever, haemorrhage fever), hookworm, leishmaniasis, malaria, schistosomiasis, trypanosomiasis
Construction work, land excavation, sewer work, diatching, mining	Coccidioniycosis, hookworm, histoplasmosis, Icptospirosis, tetanus, wound sepsis
Meat and fish handling and packing	Bovine tuberculosis, brucellosis, erysipeloid, fungal infection, Q. fever, tularraemia
Poultry and bird handling	Fungal infections, newcastle virus diseases, ornithosis
Work with hair, hides, wool	Anthrax, Q. fever
Veterinarians	Tuberculosis, brucellosis, fungal infections, leptospirosis, newcastle virus disease, ornithosis, Q. fever.
Physicians, nurses, dentists, laboratory technicians	Viral hepatitis, tuberculosis, other communicable infections
Work in warm, humid conditions (Kitchens, gymnasiums, swimming pools, etc.)	Fungal infections of the skin

The diseases may be transmitted from man to man in the workplace duo to close contact with infected persons. This also conies under biological hazard if proper precautions are not taken at the workplace.

The effects of biological agent niay be further increased by presence of physical or chemical pollutants in the work environment. For example, the incidence and severity of respiratory infections are enhanced by irritant gases and fumes, exposure to nitrogen oxide may increase the chances of pneumonia in human beings, tuberculosis niay spread through dust while working in dusty environment. Bio-safety measures should be adopted to reduce or eliminate these hazards.

4.4.4 Psycho-social Hazards

Due to globalisation of economy and intense competition in every sphere, the human aspect of work has been strained to a great extent. Introduction of new technology, automation, computerisation, emphasis on quality of product, competitive price and changing work environment put a lot of stress on the workers. To cope up with the emerging situation, the old workers have to bc retrained or rehabilitated, whereas the new recruits have to face a greater challenge for which they have to be prepared. This induces job stress and if a suitable coping strategy is not adopted, the workers and supervisors may suffer from psychosomatic diseases like mental illness, hypertension, insoninia and depression. This will be more pronounced in the coming decade, because the physical and chemical hazards at the workplace will be taken care to a greater extent and psycho-social hazards will take their place.

Many of the workers today are better off economically but they have to face the hazards of industrialisation particularly in large cities. The problem of transport, housing, medical

facilities, lack of amenities and such other problems are still unsolved. This causes behavioural changes among the workers such as anxiety, depression, hostility, aggressiveness and alcoholism, etc. which are responsible for poor work performance and abnormal mental health. Psycho-social ill health like fatigue, body pain, headache, peptic ulcer, hypertension and rapid ageing have been seen very frequently. Boredom, repetitive work, sedentary jobs and monotonous daily routine are some of the problems which affect the physical, mental and social well-being of the individual and their family members. This will be a major problem in future. Every industry should take care of these issues to keep the workers healthy, productive and free of job stress.

4.4.5 Prevention and Control of Hazards

You have learnt about various occupational health hazards likely to be encountered during work. You will also appreciate that work cannot be avoided and industries cannot be closed because of existence of various hazards. The work has to be performed safely and health hazards have to be preverited by adopting various control measures. Before any control measures has been adopted in any industry the following points have to be considered.

i) Finished product and intermediate products
ii) Raw materials used
iii) Equipment/machines involved
iv) Operative procedures
v) Manpower employed
vi) Automation and computerisation
vii) Prevailing statutory provisions

The control measures may be adopted at the workplace by adopting engineering and ergonomic control measures, statutory control measures during operation and maintenance and medical control measure to protect the workmen from various hazards and environmental control measures to safeguard the working environment and the environment around the factory. The occupational physician should be involved in planning, implementing and monitoring such control measure from time to time in the best interest of the workers and the industry as a whole. A few control measures are enumerated below.

Engineering Control

Appropriate engineering design, total or partial enclosure of the process, providing ventilation (air changes), changing the raw material or process, isolating or shielding the hazardous process and providing exhaust system and maintenance of the machines1 equipment.

Statutory Control

Good housekeeping, following standard operating practices, keeping the contaminants within permissible limit, periodic inspection of work and conducting hazard studies.

Medical Control

Work environment monitoring, use of appropriate personal protective equipment, periodic health check up of exposed employees conducting health education and training and organising special biological monitoring programmes for the vulnerable group of employees on various health hazards.

Environmental Control

Work environment around the factory should be improved by proper sanitation, waste disposal, tree plantation and improving ecology.

4.5 OCCUPATIONAL DISEASES

You will agree that the incidence of occupational diseases is as old as our civilisation. The earliest observations on occupational diseases were found in the times of Pharaohs, around 4000 BC among the builders of pyramids where slaves and prisoners were engaged in building them. In Europe, mining was earliest industry and occupational diseases were observed among the Austrian and Bohemian miners and premature death among miners was very high as recorded by Paracelsus (1493-1541) and Agricola (1494-1555). The working condition in gold, silver and lead mines of ancient Greece and Egypt were so bad that the miners were the victim of many diseases.

The first book on occupational diseases and metal toxicology named "De Re Metallic" written by Agricola was published in 1556 although after his death. Bermardino Ramazzini (1633-1714), the Father of Occupational Medicine brought out a revolutionary change and devoted his entire life to the prevention of occupational diseases and to the improvement of workers' life.

During the twentieth century after the formation of International Labour Organisation, the member countries paid more attention to the workers' health and occupational diseases were identified. Although Rarnazzini laid emphasis on occupation on disease causation, many contemporary physicians did not consider it important. For the first time in 1925, ILO prepared a list of 3 occupational diseases (Convention No.18 of 1925) to which many more diseases were added making the total number to 76.

In 1989 occupational disease was defined as diseases known to arise out of the exposure to substances and dangerous conditions in processes, trades or occupations. Occupational diseases are caused due to work whereas certain diseases aggravated due to work are termed as work-related diseases.

In 1993 this was further reviewed by ILO during the Linz (Austria) Conference wherein a cause and effect relationship between the occupation and disease was established,

4.5.1 Identification and Diagnostic Criteria of Occupational Diseases

Following are some of the identification and diagnostic criteria of occupational diseases:

- The disease should have exposure-effect relationship with work, work method or work environment.
- The disease occurs among a group of individuals engaged in same type of work or occupation.
- The frequency and prevalence of the disease should be above the average morbidity of the rest of the population.
- The diagnosis should be established by clinical and pathological data, occupational back ground and epidemiological data.

The following diagnostic criteria should be adopted.

- Strong association with occupational exposure.

- Consistency: The independent research studies and reports should give similar results and conclusions.
- Specificity: The disease should depict clearly defined pattern.
- Appropriate time relationship: There should be appropriate time interval between the disease causation and exposure.
- Biological markers: There should be certain biological markers to assist diagnosis. Greater the exposure, greater is prevalence and seriousness.
- Damage-risk criteria: The risk and disorder criteria of the causative agent and the host should be established.
- Coherence: All studies and evidences should lead to same/similar conclusion.
- Quantitative and Qualitative criteria: The risk assessment should be done qualitatively and quantitatively which establishing the diagnosis.
- International/National recognition: The disease should be recognised as 'Occupational' as per international/national standards or documents legally.

4.5.2 Examples of Some Occupational Diseases

The examples of some occupational diseases prevalent in India and other industrialised countries are given below.

a) Occupational Lung Disease

Pneumoconiosis, occupational asthma, lung cancer and allergic bronchitis are some of the occupational lung diseases caused due to exposure to particulate matter and gases at the workplace. Aetiology of more and more such diseases reveal their occupational origin. Pneumoconiosis is caused due to inhalation of different types of respirable dust which get deposited in the alveoli of the lungs and produce fibrotic reaction. Silica (SiO_2) is most harmful dust which causes silicosis after prolonged exposure. The disease is common among stone crushers, miners, foundry and refractory workers. The disease produces malaise, low grade fever, breathlessness, mild pain in chest and may be confirmed by X-ray of chest and pulmonary function test. It aggravates tuberculosis if present.

Depending on the nature of dust, which is the causative agent, the pneumoconioses are named accordingly.

Table 4.3: Various Types of Pneumoconioses

Causative Agent	Type of Pneumoconiosis
Silica (SiO_2)	Silicosis
Coal dust	Anthrocosis
Iron oxide	Siderosis
Barium	Baritosis
Calcium dust	Calcosis
Tin	Stannoris
Asbestos fibre	Asbestosis
Sugarcane fibre	Baggasosis
Mouldy hay	Hay fever

Exposure to asbestos fibres in asbestos mines or industries produce mesothelioma of pleura after 15-20 years. Due to its intense toxicity use of asbestos has been banned in developed countries by regulation. In India, it is still used in abundance but many cases of asbestosis have not been reported in India,

Occupational asthma is caused due to a wide range of contaminants of occupational origin. This is emerging as an acute respiratory problem among the,industrial workers, which has to be prevented.

Allergic respiratory diseases caused due to air pollutants among the sensitive workers and in the surroundings of the industries are emerging as a problem of indiscriminate industrialisation. While diagnosing chest diseases, this should not be lost site off.

b) Occupational Dermotoses

Skin disease caused due to exposure to various substances, most of them of chemical origin, bring about a great deal of suffering among the industrial workforce. It occurs in all age groups, in any work setting and brings about personal misery and loss of productivity. The occupational dermatitis may be classified as contact dermatitis, photodermatitis, occupational acne, pigmentary abnormalities, exposure to excess beat or certain chemical substance. Most of these skin disorders can be prevented by adopting safe method while handling chemical, maintaining cleanliness and personal hygiene of the workers, using barrier creams and skin cleansers and minimising exposure to contaminants. Occupational cancer of skin may be caused due to certain chemicals.

c) Systemic Occupational Diseases

Certain substances in the work place may enter the body in sufficient concentration through inhalation, ingestion or direct absosption through tlie skin and enter the blood steam. These substances affect specific organs or organ systems of tlie body to produce occupational diseases in tlie long run. Some of the occupational diseases are given in the Table 4.4.

Table 4.4: Occupational Diseases

Causative Agent	Body System Affected	Occupational Disease
Carcinogens	Skin	Skin cancer
Chromium	Skin	Chrome ulcer
Manganese Mercury	Nervous system	Manganism (like Parkinsonism), mercury poisoning
Organic lead	Nervous systeni	Psychosis, cncephalopathy
Lead	Digestive system	Lead colic
Nitrates, aniline derivatives, chlorobcnzc, benzene, nitro & amino compounds	Blood formation system	Bone marrow depression Formation of abnormal haemoglobin (metharmoglobin) anaemia
Cadmium	Kidneys	Renal failure
Calcium		Renal failure
Asbestos, chromium	Lungs	Occupational cancer of lungs
Benzene	Blood tissue	Leukaemia
Vinyl chloride	Liver	Liver cancer
Benzedrine, Benzene	Urinary bladder	Urinary bladder cancer
Arsenic, soots, tar, mineral oils.	Skin	Carcinoma

In addition to this, certain other diseases are caused due to physical agents, e.g. Noise induced hearing loss due to excess noise, vibration white finger, steel workers' cataract and arc eye due to radiation, telegraphists cramp due to vibration, etc,

Some of these occupational diseases are notifiable under the Indian Factories Act and compensable according to Workmen's Compensation Act.

4.5.3 Notifiable Occupational Diseases

The following occupational diseases as listed in the schedule-I11 of the amended Factories' Act are to be notified to the Chief Inspector of Factories of the state under the sections 89 and 90.

- Lead poisoning, including poisoning by any preparation or compound of lead or their sequelae.

- Lead tetra-ethyl poisoning
- Phosphorous poisoning or its sequelae
- Mercury poisoning or its sequelae
- Manganese poisoning or its sequelae
- Arsenic poisoning or its sequelae
- Poisoning by nitrous fumes
- Carbon bisulphate poisoning
- Benzene poisoning, including poisoning by any of its homologues, their nitro or amido derivatives or its sequelae
- Chrome ulceration or its sequelae
- Anthrax
- Silicosis
- Poisoning by halogen derivatives of the hydro-carbons of the aliphatic series
- Pathological manifestation due to: (a) radium or other radio-active substances
  (b) X-rays
- Primary epitheliomatus cancer of the skin
- Toxic anaemia
- Toxic jaundice due to poisonous substances
- Oil acne or dermatitis due to mineral oils and compounds containing mineral oil base.
- Byssionosis
- Asbestosis
- Occupational or contact dermatitis caused by direct contact with chemicals and paints. These are of two types, that is, primary irritants and allergic sensitizers
- Noise induced hearing loss (exposure to high noise levels)
- Beryllium poisoning
- Carbon monoxide
- Coal miners' pneumoconiosis
- Phosgene poisoning
- Occupational cancer
- Isocyanates poisoning
- Toxic nephritis

4.5.4 Cornpensable Occupational Diseases

The following occupational diseases are cornpensable as per the Section 3 of the Workmen's Compensation Act, 1923 (Schedule-III) and Section 52 of the Employees' State Insurance Act, 1948.

List of Cornpensable Occupationat Diseases

- Infectious and parasitic diseases contracted in an occupation where there is a particular risk of contamination
- Diseases caused by work in compressed air
- Diseases caused by lead or toxic compounds
- Poisoning by nitrous fumes
- Poisoning by organo-phosphorus compounds. .

- .Diseases caused by phosphorus or its toxic compounds
- , Diseases caused by mercury or its toxic compounds
- Diseases caused by benzene or its toxic homologues
- Diseases caused by nitro and amido toxic derivatives of benzene or its homologues
- Diseases caused by chromium or its toxic compounds
- Diseases caused by arsenic or its toxic conlpounds
- Diseases caused by radioactive substances and ionising radiation
- Primary epitheliomatous cancer of skin caused by tar, pitch, bitumen, mineral oil, anthracene, or the compounds, products or residues of these substances.
- Diseases caused by the toxic halogen derivatives of hydrocarbons (of the aliphatic and aromatic series)
- Diseases caused by the carbon disulphide
- Occupational cataract due to infra-red radiation
- Diseases caused by manganese or its toxic compounds
- Skin diseases caused by physical, chemical or biological agents not included in other items
- Hearing impairment caused by noise
- Poisoning by dinitrophenol or a homologue or by substituted dinitrophenol or by the salts of such substances
- Diseases caused by beryllium or its toxic compounds
- Diseases caused by cadmium or its toxic compounds
- Occupational asthma caused by recognised sensitising agents inherent to the work process
- Diseases caused by fluorine or its toxic compounds
- Diseases caused by nitroglycerine or other hitroacid esters
- Diseases caused by alcohol and ketones
- Diseases caused by asphyxiants: carbon monoxide, and its toxic derivatives, hydrogen sulphide
- Lung cancer and mesotheliomas caused by asbestos
- Primary neoplasm of the epithelial lining of the urinary bladder or the kidney or the ureter
- Snow blindness in snow bound areas
- Disease due to effect of heat in extreme hot climate
- Disease due to effect of cold in extreme cold climate
- Pneumoconiosis caused by sclerogenic mineral dust (silicosis, anthraoosilicosis, asbestosis) and silico-tuberculosis provided that silicosis is an essential factor in causing the resultant incapacity or death
- Bagassosis
- Bronchopulmonary diseases caused by cotton, flax hemp and sisal dust (Byssinosis)
- . Extrinsic allergic alveolitis caused by the inhalation of organic dusts
- Bronchopulmonary diseases caused by hard metals

There are many occupational diseases which were identified years back are not prevalent today, e.g. Bursitis of the elbows among the miners, telegraphists' cramp, hatter's disease (mercury poisoning) etc. Due to change of technology and introduction of complex

chemicals and monotonous electronic devices, newer occupational diseases are appearing. Job stress leading to psycliosoniatic disorders, diseases due to continuous over work, eye strain among the VDU operators and many occupational cancers have been identified during this century. The reporting and notification of such diseascs particularly in developing and underdeveloped countries are almost negligible. Burdened with other health problems arising due to poverty, malnutrition, communicable diseases and uncontrolled life style diseases, the occupational diseases have been lost sight of. Derth in diagnostic facilities and lack of awareness among the industrial workforce and even the health professionals has resulted in low reporting of occupational diseases which is expected to improve in corning decades.

4.5.5 Prevention of Occupational Diseases

You arc aware that treatment is not available for most of the occupational diseases although most of them can be prevented. Since most of these diseases develop days or years after exposure and do not produce any acute symptoms in initial stage, diagnosis is delayed or missed invariably. The disease develops silently among the exposed workers and remains so even after cessation of employment. Won-availability of treatment, lack of laboratory facilities to clinch the diagnosis and apathy of the employers and employees are the constraints in identification, notification and prevention of these diseases. However, preventive measures should be taken by the industries, mines, plantations and agriculture sector against the occupational diseases.

As discussed earlier, engineering control, medical control, statutory control and environmental control measures have to be applied for this purpose.

It also becomes the responsibility of any treating doctor, factory medical officer or occupational physician to notify the occupational diseases detected by them to the statutory authorities. If not complied with this provision, the doctor may be penalised under the Factories Rules.

4.6 OCCUPATIONAL HEALTH SERVICES

Occupational Health Services (OHS) have been provided in industries and mines in most of the developed countries based on recommendations of ILO and WHO: But in Indian

industries, it has not yet gained a foot hold. Of late, establishment of a need-based occupational health centre in tlie industries involving hazardous processes and employing more than 200 persons has been brought under the statute in many states of India. It is expected to be adopted widely by different industries in tlie coming decades to provide health care to the industrial workforce and to keep them fit and productive.

As mentioned earlier, many occupational diseases have been identified during this century. . Earlier only workplace hazards and work injuries were dealt by OHS and it was considered as a preventive service. Subsequently, other factors related to work were studied in detail and impact of working condition, work organisation, work methods and work environment were identified as occupational diseases although many of them have not been reported today.

The statutory requirement of notification and compensation of occupational diseases called for development of occupational healtli services in most of the developed countries of the world based on the principles of the ILO/WHO Joint Committee. Subsequently, for fulfilling the above objectives, a multidisciplinary team-approach was advocated. Since, it is beyond the capacity of any single individual to provide this service, this has been developed as a multidisciplinary and multidimensional specialised team-work.

4.6.1 Role of International Organisations

ILO is instrumental in promoting occupational health services in industrialised member countries. During last four decades, ILO adopted many Conventions and Recommendations on Occupational Health for implementation by tlie member countries first being Recommendation No. 112 (1959). This recommendation gave a direction to the practice of occupational health by defining its purpose, condition for establishment, location, role, organisation and functions. The Convention No. 155 (1981) and Recommendation No. 164 (1981) further specified the responsibility of the employers, bipartite committee, national policy and statutory responsibilities. Convention No. 161 (1985) and Recommendation No. 171 (1985) on OMS made concrete recommendations on purpose, aims and objective and functions of OHS under changing world situation. These Conventions and Recommendations facilitated development of occupational health services at the place of employment. In India, some undertakings in organised sectors like coal, steel, petrochemicals, heavy engineering and some chemical industries (mostly multinationals) followed some of the reconimendations in a sporadic manner, However, as per amended Factories' Act (1987) and rules made thereunder it is mandatory to establish occupntional health centres in industries employees more than 200 persons and involving in hazardous processes as per Schedule II of the Act. Similar provisions have been reconimended for the mines. This has created an atmosphere of change in attitude of tlie occupiers and owners of industrial/mining organisations. Many organisations agreed in principle to provide optimum occupational health care for their workforce. The dearth of resource in terms of money and qualified man power was a constraint. In this context, it may be pointed out that the role of occupational physicians already employed in such organisations is very important. They should be able to sell the idea of investment on occupational health as a benefit rather than an avoidable expenditure. In these industries OIIS can be developed in stages to derive benefit in the long run.

4.6.2 Need for OWS in Industries

You will agree that the medical facilities during last half a century has undergone phenomenal changes. The different medical specialities have undergone changes by further dividing tlie specialities and super specialities into various micro specialities. The field of practices have been narrowed down into high tech, skill-intensive activities which are beyond the scope of many practitioners. A modern hospital today consists of not only highly qualified and specially trained medical professionals but also sophisticated equipment and electronic gadgets for diagnosis and user-friendly devices, Thus, medical care is becoming complicated and costlier day by day and going beyond the reach of tlie majority and thriving because of the patronage of a group of affordable few. Tlie occupational health today has branched into many sub-specialities and has become niultidimensional in nature involving a wide range of professionals and not confined to the medical discipline alone. It is a team effort, it is a group activity, it is a purposeful endeavour for achieving the objectives of total

health care at the place of work. It is not limited to the expertise of a single individual, but the excellence of well co-ordinated team-work with multipronged approach to problem solving. In fact, occupational health activities extend beyond the boundaries of human body today and have to be managed by adopting modern management principles. Based on the changing socio-cultural context of work ethics, occupational health today is considered as a health promotional activity for protecting and preserving the human resource. The OHS has a total health care approach consisting of preventive, curative, promotive and rehabilitative services to give benefit to the individuals and to the organisation. In modem times, OHS has been conceptualised as a tool for improving organisational image by increasing productivity and profit by reducing absenteeism, preserving human resource and creating a motivated and productive workforce for organisational gain. Therefore, modern concept of occupational health services is: "services established in or near the place of employment for the purpose of protecting workers against any health impairments which may arise out of their work or the conditions in which it is carried out and promoting their health in relation to work" (ILO Reconmendations No.171-1985). Occupational Health Service (OHS) may be defined as:

"Preventive, promotive, curative, rehabilitative, environment conscious, safety oriented, employer-employee friendly service which aims at health preservation and health promotion of all those who are engaged in any type of work or occupation".

4.6.3 Organisation of OHS

As indicated earlier, need-based **OHS** should be provided in every industry to cater to the health needs of the employees. The service should necessarily be a multi-disciplinary in nature. Following are some of the considerations required for organisation of OHS:

- Every large enterprise, therefore, should have a written down occupational health policy indicating the objectives, role and responsibilities of employees and the occupier.
- Every employee should read and understand this policy and should co-operate with the employer to implement this.
- Adequate infrastructure in terms of trained manpower, equipment and other physical facilities should be made available by the enterprise to put the policy into action.

  Occupational Health Centre may be established as an integrated centre with total health care approach nearer to the workplace.
- The services provided are: treatment of injured and the sick, referral facilities and well organised health education programmes.
- The different sections of the services may consist of some or all of the following: Occupational Medicine, Occupational Hygiene, Occupational Physiology and Ergonomics, Biochemistry & Toxicology, Occupational Health Nursing, Health Education, Occupational Psychology, Health Information System (HIS) and Applied Research.

4.6.4 Functions of OHS

The main task of **OHS** is health protection and health promotion of the employees. The activities should consist of:

- Identification, evaluation and control of occupational hazards likely to exist in the industry.
- Treatment of work injuries and emergency medicare..

  Conducting pre-employment, pre-placement, periodical, promotion, post-sickness and pre-retirement medical examinations of all the employees at suitable intervals and maintaining their health records in health cards/computer.
- Regular work environment monitoring and assessment of the impact of work environment on exposed workers.
- Evaluating the exposure status of the risk group with the help of dosimeters.
- Organisation of special health programmes at work site for the identified target group such as women, food handlers, high risk workers, physically handicap, ageing workers and executives.

- Identification of regular follow up and rehabilitation of disabled and chronic sick employees.
- Training employees at different levels on health matters and preparation of health education material for creating health awareness among the employees.
- Mental health assessment and counselling of special risk groups through Employee Assistance Programme (EAP).
- Conducting epidemiological studies, health surveys and applied research and publication of reports for information sharing and bench marking.
- Developing computerised Health Information System (HIS).

Advising the management on health, safety, environmental matters and statutory requirements as and when required.

4.6.5 Model Occupational Health Services for Factories and Mines

You will appreciate that in our country, Occupational Health Services in industries and mines need re-organisation. The health care for industrial and commercial establishment workers is provided through the Employees State Insurance Scheme (ESIS) as per the provisions of ESI Act. But this is limited to certain treatment-related and compensation-oriented benefits only for the insured workers and their family members. But all the workers are not covered under this Scheme and there is also a limit to the medical expenditure. Miners get treatment facilities through cess and mining welfare organisation. To give a coverage to all the. employees, the factories and mines run their dispensaries/hospitals through listed specialists. By this method only the treatment needs of the sick workers and their family members are met to some extent. But the modem concept of health aims at total health care approach for all the employees which includes preventive, curative, promotive and rehabilitative health care as mentioned earlier. Hence the thrust of occupational health has shifted from preventive to prevento-curative approach.

While designing OHS for any industiy or mines in our country, it is not necessary to adhere to the developedcountry-model. Keeping the basic principles intact, the design should be need based and modified to match the politico-socio-cultural situation of the country, As discussed earlier, even today, some factories and mines are not working with bare minimum of safety and health conditions except a few hand-counted industries and business organisations who have fulfilled the statutory requirements in the real sense. Some of them haw gone even beyond. OHS should never be considered as statutory compulsion but as an organisational commitment. A model Occupational Health Centre at the workplace should provide all the components of "total health care", i.e. emergency medicare, treatment facilities, health monitoring, health counselling, health promotional activities, disease prevention, protection from specific diseases (occupational and work-related) disability limitation, rehabilitation and health education – "all in one package".

Generally, three models of OHS are recommended to cater to the needs of factories, mines and business service or business organisations in our country. The centres should start in a small way and expanded gradually with multiple activities depending on requirement:

Model I

Category	Facilities	Manpower
Small factories, mines Occupational and service organisations having 1000 or less persons. The operations arc non-hazardous in nature even a group of small organisations may develop a centre jointly.	• Emergency medicare • Preventive, eurativc and health education • Work environment monitoring	One Physician, medical employing hygienist, Nurse, laboratory assistant and. medico-social worker.

Model II

Category	Facilities	Manpower
Organisation employing 1000 to 5000 persons and/or factories in hazardous operations as per statute	• Emergency medicare preventive, curative, rehabilitative, health education, psychology, physiology and ergonomics and computerised health information • Work environment monitoring.	Occupational Physicians, hygienist, psychologist, health educator, toxicologist, physiologist, nurse and medical social worker and computer operator

Model III

Category	Facilities	Manpower
Large industries and mines employing more than 5000 workers	• Emergency medicare, curative, rehabilitative, laboratory services. • Referral system • Specialised care on different disciplines. • The computerisation facilities for health records • Work environment monitoring • Psychological counselling	The manpower should commensurate with the size of the factory/mines. In addition to above Manpower (Model II) epidemiologist, health statistician and more doctors and nurses need to be employed.

In addition to this, industry-wise referral centres have to be developed in phases to cope up with multi-centre activities. Health Information System, Research, Consultative Services and Effective Co-ordination with local, national and international institutions/organisations should be ensured for better functioning when adequate infrastructure facilities are available.

4.7 OCCUPATIONAL HEALTH MANAGEMENT

You have already learnt in earlier courses that in large enterprises now more emphasis is given on human resourse development. To keep the employees fit and productive, the subjects like safety, health and environment are gaining more and more importance in organisational policies and practices. For efficient management of any industrial organisation, these three factors have also to be managed in the present context. The word management, according to Peter Drucker "*denotes a function but also the people who discharge it. It denotes a social position and rank but also a discipline and field of study*". For success of any enterprise or institution management techniques are applied scientifically and methodically. This is also applicable in the field of occupational health management. To start with every industry should have an occupational health policy. The provisions made in the occupational health policy of any company will not come into force as such but has to be put into practice by the managers who are also instrumental in implementing the other policies and procedures of the company. Hence, the implementation of such policies depends either on unilateral decision of the company or through the participative action depending on the prevailing organisation culture. The experience from the industrialised countries and from public sector undertakings in India indicates that a greater success through joint participation have been achieved in the area of occupational health, safety and health should not necessarily be viewed as the sole responsibility of the employer or the occupier as laid down in the statute, but the role of each of the social partners jointly in achieving the objectives of law should be encouraged. Health of the workforce in any industry should be accepted as a fundamental requirement of good management, its implementation without participation and co-operation of the employees and trade unions is quite difficult. Issues such as formulation of a health policy, identification of hazards and their impact on health, education, provision of immediate and emerging medicare facilities at the workplace, medicare for employees and their family members, training of the employees, etc. cannot be

settled unilaterally even if the management wishes to do so. As a partner of progress and industrial growth, every employee should get involved in these issues for developing better solutions to the day-to-day problems of mutual benefit. In the UK, Lord Robens stressed on the working relationship between the employer and the workers and the contribution which each should make for overall improvements in the work environment have also been identified.

4.7.1 Occupational Wealth Policy

The first step in management of occupational health in our country is formulation of a written policy depicting the management's commitment to safety and health. It should also be followed in letter and spirit. The amended Factories Act, 1987 has ernphasised the need for such a policy for every industry should be signed by the chiefexecutive and it should be circulated among each and every employee and should be understood by them clearly. The employees should also feel that the management really means what has been written down in the policy. Occupational health policy should reflect the following components in the document:

- Setting out objectives for all employees on occupational health and safety
- Arrangements for accident prevention and health care programmes and participation by the workers, trade unions and management team.
- Provision of adequate fund, infrastructure facilities and personnel for occupational health services and safety organisation at the workplace.
- Fixing reasonable responsibility and accountability at appropriate management level for implementation of the policy.
- Provision for education and training of employees of different levels.
- Periodic monitoring implementation of the policy and review at board level.

4.7.2 Organisation Structure

The second step is to set out the proper arrangements for implementation of tlie policy to achieve the goal. This calls for the appropriate organisational structure by understanding the need and multifactorial causes of the accident prevention, safety promotion, health care and rehabilitation. Therefore; qualified and experienced safety, health and personnel professionals have to be deployed by the industry to take charge of this. Although statutory provisions have been made for appointment of labour welfare officers, safety officers and medical officers in industries under the Factories Act and Rules, many management did not attach much importance to it, except employing a labour welfare officer to take care of all the three lines. While making necessary arrangements for safety, health and good work environment for the workers, the employer should not look through the narrow statutory framework, but consider certain basic requirements for effective implementation of the policy. These are:

- Distribution and decentralisation of powers, responsibility and authority.
- Dissemination of knowledge and information related to the safety and health precautions in the workplace to the managers and supervisors and trade union leaders.
- Analysis of work accident data and occupational diseases for taking preventive actions.
- Provision and use of personal protective equipment, suitable tools and instruments during work,
- Formulating and following guidelines and protocol for performance of hazardous work.
- Promoting to adopt safe operating and maintenance practices.
- Leadership quality and initiatives of the safety and health professionals.

4.7.3 Participative Approach

The third element worth mentioning is participative approach. The agreement of safety and health cannot be achieved through collective bargaining but by mutual trust and discussions. Particularly in multiple union situation in the industry, this becomes a difficult task to make every one agree to a proposal. Although the employer should take the initiative to inculcate good safety and health practices among the workers, the workforce should also realise its importance and practice the same voluntarily. All trade unions should understand that safety and health measures are essential and beneficial for their members irrespective of their ideology and any positive thinking by the management in this direction should be accepted and adopted. By participating in safety and health programmes the trade unions can bring benefits in cash and kind for their members through humanistic approach. The provisions of joint participation should include:

- Identification of suitable trade unionists with aptitude for safety and health activities.
- Assigning the roles and functions to the identified/nominated safety and health representatives.
- Formation of bipartite Safety and Health Committees and defining their roles and functions.
- Linking wage agreements with safety performance and productivity.
- Education and training of trade union leaders including as trainers.
- Translating the decisions on safety and health into action.

4.7.4 Action Plan

The fourth aspect is to prepare long-term and short-term action plans with mutual agreement of the employer and the employees. The long-term action plan may be pre-tested and modified on the basis of the success achieved through the short-term plan. With a view to promote participation in the programmes for safety and health by all workers, a model agreement may be signed with the management so that the programmes are implemented effectively. The document should contain the following:

- The short-term and long-term actions identified by microplanning
- Responsibility and implementation within a reasonable time frame spelt out clearly.
- The thrust area to be identified for initiation of action to give tangible benefits,
- Periodic review of the action plan be done.
- Good performance and performers be encouraged by appreciation or reward.

4.7.5 Duties and Responsibilities to be Fixed

The fifth factor is to recognise that the prime responsibility of safety management and overall control should rest with the emplbyer or at higher management'level. A hierarchy of responsible managers and supervisors should be created at organisational level for interfacing at different levels. The occupational health specialists'should provide expert knowledge and advice to this group as well as the top management on matters of health promotion of workforce. The occupational physician should also have regular interaction with the hospital/specialists wherever available.

4.7.6 Involvement of the Employees

The sixth element is to make the individual worker realise his presence felt in the health programmes, His obligations towards his ideologies, group and the organisation as a whole in maintaining a safe and healthy work culture. The workers should:

- take initiative and co-operate in maintaining the safety devices in the workplace and following the safe and healthy work practices.

- take reasonable care that no worker wilfully or intentionally interferes or disregards the safety devices.
- educate himself as well as the co-workers on identification and elimination of hazards and unhealthy work situations.
- motivate and train the committee members to adopt health and safety voluntarily.
- .take initiative to form safety and health groups in the departments/sections.

4.7.7 Role of Trade Unions

The seventh factor is encouraging the trade unions to develop their safety and health programmes independently by complementary to bipartite agreement. Many trade unions have recognised today that it is their responsibility to promote the health of the workmen by improving the quality of work environment by reducing the risks and creating consciousness among the workers towards health. This could be achieved through general and specialised training organised for the workers' representatives and providing them specific guidance to train others. The industries may support or sponsor such programmes. The trade unions should also develop expertise through interaction with international organisations and professional associations. If necessary, expert advice from the safety and health professionals may be sought as and when necessary to strengthen their points ofdiscussions with the management.

4.7.8 Sharing Information

There is almost an explosion of knowledge on health today. Due to free and wide discussion on health issues by the media including internet in most of the countries, the workers have the access to the latest health information. The employers have to keep track of this while dealing with the workers and their trade unions. The "right to know" clause introduced in statutes makes it almost mandatory for the occupier to share the information with the workers on health hazards and preventive measures. The safety and health professionals of the employers and trade unionists should have free access to such information either through computer network or data bank. Organising problem-oriented workshops and sharing solution through technological innovations will be beneficial.

4.7.9 Human Resource Development

Human resource development in any sphere of activity has become a necessity due to rapid technological changes and Occupational health is no exception too. To match with the changing needs one has to gather knowledge and skills through education, training and re-training. By imparting training to the individuals engaged in various jobs, the efficiency increases, output improves, errors are reduced and accidents are minimised. Designing modular health education programmes tluough audio-visual aids is the order of the day. Incorporating health management in the Corporate Policy, the hands of the entrepreneurs will be strengthened to deal with the task firmly which may arise due to changed socio-political situation, They cannot remain as silent on-lookers any more. Management strategies on safety, health and environment have to be adopted by rational thinking, clear objectives and strategic planning to achieve the desired industrial growth. It should be emphasised that safety and health factors contribute a lot for welfare of the workforce as well as the production process. If managed well, the investments will give rich dividends and generate resource. The secret of success lies with the managers and occupiers.

4.8 OCCUPATIONAL HEALTH IN INDIA: PRESENT SCENARIO

India is becoming industrialised rapidly. Not only the industrial process but also other economic activities are expanding vibrantly all over the country. You must have observed that more and more active population from rural agricultural community are migrating into the newly developed industrial cities and towns to earn their livelihood. This produces direct and indirect impact on the industry, Although the process of industrialisation started in our country during late fifties, unfortunately it could not be done in a planned manner or organised way. The industries existed in this country at certain locations for many years and labour force was available cheap or for part time work. Acute scarcity of accommodation, transport, health care, education and other infrastructure facilities for industrial workers was not experienced. Therefore, much emphasis was not laid on occupational health. The workmen were contented with whatever they got for medical treatment. Most of them were covered by Employees' State Insurance Scheme. Emergency medical care was provided in the factory dispensary. This was the situation in industries, mines, tea gardens, ports and railways till sixties. When the huge public sector industries like steel, cement, engineering and petro-chemical complexes were established and the coal mines were nationalised the workforce got organised. Provision of medical facilities by the employer was envisaged and these industries started their hospitals and dispensaries without depending on ESI Scheme. In some industries only eniergency treatment facilities were provided by the employer as envisaged and these industries started their hospitals and dispensaries without depending on ESI Scheme. In those industries only emergency treatment facilities were provided at the workplace initially. Even in these large industries occupational health services did not develop per se.

Tata Iron & Steel Co. Ltd. (TISCO), Jamshedpur is a pioneer in developing factory medical service inside their steel works in first quarter of this century in form a "First Aid Station (Plant)". A medical teani headed by a doctor and other paramedical staff round the clock provided emergency medicare to the accident victims and workers falling sick in the workplace, The other private industries and multinational companies operating then had some make-shift arrangement at the workplace for treatment of the injured and sick by part-time or visiting medical officers.

As the Factories Act was enacted in 1948, workers were organised through trade unions. Public voice was raised for protection of human health and safety and many of the employers were awakened. They took some steps for welfare of workers as generous gesture or for statutory compulsion. Some multinationalcompanies and enlightened employers considered occupational health and safety measures as a fulfilment of statutory provisions rather than as a welfare and humanitarian approach. Many large industries and most of the public sector undertakings established their medical services exclusively for the employees and their family members. At this point, nucleus of Occupational Health Services were established in many industries at the precincts of the factory with variable facilities as first aid station, factory clinic, work surgery, plant dispensary of plant medical unit to render emergency medicare,

In mid-sixties when safety movement became more pronounced and compensation for accidental death was heavy, safety and occupational health were developed per se, not in a planned manner but haphazardly. Some organisations with a motivated Occupational Physician as a leader, developed their OHS with available manpower and resources, other managements realised its importance but hesitated to invest more capital, whereas a few undertakings considered OHS as wasteful expenditure although they spent enough money for curative services.

The major hindrance in development of occupational health in India is that the subject was not given proper attention in postgraduate medical curriculum – what to speak about the undergraduate level'? Medical education with excess curative bias and minimum preventive orientation, importance of occupational health even for the doctors working in industrial hospitals were not considered important by the medical professionals and teachers. A medical graduate was also not allured or attracted very much to take up occupational medicine as a career as job opportunity was limited. But a few motivated Occupational Physicians have performed their job very well by becoming a change agent particularly in the attitude of administrators and employees by showing their effectiveness in the field.

OHS in many large industries existed in rudimentary in many multinational companies like Lever Brothers, Imperial Chemical Industries, Guest Keen Williams Co., Union Carbide etc., established factory-level OHS in India, TISCO, augmented its services. Public sector steel plants adopted IISCO model and established plant medical units which functioned in a limited manner. In Rourkela, Durgapur, Bhilai and Bokaro Steel Plants, these services were established at the plant site which have been strengthened during last few years based on ILO recommendations. Steel Authority of India Limited has established OHS Centres in its integrated steel plants, alloy steel plants and mines along with their modern hospitnls. A National Occupational Health Services Centre for the steel industry has been functioning in Bhilai Steel Plant, Bhilai, since 1990.

In 1970s the first national level Model OHS Centre was established in Bharat Heavy Electricals Limited, Trichy, an UNDP project in ILO collaborations to cater to the needs of Engineering Industries. Particularly during the last two decades many public sector, government and private sector industries have established their own OHS in different plants and mines in India.

Employees' State Insurance Scheme. which was considered as a contributory health scheme for the industrial and commercial establishments was governed in almost all states under ESI Act, 1948. Many industries do not consider it important to establish their OHS even though ESI Scheme was mostly curative biased and there is hardly any component of preventive care for health protection of insured workers, The scheme is operating through the panel doctors of occupational ESI hospitals under the administrative control of state and central labour departments. ESI corporation has occuptional disease centres for early, defection and diagnosis of diseases, The regional centres are in Calcutta, Mumbai, Chennai, Delhi and Nagda. Health Department does not have major role to play in this scheme and, therefore, occupational health is not under the health department in any state.

Even today, there are many organised sectors in India like railways, ports and docks, petro-chemical complexes and mines where occupationnl health has not been organised in a way as it should be. Efforts made by certain individuals to organise OHS are praise-worthy but the real impact has not been felt either by the government, employers or the employees for whose benefit the services are meant.

A large number of unorganised small scale industries, cottage industries and rural occupations have not conceived the idea of health and safety of the workers engaged in production of consumer goods because of socio-economic reasons.

Agriculture, which is the main occupation'of the Indian community is also not brought under the purview of OHS. During last five decades there is enough advancement in the field of agriculture and hazard has increased due to use of mechanised tools, chemical fertilizers and pesticides. The green revolution in the country has brought about certain safety and health

problems for the agricultural rural community which was not heard before. More emphasis is now given on rural development. An integrated approach to develop safety and health aspects for this vital section of our community cannot be ignored in future.

In the field of research there is considerable improvement during last three decades. National Institutes have been established in sixties to undertake research studies through collaborative effort. National Institute of Occupational Health, Ahmedabad with regional centres at Calcutta and Bangalore, Industrial Toxicological Research Centre, Lucknow, Defence Research Laboratory, New Delhi, Central Mining Research Station. Dhanbad, etc, have made significant contribution in the field of research in occupational health and safety,

In the field of education and training country is lagging behind. Training facilities for doctors and supporting staff in various disciplines of occupational health in the national and international institutions and universities is not available adequately. Only diploma courses and certificate courses of three-months duration are available in Calcutta and Mumbai alone. Occupational medicine has not come to the main stream of medical sciences education. Medical Council of India whose function is also to promote education in different specialities of medical sciences has not shown any concern about it.

The Indian Association of Occupational Health (IAOH), professional association of doctors working in industries, mines, plantations and research institution was formed more than 50 years ago. The members of the association are trying to spread the awareness about occupational health among the employers, workmen, trade unions, doctors and statutory authorities as far as possible. The association organises conferences, workshops, training programmes in collaboration with ILO, WHO and International Commission on Occupational Health (ICOH) also co-operate and collaborate in many programmes. Medical Division of DGFASLI, Mumbai and Medical Inspectors of different states where existing, also organise some programmes for industrial workers and factory managers. Interestingly, this association was started by a handful of ex-army doctors working in the Tata Main Hospital, Jamshedpur as a Society for Study of Industrial Medicine (SSIM), whose name was changed subsequently. The association publishes a quarterly journal, regularly for last 50 years. The name of the Journal changed to "Journal of Occupational and Environmental Medicine" as per the new concept. It is heartening to note that some occupational physicians have started their consultancy in industrial cities.

The national scene although appears gloomy at present, an awareness about the health among the industrial community is growing. The safety-health-environment trio in the industrial atmosphere is gaining prominence. It is expected that occupational and environmental health issues will be integrated with industrial progress in future. The medical profession has to play its significant role in this field, particularly you as a health manager.

4.9 EMERGING OCCUPATIONAL HEALTH ISSUES IN FUTURE

Liberalisation of economy, technological changes, socio-political impact, wider export-import market and competitive trade practice will bring significant changes in the process of industrialisation all over the world. India will be no exception to this. Being a developing country, the impact will be felt more among the working population. Therefore, as a preparation for the 21st century, certain issues have to be given a relook in the context of occupational health in our country,

In the coming decades, in India, the employees of the factories will face increasing competitions with their counterparts in developed countries to stay in business, customer satisfaction, quality control, timely delivery schedule, increased production and application of appropriate technology will have to be taken care of by the entrepreneurs. Due to economic recession and dull market conditions, in certain sectors many of the large industries in this country have been recourse to manpower rationalisation (reduction), system changes, cost control, reducing wasteful expenditure, optimum utilisation of available resources, multiskill development among the existing workforce, automation and

computerisation wherever feasible. In future, the availability of limited high skilled workman have to be hired at a high salary and, therefore, the companies have to keep them healthy and fit for work. The occupiers have to adopt internationally approved practices as per the guidelines issued by ILO, WHO, International Standard Institute and Social Security Organisations. The nature and level of education of the working population will shift from general to technical in nature. The employment potential, values of life expectations at work, freedom in work and stronger trade unions will bring about a different work culture than what it is prevalent now.

Consequently, the emerging issues during the 21st century will be:

- Application of advanced technology in industries
- Need for developing new skills among the workforce
- Changing political and social situation
- Age mix and composition of workforce

  Employment of more women and elderly persons
- High expectations of the employees and surrounding community
- Workers' right to know about hazards
- Stringent statutory provisions and emergence of socially conscious groups
- Psychological stress among the younger generation due to unemployment
- Changing worker-employer relationship
- Well organised and demanding trade unions, etc.

To face the newer challenges arising out of the above issues, the employees have to be given importance and they should get along with the employers. The earlier strategy of "hire and fire" will not apply any more and participative approach has to be adopted to boost up production and productive. Therefore, health and welfare of the workforce have to be given due attention. In other words, better healthcare for the industrial workers have to be provided through occupational health services in every industry to keep them healthy, motivated and productive.

In the context of the above, the occupational health scenario will be changed to a great extent. The imminent changes are envisaged as follows:

- The increasing number of ageing workers and higher longevity will make it necessary to raise the age of superannuation with maintenance of physical capacity, mental alertness and audio-visual performance,
- The multiskilled professionals to handle the advanced technology have to be developed.
- The traditional approach of master servant relationship have to be replaced by new managerial techniques and better trade practice. This trend will continue and will undoubtedly extend to communication of risks to employees and the public through the opinion makers, social conscious group and NGOs.
- The employment opportunities of average workers will be limited whereas high skilled, high-tech professionals will have better job availability with good quality of working life. Therefore, preventive and promotive health care will be preferred by the workers rather than curative services alone or compensation benefits.
- The innumerable legislation enacted in our country for labour protection will be replaced by comprehensive umbrella acts/rules as prevalent in developed countries.
- The statutory authorities will play the advisory role on safety, health and environmental issues rather than the role of a police man prosecuting the occupiers for violation of statutory provisions. More stress has to be given on implementation of recommendations.

- The medical professional working in industrial hospitals have to be oriented towards changing events in the health care. The increased risk to health of workers arising due to new work methods, work processes and work environment have to be identified and mitigated.
- The age-old curative-biased health care will be replaced by preyento-curative approach because most of the occupational and work-related diseases are preventable but not curable.
- The occupational health professionals in future, have to develop an integrated approach to provide total health care to the workmen and not confining to hazards or occupational diseases alone. The newly emerging diseases like psycho-social job stress, musculo-skeletal disorders due to repetitive strain, radiation hazards and occupational concerns which are not prevalent in many industries today have to be taken care.

In addition to this, many of the industrial hygiene activities such as work environment monitoring, workplace hazard cantrol, risk assessment of exposed workers have to be pursued to study the impact of work on health. Industrial workers being a special group, their health has to be monitored regularly and a computerised health record maintained in the, Occupational Health Centre for follow up and referral.

The industrial wastes, both hazardous and non-hazardous in nature will pose a special problem for the industries. Lack of space for dumping and disposal of waste, non-biogradability of certain wastes, non-availability of facilities for recycling/reuse of the waste material, resistance from public to protect the water courses will be felt acutely in our country which has been neglected so far. The activities of the Central and State Pollution Control Boards will be extended to the polluting and dirty industries which may get a threat for closure or shifting elsewhere. To protect the environment and to conserve the economy, the industries will be compelled to adopt expensive measures, which will also produce an impact on their production cost and profit.

The international organisations, non-governmental organisations (NGOs) and professional associations will press the government to implement certain stringent measures to achieve their objectives. Of course, they will extend their helping hand to find out a solution to the emerging problems. Being a member of ILO & WHO, India has to adopt the recommendations on occupational heahh, safety and environment sooner or later.

More thrust will be laid on human resource developing in collaboration with international institutions and professional bodies. Specialised teaching on occupational health will be provided in medical colleges and national institutions at par with developed countries. The doctors and para-professionals will be encouraged to take up careers in this field and job opportunity is bound to expand.

The research in the field of occupational health is continuing in our country in many institutions and many reports have been published. More and more need based research projects will be undertaken in future being sponsored by the industrial houses or in collaboration with industrial undertaking and universities. Many research laboratories and field practising units will be established to translate the research findings into practical solutions. The future field of research will be for combat hazardous operations and finding out treatment for occupational diseases.

As the development process will continue and the industries will be intensified further in coming years, one can anticipate the increasing need for occupational health in our country which now is in rudimentary stage. Introduction of new legislation amendment of the existing ones, implementation of national health policy, preparation of a standard code of practice for health professionals and standardisation of procedures under the framework of acts, regulations and rules will come up in future. A nmlti-disciplinary team approach for effective solutions of health problems and other issues in the field of occupational health will be encouraged and strictly enforced by the statutory authorities. What is considered as voluntary action today, will be brought under the statute in future and occupiers will be required and adopt these measures in their respective work places even though it involves a good expenditure. There will be cost benefit in long run.

The name of occupational health has been changed to "Occupational and Environmental Medicine" in many developed country. This name will be adopted in India also, because more and more diseases are encountered today due to environmental pollution and unplanned industrialisation. The occupational and environmental diseases will be more pronounced in future and may appear in epidemic proportion in certain areas. Communicable and nutritional diseases being controlled to a greater extent in our country today, more non-communicable, occupational and genetic diseases will occur in the coming century due to impact of environment and psycho-social stressors. Therefore, the health professionals have to redefine their roles. While entering into the twentyfirst century, our endeavour should be to achieve what could not achieve during century in the filed of health and India should not lag behind. We can achieve this by optimistic approach and determination and let the situation not go out of our hands.

4.10 LET US SUM UP

In this unit, you have leamt about the definition, scope and applicationof occupational health in industries, mines and other occupations. The health effects of industrialisation and impact of various workplace hazards on health have also been elucidated to impress that the occupations have definite impact on health of the'working population. The newer hazards arising out of ergonomic and psycho-social stress have also been described. The occupational and work-related diseases, their diagnostic criteria, notification, compensation, prevention and control measures have been mentioned in this unit for application in occupational medicine practice. Organisation of OHS in factories and mines which should be done under the leadership of an occupational physician has been emphasised and management principles applicable to occupational health has also been indicated. The present occupational health scenario in India, although gloomy at present, have to be raised to the international level in the coming century as per the expectations of the ILO and WHO. You have also leamt that for better trade practice, a healthy workforce have to be sustained by the industries for their future growth and development and hence occupational health should be given due importance.

4.11 KEY WORDS

Caison chamber	:	A pressurised air tight chamber in which workers have to work during tunnel and bridge making under water.
Compensable	:	Diseases for which compensation has to be paid to the workers diseases as per Workmen's Compensation Act and ESI Act.
Decompression sickness	:	Disease caused due to sudden decompression cause release of nitrogen from blood in form of large bubbles affecting lungs and other organs.
Ergonomics	:	It is inter-disciplinary approach to interface between the worker, workplace and equipment.
NIHL	:	Noise induced hearing loss caused due to exposure to high noise.
Noise dosimeter	:	A personal monitoring instrument to measure exposure to the noise during a work shift.

Notifiable diseases	:	Diseases to be notified to the statutory authorities as per Factories Act.
Octave band analyser	:	An instrument used to measure frequency (in hertz) of noise.
OHS	:	Occupational Health Services
Sound level meter	:	An instrument used to measure sound level in decibel (dB).

4.12 ANSWERS TO CHECK YOUR PROGRESS

Check Your Progress 1

I) The salient features of occupational health are:
- the promotion and maintenance of health
- the prevention among workers the departures from health
- the protection of workers from adverse health effects
- the adaptation of work to man and each mean to his job.

2)
- protecting workers' health against hazards at work
- adapting work and work environment to the capabilities of the workers
- enhancing physical, mental and social well-being of workers
- minimising occupational hazards, accidents, work injuries and work-relatad diseases
- providing total health care to the workers and their family members.

3) The modern concept of occupational health is to provide preventive, curative, promotive and rehabilitative medical services to the workforce and their family members.

Check Your Progress **2**

1) The major health problems arising out of industrialisation are:
- lack of adequate infrastructure facilities
- growth of slums
- poor sanitary condition of industrial towns
- industrial waste dumping
- degradation of environment

2) The common physical hazards in the workplace are:
- heat, cold, pressure changes, noise, vibration, radiation (ionising and non-ionising) and ergonomic problems.

3) Heat balance equation of the body

$$M \pm Cv \pm Cd \pm R - E = 0$$

where,

M = Metabolic heat
Cv = Convection
Cd = Conduction
R = Radiation
E = Evaporation

4) Decompression sickness is caused among the workers due to sudden release of pressure while working in a highly pressurised chamber during bridge or runnel making under water, Sudden death may be caused due to release of dissolved nitrogen from blood which ruptures the alveoli of lungs forming large bubbles (bullies).

5) The occupational diseases are:
Noise – High frequency hearing loss usually bilateral (noise induced hearing loss)
Vibration – Vibration induced white finger and hand-arm vibration syndrome.
Radiation – Acute radiation syndrome. Leukaemia and radiation cancer.

Check Your Progress 3

1) Respirable dust particles which are fibrogenic, carcinogenic or systemic poison in nature are hazardous to health, e.g. silica, asbestos, manganese.

2) "Pneumoconis" of lungs is the common dust disease.

3) The methods of prevention and control of various hazards are:
   - engineering control,
   - statutory control,
   - medical control, and
   - environmental control.

Check Your Progress 4

1) Occupational disease is defined as diseases known to arise out of the exposure to substances and dangerous conditions in process, trades or occupations.

2) Tlie diagnostic criteria of occupational diseases are:
   - strong correlation between disease and occupation,
   - consistency,
   - specificity,
   - biological markers,
   - damage-risk criteria, and
   - international/national recognition.

3) a) Manganism due to manganese: Affects central nervous system and symptoms are similar to Parkinsonism.
   b) Lead poisoning due to lead dust - lead colic, wrist drop, blue line on the gums, high blood lead level.

4) i) Leukaemia or bladder cancer
   ii) Vinyl chloride
   iii) NIHL
   iv) Chromium
   v) Mineral oil

Check Your Progress 5

a) Participative Approach: The occupier and the trade unions should participate in all health programmes and arrive at solutions after discussion. Since the objective of health and safety is to benefit the workers, the management and trade unions should have participative approach while signing agreements.

b) Action Plan: To implement the safety and health programme, every industry should have a written down short term and long term plan, The responsibility for implementation within a specified time frame should be nientioned in the action plan. Thrust areas to be identified and periodic monitoring of the plan should be ensured.

c) Role of trade unions in promoting Occupational Health in Industry: The trade unions should promote occupational health by bipartite agreement. They should participate actively in improving work environment, preventing hazards, educating workmen and taking part in training and education programmes.

Check Your Progress 6

a) National Institute of Occupational Health (NIOH), Ahmedabad

b) Director General of Factory Advisory Services and Labour Institutes (DGFASLI), Mumbai

c) Employees State Insurance Scheme (ESIS)

UNIT 5 HEALTH INSURANCE

Structure

5.0 OBJECTIVES

After going through this unit, you should be able to:

- describe the concept of health insurance;
- appraise the functioning of Central Govemment Health Scheme and Employees Slate Insurance Scheme; and
- understand the emerging trends in the field of Health Insurance.

5.1 INRTRODUCTION

In this unit you will learn about the basic concept of health insurance and its historical development. You will also learn in detail about the two important ongoing schemes namely Central Government Health Schemes (CGHS) and Employees State Insurance Schemes (ESIS) which are now in operation for over five decades. The Employees State Insurance and the Central Government Health Schemes are the two major schemes in this sector and have been in operation for over five decades.

The idea of opening up of the insurance sector to private sector has been under discussion for quite sometime. This issue has been discussed in later part of this unit.

You will also learn about the emerging trends in health insurance towards the end of the unit.

5.2 HISTORICAL OVERVIEW AND EVOLUTION

The concept of good health has gradually moved away from its traditional connotation of 'not being ill' and has assumed new dimension of a "state of complete physical, mental and social well being and not just absence of disease". This is the definition of health as embodied in the WHO charter.

The term Insurance according lo the Dictionary means to Indemnify against, another meaning given to this term is to Transfer the risk or to Monetise the risk i.e. in terms of monetary value.

In the life of an individual there are periods of 'Dependency' that is at the two extremes of life span. The period in infancy and old age are the times an individual is very dependent. In our society from times immemorial the period of childhood has always been taken proper care of and the elderly in the family were also considered an asset. Due to the agrarian make up of the society; the rich experience of the elderly to cope with natural and other vagaries were very useful to the younger generation in managing the fields and crops. With Industrialization, migration of workers from the villages to the urban centres, there has been a breakdown of the joint family system adversely affecting the care of the elderly.

In between the two extremes of life and during the working span of an individual's life there are period when one cannot work and earn the livelihood. These periods occur due to many causes, prominent among them being illness, injury and maternity. These lead to a condition of destitution.

In the first half of the 20th century the industrial workers were very poor and there were hardly any good health care facilities. Any interruption in work meant loss of wages (absence from work for whatever reason meant no wages). This posed a big problem for the worker and also the family who were then deprived of even the daily necessities of life including food at times.

The year 1923 was the dawn of Social Insurance in ow country when the Workmen's Compensation Act was passed. This provided financial protection to the workers against injury and death arising out of employment. This was followed by the 'Maternity Benefit Act'. In both cases the payments were to be made by the employer.

In subsequent years repeated efforts were made in the direction of implementing the ILO Convention for 'Health Insurance' for workers in Industry, Commerce, and Agriculture. From 1927 to 1943 many meetings were organised among various interest-groups (i.e. representatives of employers, workers and state government) and essential common ground/ consensus could not be achieved.

It was at this stage that the central government appointed Prof. Adarkar (a Social Scientist) to prepare a background paper. Professor Adarkar's report finally formed the basis of future discussions and developments. A 'Bill' presented in the Legislative Assembly in 1946 and was finally passed in 1948 by the Lok Sabha in independent Indh as the "Employees State Insurance Act",

5.2.1 Constitutional Provisions

Health has been at the centre of the concern of the individual and his family. Health is duly recognised as a human right to be made available universally to all members of the society. The constitution in our country provides for health care among other services.

The Government provides medical relief and health care facilities to all being a welfare state, the constitution of our country under Article 41 and 42 of Part IV provides security measures as follows:

Article 41: The state shall, within the limits of economic capacity and development, make effective provision for securing the right to work, to educate and to right of assistance in case of unemployment, oldage, sickness and disablement and in cases of undeserved want.

Article 42: The State should make provision for securing just and equitable conditions of work and for maternity relief

5.2.2 Social Security Concepts

Social security has been defined as the security that the society furnishes through some appropriate organisation against certain risks to which its members are exposed. These risks are essentially contingencies against which the individual of smaller means, meager resources, and common prudence cannot effectively provide. The risks are mainly sickness, injury, maternity, invalidity etc.

The pattern of social security is the product of historical development and socio-economic situation in a country. Social insurance is an important part of social security. Broadly social insurance differs from commercial insurance in as much as it is an insurance against social risks. It will be useful to note that in social insurance:

a) There is no individual equity.

b) Contributions are compulsory.

c) Cost is borne by the individual, the employer and the state.

In social security the benefits start from before birth. In terms of pre-birth care and maternity benefits and continue even after death in the shape of family benefit and death benefit. In true terms thus we can afford to call social security as the provision of security from "Womb to **Tomb".**

Under social security pattern 'Health Insurance' is one of the many benefits and the spectrum of total number of benefits provided is much larger in content, scope, and applicability.

Check Your Progress 1

Fill in the blanks:

a) The workman compensation act was passed in the year .....

b) The ESI Act was passed by the first Lok Sabha in the year .....

c) Who all bear the cost in social insurance .....

5.3 WEALTH INSURANCE SCHEMES

There are not many health insurance schemes in country.

Two main ongoing Health Insurance Schemes in our country are:

- Central Government Health Scheme (CGHS)
- Employees' State Insurance Scheme (ESIS)

In addition, some well defined category of industrial workers falling within the purview of certain labour welfare act are also covered for medical care **(viz.** iron and manganese, mica mines and chrome ore mines, limestone and dolomite mines workers, and beedi workers).

You will learn in detail about these two schemes.

5.3.1 Central Government Health Scheme (CGHS)

Earlier, the scheme was known as 'Contributory Health Scheme'. It was designed to do away with the expensive and cumbersome system of reimbursement. Currently the scheme is known as Central Govt. Health Scheme (CGHS).

Objectives **of the Scheme**

The Central Government Health Scheme (CGHS) commenced in Delhi in the year 1954 with a view to provide comprehensive medical care to the employees of Central Government and pensioner based locally. Broadly the objectives of the schemes ate providing:

- Comprehensive medical care facilities to the Central Government employees and their family members.
- To avoid cumbersome system of medical reimbursement.

Coverage

The scheme has been gradually extended over the last above 50 years to various towns beyond Delhi. Currently the scheme is in operation in the towns at Mumbai, Allahabad,

Meerut, Kanpur, Calcutta, Nagpur, Chennai (Madras), Bangalore, Hyderabad, Patna, Jaipur, Pune, Ahemdabad, Lucknow, Bhubaneshwar, Jabalpur, Ranchi, Guwahati and Trivandrum. The employees of Accountant General of India are being provided CGHS coverage at Bhuvaneshwar and Ranchi.

The towns of Gurgaon, Faridabad and Ghazjabad at the periphery of Delhi have been covered under the Delhi scheme.

Extent of Application

In addition to central government employees the scheme also caters/provide services to:

- Members and Ex-members of Parliament
- Judges of supreme court and high court (sitting and retired).
- Freedom fighters
- Central government pensioners, employees of semi-autonomous bodies/semi-government organisations.
- Accredited Journalists
- Ex-Governors and Ex-Vice President of India.

The scheme operates through service dispensaries mainly Allopathic. The benefit of care under other systems of medicine including Ayurvedic, Homeo, Unani, Sidha and Yoga are also available in some centres. As per published figures (as on March 1999) the broad statistical data about the scheme coverage is:

No. of Town		20
No, of cards		**9.74** lacs
No, of beneficiaries		**43.66** lacs
No, of Dispensaries		**320**
- Allopathic	**241**	
Other systems:	79	
- Ayurvedic	31	
- Homeopathic	**34**	
- Unani	'9	
- Siddha	**2**	
- Yoga	3	
No, of Poly Clinics		19
CGHS Labs		**72**
Dental Units		17

Facilities Provided under CGH Scheme

The following facilities are being provided to the beneficiaries of the scheme. These are organised through dispensaries, poly clinic and Government/recognised hospitals. These comprise:

i) Out-patient care facilities in all systems,
ii) Emergency services in allopathic system,
iii) Free supply of necessary drugs,
iv) Laboratory and Radiological investigations,
v) Domiciliary visits to seriously ill patients,
vi) Specialists consultation both at the dispensary and hospital level,
vii) Family welfare services,
viii) Treatment in specialized hospitals both Government and private recognised reputed hospitals, and
ix) 90% advance for undergoing specialised procedures after admission in hospitals when required.

Special Facilities for Pensioners

The pensioners are provided special facilities as indicated below:

- Option to join CGHS
- Option of obtaining a 'whole life' CGHS and card by paying ten years' subscription
- Card valid in any CGHS covered city
- Those living in non-CGHS areas can have a CGHS card in the nearest CGHS covered city
- Separate queue for senior citizens in CGHS dispensaries, and
- Facility to obtain medicines for chronic ailments up to three months at a stretch.

Referral and Reimbursement Procedure Simplified

The scheme allows the option to the beneficiary to avail specialised treatment at any hospital of their choice from out of the ones recognised by the CGHS. The facility can be availed after a specialist of CGHS/Government hospitals as recommended the procedure.

The reimbursement in such case is restricted to the package rate/ceiling prescribed by the government for the procedure. Any expenditure in excess is to be borne by the beneficiary.

In an emergent situation, to be recorded in writing by the CMO Incharge of the CGI-IS Dispensary the concerned CMO may directly (even before a specialist advise has been obtained) refer the beneficiary to a private recognised hospital for further management and treatment.

The beneficiaries have the option to taking treatment of their choice. When the beneficiary chooses such a hospital in another city (while facility for same are available in same town) the permission can be given, but the TA/DA shall be borne by the beneficiary.

Details of City-wise of Recognized Hospitals

The number of hospitals recognised in various cities are indicated as below:

Name of Town	No. of Hospitals Recognized
Ahmedabad	2
Allahabad	5
Bangalore	16
Calcutta	15
Chennai	20
Delhi	24
Heyderabad	23
Jaipur	10
Jabalpur	20
Kanpur	17
Lucknow	8
Mecrut	9
Mumbai	7
Nagpur	26
Patna	10
Pune	36
Ranchi	3

For indoor care in addition to the two main Central Government Hospitals in Delhi viz. Safdarjung and Ram Manohar Lohia Hospital, there is provision in Lady Hardinge (Sucheta Kirpalani Hospital) also. Some maternity hospitals for exclusive use of the beneficiaries are also being run. For treatment of cases specially so needing super speciality care in the field of Cardiac Surgery, Renal Dialysis Transplant etc., the scheme has arrangements with a number of private and corporate hospitals all over the country. The beneficiaries on proper referral from scheme specialists can take treatment at these institutions,

It may be seen that looking at it from the point of view of social security during the five decades or so that it has been in operation the benefits of the scheme have been extended to a very small number of card holders i.e. 9.7 lakhs only and to a limited number of towns across the country. It has been so partly due to the inherent nature of the scheme being meant basically for central government employees.

5.3.2 Employees State Insurance Scheme

Administration

The ESI scheme operates under the ESI Act, 1948. In accordance with the provisions of the ESI Act the Central Government has set up a body called the 'Employees State Insurance Corporation' for the overall supervision and guidance of the scheme. This 'Apex' body comprises representatives of employers, the enlployees, central government, medical profession, parliament etc. The Union Labour Minister is the Chairman while the Union Labour Secretary is the Vice Chairman of the Corporation. Under the general superintendence and control of the corporation a representative body (from out of the members of the corporation) called the 'Standing Committee' acts as the executive body.

The 'Medical Benefit Council' is chaired by the Union Director General of Health Services and comprises the states represented by the Director Medical Incharge of the scheme along with representatives of employers, enlployees, parliament, and medical profession. The Medical Benefit Council advises the Corporation on all medical matters concerning the scheme.

A Regional Board is set up for each state/union territory by the chairman of the corporation. The regional board may set up a local committee for such areas as be appropriate. A noteworthy feature of this is their 'Tripartite'nature. The representative of all interest groups are involved at all levels to ensure participation for smooth working.

The administrative office/national headquarters of the scheme is located at New Delhi. The Chief Executive at the Head Quarter is the Director General (DG). The DG is assisted by a Commissioner each on all matters related to Medical care, Insurance and Finance. Another Chief Officer is the actuary (for all actuarial work), while a Director Administration assists on all matters related to administration.

Coverage

The scheme was first implemented in the towns of Kanpur and Delhi in 1952. It has been progressively implemented in other states and towns and is in operation in 652 towns as of December 1999. Thus, it has, truly an all India presence. Initially the scheme was applicable to workers in lion-seasonal industries using power and employing 20 or more workers drawing wages not more than Rs. 400/- per month, later raised to Rs. 1000/- per month. On the recommendations of its committee on Perspective Planning and keeping in view the need to provide 'Health Insurance' protection to a larger number of workers in the organised sector the criteria for coverage was modified. Currently the scheme is applicable to:

- Non-seasonal factories using power and employing 10 or more workers.
- Non-power using factories employing 20 or more workers.

The provisions of the Act have been amended and further extended to establishments so as to cover workers in:

- Shops
- Hotels and Restaurants,
- Cinema Houses,
- Road transport undertaking,
- Newspaper establishments etc.
- Workers in establishment employing twenty or more,

Only workers as above and drawing wages not more than Rs. 6500/- per month are covered under the scheme.

Subjects like coverage, collection of contribution and payment of cash benefit are all done through the offices of the corporation (22 Regional/Sub-regional offices and 844 Local/Cash Offices) spread all over the country.

Implementation

The ESI is a Central Act operating all over the country. Since health is a state subject under the constitution, the provision of medical benefit is the responsibility of the respective state government. The two exceptions to this are Delhi and Noida (a town in western UP) where nledical care is provided directly by the corporation.

Contribution and Finances

The employer and employee are the main contributor to the scheme. The employer has to contribute @ 4.75% of the wages, and is empowered to deduct the contribution of the employee @ 1.75% of the wages, and deposit the total amount with the corporation. However, currently workers having a daily wage of Rs. 40/- or below are exempt from any contribution to the scheme, the employer however, continues to contribute his share to the ESI corporation.

Ceiling on Expenditure

The corporation fixes an annual ceiling of expenditure on medical care. It is reviewed periodically, for the year 2000-2001 the ceiling of expenditure of medical care is Rs. 600/- per annum, per family unit. This expenditure on medical care is shared by the corporation with the state goveniment. The corporation bears up to 87.5% of the expenditure and balance 12.5% is borne by the state government. Any expenditure incurred beyond the prescribed ceiling is at the sole cost of the state government.

Absolving Employers under other Acts

Once the provisions of the ESI act come into force in respect of the establishment, the employer is absolved of the liabilities of payments under the Workmen's Compensation Act and the Maternity Benefit Act. Provision of medical care and the payment of cash benefits under these two acts are taken care of by the corporation.

Benefits

There are two types of benefit under the scheme i.e. benefit in kind and benefits in cash.

a) ***Benefit in Kind***

Medical Benefit: This is the only benefit in kind and thus cannot be quantified. The scale of medical benefits includes:

i) Out-patient care, including emergency care
ii) Domiciliary care
iii) Specialists consultation, investigation and treatment
iv) In-patient care
v) X-ray, Laboratories and other investigations
vi) Preventive inoculation and immunization
vii) Free supply of drugs, dressings, artificial limbs and aids viz. caliper braces etc.
viii) Free supply of special aids for insured person only i.e. spectacles, dentures, intra-occular lens etc,
ix) Antenatal, confinement and post-natal care including domicilliary confinement.
x) Ambulance service or conveyance charges in lieu thereof.
xi) Family Welfare Planning Services and other National Programmes.
xii) Medical certification.

High Costs-Episodes: Keeping in view the development of technology and advancement in medical sciences the scheme provides (by arrangingladvance payment) specialised treatment

for cardiac care viz. pacemaker, valve replacement, by-pass surgery, renal dialysis and transplant, treatment for cancer and any other such like high cost treatment.

Out-patient Care: Out-patient care comprises direct system and indirect system which are being described here:

Direct System: For out-patient care the corporation organises a direct system through the aegis of dispensaries (full time, part time, mobile etc.) for the exclusive use of scheme beneficiaries. The full time dispensaries, meant for the exclusive use of scheme beneficiaries are manned by a minimum of two doctors and function in two shifts – morning and evening. At some places the dispensaries work for twelve hours by deploying two teams of doctors and para-medical staff, one team each for the morning and evening shifts. These dispensaries also have the facilities of dressing room, injection room, supply of special drugs and in some cases routine laboratory investigations. The facilities of lab investigations where provided are shared among a group of neighbouring dispensaries. In a group of dispensaries one is designated as an 'Emergency Dispensary' to function round the clock and cater to the requirement of beneficiaries when other dispensaries are not functioning. As of December 1999 there were 1452 dispensaries (including 1394 full time).

Indirect System: In certain areas the scheme has recognised the clinics of general medical practitioner, called Insurance Medical Practitioner (IMP) for providing out-patient care as an indirect mode. The IMPs ore entitled to register a restricted number of family units on their roll and notify a part of the out-patient working hours for the exclusive care of the scheme beneficiaries. In December 1999 there were a total of 2722 clinics of insurance medical practitioners recognised in various implemented centres. This system is in practice mainly in Maharashtra, Gujarat, Punjab and Goa.

Due to the very nature of the whole time set-up, much larger accommodation is needed which is not always easy to find, more so in metropolitan areas. Hence, the need of having panel doctors (who already have their own premises and skeleton staff) and are willing to work for the scheme on a part time basis i.e. in addition to their own routine out-door work. In experience both the direct and indirect system have their own advantages and disadvantages (the advantage of one system being disadvantage for the other and vice-versa).

Broadly the advantages of the indirect system are:

- It is less costly to run
- Capital outlay is nil
- The panel doctors are available at shorter distance, hence, very useful where the population is sparse.
- There is better inter-personnel relationship between doctor and the patient.

The **disadvantages** of the system are:

- Being a part time arrangement, the patient feel they are not getting appropriate attention. Panel doctors devote more attention and time to their direct paying patients.
- Laboratory services are not available and patients have to travel some distance for availing this facility.
- Medicines are not always available, more so the specialist drugs for which the beneficiary have to travel either to the Chemist or to the drug store.
- The doctors are less amenable to administrative and other controls.
- The desired level of equipment is not always available at the clinic of the panel doctor.
- It is difficult to enlarge/increase the facilities specially with regard to preventive service, immunization etc.
- There is some possibility of undesirable understanding between the doctor and patient in respect of certificate for leave and between these two and chemist with regard to drugs.

Specialist Care: The scale of care under the scheme provides for the facility of specialists, consultation (investigation and treatment included) for the scheme beneficiaries. A specialists centre is established in the hospital where facilities for indoor care are provided. This can be a scheme hospital or even in a hospital where beds for the beneficiaries are reserved.

Another pattern is to establish specialist centre in a dispensary to obviate the necessity of beneficiaries traveling long distance to the scheme hospital. The specialist centre are managed by full time scheme specialists (at ESI hospitals) or by part time specialists separately engaged for the centre.

In-patient Care: The scheme has a norm laid down for construction and provision of hospitals depending on the workers' population at tlie centre. Currently the scheme envisages to provide 4 beds per one thousand covered eniployees (can go upto 5 beds per thousand, if necessary). The emphasis has been on attempting to provide full time scheme hospitals so that beneficiaries have a sense of belonging and tlie provision of services is up to the norms laid down by the corporation.

For in-patlent care the corporation has already constructed and commissioned 129 hospitals, aiid 43 annexes providing a complement of 22642 beds. In addition 3519 beds have been reserved in government and non-government hospitals making a total of 26161 beds. It will thus will seen that for approximately 344 lakh beneficiaries the scheme has provided 26161 beds. It comes to about 0.74 beds per thousand population, which in any case compares well with the national average. Under an on-going programme five more hospitals arc in various stages of construction (us of December 1999).

Diet for In-patient: The scheme has laid down a scale of diet for patients admitted in the Irospitals. This is in terms of ingredients and not in terms of price (price may vary from season to season and place to place). The concept is to provide full caloric value ofbalanced diet to all beneficiaries admitted for in-patient care except those on therapeutic diet.

Treatment in a Neighbouring State and at Two Places in same State: The workers who are employed in one state and arc residing in a neighbouring town in another state are provided care at the town of residence (eventhough their contribution are deducted in another state).

Similarly when a worker is employed and living in one town and family is living in another town of the same state, the family is also entitled to medical care at the town of residence (the worker will get medical care at tlie town where he/she is employed and the family at the town of residence) in cnsc the same are available in that town.

Retired Workers: Medical Benefit is also provided to retired insured workcr and their spouses. Similarly those who cease to be in insurable employment on account of permanent disablement due to employment injury are also provided medical benefit. Each worker has lo make payment on annual basis. The current rate is Rs. 1201- per annum.

Indian System of Medicine: Beneficiaries under the scheme have the option to utilise tlie facility of treatment in systems other than allopathic. Dispensaries and clinics of IMPs in Ayurvedic systeni and integrated systeni are available in various states. In some states facilities for treatment in homeopathy, Unani, Siddha and Yoga are also available at some centres. Few beds for indoor care for Ayurvedic and Homeopathy are also available in some state.

Occupational Diseases: 'The corporation has set up four occupational disease centres for the four zones in the country. Each one is attached to an existing ESI hospital. These are Calcutta in East, Chennai in South, Mumbai in West and Delhi in North. Recently an occupational diseases centre has been commissioned at ESI hospital Nagda. This caters to tlie needs of insured workers in tlie state of Madhya Pradesh.

The'concept is to organise for the early detection and diagnosis of occupational disease in respect of ESI beneficiaries.

b) *Benefits in Cash*

These are statutory obligations under the act. The expenditure on cash benefit is borne directly and entirely by the'corporation. There is no ceiling of expenditure on cash benefits.

In addition to medical benefit the beneficiaries of the scheme are also entitled to various Cash benefits as briefly described hereunder:

i) *Sickness Benefit*

a) A worker gets cash compensation at the rate of approximately 50% of the wages for a period of upto 91 days per annum for 'certified absence' from work on account of sickness.

b) *Extended Sickness Benefit:* In case of a worker suffering from any of the 35 specified diseases (Tuberculosis, Fracture, Cancer etc.) from which the workers is not likely to recover in 91 days, the worker is entitled to cash compensation @ of 70% of wages upto period of two years. The list of diseases is updated periodically.

c) *Enhanced Sickness Benefit:* For undergoing Vasectomy/Tubectomy the worker gets 7/ 14 days leave with full wages. In case of postoperative complication, it can be extended by another 7 days.

ii) *Maternity Benefit*

Payment is made at the rate of full wages for a period of 12 weeks (Six week for miscarriage). An additional four weeks cash compensation can be made for complication/sickness arising out of pregnancy-confinement.

iii) *Employment Injury Disablement Benefit*

An insured worker whenever he/she meet with an employment injury is provided medical care for as long as is necessary for the recovery of the individual. Similarly leave of absence from work is also provided to an employment injury case for as long as is necessary without any limitation of number of days per annum.

Cash benefit/disablement benefit during this period is around 70% of the daily wage of the workers, this is much higher than the cash benefit given to the worker on account of absence from work due to sickness.

The treatment provided to a case of employment injury may result in a complete recovery with no disability, or go to permanent disability (partial or total). For residual permanent disability the worker is provided cash benefit. A medical board examines such cases to assess the 'percentage of loss of earning' on account of the disability. This recommendation entitles the insured worker to get permanent disability benefit (partial or complete) for the rest of life in the form of periodic cash payments.

iv) *Death Due to Employment Injury – Dependant Benefit*

In an unfortunate case the nature and effect of employment injury may lead to death of worker. In case of death due to employment injury the family of the worker is provided with Dependent Benefit. It is paid at the rate of 70% (approximately) of the wages. The widow gets 315th of the share and each child gets 215th of the share. Widow gets it for life (or up to tlie date of re-marriage) and the child gets up to the age of 18 years.

v) *Funeral Expenses*

To part meet the expenses on funeral of a deceased insured worker a sum of Rs. 1500/- or actual whichever is less is re-imbursed to the next of kin.

vi) *Rehabilitation Allowance*

For workers visiting Artificial Limb Centre for fitment and training are paid full wages for the days they are admitted.

vii) *Cash Benefit – 'Occupational Diseases'*

Workers suffering from specified occupational diseases are given cash compensation for "Loss or Earning Capacity" as determined by specially constituted medical board,

The following table depicts the salient features of the ESIS as on Jan. 2000:

Salient features of the ESI scheme as on Jan.2000	
States in which scheme is implemented	All states (except Nagaland, Manipur, Tripura, Sikkim, Arunachal Pradesh and Mizoram)
Union Territories and Centrally Administered Area	3 (Delhi, Chandigarh and Pondicherry)
Family units covered	88.76 lakhs
Beneficiariescovered	344.38 lakhs
No, of local offices and Cash Offices	844
No. of Centres where scheme is in operation	652
Total no, of dispensaries (Full time, part time, mobile & Employers run dispensaries)	1452
Full time dispensaries	1394
Clinics of insurance medical practitioner recognised	2722
No. of Doctors in dispensaries	6319
Exclusive ESI hospitals (five more hospitals under construction)	129
ESI Annexe/Annexes Attached to hospitals	43
Beds in ESI hospitals and Annexes'	22642
Beds reserved in govt, nnd other hospitals	3519
Total beds available	26161

In conclusion it mny be seen that from a modest beginning of just two towns in 1952 the ESI scheme has progressed to be implemented in 652 towns. Similarly, the coverage has been extended to over 88 lakh card holders comprising over 344 lakh beneficiaries (a little over 3% of the countries population). All this is impressive enough by itself. The ESI scheme is today the largest social security set up in this part of the world with a widespread network of facilities and very comprehensive range of benefits in kind and in cash comprising the health insurance set-up. However, due to the limitations in the applicability of the Act (and other factors) the ESI scheme did not develop to be true National Health Insurance Scheme.

Workers in Organised Sector – General Observations

It has been observed that out of a total of over 3100 lakh work force in the country only 9 % (i.e. 282 lakhs approximately) are in the organised sector. Out of these 282 lakhs the ESI scheme covers only 33% approximately i.e. 88 lakhs approximately. These 88 lakhs constitute even less than 3% approximately of the total workforce in the country. This is an indication of the magnitude of the *'unfinished task'*.

Out of the workers (in organised sector) who are not covered under the scheme a good number comprise:

- ***Central Government Employees:*** They in any case are availing of some benefits with regard to medical care health insurance.

- ***Workers who are Outside the Coverage of the Scheme:*** They are not getting the benefit of health insurance. They comprise mainly workers in factories/establishments where:-

  Number of worker is below 10 using power

  Number of workers is below 20 not using power

  Workers drawing wages above Rs. 6500/- per month

  Located in areas where the scheme has not been extended so far

  Employed in industries which are 'seasonal' in nature.

Check Your Progress 2

1) Fill in the blanks:

   a) Only workers earning a wage of up to Rs. ..... per month are covered under the scheme.

   b) The rate of contribution per month for the worker is ..... and for the employer is ..... of the wages.

   c) A worker with a daily wage of Rs. ..... or below is exempt from contributions.

2) Name the two systems for provision of out-patient care under the scheme.

   .....

   .....

3) What are the advantages under the indirect system?

   .....

   .....

   .....

4) What are the norms for provision of beds for indoor care under the scheme?

   .....

   .....

   .....

   .....

5) In a health insurance set-up under social security :

   a) An insured worker gets cash compensation for certified leave of absence From work and in addition full medical treatment. True/False

   b) 'Maternity benefit' payment to Insured lady cannot be extended beyond 12 weeks even for complication arising out of pregnancy/confinement. True/False

   c) The scheme pays a sum of up to Rs. 2500/- or actual whichever is less to part meet the funeral expenses of the deceased insured worker. True/False

5.4 EMERGING SCENARIO

5.4.1 Situational Analysis

The awareness about health has been increasing and has led to an increase in the demand for services. It is estimated that a very small segment of these consumers are as of today availing of the facilities of health insurance. Out of these a small segment only is availing the facilities through their employer. In effect most of those who avail of the facility pay out of their own pocket. It is believed that more and more people are willing to pay more and expect better facilities.

It is Pelt that the type of health insurance we have today is merely a means of financing health care. The provision of insurance coverage is primarily in terms of "monetary limits" and not 'on the extent of medical care. There is no provision for preventive care. The cost of care is not under any control. Thus, the total cost is borne mainly by the consumer who is unenviably placed between the insurer and the provider of care.

It is believed that the cost of medical care has been growing up slowly. There are a number of factors contributing to the higher cost of care today. Some of these are:

i) Recent advances in technology

ii) Higher utilisation of diagnostic aids

iii) Higher cost of drugs

iv) Higher incidence of chronic diseases

v) Increase the expectancy of life

vi) Change in the population profile with an increasing geriatric population.

vii) Higher morbidity – specially so, due to environmental changes, pollution, smoke etc.

With increase of the segment of "Middle Class" in the society there is an increase in the demand for better health care. The average household today thus spends fair amount of their earnings in obtaining health care. The inadequacy of the misting medical facilities has thus, become more pronounced.

The liberalisation and globalisation of the economy in our country has had its own effect. One view propounded is that in the post liberalisation and globalisation era the middle class have lower standards of living and also it has brought an element of job insecurity for the workers.

Some of the health insurance schemes currently available to the public are listed below:

a) Asha Deep Policy

b) Jeevan Asha Policy

c) Senior Citizen Plan

d) Cancer Related Policy

e) Jan Arogya and Bhavishya Arogya Policy

f) Personnel Accident Insurance (also available for groups)

g) Mediclaim individual

h) Mediclaim group

i) Overseas mediclaim

j) Specially designed policies for the benefit of
   - credit card holders
   - public sector undertakings

The above policies am provided mainly by:

a) Life Insurance Corporation of India (LIC)

b) General Insurance Corporation of India (GIC) through its four subsidiaries
   i) New India Assurance Co.,
   ii) United India Insurance Co.,
   iii) Oriental Insurance Co., and
   iv) National Insurance Co.

c) Unit Trust of India (UTI)

d) Policy provided by the hospitals viz. Cancer related

The Asha Deep Policy has been an endowment Life Insurance Policy. In addition it provides financial support on the beneficiary contracting any of the four major diseases.

i) Cancer.
ii) Renal Dialysis and Transplant
iii) Heart Disease including Coronary Artery By-pass Surgery
iv) Paralytic Stroke

Similarly, the Jeevan Asha Policy provided financial help periodically and lump-sum benefit in any emergency situation.

The mediclaim policy (both for within the country as also for videsh yatra) are also being used in increasing numbers for some time.

The drawback of commercial insurance and the policies available have been:

i) Exclusion clause – for existing conditions – not covered.
ii) Non-coverage of certain conditions during first year.
iii) The beneficiary has to spend the money initially from out of his pocket and claim reimbursement later on. This is a lengthy and at times tedious process.

Compared to commercial insurance in the case of health insurance through the social security route the distinguishing features are;

i) Participation is compulsory
ii) Financed by contribution mainly from the employer and the worker
iii) Contribution and cash benefits are proportionate to the earning of the worker
iv) Coverage is without a means test – coverage has no relevance to the income of the worker. The contribution from the workers is deducted at source as a percentage of the monthly wages.
v) Scale of Medical benefit is not related to contribution i.e. irrespective of the amount of contribution a worker and family is entitled to full scale of medical benefits.

It may be seen from above that apart from the fundamental differences in the provision of benefits of health insurance there are some Advantages (for the insured) under social security set up. These are:

a) There is no pre-entry medical examination
b) Pre-existing conditions are no bar to coverage
c) Rate of contribution does not increase even when there are pre-existing conditions
d) The rate of contribution remains the same and is irrespective of the number of members in the family. The contribution ddes not increase with the side of the family.

Parties Involved

In the field of medical insurance today there are three parties concerned. The consumer, the provider of care and the Insurance company – insurer. The role of the insurance company and the provider of care revolves round the needs of the consumer. The insurer and the provider of care generally do no interact with each other. In addition the pricing of services is not at all regulated.

During the operation of the policy in the last few years, the insured (beneficiaries), the general practitioner and the doctors in hospitals (the providers of care) and the insurer agency (providing insurance cover) have all been encountering difficulties with regard to their specific areas of operation and interest. Some of the difficulties are listed out below:

a) For the Beneficiary – Insured
   i) Options available are very limited
   ii) Admission in a hospital of choice is not/not always available
   iii) Hospital chosen invariably asked for deposit in advance (not at all easy–specially so i.e. at short notice).

iv) Long at times tedious wait and procedure for claiming reimbursement (some claims are rejected in part also).

v) Difficult to identify avoidable investigations advised ordered by the treating physician.

vi) Taking treatment at a place away from the town'when facilities for same are not available locally.

b) The Insurance Company – the insurer

i) Absence – paucity of facilities for regular – pre-insurance check up of the beneficiary

ii) Absence of organisation of providers both for outdoor care as well as for indoor-hospital care.

iii) Tendency for increasing number of claims.

iv) Purported – supposed malpractices.

c). Providers Difficulties

i) Absence of organised set-up of providers with respect to provision of care at the:

- Out-patient level
- Laboratory and other diagnostic procedures
- Indoor care .

ii) Delay in obtaining reimbursement from the insurer, at times only part of the claims are accepted.

iii) Difficulty (likely to come up at later stages) with regard to availability of beds. This is likely to be experienced more when the facilities for health insurance are provided in the rural areas.

5.4.2 Insurance Regulatory and Development Act (IRDA)

In the background of the discussions in the previous pages and the evaluation of the system the subject of opening up of "Insurance Sector" has come up repeatedly. This topic has been under scrutiny and discussion at all levels including the media and the parliament for the last couple of years. The government of India has now in the year 1999-2000 passed the Insurance Regulatory and Development Act (IRDA). With the provisions of this act coming into being the field of insurance (Life and General) will be open for Private Sector, Foreign Institutional Investment (FFI) and the Non-Resident Indians (NRIs) etc. With these developments medical insurance will never be the same again, change and change for better. What is expectedto develop is a more consumer friendly service.

5.4.3 Likely Set-up after Privatisation

Managed Care — Third Party Administrator

The changes that are coming about have helped in developing the concept of "Managed Care". This has been defined by the United Health Care Corporation (1992) as "A system of health care delivery that influences utilisation of services, cost of services, and measures performance".

It is expected to lead to development of

a) Network of providers, under contract with the insurer in the field of:

i) General Practitioner for out-patient care,

ii) Consultant for out-patient and indoor care,

iii) Diagnostic centre.

iv) Hospitals, and

v) Pharmacies.

b) Criteria of selection and development of the network

c) Criteria for review of the utilisation of the facilities

The IRDA Bill (in respect of health insurance sector) will broadly protect the interest of the consumer and simultaneously allow for the growth in the size of insurance market. It is said that there will be no restriction on the number of licences to be issued to thus there will be a healthy competition which is likely to result in:

i) A lowering of the premium rates for the consumers,

ii) Availability of a wider range of products for the consumers,

iii) Some element of cost control, and

iv) A wider penetration of the insurance in the society.

Coupled with the concept of the managed care is coming up the agency called as Third Party Administrator (TPA). This is expected to provide the much needed interface between the three components in the field, the consumer, the provider and the insurer. Thus, TPA will act as a interface between the consumer and the provider, the provider and the insurer and the insurer and the consunler. The TPA are likely to be a professional body of hospital/health administrators, specialists, or association thereof or such groups who may take up the roll of third party administrators in the emerging scenario.

Some professional bodies of management experts have also come up and started setting up office in metro towns. Even some corporate hospitals who have hospital of their own/or are networking in metropolitan towns are likely to take up the role of TPA.

The TPA is likely to provide administrative services which among other things may comprise:

i) Provision of Photo ID Cards for the consumers

ii) Twenty-four hour call centre as an interface between the provider and the insurer to facilitate availability of proper care to the consumer.

iii) Management of claims

iv) Report of clinical and administrative data

v) Development of selection criteria for network

vi) Utilisation and management review of work

vii) Increase in the volume of work

viii) A concept of accountability leading to improved quality

The TPA is also likely to help in the development of;

a) Provider network (provider of various categories; i.e. general practitioners, consultant, hospitals etc.)

b) In view of the volume of services offered the facility will be available economically at pre-negotiated prices and may also allow for credits and discounts.

c) A system of accreditation

The TPA is also likely to help the medical management by:

a) Interacting with the consumers and the families

b) Developing a system for medical audit – evaluation of care

c) Developing system for utilization management, specially so in the field of;

- pre authorisation
- cost management
- pharmacopoea – drug formulary

The entry of the TPA may be useful to the consumer by way of:

a) Help choose the appropriate policy by providing more information

b) Help choose the right provider of care

c) Improve quality of care

d) Likely reduction in cost of care

e) Speedy settlement of claims – there is a possibility of direct payment of the claim by the insurer to the provider, thus, obviating the necessity of consumer spending the money and getting reimbursement.

The TPA is likely to help the provider by:

a) Larger volume of practice

b) Assured volume of practice

c) Network with other leading providers

d) Development of packages for different ailments.

TPA is likely to help the insurance company i.e. insurer by:

a) Increase in the voluinc of policies

b) Direct contact with the providers of care

c) Satisfied consumer specially so with the TPA taking care of claim administration and speedy reimbursement thereof.

We can now conclude on a positive note that this development (opening up of the insurance sector) will mean:

- The new dispensation will be more efficient
- Services will be provided at a lower cost
- We may expect improved quality of care
- The system will develop in a manner that the payment to the Doctor, the Hospital, the Laboratory etc, will be made directly by the insurer (may be managed by TPA).
- Such a scheme will relieve the insured of having to incur expenditure and claim reimbursement. This will also reduce the element of malpractice reported to be in vogue (i.e. Collusion/Nexus between Hospital – Surveyor Officials of the Insurance Company etc.).

The anticipated changes in service as above with the entry of private sector, and competition in the field is bound to improve the services all to the advantage of the consumer.

In health insurance through social security

a) Participation is voluntary True/False

b) The scale of medical benefit depends on the amount of contribution True/False

c) Pre-existing condition are no bar to coverage True/False

d) There is necessity of pre-entry medical examination True/Farse

5.5 LET US SUM UP

Having gone through this unit you are now better placed to appreciate the evolution and development of 'Health Insurance' in our country.

In this unit you have learnt that in the beginning it was rather slow and the pace increased in good measure in the post-Independence era. It peaked after covering a little over three

percent of the country's population. The quantity and quality of services and the benefits have been improving constantly all these years. The inherent limitations of the 'Act' have been, only partly, responsible for the limited expansion of the scheme.

You have learnt in details about the functioning of two of the ongoing schemes in the country i.e. CGHS and ESIC. You have also learnt that there are going to be tremendous changes in the Health Insurance scenario in the years to come.

Towards end you have also learnt that in the era of Liberalisation, Privatisation, and Globalisation and the opening up of the Health Insurance Sector will help provide benefits to a much larger population in the country. We can safely expect that with the introduction of 'Accreditation System' and 'Medical Audit' the quality of services will improve in the years to come.

The readers will do well to kindly up-date themselves as the Anatomy and Physiology (structure and functions) of health insurance evolve in the emerging scenario.

5.6 ANSWERS TO CHECK YOUR PROGRESS

Check Your Progress 1

a) 1923

b) 1948

c) The individual, the employer and the state.

Check Your Progress 2

1) a) Rs. 6500/- per.month

b) 1.75 per cent, 4.57 per cent

c) Rs. 40/- per day

2) Direct System, Indirect System

3) • Less costly to run
• Capital outlay is nil

4) The Panel Doctors are available at short distance and is suitable for thinly populated area Better inter-personal relationship between the treating doctor and the patient

5) a) True

b) False

c) False

Check Your Progress 3

a) False

b) False

c) True

d) False

UNIT 1 OVERVIEW OF HEALTH CARE DELIVERY SYSTEM,

Structure

1.0 OBJECTIVES

After going through this unit, you should be able to:

- describe briefly how the health care delivery system has evolved over a period of time;
- list the recommendations of important health committees;
- describe the health care infrastructure at various levels;
- specify the services provided at various levels; and
- relate the infrastructure to requirements of health services.

1.1 INTRODUCTION

In the previous block of this course you have learnt about the basics of community health, health for all and primary health care. In this unit you will learn about the overview of health *care* delivery system in the *country.* In the beginning of the unit, you will learn about the evolution of health *care* delivery system including the recommendations of various committees. Thereafter you will learn about the health *care* infrastructure at various levels. Towards the end of this unit you will learn about the role of voluntary organisation, private practitioners and indigenous system of medicine in the health delivery system of the country.

1.2 EVOLUTION OF HEALTH CARE DELIVERY SYSTEM

In this section you will learn about the health services in India which have evolved over a period of time. Salient features of various committees and shifts on thrusts under various Five Year Plans are the following:

1.2.1 Brief History of Evolution

Health, as you know, is defined as a positive state of well being in which the harmonious development of physical and mental capacities of the individual lead to the enjoyment of a rich and full life. It is not a negative state of mere absence of diseases. Health, further implies complete adjustment of the individual to his total environment, physical and social. Health involves primarily the application of medical science for the benefit of individual and society. But many other factors like social, economic and educational have an intimate bearing on the health of the community. Health is thus, a vital part of a concurrent and integrated programme of development of all aspects of community life.

In the subsequent gages you will learn that how health had been valued at individual community and organisation levels since Vedic times to-date and what shape health care system took in this country particularly since independence. It also indicates that to what extent it has assumed the dimensions to achieve the goals of Health for All through Primary Health Care approach. It is in no way alien to our thinking. Rather it presents revival of our approach in designing a health care system to solve the community health needs and to make health a cherished value of every one. The efforts under various committees within the framework of national development plans will also be reviewed to unfold the process of evolution of health care systems and its strategy in the country.

India as you must be knowing has a rich, centuries-old heritage of medical and health sciences. The experience and concern in health development and primary health care in India dates back to the Vedic period. As far back as 3000 B.C., in the Indus Valley Civilisation, one finds evidence of well-developed environmental sanitation programmes in the cities such as underground drains, public baths etc. Almost all households had bathrooms, latrines, water-closets and carefully built wells. Marshall (1931) remarked that public health facilities of Mohenjodaro *city* were superior to those of all other communities of the ancient orient states. The elaborate public health organisation of that time is an indication of the extent of health consciousness among the people of ancient Indus Valley Civilization. The emphasis on preventive aspects of health care indicates a fairly mature attitude towards health "Arogya" or "Health" was given high priority in daily life and this concept of health included physical, mental, social and spiritual well-being.

Irrespective of the phenomenal growth and development of modem Allopathic system of medicine, the fact remains that as late as the beginning of the 19th century, the only medical practices used for health care and treatment of sickness in India were largely "Traditional Indigenous System of Medicine".

Health Status and Health System Till Independence

This period covers a very large span of time starting with the origin and first mention of Ayurveda in the Rigveda and Atharvaveda, describing various diseases and treatments in the form of 114 Hymns (3000 B.C.). Presence of rich and unlimited wealth of varied medicinal herbs, plants and minerals proved exceptionally favourable to the growth and development of the Science. In course of time, it became a teaching subject in the Universities of Takshashila and Nalanda. In Ayurveda, one finds even in 1400 B.C. emphasis on health promotion and health education.

During that time the life style was conducive to health promotion and in the daily activities of life, various essentials of health care were emphasised i.e. health education, personal hygiene and habits, exercises, dietary practices, food, sanitation, code of conduct and self-discipline, civil and spiritual values, treatment of minor ailments and injuries etc. Vedic medicine, which developed after the migration of the Aryans to the Indus Valley took the momentous step from magico-religious therapeutics to rational therapeutics (Chattopadhyaya, 1977). The pharmacology which Ayurvedic medicine developed is colossal and is significant for giving direction even to current pharmacological research (Banerji, 1985). The Buddhist medical text "Millindepanha", of around the 1st Century A.D., also adhered to rationalism and secularism. According to Zimmer (1948), by the 10th Century A.D., often referred to as the age of Indian Renaissance, the scientific core of Indian medicine had reached its high point and social-medicine was being practiced in various parts of the sub-continent including the southern peninsula. Al-Biruni, the visiting scientist from Central Asia, who came to India in the early part of the 11th Century, spoke of the practice of herbal medicine (Chattopadhyaya, 1977). There were three major indigenous systems of medicine (ISM) in the early period i.e. Ayurveda—the Hindu system; Unani—the Greek System which was brought to India from West Asia around 10th Century A.D. by the Muslim rulers and became indigenous to the country along with them; Siddha system which prevailed in Tamil Nadu and some other parts of South India. Ayurveda, Unani and Siddha enjoyed universal acceptance by virtue to their being the only available system for care and cure of the health problem.

During the middle of the 18th Century, the British Government in India established medical services. Allopathy was introduced primarily to look after the health needs of British armies, their civil servants and labour employed in colonial enterprises and industries. General public was given the lowest priority. Indigenous systems of medicine were totally neglected and allowed to languish. The state of public health in British India was low as evident by wide prevalence of diseases like malaria, tuberculosis, cholera, small-pox, plague etc. and the conscqucnt high rates of mortality in the community as a whole. In the forties, the death rate for the general population in British India was 22.4 per 1000 inhabitants and for infants (children under one year of age) 162 per 1000 live births (Bhorc Committee, Vol.1, 1946). Services which were available in general hospitals located in big cities and commercial centres were largely curative for the care of the sick and injured. Later on, some preventive measures were provided for the control of epidemics and dispensaries were also opened in some remote villages. Provincial health departments were established in 1919. But neither health planning nor medical education was related to the health needs of the people (Roy, 1985).

Medical services were scattered inadequately, not only in number but in the kind of medical care they delivered. Rural population in particular were starved of services. In the United Provinces, one institution served a population of about 1,05,626 people inhabiting about 202 villages. The total number of beds available were 73,000 or 0.24 per thousand population. The same dismal picture existed with regard to health personnel. A ratio of one doctor to 6,000 population, one nurse to 43,000, one health visitor to 400,000, one midwife to 60,000, one qualified pharmacist to 4,000,000 and one dentist to 300,000 (Bhore Committee, Vol. 1, 1946 & Baneji, 1985).

An important feature of health policies, plans and programmes in India is that they started taking shape prior to Independence along with the growing national movement. The National Planning Committee (NPC) of the Indian National Congress was set up in 1938. This Committee set up a sub-committee on National Health chaired by Colonel Santok Singh Sokhey which made a penetrating assessment of then health situation and health services in tho country and recommended measures for their improvement in the interim report submitted in 1940. The integration of curative and preventive functions in a single state agency was urged and it was stressed that the maintenance of the health of the people was

the responsibility of state. The need for training large numbers of health workers in practical community and personal hygiene, first aid and simple medical treatment, with stress on the social implications of medical and public health work was emphasised. Practitioners of the Ayurveda and Unani systems were to be drawn into the state health system, after giving them further scientific training where necessary. Other aspects covered were nutrition, expansion of medical education and research, compilation of an Indian pharmacopoeia and production of drugs. Thus even as early as 1940, India's leaders had already envisaged a people oriented health service and had then advocated the concept of a community health worker to serve the rural community.

Growth of Health Care Services After Independence

During the period, vertical programmes of control of different communicable diseases, family planning and nutrition programme ran independent of each other. However, at peripheral level, they were working within the parameter of Peripheral Health Units system. It implied that for same geographical area, a large number of health workers belonging to different vertical programmes were covering a very large identical population at any point of time. Kartar Singh Committee found that the concept of the multipurpose workers at the periphery was both feasible and desirable. The Committee's recommendations were accepted and a new set of worker (multipurpose) drawn from the supervisory and field level of existing health functionaries at PHCs working under different vertical national programmes was created to work in the field in an integrated way for most of the existing vertical programmes at peripheral level. In other words, attempt was made to integrate the services at peripheral level maintaining the vertical structure at top. The launching of Multipurpose Worker's Scheme marked the establishment of an integrated health care delivery system. This led to establishing of the Primary Health Centres. Being conscious of curative services as support to Preventive Health Care services, it was essential to look into the condition of existing medical care services as well. Jain Committee gave several recommendations for the improvement of hospital medical care services and the Central Government Health Scheme. Later Shrivastava Committee suggested several measures for the improvement of medical education and support manpower to extend the outreach of the primary health care services. You will learn in more detail about the recommendations of these committees subsequently.

On achieving Independence, India embarked upon a planned effort for raising the standard of living of the masses. Health planning in Independent India was made an integral part of the overall planning for socio-economic development.

A major landmark in the development of health services in India was the establishment of the first Primary Health Centre (PHC) in October, 1952. The PHC, as part of the Community Development Programme signified the putting into practice of the concept of community participation and inter-sectorial development for health care.

A major step was taken in 1952 to bring about a reorientation of education and training of health workers to make them more relevant to conditions prevailing in the country. Upgraded departments of preventive and social medicine were established in medical colleges to relate the complex field of community health to the social, cultural and economic context (Banerji, 1973). Other major watersheds in the history of health services in India were the introduction of *Community* Health Volunteer's (Guides) Scheme and introduction of ROME Scheme (Reorientation of Medical Education) in 1977 as a consequence to Shrivastava Committee report. The idea was to entrust people's health in people's hand and involve medical colleges in community health problems and reorient medical education to achieve social objectives-of national health services.

As you know, the basis for organisation of health services in India through the basic health care approach in modem time, was laid by the recommendations and guidance provided by the "Health Survey Development Committee" (Bhore Committee) in 1946 which subsequently has moved to primary health care approach. Over the past more than four decades, the health services organisation and infrastructure have undergone extensive changes and expansion in stages following review by a number of expert committees (Mudaliar, 1961; Chadha, 1963; Mukherjee, 1966; Jain 1967; Kartar Singh, 1973; Srivastava, 1975, Alma Ata Declaration, 1978; National Health Policy, 1983; and various Five Year Plans). In subsequent sub-section you will learn in detail about the recommendations of these committees.

1.2.2 Salient *Features* of Various Committees

Bhore Committee (1943-46)

Taking into consideration the findings of interim report of National Planning Committee on Health (1940) and being dissatisfied with the then health care system in meeting of health problems of the community, particularly of rural population, in 1943, the then British Government appointed the 'Wealth Survey and Development Committee" with Sir Joseph Bhore as Chairman to make a survey of the existing health conditions and health organisations and to make recommendations for future development.

The recommendations and guidance provided by the Bhore Committee formed the basis for organisation of basic health services in India. The report was submitted to the Government in 1946.

The Bhore Committee emphasised the need for social orientation of medical practice, a high level of public participation to lay special emphasis on preventive work and consequent development of environmental health.

The Bhore Committee made two types of recommendations:

a) A comprehensive blue print for the distant future (20 to 40 years)—the smallest service unit was to be a Primary Health Unit, serving a population of 10,000 to 20,000; and

b) A short term scheme covering 2 to 5 years period–the emphasis would be on setting up 30 bedded hospitals, one for every two Primary Health Units.

The country-side was the focal point of these recommendations. Other recommendations of the committee were:

- Formation of Village Health Committee to secure active cooperation and support in the development of health programme.
- Provision of Doctor of future who should be a "Social Doctor" who combines both curative and preventive measures.
- Formation of a District Health Board for each district with district health officials and representatives of the public.
- To ensure suitable housing, sanitary surroundings, safe drinking water supply, elimination of unemployment and lay special emphasis on preventive work.
- Intersectoral approach to health services development.

Mudaliar Committee (1959-61)

The Government of India in the Ministry of Health set up a Committee on 12th

June, 1959 under the Chairmanship of Dr. A. Lakshmanswami Mudaliar for the assessment in the field of medical relief and public health since the submission of Bhore Committee Report and formulation of recommendations for the future plan of health development in the country.

Detailed recommendations on these aspects were submitted in 1961. Their salient features were:

- Upgrading and strengthening of PHUs
- Strengthening of District Hospitals
- Mobile Service teams for rural areas
- Levying of small fee for those availing hospital facilities, except on those who are really poor
- Long range health insurance policy for all citizens
- Formation of Central Health Cadre in which senior posts in the Central and State Ministries of Health will be included,
- Extension of the functions of the University Grants Commission to education in the fields of Medicine, Engineering, Agriculture and Veterinary Sciences
- Institution of National Programmes in regard to Malaria Eradication, Small Pox, Cholera, Leprosy, Tuberculosis and Filariasis
- Making the Central Council of Health more effective
- Director General of Health Services should enjoy the status of an Additional Secretary.

Chadha Committee (1963)

In April 1963, a special Committee was constituted by the Government of India under the Chairmanship of Director General of Health Services, Dr. M.S. Chadha to go into the details of the requirements related to the primary health centres, their planning, the necessary priority required according to the 'needs of the maintenance phase of Malaria Eradication Programme' and also for other health activities and the manner in which the technical and supervisory staff of the NMEP organisation should be utilised after malaria eradication has been achieved. The Committee considered that the maintenance was the responsibility of the general health services which should be adequately strengthened, particularly the rural health services. Vigilance through medical institutions (government or non-government) must be developed. Multipurpose domiciliary health services should be developed for all health programmes including malaria, small-pox, control of other communicable diseases, health education etc.

Mukherjee Committee (1966)

The Central Council of Health at its meeting on the 31st December, 1965, in Madras, appointed a Committee under the Chairmanship of Union Health Secretary to undertake the review of Family Planning Programme and its *strategy*. The Committee while recommending the strengthening of the administrative set up at different levels from the Primary Health Units up to the State Headquarters, also recommended to some extent, delinking of malaria maintenance activities from Family Planning Programme in order that the latter could receive undivided attention of its staff and could be carried through as a crash mass programme.

Jain Committee (1966-67)

Due to rapid industrialisation of the country and continuous growth of population, a number of medical and health problems were brought in. The Government of India, Ministry of Health and Family Planning set up the study group in August 1966

under the Chairmanship of Shri Ajit Prasad Jain to look into medical care services, It undertook:

- study of the working of different classes of hospitals in the country with a view to improve the standards of medical care and developing sound guidelines for the future expansion of the hospital services.
- review of the working of the Central Government Health Scheme (CGHS), to evaluate its progress and performance and to make suggestions for improvements and reduction in government liability.

Kartar Singh Committee (1972-73)

In pursuance of the recommendations made by the Executive Committee of the Central Family Planning Council, the Government of India constituted a Committee in October 1972 to study and make recommendations on:

- The structure for integrated services at the peripheral and supervisory levels.
- The feasibility of having 'multipurpose/bi-purpose workers' in the field.
- The training requirements for such workers.
- The utilisation of mobile service units set up under family planning programme for intergrated medical, public and family planning services operating from tehsil/taluk levels.

Its detailed recommendations were submitted in 1973 which highlight that:

- Multipurpose workers for the delivery of health, family planning and nutrition services to the rural cornmunitics arc both feasible and desirable.
- To begin with, one Male Health Worker (Multipurpose) should be available for a population of six to seven thousand.

  At least one Female Health Worker (ANM) should be available for a population of ten to twelve thousand.
- Each PHC should ultimately serve 50,000 population and should have 16 sub-centres spread over its area.
- Training for all workers engaged in the field of health, family planning and nutrition should be integrated.

Shrivastava Committee (1974-75)

The Government of India in 1974 formed a Committee on 'Medical Education and Support Manpower' under the Chairmanship of Dr. J.B. Shrivastava. The terms of references were as follows:

- To devise a suitable curriculum for training a cadre of Health Assistants conversant with basic medical aid, preventive and nutritional services, family welfare, maternity and child welfare activities so that they can serve as a link between the qualified medical practitioners and the multipurpose workers, thus forming an effective team to deliver health care, family welfare and nutritional services to the people.

  Keeping in view the recommendations made by earlier committees on Medical Education specially the Medical Education Committee (1968) and the Medical Education Conference (1970), to suggest suitable ways and means for implementation of these recommendations, and to suggest steps for improving the existing medical education process so as to provide due emphasis on the problems particularly relevant to national requirement.

- To make any other suggestion to realise the above objective and matters incidental thereto.

The Committee submitted its detailed report in 1975 and made specific recommendations for the initiation of the following major programmes for immediate action:

- Organisation of the basic health services (including nutrition, health education and family planning) within the community itself and training the personnel needed for the purpose.
- Organisation of an economic and efficient programme of health services to bridge the community with the first level referral centre, viz., the PHC (including the strengthening of the PWC itself).
- The creation of a National Referral Services Complex by the development of proper linkages between the PWC and higher level referral and services centres.
- To create the necessary administrative and financial machinery for the re-organisation of the entire programme of medical and health education from the point of view of the objectives and needs of the proposed programme of national health services.

Implications of Various Committees

Analysing the recommendations of various expert committees set up for the development of health care services, it is quite apparent that Bhore Committee set out a pattern of health development through primary health care units which continues till date; the basic framework of all the subsequent Health Development Plans. It is striking that the recommendations of the Bhore Committee spoke of "Primary Health Care Unit" with people's active cooperation long before the Alma Ata Declaration of 1977. Even in those early days, the Bhore Committee could visualise the importance of studying heredity and environment to promote the creation of a healthy and well-endowed community. The recommendations of Bhore Committee, therefore, provided inspiration for the development of comprehensive health services for India.

Several vertical programmes for control of communicable diseases were initiated following the suggestions of Mudaliar Committee. It recommended the introduction of Mobile Health Care Unit for Basic Health Care which was not found to be effective later on. Levying of small fee for those availing hospital facilities and long range health insurance policy for all citizens were some of the important recommendations of Mudaliar Committee.

As early as in 1963, the multipurpose concept could be seen in one of the recommendations (i.e. multipurpose domiciliary health service for all health programmes) of Chadha Committee dealing with Malaria Eradication Programme. However in 1965, Mukherjee Committee, in order to boost family planning activities delinked malaria maintenance activities from family planning programme.

1.23 Changing Trends in Evolution of Health Care Delivery System

At the time of Independence, the country's health care infrastructure was mainly urban and clinic based. Outreach of services in the rural areas was very limited; there were very few preventive and rehabilitative services available. From the First Five Year Plan, Central and State Governments made efforts to build up primary, secondary and tertiary care institutions and tried to link through appropriate referral system. The private and voluntary sectors also tried to cater to the health care needs of the population. Efforts to train adequate number of medical, dental and paramedical personnel were also taken up. National Programmes for combating major public health problems were evolved and implemented during the last 50

years. Efforts to further improve the health status of the population by optimizing coverage and quality of care by identifying and rectifying the critical gaps in infrastructure, manpower, equipment, essential diagnostic reagents, drugs and enhancing the efficiency of the health systems are underway.

The National Health Policy was formulated and adopted in 1983 by providing comprehensive framework for planning, implementation and monitoring of health services. Successive Plans have evolved various health programmes to achieve the goals set in the National Health Policy. Alma Ata Declaration of WHO adopted by India, envisaged availability of Health for All by Year 2000 AD.

Improvement in coverage and quality of health care and implementation of disease control programmes resulted in steep decline in the Crude Death Rate (CDR) from 25.1 in 1951 to 8.9 in 1997. Life expectancy rose from 32 years in 1947 to 61.1 years in 1991-96 with female life expectancy (61.7 years) higher than the male (60.6 years). However, the morbidity due to common communicable and nutrition-related diseases showed a progressive increase because of increasing longevity and. alterations in life style. During the 9th Plan, efforts are being made to tackle this dual disease burden effectively so that there is sustained improvement in the health status of the population. During the last 50 years a large network of health facilities in rural areas have been established. The number of 132730 Sub-centres, 21854 Primary Health Centres and 2424 Community Health Centres have been established to cater to health service requirements of the rural areas. It provides integrated promotive, preventive, curative and rehabilitative services to the population close to their heart and home. However, there are marked disparities at the state and district level. There is considerable backlog in terms of construction of the building for sub-centres and PHCs. Apart from funds made available to States under Minimum Needs Programme, additional central assistance is now being made available under Basic Minimum Services.

The outcome and impact of any health programme depends on the competencies and skills of the personnel who implement it. The Bhore Committee was the first to recommend a population based norm for medical (1/1500) and nursing personnel (1/500). Medical Education has been given a priority during all the Plans in the country. This was essential in the initial years of the Planning, as there existed a wide gap in the availability of skilled and trained manpower. During the 9th Plan, health manpower planning is being linked to the needs and demands of health services.

At the time of Independence, communicable diseases were the major cause of morbidity and mortality in the country. Efforts were, therefore, initially directed towards their prevention and control. Small pox, a major killer in pre-independence era has been eradicated. In 1953, malaria affected over 75 million and killed 0.8 million people. The National Malaria Control Programme, which was launched in 1953, successfully brought down the incidence of malaria to 0.1 million cases with no death by 1965. Subsequently, there has been a resurgence of malaria. Modified Plans have succeeded in keeping morbidity and mortality at relatively low levels. Effective therapy for infections and vaccines for prevention of infection were the major factors responsible for the steep fall in crude death rate from 25.1 in 1951 to 8.9 in 1997.

Even though health is a State subject, the Central Government has over the last 50 years, provided additional funds through centrally sponsored schemes for control of some of the major communicable diseases. Apart from programme for control of malaria, the national programme for control of tuberculosis, blindness, leprosy and HIV/AIDS etc. have been undertaken.

Sexually transmitted diseases (STDs) have been a global problem since time immemorial. A national STDs control programme has been in operation since 1967. With the advent of HIV infection the situation underwent dramatic change because

there is no effective drug for treatment or vaccine for protection against HIV infection. Available data indicate that HIV infection exists in all states both in urban and rural areas. ICMR had estimated that the number of HIV infected persons in the country is between 2-3 million. At present the number of AIDS patients in the country is small. However, over the next decade persons who got infected in the eighties will develop AIDS, resulting in a steep and progressive increase in the number of AIDS patients in India. Realising the gravity of the HIV epidemic in the country, a National AIDS Control Programme was initiated in 1992 as a 100% Central Supported Scheme. You will learn in detail about these national health programmes in Block 3 of this course.

Shifts in Thrusts Under Various Five Year Plans

The planning process in the country was initiated in April, 1951 when the First Five Year Plan was launched. Progressive changes in thrust areas have been introduced into the programmes over the seven Five Year Plan periods. The First Five Year Plan (1951-56) initiated a process of all-round balanced development to ensure a steady improvement in the living standard over a period of time. New programmes for the control of communicable diseases such as malaria, filaria, tuberculosis, leprosy etc. were instituted. Health and medical care infrastructure facilities and water supply and sanitation were expanded with a view to improve the accessibility and availability of services. Education and training facilities for medical and para-medical personnel and other health functionaries were also instituted and expanded.

The subsequent Five Year Plans (2nd, 3rd and 4th) aimed at extending health and family planning services to bring those increasingly within the reach of all the people for improving their health status. In the first year of the Fifth Five Year Plan, 'Minimum Needs Programme' was introduced. The objective of the programme is to establish a network of basic services and facilities of social consumption in all the areas within a specified time frame. This package of 'Minimum Needs Programme' contains important elements from the fields of health, nutrition, environmental improvement and water supply, apart from elementary and adult education, roads and electrification in rural areas and housing for landless labourers.

During the Fifth Plan (1974-79), removal of poverty and achievement of self-reliance on the part of the community were given emphasis. For preventing and correcting nutritional deficiencies, supplementary feeding programmes for the children and expectant mothers were initiated on a country-wide basis. The family planning programme was integrated with the MCH and nutrition programmes.

India is a signatory of the Alma Ata Declaration of 1978 and it is committed to attaining the goal of "Health For All" (HFA) by the Year 2000 through the primary health care approach. Consequently, while formulating the Sixth Five Year Plan (1980-85), a critical review was made of the approaches in the past Five Year Plans. Based on these, a long term perspective was outlined by the Government for achieving the HFA goals. Efforts were initiated for the formulation of the National Health Policy, keeping in view the HFA principles and strategies. These strategies were also incorporated in the Sixth Five Year Plan. The National Health Policy was essentially a policy of democratisation of the health services, based on the concept of people's health in people's hands. During the Sixth Five Year Plan emphasis was given on health problems, contraceptive practices and diseases among tribal groups of India.

The objectives and thrusts of the Seventh Plan (1985-90) were formulated as a part of the long term strategy which seeked by the year 2000 to virtually eliminate poverty and illiteracy, achieve year-full-employment, secure satisfaction of the basic needs of food, clothing and shelter and provide health for all. The working group on Population Stabilisation and Maternal and Child Health Care felt that strategy during the Seventh Five Year Plan for achieving the targets should comprise of:

- improvement of efficiency and effectiveness of the programme infrastructure,

- enforcement of the law relating to minimum age at marriage,
- special programmes for low performing states,
- more involvement of voluntary organisations,
- greater emphasis on spacing methods,
- efforts to achieve much higher protection rate for cities with population over 10 lakhs.

Health w e for mothers and children were to be strengthened through the Primary Health Care approach which includes integrated comprehensive MCH Care, suitable strengthening of referral services and logistic support. Each major state should have at least one centre of excellence for re-canalisation. The main focus of Eighth Five Year Plan was on integration and consolidation rather than expansion of the infrastructure. The objectives of the plan also included:

Strengthening of physical facilities,

- Provision of essential equipment, and
- Filling up of vacant posts.

1.3 WEALTH CARE: INFRASTRUCTURE

In this section you will learn about health care infrastructure in the country at various levels.

1.3.1 National Level

Health and human development are integral to overall socio-economic development. The Ministry of Health and Family Welfare "plays a vital role in the effort to enable the citizens to lead a healthy life by promoting policies and programmes covering preventive, promotive and curative health care. Under the constitution, the items' like public health, sanitation, hospitals and dispensaries fall in the *state* list. Population control and family planning, medical education, adulteration of food stuffs and other goods, drugs, compilation of vital statistics including registration of births and deaths and lunacy and mental deficiency find a place in the concurrent list, while international health comes under union list.

The official organs of the general health system at the central consists of

1) Union Ministry of Health and Family Welfare
2) Directorate General of Health Services and Central Council of Health and Family Welfare.

Ministry of Health and Family Welfare is the apex executive organisation dealing with the issue of health and family welfare in the country as per guidelines enshrined in the Constitution of India and depicted in the National Health Policy and in accordance with the policy decisions of the cabinet.

Ministry of Health and Family Welfare is headed by:

- Cabinet Minister

  Minister of State

  Deputy Health Minister

Currently, it has following two departments:

- Department of Health

  Department of Family Welfare

Department of Health

Department of Health is headed by Secretary to Govt. of India as its executive head and is assisted by Additional Secretary, Joint Secretary and Deputy Secretary and a large administrative staff.

The Union Ministry formulates national policies on health and gives advice on health and allied matters, coordinates health programmes and policies, supplies technical information and equipment and provides financial and other assistance towards health measures which promote in general, the health and well being of the people.

It is also responsible for implementation of numerous programmes of national importance like Family Welfare; Child Survival and Safe Motherhood; Prevention, Control and Eradication of major diseases; propagation of Indian systems of medicines etc. The Ministry implements several centrally sponsored schemes through the state governments. These schemes aim at fulfilling the national commitment to attain the goal of Health for All by the Year 2000 AD.

Health is a state subject in India and Union Ministry of Health and Family Welfare acts only as the coordinating agency between the State Health Departments, Planning Commissions and Central Council of Health etc.

Department of Family Welfare

Department of family welfare was created as a separate department in 1966 in Ministry of Health and Family Welfare. The Maternity and Child Health section comes under the Department of Family Welfare.

The Mother and Child Health and Family Planning Services were integrated in the Fourth Five Year Plan for better effectiveness. The organisation pattern for MCH and Family Planning Services cannot be considered apart.

The Secretary to the Government of India in the Ministry of Health and Family Welfare is in overall charge of the Department of Family Welfare who is assisted by an Additional Secretary (Commissioner, Family Planning/MCH), Joint Secretary (MCH), Director (Technology Mission on Immunization), Deputy Commissioner (MCH) and a team of Assistant Commissioners (EPI, MCH, ORT and Child Survival).

Policy formulation, intelligence and evaluation, planning and budget formulation, autonomous bodies and subordinate officers, supply of contraceptives, International Aid for Family Welfare, Urban Family Welfare Programme and contraceptive research programmes are looked after through various divisions by Joint Secretary.

Maternal and Child Health Services including child survival programmes like universal immunization, control of acute respiratory infections, oral rehydration therapy programmes, infrastructure and social safety network, training programmes, voluntary organisations sector and technical operations are looked after by Director, Technology Mission.

Various technical divisions functioning in the department are programme appraisal and special schemes, technical operation, maternal and child health, evaluation and intelligence, information, education and communication (IEC), supply division, transport, universal immunization programme, area projects and rural health division.

The technical divisions look after the technical aspects of family planning. Evaluation and intelligence division helps in perspectives planning and monitoring and evaluation of the performance of the various programmes. It also coordinates demographic research. The rural health division looks after health infrastructure at the peripheral level, training, extension components, facilities and services. The IEC division is responsible for providing communication, educational publicity and extension support to the programme through mass education and extension education with emphasis on interpersonal communication. It is also looking after population education activities.

Directorate General of Health Services

Director General of Health Services (DGHS) is the executive head of the technical wing of the Union Ministry of Health and Family Welfare. He renders technical

advice to the Government of India in all medical and public health matters and in the implementation of various health schemes.

DGHS is assisted by an Additional Director General of Health Services, a number of Deputy Director Generals, Assistant Director Generals and Deputy Assistant Director Generals. Deputy Director General (Planning) and Deputy Director General (Rural Health) look after MCH activities. Deputy Director General (Planning) is assisted by Assistant Director General (EPI) who supervises vaccine production and quality control.

Majority of maternal and child health services are under control of Director, Technology Mission (Immunization) in the Ministry of Health and Family Welfare.

Directors of various health institutions such as National Institute of Communicable Diseases (INCD) and All India Institute of Hygiene and Public Health (AIIPH) etc. are in the cadre of Deputy Director General.

Central Council of Health and Family Welfare

Central Council of Health and Family Welfare was set up by a presidential order on August 9, 1952, for promoting coordinated and concerted action between the centre and the states in the implementation of all the programmes and measures pertaining to the health of the nation.

The union health minister is the chairman and the state health ministers are the members of this council.

1.3.2 State Level

Under the provision of our Constitution, the main responsibility of providing the health services to the people through hospitals, dispensaries, health centres, clinics, public health and sanitation projects etc. lies with the state govemments.

The state is the ultimate authority responsible for all the health services operating within its jurisdiction.

At present there are 29 states and 9 union territories in India and as many types of health administrations. In all the states, the management sector comprises the S t . Ministry of Health and Directorate of Health.

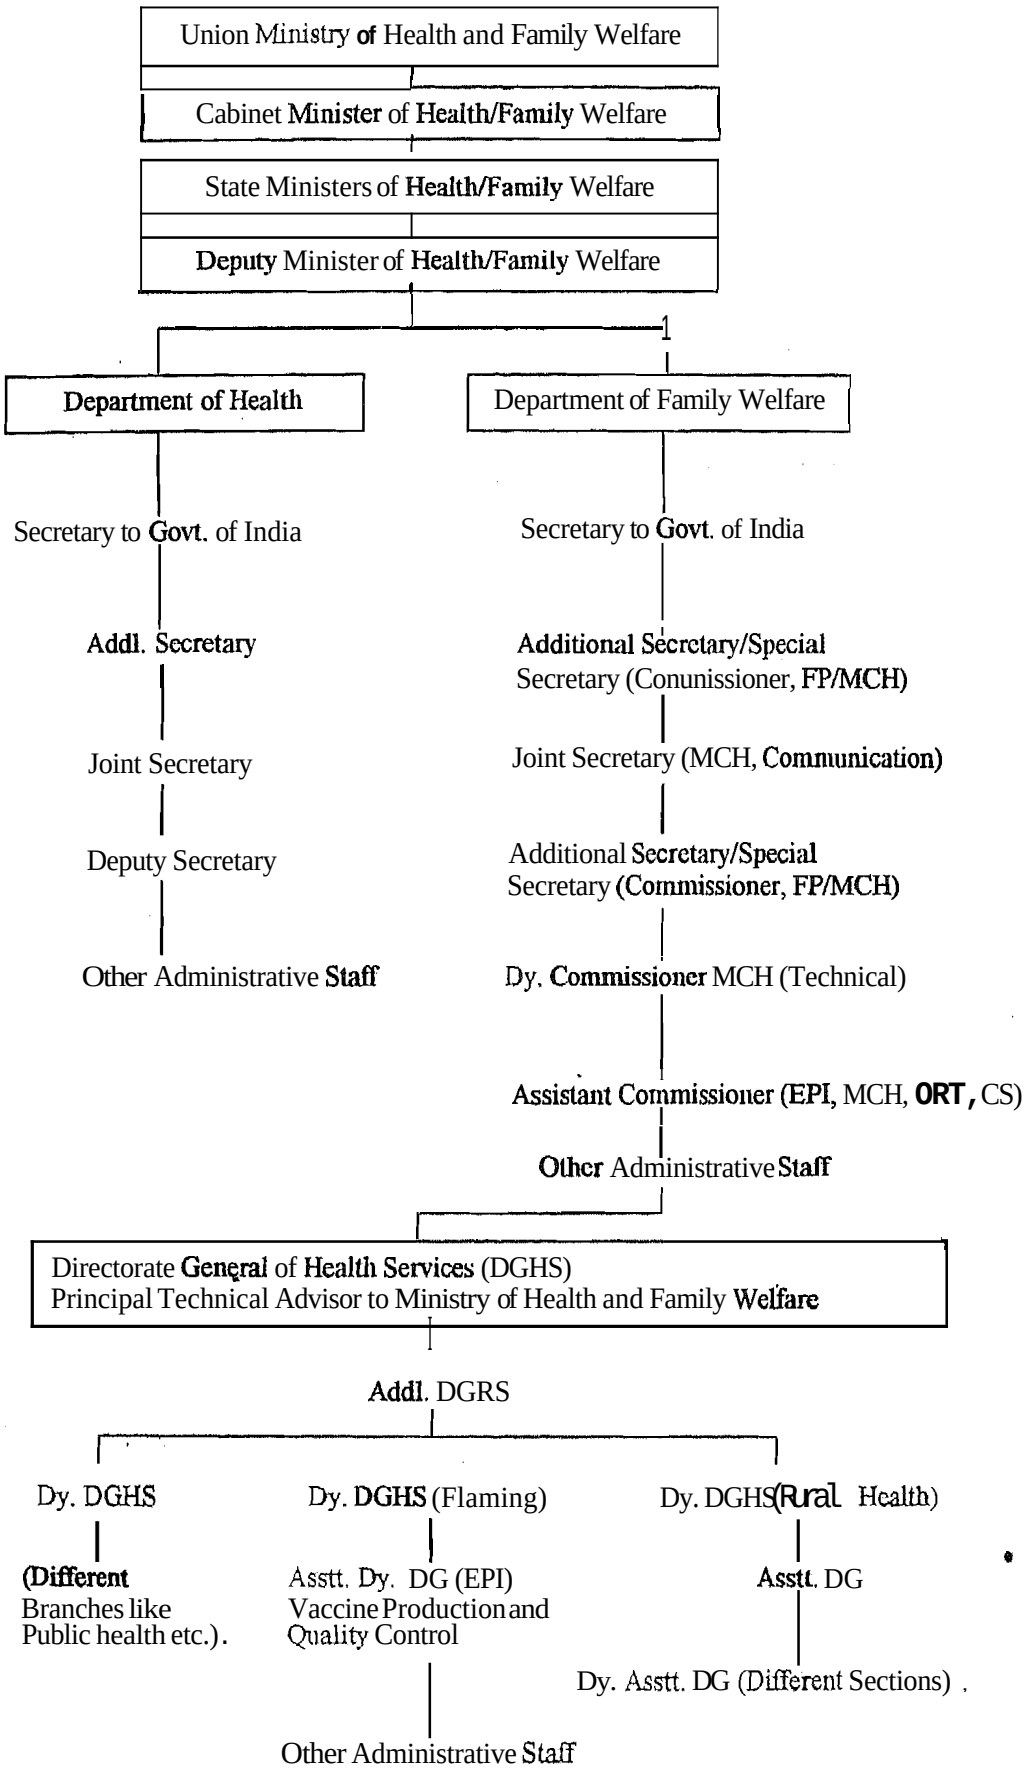
During the past few years, the state governments have assumed major responsibility for delivering of primary health care services including maternal and child health services. All the states have appointed qualified women medical officers to render mother and child health services. Some states have also appointed regional officers known as Additional Director (Range) to supervise maternal and child health work at the divisional level. Similarly, Government of India has appointed Regional Directors who work at state level.

State Ministry of Health

The State Ministry of Health is headed by a Minister of Health and Family Welfare and a Deputy Minister of Health and Family Welfare.

The Health Secretariat is the official organ of the State Ministry of Health and is headed by a Principal Medical Health and Family Welfare Secretary who is assisted by a Secretary, 3 or 4 Special Secretaries, Joint Secretaries, Deputy Secretaries and Under Secretaries.

The Director General of Health Services (known in some states as Director General—Medical/Health and Family Welfare or Director Genera—Family



Organisationdl Chart at the Centre

Welfare) is the chief technical advisor to the state government on all matters relating to medical and public health including **MCH** or **solely and family welfare. He is also responsible for the organisation and direction of all health activities including family welfare activities.**

The organisational structure of the State Directorate of Health Services is not uniform throughout the country. For example, in some states the programme officers below the Director General of Health Services (or Director of Health and Family Welfare) are called Additional Directors, while in other states, they are called Joint/Deputy Directors. But regardless of the job title, the programme officers below the Director General of Health Services may be for two types:

- Regional
- Functional

The Regional Directors are at divisional level and are classified on the basis of geographical distribution. They inspect all the branches of public health within their jurisdiction, irrespective of their speciality.

The Functional Directors are in a particular branch of public health such as mother and child health, family planning, nutrition, health education etc. Director, Family Welfare is assisted by Additional Director, Family Welfare; Joint Director, Family Welfare; State Demographer and Assistant Directors.

Similarly, Director, Mother and Child Health is assisted by Additional Director (UIP/EPI), Joint Director (also known as State MCH Office) and Assistant Directors (MCH, UIP and Child Survival).

In some states the area on medical education is integrated with the State Directorate of Health Services but in other states (e.g. Uttar Pradesh) medical education area maintains a separate identity.

To coordinate the family welfare activities between the state government and the central government, one family welfare cell has been sanctioned for each state. Regional Director, Govt. of India is responsible for coordinating between State and Centre.

1.33 District Level

The district level structure of health services is a linkage system between the state as well as regional structure on one side and the peripheral level structure such as primary health centres and sub-centres on the other side. It receives information from the state level and transmit the same to the periphery by suitable modifications to meet the local needs.

The district officer with the overall control is designated as the Chief Medical and Health Officer (CM&HO) or as the District Medical and Health Officer (DM&HO). These officers are popularly known as CMOs or DMOs. They are responsible for implementing health and family welfare programmes according to the policies laid down and finalised at higher levels i.e. state and centre.

DMOs/CMOs are assisted by 3-4 Deputy CMOs. The exact number of such officers, their specialisation and status in the cader of State Civil Medical Services differ from state to *state.*

One of the Deputy CMO who was previously known as Dy. CMO (UIP) has been designated as District MCH Officer who is a nodal officer of MCH activities in the district and works under the supervision of CMO.

The major contribution of district health administration towards MCH services is to make available medical care and family welfare services, free of cost to all sections of the community in the district, through the primary health centres and down. You will learn in detail about the District Health Organisation in Unit 4 of this block.

1.3.4 Block Level

Rural areas of the district have been organised into blocks, known as Community Development Blocks. The block is a unit of mral planning and development and comprises of approximately 100 villages and about 80,000 to 1,20,000 population, charge of a Block Development Officer.

To provide effective services and referral support to primary health care programme, one Community Health Centre (CHC) is being established in each block. The CHCs are framed by upgrading some of the block level PHCs or by creating new centres, whenever absolutely needed. The officer in-charge of CHC is known as superintendent CHC or medical officer in-charge block PHC.

Each CHC has been envisaged to get primary and secondary care needs of one lakh population. It is intended to be a first level referral institution. Normally onc CHC should have 4 Medical Officers who are either qualified or specially trained to work as Surgeon, Obstetrician, Physician and Paediatrician. One of the existing medical officer similarly should be either qualified or specially trained in Public Health. One CHC should have 30 beds.

Social Safety Net Scheme

Under this scheme, additional funds arc provided to community health centres in the districts, where birth rate is more than 39 per thousand population. 90 such districts have been identified all over the country.

Each CHC is given funds for providing facilities like provision of an operation theatre, a 30 bedded observational ward, a labour room, onc electricity generator, one water pump and one ambulance, if not already available. This scheme helps in strengthening of emergency obstetric care at community health centres.

1.3.5 Primary Health Centre Level

The delivery of primary health care is the principal objective of the rural health care system and forms the foundation of the National Health System. The services are provided through the network of integrated health and family welfare delivery system. The infrastructure is based on the complex of Primary Health Centres and their sub-centres.

A Rural Family Welfare Centre with a medical officer and supporting staff (Health Assistant—Male and Female, Clerks, Laboratory technicians and others) forms an integral part of the Primary Health Centre. One PHC covers a population of 30,000 and as such there are 3-4 PHCs in a block. These PHCs are now known as New PHCs or Mini PHCs in some of the states. The Primary Health Centre is expected to provide fairly comprehensive "essential health care" including MCH and family planning care. The details of primary health care infrastructure have already been discussed in the unit on health for all and primary health care (Unit 2, Block 1 of this course)

1.3.6 Sub-centre Level

Sub-centres are the peripheral outposts of health care delivery system. These are to provide main thrust of the programme. Each sub-centre covers the population of 5000 and is manned by a team of one health worker male and onc health worker female. They provide preventive and promotive health care in addition to MCH and family planning services. Health Worker (Female), previously designated as Auxiliary Nurse Midwife (ANM) is crucial in providing mother and child health care services in rural area. She conducts immunization sessions, distributes Iron and Folic acid tablets, vitamin A and provides antenatal, natal and postnatal services to pregnant mothers along with family planning services to eligible couples. She also

provides knowledge and information to mothers about nutrition, lactation and correct weaning practices. The work of Multipurpose Worker (Family) is supervised by Health Assistant (Female), also known as Lady Health Visitor (LHV). The Multipurpose Worker (Male) as you know perform activities other than MCH w e and is supervised by Health Assistance (Male).

1.3.7 Village Level

At the village level primary health care activities are carried out by supporting health worker like Village Health Guides, Traditional Birth Attendants, Anganwadi Workers (AWW) and others.

1) Village Health Guides

Village health guide scheme was initially started as Community Health Workers scheme on October 2, 1977 in all states except Tamil Nadu, J&K, Kerala and Arunachal Pradesh. The scheme was renamed as Village Health Guide scheme in 1981 when it was made 100 per cent centrally sponsored scheme under family welfare programme.

You will recall that a village health guide is a person with an aptitude for special service and is not a government functionary. These village health guides serve as link between the community and the governmental infrastructure. They provide the first contact between the individual and the health system. They mainly provide health education and create awareness in MCH and family welfare services. They also treat minor ailments and provide aid to the patients.

2) **Trained Dais**

Most deliveries in rural areas are still handled by untrained dais who are often the only people immediately available to women during the prenatal period. An extensive programme has been undertaken to train all categories of local dais (Traditional Birth Attendants) in the country to improve their knowledge in the elementary concepts of maternal and child health and sterilisation besides obstetric skills. The training is for 30 working days. The emphasis during training is asepsis so that home deliveries are conducted under safe hygienic conditions with observation of five cleans, thereby reducing the maternal and infant mortality.

1.4 NON-GOVERNMENTAL SECTOR

In this section you will learn about the involvement of voluntary organisations, private practitioners and indigenous system of medicine (ISM) in the national health care delivery system.

Voluntary or non-governmental health organisations occupy an important place in health care delivery of the country. The National Health Policy has envisaged key role of voluntary organisations in the two most vital components of health and family welfare programmes i.e. population stabilisation and primary health care. NGOs have been playing a significant role in the provision of health care services including medical care. They also play an important role in educating and motivating the people to adopt the small family norm. Voluntary agencies are also involved in ICDS programmes and other community health programmes. These agencies are able to tailor the programmes to take account of the local situations.

1.4.1 Role of Private Sector

You have learnt that the public health infrastructure in the country is small and inadequate to meet the health care demands of the people. As a consequence the private health care sector has taken a dominant position, especially with regard to treatment of routine illnesses. Private general practice is the most commonly used health care service by patients in both rural and urban areas. While this has been known all these years, data in the eighties and nineties from small micro studies as well as national level studies by the National Sample Survey Organisation and the NCAER, provided the necessary evidence to show the overwhelming dominance of the private health sector in India. These studies show that 60-80 per cent of health care is sought in the private sector for which households contribute out-of-pocket 4-6 per cent of their incomes. This also includes the hospital sector where the private sector has about 50 per cent of the market share.

You will agree that, for all practical purposes the private sector provides mainly curative services whereas the emphasis of public sector is on preventive services.

To re-emphasise two sets of dichotomies have been identified in health sector: the curative (private)-preventive (public sector) dichotomy and the rural (preventive)-urban (curative) dichotomy.

It is important to remove these dichotomies for universal coverage and equity consideration. For this purpose, it is essential to dovetail the services provided by the private practitioners/hospitals into primary health services so that comprehensive health services without any social and geographical discrimination can be provided to the people at large.

To achieve this, general practitioners/family physicians besides providing services for personal health care need to be involved in the following:

- First level referral hospital care and basic speciality services, including dental and ophthalmic services.
- Immunization services against vaccine preventable diseases.
- Supply of rational and essential drugs as per accepted standards.

- Ambulance services
- Contraceptive services
- Health education.

1.4.2 Role of Voluntary Organisations

Government attitude towards involvement of NGOs has changed in recent years towards equal partnership as against the earlier relationship which tended to be one of patron and supplement. Still there is a need for development of better understanding between NGOs and government, for joint planning and delivery of health services.

Involvement of NGOs in Health and Family Welfare Programme will give it the much desired impetus as the voluntary workers can work in close collaboration with the people and bring about desired change in social personal attitudes, perceptions and behaviour more than the staff of the government hierarchy.

The voluntary agencies can effectively supplement the government efforts in implementing various national and other programmes like population stabilisation, strengthening and rural women organisations (Mahila Mandals), School Health Progamme, Control of STDs through education and treatment and family planning programme.

1.4.3 Role of Indigenous System of Medicine

Indigenous Medical Practitioners (IMPs) including registered/non-registered medical practitioners (RMPs/NRMPs) are recognised as human resources who heal simple and complex health problems through different approaches using either single or combined system of medicine. By now, it has been well recognised that there is a huge battalion of these IMPs practising mainly in the rural areas and urban slums. They have a good rapport with the community and are widely acceptable to the people and provide health care in a more friendly manner. They have a say in the community and people by and large respect them and tend to follow their advise and instructions.

Thus IMPs can be of great help to the government in promoting the preventive aspects of health, especially in the field of MCH and family planning. There have been researches to demonstrate their role in National Health Programmes and their acceptance by community.

1.5 LET US SUM UP

In this unit you have learnt about an overview of health care delivery system in the country. To start with, you learnt about the brief history of evolution of health services in the country both in prc and post-independence era. You learnt about salient features of various committees from time to time which formed the basis of present day health care delivery system of the country. You also learnt about the changing trends of health care delivery system across various Five Year Plans. Subsequently you learnt about the organisation of health infrastructure at various levels i.e. Central, State, District, Block and Village. Towards the end you learnt about the role which voluntary sector, private sector and ISM can play in the delivery of health care services.

1.6 ANSWERS TO CHECK YOUR PROGRESS

Check Your Progress 1

1) The Bhore Committee made two types of rccornmendations:

   a) A comprehensive blue print for the distant future (20 to 40 years)—the smallest service unit was to be a Primary Health Unit, serving a population of 10,000 to 20,000;

   b) A short term scheme covering 2 to 5 years period—the emphasis would be on setting up 30 bedded hospitals, one for every two Primary Health Units.

2) Kartar Singh Committee

3) Shrivastava Committee

4) Mudaliar Committee

5) Fifth Five Year Plan

6)
   - improvement of efficiency and effectiveness of the programme infrastructure
   - enforcement of the law relating to minimum age at marriage
   - special programmes for low performing states
   - more involvement of voluntary organisations
   - greater emphasis on spacing methods
   - efforts to achieve much higher protection rate for cities with population over 10 lakhs.

Check Your Progress 2

1)
   - Formulation of national policies on health
   - Advice on health and allied matters
   - Coordinates health programmes and policies
   - Supplies technical information and equipment
   - Provides financial and other assistance towards health measures
   - Implementation of programmes of national importance like Family Welfare; Child Survival and Safe Motherhood; Prevention, Control and Eradication of major diseases.

- Propagation of Indian systems of medicines
- Implementation of centrally sponsored schemes through the state governments.

2) Union Health Minister and the State Ministers

3) Primary Health Centres and their sub-centres

4) At village level there is one village health guide for every 1000 population

Check Your Progress 3

1)
- First level referral hospital care and basic speciality services, including dental and ophthalmic services
- Immunization services against vaccine preventable diseases
- Supply of rational and essential drugs as per accepted standards
- Ambulance services
- Contraceptive services
- Health education

2) **Involvement** of NGOs in Health and Family Welfare Programme will give it the much desired impetus as the voluntary workers can work in close collaboration with the people and bring about desired change in social personal attitudes, perceptions and behaviour more than the staff of the government hierarchy.

UNIT 2 HOLISTIC APPROACH TO HEALTH

Structure

2.1 OBJECTIVES

After going through this unit, you should be able to:

- understand the need, concept and basis of holistic medicine;
- fulfil the needs of the people by adopting holistic medicine;
- prepare inputs required to develop infrastructure for holistic medicine;
- appreciate that holistic medicine makes a physician more effective; and
- develop comprehensive and efficient strategy to achieve 'Health for All',

2.2 INTRODUCTION

Health as you know has been a common basic theme, essential to human survival, for all the cultures throughout the world. The holistic model of health would be an optimum synthesis of all these concepts and could be described as a

multidimensional synergistic synthesis for the well-being of the individual as a whole, to correspond to the views held by the ancients that health implies a sound mind, in a sound body, in a sound family, in a sound community, in a sound environment. The universally accepted emphasis should be on the promotion and protection of health, with early recognition of disease and effective cure with minimal disability, as well as efficient scope for rehabilitation with useful , productive participation in the community.

In this unit, you will learn about the concept and various aspects of the practice of Holistic Medicine for the physical, mental, emotional, social and spiritual well-being of the individual, family, community and the mankind as a whole.

You will also learn about the evolution of medicine including the principles and philosophy of various systems of medicine. Having understood the basic principles and philosophy of various systems of medicine you will also learn about the need and scope of integration of that system at various levels of health care delivery system including the training needs.

2.3 EVOLUTION OF MEDICINE

From time immemorial, the man has been interested in his health and has tried to find various means to prevent or eradicate disease or illness. It has been said that the first doctor was the first man, and the first nurse was the first woman. Medicine was conceived in sympathy and born out of necessity. The prehistoric man, motivated by feelings of kindness, was always at the behest of his kindred, trying to provide relief in the times of sickness or suffering.

The history of medicine originates to great degree from intuition, observation and cumulative experiences. It is a study of accomplishment and errors, as well evolution of man and of human knowledge down the ages and across the various cultures of the world. Medicine is built on the best of the past. The goal of modern medicine became enlarged beyond the mere treatment of sickness to the more important objective of prevention and as an essential component of socio-economic development.

However, the explosion of knowledge during the later half of 20th century has made the practice of medicine very complex and expensive. The benefits of modern progress in medicine have not been able to reach the social periphery of most nations of the world. The glaring contrast in the state of the health between the developed and developing countries, between rural and urban populations, and between the rich and poor has become the source of worldwide criticism as lack of "social injustice". There is an ever-increasing hiatus between the resources available and the needs and demands of the public.

The WHO objective of "Health for All by 2000 AD" by all the nations of the world and attainment by all the people of the highest possible levels of health across the globe has proved to be a failure with more than half the world's people still not having any access to health care at the turn of millennium. The death rates and life expectancy have remained unchanged for the last two to three decades in the developed countries. The statistical gain of the health indices of developing nations are being attributed to improved public health and economic progress. According to Rudolf Virchow, the western father of biomedicine and public health, "Social equity is perhaps the single most important factor if uniform improvements in the health of a population are to be achieved. The improvements of medicine will eventually prolong human life but the improvements of social conditions can achieve this result more rapidly and more successfully."

Through this period, the overall morbidity has perhaps gone up as never before. Even in areas where people are living longer, it has been at the expense of 'quality of life'. Dr. Hiroshi Nakajama, the former Director General of WHO stated, "Our goal should not be solely to extend lives in the physical sense, but to ensure that the added years are worth living with diminishing handicaps and disabilities, and with a greater degree of health security". 'Life to years' is considered equally, if not more, important than 'years to life'.

The increase in ageing population in the world has brought a new focus to the particular health needs of the older persons. Urgent action is needed in preparation for this situation as it is largely not included in the scope of current health care services.

While the WHO Alma Ata declaration called for 'indigenisation' and 'deprofessionalisation' of medicine whereby a medical doctor, besides playing the core curative role should also supplement this by being an educator, case finder, preventer, counsellor and agent of social change through a team of health workers comprising community health workers, anganwadi workers, multipurpose workers, social workers and practitioners of indigenous systems, the approach remained heavily dependent on the modem or the 'allopathic' system of medicine with all its inherent limitations.

The modem system of medicine is confined to the care of health only in its 'physical sense'. At the most, drugs and surgery nay provide some relief, but cannot cure nor reverse the disease process. The patients continue to suffer increasing morbidity in spite of the best medical care. Even when people are living longer, it is at the expense of quality of life. Society-is also becoming increasingly aware of 'iatrogenesis'. Besides, even the richest nations of the world find it difficult to cope with their financial constraints and are unable to extend quality health care to their entire populations.

It has been the official policy of the Government of India to encourage all the systems of medicine, regardless of their origin. The initial recognition of Modern Medicine, Ayurveda, Unani, Homeopathy and Naturopathy was extended to Yoga which has important therapeutic aspects, the Tibetan System of medicine called Alchi, and Acupuncture. Various boards and committees were set up for each one of the systems, way back in 1970s, and it was decided that National Institutes would be established. However, despite all *these* efforts, alternative systems of medicine have not attained Government support nor the acceptance and popularity of the public that was expected.

The National Health Policy adopted by Government of India in 1983 covers almost all the systems and sub-systems required for Health for All by 2000 AD, yet what is realised today is a model truly inconsistent with the desirable goals and objectives. The developed infrastructures and human resource are largely unresponsive to the needs and expectations of the people. The conspicuous lack of political will throughout is reflected in the low priority for 'health' with progressively reducing per capita budgetary outlay in the successive Five Year Plans.

In the subsequent sub-section you will learn in brief about the principles and philosophy of various systems of medicines which need to be integrated with modem medicine to make it holistic.

2.3.1 Ayurveda

Ayurveda, as you know is India's ancient science of life and has a legacy of more than 3000 years. As a system of medicine, it has become thoroughly blended in the philosophy and become a way of life. Jt has been in continuous practice throughout

this period undergoing improvisation, research and development through the human quest for perfection in health. It is termed as a holistic system by itself, for its simultaneous effect on physical, mental and emotional aspects of health. It uses herbal minerals to preserve homeostasis and prevent illness.

Ayurvedic treatment focuses on the cure of the disease, not merely its symptoms. Thus, it provides not only curative but also preventive and promotional applications. It simultaneously restores physiological as well as consequent imbalances, thus *curing* very chronic diseases.

The medicines used in Ayurveda are mostly extracts of herbs and vegetables. Herbal oils play a major role in massage treatments.

The Ayurveda system of medicine has its foundation in the theory of ***'Tri-dosha'*** and ***'Pancha-Bhuta'***. It propounds that everything in the universe is made up of a specific combination (ratio) of these ***bhutas*** and ***doshas.The*** derangement of this particular ratio leads to diseases and hence the physician's role is to restore this ratio.

In Ayurveda equal importance is given to enhancing the health of the healthy, preventing the concept of disease in all and curing the diseases of the ill.

There are eight specialities in Ayurveda:

I) ***Kuyachikitsa*** (General Medicine)

2) ***Koumarabritya*** (Paediatrics)

3) ***Manasika Chikitsa*** (Psychiatry)

4) ***Salakya Chikitsa*** (Surgery)

5) ***Salya Chikitsa (ENT*** and Ophthalmology)

6) ***Visha Chikitsa*** (Toxicology)

7) *Rasayana* (Geriatrics) and

8) ***Vajeekarama*** (Sexual dysfunction and sub-fertility)

Ayurvedic treatment is divided into:

- Sodhana (Process of cleansing the disagreeable elements or toxins) and
- Samana (Symptomatic treatment)

Sodhana is given higher importance for the following reasons:

- It prevents the development of morbidity.
- It impedes the further development of the disease.
- It cures the manifest disease.
- It prevents the reoccurrence of the disease.

Sodhana Chikitsa has five activities—the Karamas known as 'Panchkarama':

- Vamana
- Virechana
- Nasyam
- Kashayavasti and Snehavasti
- Ratha Moksha

Yoga as you must be knowing is a life of self-discipline based on the tenets of 'simple living and high thinking'. It is a very ancient Sanskrit word and has two different meanings, a general one and a technical one. In a general sense, the word 'Yoga' is derived from the root 'yujir-yoge', which means union, union of the self with the Supreme. The technical meaning of the term 'Yoga' is derived from another root 'yuj', which means a state of stability, peace and stillness. The 'Yoga Sutra of Patanjali' (second century B.C.), describes the 'Ashtanga' or eight-fold yoga, which includes outer and inner aspects of disciplining and training the mind and body. 'Ashtanga Yoga' consists of following:

- Abstinence or 'Yama'
- Observances or 'Niyama'
- Postures or 'Asanas'
- Breath control or 'Pranayama'
- Detachment from objects of enjoyment or 'Pratyahara'
- Concentration or 'Dharana'
- Contemplation or 'Dhyana'
- Absorption or 'Samadhi'

The two main purposes of practicing yoga today are:

a) to gain fitness of body and mind to reduce the adverse impacts of the environment we live in; and

b) to prevent and cure the various disorders that afflict the human body.

The body is seen as a temple or vehicle for the soul, and has specific requirements, which must be fulfilled for it to function smoothly. This body-vehicle needs following:

- Proper Exercise: Acts as a lubricating routine to the joints, muscles, ligaments, tendons, and other parts of the body by increasing circulation and flexibility.
- Proper Breathing: Aids the body in connecting to its battery, the solar plexus, where tremendous potential energy is stored. When tapped through specific Yoga breathing techniques (Pranayama), this energy is released for physical and mental rejuvenation.
- Proper Relaxation: Cools down the system. When the body and mind are continually overworked, their efficiency diminishes. Relaxation is Nature's way of recharging the body.
- Proper Diet: Provides the correct fuel for the body. Optimum utilization of food, air, water, and sunlight is essential.
- Positive Thinking and Meditation: Puts you in control. The intellect is purified. The lower nature is brought under conscious control through steadiness and concentration of the mind.
- Cleansing techniques or 'Shuddhi Kriyas': Clean the various internal organs of the body by using various techniques such as Neti, Dhouli, Basti, Tratak, Nauli and Kapalbhati.

Thus the main aim of yoga is to bestow on an individual a perfect state of mental and physical health. This can be described as a state in which all the organs must perform their functions effectively and in a coordinated manner, to enable one to fulfil, the higher purpose for which one is born.

Yoga has many advantages over other methods of maintaining health. It does not need any costly equipment or material. The only requirement is a thick carpet for spreading on the floor, personal dedication and time. It is beneficial for all individuals irrespective of age, occupation, education and economic status. It can be described as the best form of health insurance.

2.3.3 Naturopathy

According to the philosophy of nature cure or naturopathy, the origin of all diseases is an accumulation of toxins in the body. And the disease is that state in which the body tries to expel those toxins, which it could not expel in its normal condition and through its normal processes.

As per naturopathy, the body has its own power to heal itself and remain in a healthy state. But, when a person adopts a life-style in disharmony with nature and keeps on breaking the rules of nature, the natural balance of his body gets impaired and toxins begin to accumulate, as more toxins are produced than expelled by the body.

Therefore, the first and the foremost step in the cure of a disease is to improve one's life-style and start living in harmony with nature. Basic ingredients of such a life-style are:

Proper Diet

Some of the rules advocated regarding diet are as under:

- Vegetarian diet, which is light and easy to digest.
- Reduce intake of salt, avoid salt-rich substances, and preferably use rock salt.
- Reduce intake of refined sugar, preferably use country sugar, rich in minerals,
- Avoid refined and synthetic foods, use natural foods, which are easy to digest and have greater nutrition.
- Do not overeat, and have your meals at least three hours before sleeping.
- Drink plenty of water, especially after waking up in the morning.
- Do not overcook the food and use minimum spices.
- Avoid fried food and increase intake of salad and fresh fruits.
- Rest after meals and do not engage yourself in strenuous physical work immediately after meals.

Proper Exercise

Exercise should be light and invigorating. The regular practise of yogasanas and long walks preferably in natural surroundings are considered ideal to maintain a good circulation of blood to all parts of the body.

Proper Rest

When the body and the mind are constantly overworked, their natural efficiency diminishes. Therefore, our body and mind need rest to recoup their energy and to help them regenerate. During rest the body's capacity, to perform the necessary repair and eliminate toxins, increases and it gets back to normal.

Even fasting is a way of resting our digestive system, which helps the digestive organs to recoup their energy and continue performing efficiently.

Naturopathy stresses the fact that internal and external cleanliness are prerequisites for a healthy, disease-free body.

External cleanliness, which is basically related to body hygiene, is of paramount importance. By practicing external cleanliness one can also achieve internal cleanliness, as it eventually permeates to our inner self.

Bathing daily, washing hands properly before meals, keeping our teeth and nails clean are some of the simple rules, which need to be followed, apart from some advanced techniques, which could be adopted later.

Therapeutic Measures

There are also various therapeutic measures employed in Nature cure. The basic principle behind them is to affect an improvement in the blood circulation either to a particular part or to the whole body, so as to wash away the accumulated toxins.

These techniques mainly involve various kinds of baths, packs and massages. Steam bath, sun bath, cold hip bath and mud pack are some of the examples of these techniques.

2.3.4 'Siddha Vaidya System

Siddha Vaidya System is an ancient herbal medical system, which is said to have originated with the civilizations of Mohenjodaro and Harappa. Through its evolution it travelled to Southern India along with the Dravidians about 2500 years ago.

The Siddha vaids meticulously studied thousands of herbs for medicinal purposes, which were accurately defined, documented and well researched.

These herbal remedies have a tangible solution for the various types of disorders afflicting the human race. It forms an ideal bridge between modem medicine and other complementary systems of medicine and is effective in the management of:

- Chronic diseases
- Degenerative conditions
- Autoimmune diseases such as rheumatoid arthritis
- Disorders of the central nervous system such as hemiplegia
- Viral infections such as hepatitis and herpes
- Prevention of heart diseases, etc.

In short, this system of medicine promises health and productive longevity.

2.3.5 Unani Medicine

The Unani system of medicine recognizes the influence of surroundings and ecological conditions on the health of human beings. The essential factors that influence health and vitality are—air, food and drinks, bodily movements and repose, psychic movement and repose, sleep and wakefulness, excretion and retention. It aims at restoring the equilibrium of various elements and faculties of the human body and stresses on the maintenance of a proper ecological balance and keeping water, food. and air free from pollution.

The theoretical framework of Unani medicine is based on the teachings of Hippocrates. The principal, basis of diagnosis in Unani medicine is the theory of Humours.

There are mainly four Humours in the body—Dam (blood), Balgham (phelgm), Safra (yellow bile), and Sauda (black bile). According to the preponderance of these Humours, blood, phlegm, yellow bile and black bile, the temperaments of persons are expressed by the words sanguine, phlegmatic, choleric and melancholic. respectively.

Every person is supposed to have a unique, humoral constitution, which represents his healthy state. To maintain this healthy state there is a power of self-preservation called Quwwat-e-Mudabbira (medicatrix naturae) in the body. When this power weakens, an imbalance in the humoral composition occurs and disease results. The therapy in Unani medicine is aimed at restoring this humoral balance.

Another distinctive feature of the Unani system of medicine is its emphasis on diagnosing a disease through nabz (pulse), a rhythmic expansion of arteries, which is felt by the fingers. Other methods of diagnosis include examination of baul (urine), baraz (stool), etc.

Therapeutics

The various types of treatments employed in Unani medicine are:

1) *Ilaj bit-tadbeer* (regimental therapy): This therapy includes venesection, cupping, diaphoresis, diuresis, turkish baths, massages, cauterization, purging, emesis, exercise, leaching etc.

2) *Ilaj bil-ghiza* (dietotherapy): Dietotherapy aims at treating certain ailments by administration of specific diets or by regulating the quantity and quality of food.

3) *Ilaj bid-dawa* (pharmacotherapy): It deals with the use of naturally occurring drugs, mostly herbal, though drugs of animal and mineral origin are also used. Single drugs or their combinations in a raw form are preferred over compound formulations. The materia medica of Unani medicine is vast and most of the drugs are easily available. They are free from side effects. Drugs that are toxic in the crude form are processed and purified many times before use.

4) *Jarahnt (surgery): When all* other therapeutic measures fail, surgery is resorted to.

2.3.6 Homeopathy

Homeopathy was introduced by the celebrated German physician Samuel Hahnemann through his work, The *Organon of the Art of Healing*, which was first published in 1810 AD. It emerged as an important therapeutic modality during the latter half of the nineteenth century in Europe and Americas. Due to its increasing popularity in our country, the Government of India extended official recognition to Homeopathy in the year 1977 and enacted the formation of Homeopathy Council of India. The World Health Organisation has recognized it as a viable form of therapeutics.

The primary emphasis of Homeopathy is that it is a non-invasive therapy, it is low cost, non-toxic, and safe. It may be used to treat both acute and chronic disorders. However, its main utility is in the successful treatment of many chronic illnesses that are usually difficult to manage with other methods or treatment.

Homeopathy aims to restore the lost equilibrium of the sick person at the physical, mental and emotional levels by stimulating and regulating the intrinsic defence and curative mechanisms, or the so called vital forces.

The Homeopathy principle according to Hahnemann is "In order to discover the true curative powers of a remedy to treat diseases one must ascertain the specific artificial disorder it develops in the healthy human body, and then utilize it to treat similar morbid conditions. In order to radically cure chronic diseases, one must search for the single remedy that may evoke a similar disease picture, the closer the similarity the better."

Hitherto, diseases of the human organism were treated neither rationally nor on logical principles, but according to various esoteric, hypothetical, curative paradigms, among which is the palliative rule: *contraria contrariis curentur.* The truth is, in fact, diametrically opposite; to cure mildly, rapidly and permanently. In every disorder, a remedy is selected which produces a similar clinical picture when administered: *similia similibus curentur.* This is the fundamental principle of homeopathy, known as the Law of Cure.

Hahnemann's fundamental propositions, peculiar to homeopathy, may be expressed thus:

1) That the action of the drug is demonstrable by observing the signs, symptoms, and pathological changes that occur when they are administered to healthy human subjects.
2) That the action of drugs in the *healthy* constitutes their therapeutic potential with respect to the sick.
3) That a similarity between the disease process in a particular individual, and the known effects of a particular drug in the healthy will lead to its successful application in the treatment of that diseased individual.

Thus, the Law *of Similars* forms the foundation of all medicinal Iiomeopathic practice. Similia *Similibus Curentur*, "let likes be treated with likes".

Increasing concern about the dangers and complications caused by the crude physical methods employed in the therapeutics s f his day, and with his intuition coupled with careful observations, Hahnemann developed a subtle and effective approach based on ancient principles of healing. He sffectively used natural substances of plant, animal, and mineral origins that have the properties of stimulating the body's curative responses (of the vital principles) to disease. Beginning with his classical proving experiments with the quinine, cinchona or china bark used in the treatment of malaria, he was able to develop a wide range of natural healing substances during his life time of dedicated research. These remedies now form the basis of the modern homoeopathic *materia medica*, which has since been considerably cxpandcd by many dedicated workers.

23.7 Traditional Chinese Medicine

The edifice of traditional Chinese medicine was built on a solid foundation of careful clinical observations. The ancient Chinese believed that disease was caused by the imbalance in the body of two principles, which they called 'Yin' and 'Yang'. By 'Yin' they meant the negative or female principle, while 'Yang' was the positive or male principle and both of which are universally present in all nature in the healthy state. There was believed to be a harmonious balance between these opposite but mutually interacting principles—a state of affairs called homeostasis. In the healthy stat. when the Yin and Yang are in balance, normal vital energy or 'Qi', which flows through the channels of the body is produced. But when disease supervenes, it was believed that one or other principle becomes dominant at the

expense of other. Correction of this imbalance is achieved by the techniques of acupuncture, moxibustion, acupressure and auriculotherapy.

Another important aspect of Chinese medicine is the concept of the internal organ, which is radically different from that of contemporary western medicine. Understanding the difference is very important because the physiology of the organs are fundamental to the understanding and treatment of diseases. For example, assuming that treatments which are regarded by the Chinese as beneficial to the liver will automatically be useful against western defined hepatic disorders is not always correct.

There is in Chinese medicine, a lack of emphasis on the anatomical structure. The organs are divided into Yin (Zang) and Yang (fu) organs.

The five Yin organs, which form the core of the entire system are—lungs, heart, liver, spleen and kidney. A sixth organ—the pericardium exists but it is more in conjunction to the heart.

The six Yang organs are—gall bladder, urinary bladder, stomach, small intestine, large intestine and sanjiao.

The Yin organs sustain homeostasis and Yang organs transform food and dispose wastes. Each Yang organ is related to a particular Yin organ.

The forum of diagnosis and conceptualisation of the body differs in Chinese medicine. Each of the vital organs is responsible for a variety of disorders that appear along the path of its associated channels.

The channels or meridians are conduits for the smooth flow of the vital energy called 'qi' (pronounced 'chi'). Likewise there are 12 pairs of channels associated with the organs. Like the internal organs there are six Yin channels and six Yang channels. Each Yin channel is paired with the Yang channel. In addition to these, there are eight extra channels. This network of channels connects the internal organs and the exterior of man, the microcosm, with the universe, the macrocosm, to establish a universal harmony.

The six paired channels are:

1) Lungs and Large Intestines
2) Spleen and Stomach
3) Heart and Small Intestines
4) Kidneys and Urinary Bladder
5) Pericardium and Sanjiao
6) Liver and Gall Bladder

Apart from the above channels, the 'Ren' and 'Du' channels (two of the eight extra channels) play an important role in maintaining the balance.

2.3.8 Acupuncture

The word acupuncture is derived from the Latin words Acus (needle) and Punctura (to penetrate). It is the most ancient and characteristic therapeutic technique of Chinese medicine. It entails the introduction of hair-fine needles into various specific points on the body to restore lost balance. The effects observed on needling are both subjective and objective. One of the subjective effects may be slight pain at the site of needling. Another important subjective effect is the appearance of a

peculiar sensation, which is called 'deqi' in Chinese. It is a combination of numbness, heaviness, slight soreness, and distension. Radiation of these sensations may also occur along the channel.

There are six known objective effects of acupuncture:

1) **Analgesic** (pain-relieving): It is used to relieve the pain of arthritis, toothache, headache, Bow backache and other similar painful disorders.

2) **Sedation:** The needling of certain specific acupuncture points has a sleep-inducing effect. This effect is used in the treatment of insomnia, anxiety state, addictions, epilepsy, and mental disorders.

3) Homeostatic (regulatory): This is the most important feature of acupuncture It is an adjustment of the internal environment of the body towards the state of normal balance. It is achieved by balancing the activity of the sympathetic and parasympathetic divisions of the autonomic nervous system and also the endocrine system, by needling specific points.

4) **Immune Enhancing:** The body resistance to disease is strengthened. There is an increase in the white blood cells, antibodies, gamma globulins and other substances. Thus, acupuncture is useful in combating infections.

5) **Psychological Effects:** Acupuncture has a calming and tranquillizing effect.

6) **Motor recovery:** It hastens the motor recovery in patients who have become paralysed from some cause or another.

The acupuncture points are systematically arranged on the basis of the pertaining internal organs over which they have an influence. The series of points having an effect on a particular organ are connected to form a channel. Apart from body acupuncture described above, traditional acupuncture comprises the components of—Ear acupuncture, Moxibustion and Reflexology.

Moxibustion

Moxibustion is the therapeutic method of treating diseases by burning 'moxa-wool' or generating similar forms of heat on or near specific acupuncture points.

Direct Moxibustion

In direct moxibustion a small moxa-cone is placed directly on the skin surface at an acupuncture (moxibustion) point and then ignited. There are two forms of this method.

a) *Scarring Moxibustion:* The moxa is allowed to bum out completely on the skin. This results in the formation of a blister and is not used very much today for obvious reasons, although it is said to be very effective in certain chronic seasonal allergies.

b) Non-scarring Moxibustion: A cone is ignited at the top, placed Ow the point and removed as soon as a sensation of scorching with slight pain is felt. The procedure m y be repeated several times until there is redness and congestion at the site. Usually 3 to 5 cones are applied during a single session, and this is repeated daily or every other day. If performed carefully, this method is quite safe and there is no blistering or scarring.

Indirect Moxibustion

In indirect moxibustion a slice of ginger, a slice of garlic or a thin layer of salt is placed over the point before introducing the moxa. Alternatively, an ignited moxa

stick may be used to warm the point from a distance of about 3 to 5 cm. The lighted end of the stick may also be brought briefly into contact with the diseased area and immediately withdrawn. This movement is repeated at intervals of a few seconds.

Auriculotherapy

Auriculotherapy may be defined as that branch of acupuncture which makes use of the external ear to diagnose as well as to treat illness. The ear is the place where all the channels meet. It has a rich nerve supply derived from several spinal segments. In addition, branches of the vagus, glossopharyngeal, trigeminal and facial nerves supply the ear. It also has a very rich blood supply, with both sympathetic and parasympathetic fibres running close to the blood vessels. As the nerves mentioned above spread out widely connecting all areas of the body, including the internal organs, it is not surprising that any lesion, anywhere in the body, will exhibit changes in the collateral branch, which supplies the ear.

By and large, it is a more effective form of acupuncture therapy than body acupuncture in internal organ disorders. Auriculotherapy may be combined with either body acupuncture or head-needle therapy where indicated.

The external ear has an external or Yang surface and an internal or Yin surface also called the back of the auricle.

There are some 200 acupuncture points on the ear. In the practice of Chinese auriculotherapy, steel filiform needles are used. The needles may be inserted perpendicularly or obliquely. But it should not penetrate the cartilage, as any injury or infection may have serious consequences. As mentioned earlier, the results of auriculotherapy are very good in the treatment of internal organ disorders.

Reflexology

Also called foot and hand acupuncture, this is an ancient self-health technique that has been widely used through the Orient for thousand of years. It is an easy to perform method to restore health and well-being, or to bring yourself symptomatic relief. This technique may be used by any one in normal health up to several times daily.

It works by affecting the flow of the life force throughout the system. A complete healing network of energy carrying channels is said to terminate in the hands and the feet.

Various body organs and structures are located on the hands and feet at various points. The best way for actually finding your own points is to press deeply an area on your hand or foot until you contact a tender and sensitive point. The most tender points are the most effective for bringing relief and promoting healing. When they are no longer tender, discontinue the use.

2.3.9 Reiki

Reiki is the Japanese word for universal life form energy, whereby 'Rei' stands for universal cosmic energy (macrocosm) and 'Ki' denotes the vital life force energy (microcosm), very similar to the 'Prana' of Indian Ayurveda, the 'Chi' of Chinese Acupuncture, the 'Light' to Christianity, and 'Bioplasmic Energy' to Russian Researchers.

Reiki, the Universal Life Force Energy lives in all creations. It is inherent in all living beings, and is the factor that nourishes them to keep alive and healthy.

Reiki is divine grace meant for anyone who is open to receive it. The more the life force energy is free to move in the body, die energy centres known as the '*chakras* are opened to enable them to vibrate and channel higher amounts of universal life force energy. It also facilitates the '*kundalini*', the spiritual transformative energy, to be awakened. Once the kundalini is awakened, the release of emotional and mental blocks is even more accelerated.

Reiki is, thus, not only the ability to self heal and heal others, but it also enables spiritual transformation. It is an art of gaining access to one's own inner healing powers as well as the subtle energy that pervades all inner and outer manifestations of life.

Reiki increases the vitality of the individual, and works to heal on the physical, subtle and causal levels to link with all other forms s f healing on physical, mental, emotional and spiritual planes.

Through the process of initiation, or attunement, of the pupil by the teacher, one can transfer the electromagnetic life force energy to accelerate the process of healing.

Each one of us can learn how to attain consciousness of this power and put it to use for the good of ourselves and our patients. It is a natural method of healing. This can be used done or in complement with any other system of medicine.

2.4 ROLE OF ALTERNATE SYSTEMS OF MEDICINE

The practice ofmedicine is as primitive as man himself. Rudiments of primitive medicine still persist around the world in many parts of Asia, Africa, Australia, the Americas and even Europe. The progeny of the primitive man, 'the traditional healers' are found everywhere and are still popular amongst large cross-sections of society. They live close to the people and their treatments are based on various combinations of magic, mystic, empiricism and religion. Besides, every culture has developed its own traditional systems of health and even given their modern scientific growth to them to a large extent. Thus, we have a large reservoir of qualified practitioners of the various recognised systems of medicine registered with their respective councils, viz., Ayurveda, Siddha, Unani, Homeopathy, Naturopathy, Yoga, etc. in our country. One of the great advantages is that generally their cost is much lower, and in a country like ours with vast millions still struggling below the poverty line, they could fill a very important need.

The People's Republic of China has attained a health status comparable with the best developed nations of the world, within its meagre resources by judicious integration of Traditional Chinese Medicine (TCM) with Modern Medicine.

This should provide us a model frame-work to integrate our traditional/alternate systems with a 'spiritual zeal' into the primary health care of our country which would work as a successful 'mantra' for attaining the desired status of Health For All in our country.

The common factor between Indian Ayurveda/Yoga and Chinese TCM/ Acupuncture is that the both restore and 'harmonise the spirit' or the life force termed 'prana' and 'chi', respectively, to achieve the desired state of positive health.

Whereas the role of Yoga as a way of life (*Yama, Niyama, Asana, Pranayama, Pratihara, Dhyana, Dharana, Samadhi*) is essential at the promotive and preventive levels of health, Acupuncture is effectively used for further curative, limitation of disability as well as rehabilitative roles for health. The two systems in harmony shall ideally fulfil the Hippocrates' doctrine, *'primum non-nocere'*: Let there be no harm first as well as work in synergy for his intuitive observations, 'the *natural* healing *force within each of us is the greatest force in getting well'*, as the prime factor in the restoration of health. In fact, only this combination within the existing medical and health infrastructure can fulfil the entire ingredient to Health For All, into a dream reality in a short period of time.

The greatest advantage is that the Indian Ayurveda, Yoga and TCM are extension of each other in their science and philosophy, and being purely natural are easier on logistics while being devoid of any 'iatrogenesis'. Being simple in technology, as proved by the Chinese barefoot doctors, they are most practical and can be delivered at the doorstep of any community, anywhere, at any time. Thus, the judicious application of this synergy at the Primary Health Care level would lead to early management of a wide range of common health problems at a much lower cost, relieving the secondary and tertiary health services of a great burden, even to enable them to perform their services far more satisfactorily.

Thus, would be the ideal *'rasayana'* for the desired status of complete physical, mental, social and spiritual health, and positive well-being of the individual, the family, community, and the nation as a whole.

25 HOLISTIC MEDICINE

The objective of any health care infrastructure would bc to offer to the community the most simple, acceptable, accessible, cost-effective, efficient and versatile system of health. It should be easily available and accessible to any community at any time, at a cost that it can easily afford. It should be effective at all levels of health, viz. primary, secondary as well as tertiary.

The concept of Holistic Medicine comprises a synergic optimum synthesis of Modem Medicine (westcm scientific knowledge) with the so-called Alternate Systems of Medicine (oriental ancient wisdom).

It aims to restore the health and hannony of the human being (Body-Mind-Spirit) as a whole entity encompassing physical, mental, social as well as spiritual well-being.

Holistic Medicine would also aim at promoting health in all its dimensions and at various levels, as far as possible by natural (non-pharmaceutical and surgical) means, in consonance with the Indian psyche and as per health care practices imbibed in religious, social and ritualistic aspects of life.

This can be easily achieved by augmenting and sensitizing our primary' health care infrastructure which is essentially based on modern medicine with the various

traditional systems of health, viz. Ayurveda, Siddha, Unani, Yoga, Naturopathy, Homoeopathy, Acupuncture, etc.

The success of Acupuncture as a natural, harmless and highly efficient modality has been proved by its successful role through the 'barefoot doctors' in the primary health care services of the People's Republic of China (PRC).

The various modalities of Acupuncture like acupressure, reflexology, moxibustion, etc. have gained tremendous popularity in recent decades due to their easy application by paramedical personnel. In fact, Acupuncture as a system has undergone scientific research and modern development worldwide and has been endorsed as an effective cure by World Health Organisation (WHO) in a number of common diseases and surgical analgesia. It has withstood scientific evaluation for its useful role in primary, secondary and tertiary levels of health.

Acupuncture can easily integrate with all the systems of health and various specialities of medicine. It bridges the gap between modem medicine and traditional systems of health to develop the perfect integration for the most desirable health care infrastructure for any community or nation.

2.6 NEED FOR APPLICATION IN INDIAN SCENARIO

The modem system of medicine essentially forms the basis of health care infrastructure in India, with a majority of health budget being allocated to it. But the holistic approach to medicine forms an integral part of the Indian psyche. An illness is viewed as the consequence of a disharmony with the cosmic order. It is not limited in space and time. An individual is considered as a non-divisible unity, an integrated whole which cannot be reduced in terms of its parts, nor can the individual be separated from the social, cultural and spiritual environments nor the cosmic link. The universe is a perfectly organised whole where nothing happens without reason or fortuitously and everything is moving towards a definite goal.

Thus, it is not a purposeless combination and separation of certain chemicals occurring by chance which causes the disease. Malfunctions are understood and treated in the context of an individual's social, cultural and spiritual environments. The purpose of treatment of body, mind and soul are considered integral. Various health care practices are imbibed in religious, social, cultural and ritualistic aspects of the living tradition of India. For health and longevity, a state of equilibrium and harmony must be maintained with our immediate environment as well as with the functioning of the cosmos.

The human being lives as a 'host' in a symbiotic relationship with other organisms or 'agents' and the 'environment'. It is believed that generally one becomes prey to external attacks and causation of disease when inner harmony and balance is lost due to neglecting health leading to weakening of host defences. An illness is also not considered limited in space and rime and it never occurs by chance. It is due to an accumulated effect of disharmony and imbalance within an individual over a period of time; and this time period may be beyond the limited span of one life.

Ayurveda therapy is divided into three parts:

a) Rational;

b) Psychological; and

c) Spiritual.

Rational therapy consists of a rational administration of diet and drugs. It also includes instructions on nutrition, external hygiene, internal purification, various drugs to re-establish inner equilibrium and to get rid of external attacks, if any.

Psychological therapy is done by the use of the power of the mind to enhance the process of healing. A patient is directed to help oneself in this process. The important factor in this therapy is to make the patient 'know' and feel the ailment, to develop a relationship with it and then use the will power to prevent the causing factors and participate in the healing process.

Spiritual therapy consists of the recitation of ***mantras***, religious percepts invoking blessings, rendering oneself to god, offerings, auspicious acts, atonement, fasting, wearing gems and stones, pilgrimage and other similar acts. Through prayers, pilgrimage, the worship of various gods (which represent different forms of energy and five fundamental elements), the human consciousness recognises the cosmic power beyond the material in order to establish a connection with the limitless, timeless and endless energy.

These three types of therapies are applied simultaneously. In Ayurveda, the physiological and psychological are interlinked and interdependent and are thus treated simultaneously, unlike modern medicine where body and mind are considered separate and so are the ailments divided according to their origin.

Spiritual therapy does not exist in modern medicine; it is regarded as mere superstition. It is quite understandable as in modern medicine, the ailments are comprehended at biological and molecular level, and are treated by physical and chemical intervention. Therefore, reality beyond the material reality of the human physical form is not taken into consideration.

To achieve holistic health, the main task of health care should be to revive and develop the familial, social, religious, ritualistic and ethical aspects of life. We should create awareness for the people to use their home methods of health care and the fact that their health is their own responsibility and not always that of the doctor. We should revive this knowledge through school curriculum and the mass media. The undergraduate curriculum in Medical, Ayurvedic, Unani, Homoeopathic, Yoga and Naturopathy institutions should lay stress on the 'holistic' concepts of health.

Students from each system of medicine should be initiated into the basis of the other systems, with facility for postgraduate studies in the other systems so as to integrate their knowledge and promote the practice of health care offering the best from each system of health, promoting increasing use of drug-free and natural modalities of health, thereby minimising iatrogenesis, cutting down on the cost and need for sophisticated technology, making health care simple, effective, economical and acceptable and accessible to all the people.

In China, non-drug natural therapy plays a significant role in primary health care. Much of the treatment used in primary care is based on traditional medicinal plants and, when needed, modern drugs are also made available. Non-drug therapy, however, place a very important role and includes Acupuncture and its various modalities like Moxibustion, Acupressure, Reflexotherapy, Massage, Heat, Cupping, Magnetotherapy, Hydrotherapy, Remedial Exercises and Controlled Breathing. The use of ancient techniques of traditional Chinese medicine are used on a very large scale in modern China in everyday health care. They are not restricted to hospitals or health centres but form part of the general way of life of the people, as in the case of Qigong and Taiji, which have beneficial effects on health. Though not of medical origin, they are very much a part of regular medical practice.

It is a pity that our health care delivery system has not made use of this tremendously successful example at national level in our neighbourhood.

To achieve "Health for All" in our country, non-drug components of Ayurveda, Yoga and Naturopathy along with various modalities of Acupuncture must be introduced at the primary health care. Acupuncture has attracted very wide interest and is being practiced worldwide. Acupuncture can be infinitely complicated and requires great skill and experience to be used at its best, but has also been adapted arid simplified to the point where it can be used to good effect by health personnel with relatively elemental training in a limited way.

Simultaneous availability of medicinal herbs, and that of modem drugs for appropriate use will optimise the primary health services. It will enable an enhanced level of primary health and ensure timely cure of most of illnesses, thereby restricting morbidity and mortality significantly, while relieving the tremendous burden on the secondary and tertiary health care services, thus enhancing their performance too.

2.7 TRAINING AND SUPPORT

You are aware that India has a very wide base of trained medical personnel in the various systems of health registered with their respective councils i.e. Modem Medicine, Ayurveda, Unani, Homoeopathy, Yoga and Naturopathy. Following recognition by Government of West Bengal, the system of Acupuncture must be recognised by the Government of India.

In order to achieve "Health for All", a vigorous nationwide time-bound programme should be launched to create public awareness at all levels on the need and benefits of the health of body-mind-soul, with stress on primary health, promotion of public health measures and development of natural drug-free methods of treatment.

2.7.1 Education System

At school level and pre-university level, health education including civic, ethical, moral and spiritual aspects should be given due importance in the form of a compulsory subject.

2.7.2 Medical and Paramedical Education

All paramedical personnel and undergraduate students of the various systems of medicine should be introduced to the 'Science' of all the other systems, so as to enable them to develop a comprehensive outlook, especially by the natural modalities of health and healing.

2.7.3 Post-graduate Specialisation

The graduates of various systems of medicine should be encouraged to undertake post-graduate training in other systems of medicine as well, especially in non-drug or natural methods of treatment, e.g., Yoga, Naturopathy and Acupuncture should be encouraged as they can integrate with any other system of medicine to enhance the efficacy, acceptability and professional satisfaction of the practitioner.

The respective councils should offer post-graduate certificate/diploma/degree courses to such students. A doctor with basic qualification in any system of medicine with post-graduate qualifications in other systems of medicine with comprehension of health as a state of positive physical, mental, social and spiritual well-being should be termed a specialist in Holistic Medicine. Employers should give adequate incentives to such doctors and promote the concept of managing various diseases by drug-free, natural and conservative techniques. Medicinal and surgical modalities must be made available for use with total discretion. Similar incentives should also be applicable to other categories of medical and health care personnel.

2.7.4 Primary Health Care

A PHC managed by staff trained in Holistic Medicine would be far more versatile and efficacious in delivering its objectives. It would be able to achieve the objectives of promotion of health, prevention of disease, timely cure, limitation of disability and even offer adequate rehabilitation within tho limited resources of equipment and drugs. This would enable more cost-effective and reduced per capita expenditure on patient care, while bringing in a far greater sense of professional satisfaction and achievement amongst the staff.

2.7.5 Secondary and Tertiary Health Care

Secondary and tertiary health care in our country is almost entirely managed by the modern medical system. It would far more efficacious if the management of various acute and chronic diseases was done by physicians and surgeons with holistic temperament and training.

It would become possible to even permanently cure a majority of patients suffering from conventionally incurable diseases that need life-long medication with progressive deterioration and unavoidable complications.

It shall, thus, lead to reduce morbidity, restore a large percentage of such population to normal health and productivity, while relieving the nation of their medical burden.

2.7.6 Logistics of Training

The well developed training infrastructure of various systems should be used to train doctors already qualified in other systems of medicine, broadening their understanding and skills, while simultaneously understanding their scope and developing respect for the other systems. The knowledge and skills thus gained would "synergise" their professional acumen for improved patient care and eventually better health of the nation. This would also lead to higher professional satisfaction and self-esteem.

2.7.7 Economics of Holistic Medicine

The expenditure incurred on training of health care personnel would be a permanent national asset. By the increased use of natural modalities in health management, the reduced cost of health care would simultaneously lead to significantly reduced morbidity and mortality, it would lead to better national health, productivity and thereby national pride.

Cheek Your Progress 3

1) List the levels where training is recognised for holistic medicines.

.....

.....

2.8 LET US SUM UP

In this unit you have learnt that the leading cause of failure of "Health for All by 2000 AD" has been due to almost total reliance of the health care services on the modem system of medicine. While it was appreciated right in the beginning of the Alma-Ata Declaration that it would be essential to indigenise the health care services with due support from traditional systems of medicine to achieve the laudable objective, primary health care services remained largely confined to the modem system of medicine.

You also learnt that the recommendation of WHO to include 'spiritual' well-being as the fourth dimension to the definition of health as a state of positive physical, mental and social well-being, and not nearly absence of disease has to be incorporated in spirit into our scientific understanding of practice of medicine to achieve desired health objectives and control morbidity and mortality in the world.

Further you learnt about the lesson from the successful Chinese example which has its trusts in traditional Chinese medicine. Similarly, the abundant reliance of Indian population in its traditional, cultural, religious and spiritual practices need to be incorporated into our health care delivery system. The synergy between scientific knowledge of modern medicine with traditional wisdom of ancient systems of

health, with more reliability on the drug-free natural modalities of Ayurveda, Yoga and Acupuncture in health and healing offer an optimum solution to achieve human longevity and health.

Towards the end you learnt that the concept of Holistic Medicine aimed at achieving health of the individual 'Body-Mind-Soul', as far as possible by natural means, deserves increasing priority of health care strategies in future to achieve effective, efficacious, acceptable, affordable and accessible objectives. To achieve this objective it shall be essential to train and develop personnel dedicated to Holistic Medicine for health care services in the country.

2.9 ANSWERS TO CHECK YOUR PROGRESS

Check **Your Progress 1**

1) Sodhana is given higher importance for the following reasons:
   - It prevents the development of morbidity.
   - It impedes the further development of the disease.
   - It cures the manifest disease.
   - It prevents the reoccurrence of the disease.

2)
   - **Proper Exercise:** Acts as a lubricating routine to the joints, muscles, ligaments, tendons, and other parts of the body by increasing circulation and flexibility.
   - **Proper Breathing:** Aids the body in connecting to its battery, the solar plexus, where tremendous potential energy is stored. When tapped through specific Yoga breathing techniques (Pranayama), this energy is released for physical and mental rejuvenation.
   - **Proper Relaxation:** Cools down the system. When the body and mind are continually overworked, their efficiency diminishes. Relaxation is Nature's way of recharging the body.
   - **Proper Diet:** Provides the correct fuel for the body. Optimum utilization of food, air, water, and sunlight is essential.
   - Positive Thinking and **Meditation:** Puts you in control. The intellect is purified. The lower nature is brought under conscious control through steadiness and concentration of the mind.
   - Cleansing techniques or 'Shuddhi Kriyas': Clean the various internal organs of the body by using various techniques such as Neti, Dhouli, Basti, Tratak, Nauli and Kapalbhati.

3) According to the philosophy of nature cure or naturopathy, the origin of all diseases is an accumulation of toxins in the body. And the disease is that state in which the body tries to expel those toxins, which it could not expel in its normal condition and through its normal processes.

4)
   - Chronic diseases
   - Degenerative conditions
   - Autoimmune diseases such as rheumatoid arthritis
   - Disorders of the central nervous system such as hemiplegia
   - Viral infections such as hepatitis and herpes

- Prevention of heart diseases, etc.

5) a) *Ilaj hit-tadbeer* (regimental therapy): This therapy includes venesection, cupping, diaphoresis, diuresis, turkish baths, massages, cauterization, purging, emesis, exercise, leaching ctc.

b) *Ilaj bil-ghiza* (dietotherapy): Dietotherapy aims at treating certain ailments by administration of specific diets or by regulating the quantity and quality of food.

c) *Ilaj bid-dawn* (pharmacotherapy): It deals with the use of naturally occurring drugs, mostly herbal, though drugs of animal and mineral origin are also used. Single drugs or their combinations in a raw form are preferred over compound formulations. The materia medica of Unani medicine is vast and most of the drugs are easily available. They are free from side effects. Drugs that are toxic in the crude form are processed and purified many times before use.

d) *Jarahat (surgery)*: When *all* other therapeutic measures fail, surgery is resorted to.

6) The six paired channels arc:

a) Lungs and Large Intestines

b) Spleen and Stomach

c) Heart and Small Intestines

d) Kidneys and Urinary Bladder

e) Pericardium and Sanjiao

f) Liver and Gall Bladder

7) a) Analgesic (pain-relieving): It is used to relieve the pain of arthritis, toothache, headache, low backache and other similar painful disorders.

b) Sedation: The needling of certain specific acupuncture points has a sleep-inducing effect. This effect is used in the treatment of insomnia, anxiety state, addictions, epilepsy, and mental disorders.

c) Homeostatic (regulatory): This is the most important feature of acupuncture. It is an adjustment of the internal environment of the body towards the state of normal balance. It is achieved by balancing the activity of the sympathetic and parasympathetic divisions of the autonomic nervous system and also the endocrine system, by needling specific points.

d) **Immune Enhancing:** The body resistance to disease is strengthened. There is an increase in the white blood cells, antibodies, gamma globulins and other substances. Thus, acupuncture is useful in combating infections.

e) Psychological Effects: Acupuncture has a calming and tranquillizing effect.

f) Motor recovery: It hastens the motor recovery in patients who have become paralysed from some cause or another.

Check Your Progress 2

1)
- Extension of each other in their science and philosophy.
- Purely natural and easier on logistics.
- Devoid of any iatrogenesis.

2) It aims to restore the health and harmony of the human being (Body-Mind-Spirit) as a whole entity encompassing physical, mental, social as well as spiritual well-being.

   Holistic Medicine would also aim at promoting health in all its dimensions and at various levels, as far as possible by natural (non-pharmaceutical and surgical) means, in consonance with the Indian psyche and as per health care practices imbibed in religious, social and ritualistic aspects of life.

3) It will enable an enhanced level of primary health and ensure timely cure of most of illnesses, thereby restricting morbid and mortality significantly, while relieving the tremendous burden on the secondary and tertiary health care services, thus enhancing their performance too.

Check You Progress 3

1) a) Education system
   b) Medical and paramedical education
   c) Post-graduate specialisation
   d) Primary health care
   e) Secondary and tertiary health care

2) The knowledge and skills gained would "synergise" their professional acumen for improved patient care and eventually better health of the nation. This would also lead to higher professional satisfaction and self-esteem.

UNIT 3 HEALTH AND POPULATION POLICY AND STRATEGIES

Structure

3.0 OBJECTIVES

After going through this unit, you should be able to:

- describe the need for health policy;
- list of elements of National Health Policy;
- list the National Goals for Health for All by 2000 AD;
- outline the features of population policy statements; and
- identify future strategies for population control.

3.1 INTRODUCTION

This unit describes the needs for National Health Policy (NHP). It gives in detail the various elements of NHP. In the end various health goals to be achieved for attaining Health for All by 2000 AD are given along with level prevailing at the time of policy formulation.

This unit also deals with National Population Policy. It describes the population problem, existing population policies and the one recommended for future by an expert committee.

3.2 NATIONAL HEALTH POLICY

You will agree to that the policies provide framework for accomplishment of the objectives to be achieved. You must also be aware of that each country evolves its policies in light of the problems to be tackled. In the absence of a well-designed policy, tackling the problems become difficult and may result in the wastage of men, material and money. The policy prescribes the aims, objectives and the targets that would be used to achieve the objectives operationally. It specifies the expected

that would be used to achieve the objectives operationally. It specifies the expected results, the measures for achieving them and mechanisms or methods to be adopted. Succinctly, it refers to that aspect of administration, which is considered to define the objectives and determining the choice of action.

Health has been a major problem in India during the British regime, who did not pay any serious attention to improve the health standards of the people. Realising the gravity of the situation, the framers of the Constitution have made a specific mention that the state shall regard the raising of the level of nutrition and the standard of living of its people and the improvement of public health are among its primary duties. But unfortunately, till 1983 National Health Policy was not formulated and health programmes and schemes were implemented as a part of the National Five Year Plans.

The fragmented approach in the sphere of health by the Government of India exposed many shortcomings and the problems like increasing rate of population growth, high mortality rate of women and children, low nutritional standards, widespread communicable diseases, poor sanitation and non-availability of potable water to the majority of population. This prompted the government to formulate a comprehensive national health policy that could serve the actual health needs and priorities of the country. It was in this context the National Health Policy was evolved by the Government of India in the year 1983.

3.2.1 Elements of National Health Policy

In this sub-section you will learn about the important elements of National Health Policy. However the detailed policy document is given at Annexure-1. The preamble of National Health Policy document describes the progress achieved and existing health picture at the time of formulation of policy. It makes mention of considerable achievements made in reducing mortality and increasing life expectancy. However, the demographic and health scenario still has many foci for serious concern and fertility decline is not commensurate with mortality and annual growth rate is alarmingly high. Further mention has been made about high maternal mortality, high infant mortality (12911000 live births) and high child mortality (113 of total deaths below 5 years of age) besides the presence of chronic infectious diseases like Tuberculosis and Leprosy. The document further describes the dismal picture of water and sanitation facilities. It states that only 31% of rural population has access to safe water and just 0.5% of population has basic sanitation. Diarrhoea, Pneumonia and Measles keep on threatening tender lives. It has been realised that we need to identify and prioritise problems and amicably solve them in a time bound programme. Following are the elements of National Health Policy:

1) Problems Requiring Urgent Attention

The policy document has identified the following problems, which require urgent attention for improvement of overall health of people:

a) Nutrition: Policy document in reference to nutrition recommended the following:

   i) Formulation of a National Nutrition Policy with regional strategies.

   ii) Improving nutritional status of people particularly in rural areas and urban slums through well-developed public distribution system.

   iii) Increasing purchasing power of people by ensuring employment generation schemes.

   iv) Promoting low cost locally available nutritious foods.

   v) Improving nutritional practices through nutrition education.

vi) Promoting and supporting breast-feeding.

vii) Developing special schemes for supplementary nutrition of vulnerable sections like pregnant women, children and weaker sections in rural areas and urban slums.

viii) Attending to chronic nutritional problems like anaemia, iodine deficiency disorders and malnutrition through supplementation, fortification and enrichment.

b) **Preventing food adulteration and maintenance of drug quality:** The health policy stresses to enforce stringent action against:

i) Food adulteration and contamination at the level of production, processing, storage, transport and distribution.

ii) Manufacture, sale and distribution of spurious of substandard drugs, through enforcement and review of existing laws.

c) **Water** supply **and sanitation:** The policy recommends integration of safe water supply and sanitation with intensive health education for improvement in personal hygiene efforts towards economic use of water and sanitary disposal of wastes and excreta.

d) **Environmental protection:** For preventing ecological disturbances leading to fresh health hazards, following have been recommended in the policy document:

i) All economic development plans should be made in consultation with health professionals.

ii) Review of existing industrial and urban development plans to avoid congestion and unchecked release of harmful effluents and gases.

iii) Strict legislative regulations before clearing projects in future.

e) **Immunization:** The NHP suggested to launch a nation-wide programme aimed at cent per cent coverage of target groups i.e. children and pregnant women with vaccine against preventable communicable diseases.

f) **Mother and child health services: As** stated earlier, relationship of a high birth rate with high IMR has been recognised. The NHP accords highest priority to mother and child **health (MCH)** services focusing on under-served sections of the society. These services should be available as an integrated package at primary health centres on essential basis nearest to the doorsteps of beneficiaries. At present Traditional Birth Attendants may be provided orientation and refresher courses. However, for long-term benefits action should be taken to ensure that progressively all deliveries are conducted by competently trained persons.

g) **School Health Programme:** Policy lays emphasis on the health of school going children and recommends that organised school health services integrally linked with general health services to be established within a time frame.

h) **Occupational Health Services: With regard to** occupational health services, NHP document mentions that occupational hazards not only in industries but also in unorganised sectors like agriculture exist which needs to be minimised and attended timely of avert fatalities, restrict disabilities and reduce loss of man days. For this to extend the coverage of Employee State Insurance Act (ESI) of 1948 has been suggested. The centre and states

both must introduce organised occupational health services to promote health and welfare besides increasing productivity.

2) Population Stabilising

Small family norm has been recognised as a key factor in improving the health status. In view of this formulation a separate national population policy has been recommended.

3) **Provision** of **Primary Health Care**

It has been observed despite the rural character of country and shortage of resources, there is disproportionate distribution of resources on urban-based curative services. To ensure universal access, provision of primary health services has been recommended. These should be linked to a strong referral network. This will ensure optimal utilisation of expertise at higher levels.

To ensure integrated delivery of package of services establishment of nation-wide chain of sanitary-cum-epidemiological station has been recommended. These should be located between primary and secondary levels. These stations would participate in the integrated action plans to eradicate and control diseases, besides tackling local environmental health problems.

4) Medical and Wealth Education

Taking cognisance of the fact that effective service delivery would largely depend on education training and skills besides orientation of all cadres of health workers towards community health and also that the western models can't work, it is necessary to provide need based training. It, therefore, needs major changes in cumculum and training programmes to develop health workers with enough skills to deliver services within present constraints. Therefore, formulation of a National Medical and Health Education Policy has been recommended.

For reorientation of existing medical and health personnel the policy suggests a positive approach based on innovation and dynamism to ensure 'Health Team' approach in work.

5) Role of Practitioners of Indigenous **and** other Systems **of Medicine**

NHP acknowledges the relevant scientific contribution of ISM and mention that a large number of practitioners of ISM do exist without due official cognisance and census. The trust and confidence besides their local acceptance can be utilised to influence health related beliefs and practices of people. The NHP, in order to tap this potential, propounds the following:

i) Organised efforts to develop and support: these systems according to their stature and genius.

ii) Integration of the functioning of practitioners of ISM with existing system, maintaining their identity, to deliver 'preventive and promotive health services.

iii) Meaningful phased integration of ISM with modem system.

6) Health Education

NHP recognises the need for minimal level of awareness about health and health related issues among general population and calls for nation-wide health education programmes, backed by appropriate communication strategies to develop healthful behaviours.

7) Management Information System

You know that information complimented by experiences helps in planning. For this a good efficient manageable and easily retrievable Health Information System (HIS) not only timely warns but also helps in monitoring and evaluation. For this information should flow both ways, form top-to-bottom and bottom-to-top, on a regular basis. The policy document recommends the need for development of an effective Management Information System.

8) Medical Industry

Policy document states that the sound technical competence and manufacturing capability build over years, in the field of drugs, vaccines and biomedical equipment, needs to be exploited to its maximum particularly in relation to national programmes like malaria, tuberculosis, leprosy, blindness and immunisation. The production of essential drugs under generic names and economical packaging would reduce the unit cost. Also promoting the indigenous capacity to manufacture essential diagnostic equipment is to be built.

9) Health Insurance and Legislation

In order to mobilise social and community resources policy document emphasis the need of a well-conceived health insurance scheme that can ensure people sharing the cost. The health policy stresses the need to review existing health legislation particularly in relation to their enforceability.

10) Medical Research

In the policy document, high priority has been accorded to applied, operational research, including action search for continuously improving the cost effectiveness of delivery of health services. Identified with high priority areas in basic research are contraceptives, more effective therapeutics and preventive measures for communicable and other common diseases.

3.2.2 National Health *Policy-Indicators* and *Goals*

You have already learnt that India is committed to attain the goals of HFA by 2000 AD through Primary Health Care approach. In order to achieve this goal, the policy document has identified certain indicators and laid certain time bound targets with respect to these indicators.

Goals for Health and Family Welfare Programmes

Sl. No.	Indicator	Current Level	Goals		
			1985	1990	2000
1	2	3	4	5	6
1.	Infant mortality	Rural 136 (1978)	122		
		Urban 70 (1978)	60		
		Total 125 (1978)	106	87	Below 60
	Perinatal mortality	67 (1976)			30-35
2.	Crude death rate	Around 14	12	10.4	9.0
3.	Pre-school child (1-5 yrs.) mortality	24 (1976-77)	20-24	15-20	10
4.	Maternal mortality rate	4-5 (1976)	3-4	2-3	Below 2
5.	Life expectancy at birth (yrs.)	Male 52.6	55.1	57.6	64
	below 2500 gms. (percentage)	30	25	18	10
6.	Crude birth rate	Around 35	31	27.0	21 0

1	2	3	4	5	6
7.	Effective couple protection (percentage)	23.6 (March 82)	37.0	42.0	60.0
8.	Net Reproduction Rate (NPR)	1.48 (1981)	1.34	1.17	100
9.	Growth rate (annual)	2.24 (1971-81)	37.0	42.0	60.0
10.	Family size	4.4 (1975)	3.8		2 3
11.	Pregnant mothers receiving antenatal care (%)	40-50	50-60	60-75	100
12.	Deliveries by trained birth attendants (%)	30-35	50	80	100
13.	Immunisation status (% coverage)				
	TT (for pregnant women)				
	TT (for school children)				
	10 years		40	100	100
	16 years	20	60	100	100
	DPT (children below 3 years)	25	70	85	85
	Polio (infants)	5	50	70	85
	BCG (infants)	65	70	80	85
	DT (new school entrants)	20	80	85	85
	Typhoid (new school entrants 5-6 yrs.)	2	70	85	85
15.	Leprosy—permitage of disease arrested cases out of those detected	20	40	60	80
16.	T.B.—percentage of disease arrested cases out of those detected	50	60	75	90
17.	Blindness—incidence of (%)	1.4	1	0.7	0.3

f) Couple protection rate	.....
g) Deliveries by trained birth attendant	.....
h) Prevalence of blindness	.....

3.3 POPULATION POLICY

A disproportionate decline in mortality as compared to fertility is often put forth as the logic towards high growth rate. Even in mortality it is the crude death rate which has declined substantially (from 47.2/1000 in 1911-21 to 10.3 in 1991) while decline in child mortality has been relatively slow (IMR 222 in 1901-11 to 78 in 1991). Historically the sex ratio has always been adverse to females for many reasons such as illiteracy, early marriage, teen-age pregnancies, violence against women etc. The declining sex ratio—972 in 1901,930 in 1971,933 in 1981 and 929 in 1991, particularly during last two decades is matter of concern. The uneven progress of states is also a shot in the arm. The four states (UP, MP, Rajasthan and Bihar) contributed 42% of the net increase in population during 1981-91. Despite a clear recognition of problem and in spite of enjoying "first" population control programme, the population growth remains a formidable challenge. Drafts and documents on population policy have generated discussions only, waiting to get translated into a formal population policy to be approved by the parliament. With this background *you* will learn about the population policy—genesis, issues, approaches and future perspectives.

You must be aware that the national family planning programme was launched in 1951 starting with a clinical approach emphasis being on conventional contraceptives. The family planning research and programme committee observed in May 1953 that tubectomy was the most favoured method. The expectation was that growth rate would continue at 1.25% annually during First and Second Five Year Plans. In different Five Year Plans the goals of reduction of birth rates were set. Under Fifth Plan (1974-79) family planning was integrated with MCH services and birth rate was targeted to be reduced to 30 (1978-79) and 25 (1983-84). Subsequently in *NHP* (1983), the demographic goals were delineated.

3.3.1 Population Policy Statements—1976 and 1979

The philosophy underlying a population policy was conscious education for all to accept the small family norms on a voluntary basis goals of population policy were to stabilise the population and disrupt the quality of life.

April 16, 1976 and the issue of a national policy on population crossed a milestone when the first draft statement was placed in the parliament by Dr. Karan Singh.

Some of the salient features of which were:

a) Implementation of minimum needs programme.

b) Education and economic development are crucial but waiting for them is not a practical solution as time factor is too pressing and population growth so formidable.

c) The family planning programme has not made desired progress,

d) Raising the age of marriage will have demonstrable demographic impact.

e) Adoption of small family norm is vital.

f) Voluntary organisation *can* contribute effectively.

g) Research in reproductive health and contraceptive technology can strengthen 'cafeteria' approach.

h) Multi-media motivational strategy can work. On these premises the draft suggested certain approaches which were approved in the parliament and are given here:

i) Freezing the representation of states in the parliament until year 2001 on the basis of 1971 census population.

ii) 1971 population to be the basis of central assistance, devolution for taxes and grants-in-aid to states till 2001.

iii) 8% of central assistance to be linked to the state's performance in family planning.

iv) Monetary compensation to couples adopting terminal methods shall be linked to number of living children.

v) Compulsory sterilisation after 3 children in case the State feels it has enough legislative powers and enforcement structure.

vi) Raising the age of marriage--18 years for girls and 21 years for boys.

vii) Research on reproductive biology and contraception.

viii) Introduction of group incentives in a bold and innovative manner to make family planning a people's movement.

ix) Promotion of multi-media, rural-oriented communication strategy.

x) Including population education in the education system.

xi) Increasing level of female education particularly above middle level through formal and non-formal education.

xii) Involvement and support of voluntary organisations.

The statement of policy with regard to population was announced by the Janata Govt. in June 1979 and changed the nature of programme from family planning to welfare. The new policy statement was almost similar on major issues to that of the earlier one which was issued in 1976. Some of the major issues included:

a) Raising the minimum age of marriage.

b) Linkage of central assistance to states with performance in family welfare work.

c) Raising the level of female literacy.

d) Target of bringing down birth rate to 25 by the end of Seventh Plan.

e) Involvement of all ministries in the programme.

f) Continuing of monitory compensation for sterilisation operation. It was categorically stated that there would be no room for coercion or pressure of any sort. The government was not in favour of any disincentives.

The working group, appointed by Planning Commission, on population policy in 1978 proposed a long-term objective of attaining Net Reproduction Rate (NRR) of

unity by 1996 on an average and by 2001 for all states (a clear shift in priority from decreasing CBR to NRR). National Development Council approved it and incorporated the expected correlates of goal in terms of CDR, CBR, IMR and CPR.

With national health policy, approved in 1983 following demographic goals were enunciated to be achieved by the year 2000 AD.

NRR	1
Birth rate	2111,000 population
IMR	Below 6011,000 live births
CPR	60%

Life expectancy of 64 years (for both the sexes): According to progress made so far and existing rates, indications are that we may not be able to achieve the goal (NRR-1) till 2006-11, as stated in the 7th document. The Seventh Plan, therefore, set the targets to be achieved by 1990 as CPR 40%, CBR 23.1, CDR – 10.4 and 90.

3.3.2 Revised Strategy for Family Welfare

Based on the operational research studies the Government revised the strategy of family welfare in 1986. The ministry decided to adopt the following approaches and strategies beyond and within the family planning measures.

a) Beyond Family Planning Measures
   i) Increasing the mean age of marriage
   ii) Raising the status of women
   iii) Raising the literacy rates among females
   iv) Enhancing child survival and development
   v) Alleviating the poverty of the people
   vi) Ensuring old age security

b) Within Family Planning Measures
   i) Energising the existing infrastructure
   ii) Augmentation of the infrastructure
   iii) Upgrading the technical services and follow-up care
   iv) Integrated family planning in the health cart: system
   v) Generating demand for family planning services
   vi) Involving voluntary organisations to make it a people's programme
   vii) Providing family planning services as near to people as possible
   viii) Making available the contraceptives freely and widely in both urban and rural areas

3.3.3 Population Policy—Future Perspectives and Prospects

Following the approaches of present policy statements limited success has been achieved. Recognition of the fact that small family norm adoption and reaching NRR of unity is vital for population stabilisation. Government of India initiated the appointment of a committee on population by National Development Council (NDC) in 1991, which recommended that a national population policy be formulated and approved by the parliament at the earliest.

The NDC on July 13, 1993 ascribed this task to an expert group under the chairmanship of Dr. M.S. Swaminathan. The group submitted the policy draft on May 23,1994 to Ministry of Health and Family Welfare. The draft deliberated over the issue under two heads—policy framework and implementation measures. The observations and recommendation of the group are summarised below:

a) Declining sex ratio is a warning signal—gender equity and women empowerment integrated with health and family welfare can help reverse this ratio.

b) There is an in-built momentum for growth in present age structure and current levels of fertility. The empowerment and enabling environment can help reach the goal of TFR of2.B by 2010.

c) Speedy and effective implementation of Minimum Needs Programme (MNP).

d) Formation of a population and social development committee (PSDS) at district and state level which would ensure:

- Preparation of a socio-demographic charter
- Convergence of ongoing programmes
- Availability of acceptable contraceptive methods
- Priority based, area-specific approaches.

e) At the national level proposed changes are:

- merger of MCH and FW with health
- no targets and no incentives
- elimination of all kinds of discrimination against women
- involvement of voluntary organisations in policy, planning and implementation and extending authority and autonomy to be innovative within norms and resources
- monitoring and evaluation by Population and Social Development Commission (PSDC) at national level
- reproductive research with ethical considerations

IEC to have supportive role facilitating informed decisions

- decentralised locally relevant use of multi-media communication strategies.

f) The suggested national socio-demographic goals for the year 2010 will be as follows:

i) Reduction in number of marriages below 18 years in girls to zero.

ii) Reducing MMR to less than 1001100000 live births.

iii) Universal child immunization and prediction in incidence of diarrhoeal and ARI diseases.

iv) Reduction in IMR to 3011000 live births also in child mortality and incidence of low birth weight.

v) Universal access to information on contraceptives.

vi) Containment of AIDS and other STDs.

vii) Full coverage of registration of births, deaths and marriages.

viii) Laying guidelines for foreign aided population programmes.

ix) Strengthening research.

x) Preparing report on population and social development.

Recently National Population Policy has been approved by the parliament and National Commission on Population has been constituted under the chairmanship of Prime Minister. The commission will oversee and review the implementation of policy. National Population Policy-2000 document is given in Annexure-2 for your reference.

3.4 LET US SUM UP

In this unit you have learnt that the fragmented approach in health, despite planning process initiated in 1951, helped to achieve a considerable reduction in mortality. The global goal of HFA-2000 through primary health care along with the strong political commitment led to formulation of NHP in 1983 considering the issues like reorientation of medical education and restructuring of health services. Due priority was given to MCH, nutrition, immunisation, water and sanitation and health education. Accordingly output indicators were identified and goals set to be achieved in a phased manner.

You also learnt that growing population and declining sex ratio alarmed the policy makers. Ours was the first country to address population problem through a national programme way back in 1951 and consequently realised that the adoption of small family norms was vital to development, but had limited success. The need to have a population policy came up. Draft documents on population policy in 1976 placed before parliament focussed on regulating fertility through increasing age of marriage, female literacy, reduction in IMR, contraceptive method mix availability. The 1979 policy stressed on informed decisions on voluntary basis. The uneven progress among states led to freezing of states representation in parliament and central assistance to states on the basis of 1971 census population till the year 2001. Role of voluntary organisations, NGOs, professional bodies and organised sector was realised to make it a people's movement.

Towards the end of the unit you have learnt the future perspectives and prospects of population policy including formulation of National Population Policy-2000 and constitution of National Commission on Population under the chairmanship of Prime Minister.

• teenage pregnancies
• reduction in IMR
• evidence against women

3) • Raising the minimum age of marriage
• Linkage of Central assistance to states with performance in family welfare work
• Raising the level of female literacy
• Target of bringing down birth rate 25 by the end of VIth plan.
• Continuance of monitory compensation for sterilisation operation.
• Voluntary nature

4) Attaining NRR of unity (1)

5) Beyond family planning measures are:
i) Increasing the mean age of marriage
ii) Raising the status of women
iii) Raising the literacy rates among females
iv) Enhancing child survival and development
v) Alleviating the poverty of the people
vi) Ensuring old age security.

National Health Policy, 1983

Introductory

1. The Constitution of India envisages the establishment of a new social order based on equality, freedom, justice and the dignity of the individual. It aims at the elimination of poverty ignorance and ill-health and directs the State to regard the raising of the level of nutrition and the standard of living of its people and the improvement of public health as among its primary duties, securing the health and strength of workers, men and women, specially ensuring that children are given opportunities and facilities to develop in a healthy manner.

1.2 Since the inception of the planning process in the country, the successive Five Year Plans have been providing the framework within which the States may develop their health services infrastructure, facilities for medical education, research, etc. Similar guidance has sought to be provided through the discussions and conclusions arrived at in the joint conferences of the Central Councils of Health and Family Welfare and the National Development Council. Besides, Central legislation has been enacted to regulate standards of medical education, prevention of food adulteration, maintenance of standards in the manufacture and sale of certified drugs, etc.

1.3 While the broad approaches contained in the successive Plan documents, and discussions in the forums referred to in 1.2 may have generally served the needs of the situation in the past, it is felt that an integrated, comprehensive approach towards the future development of medical education, research and health services requires to be established to serve the actual health needs and priorities of the country. It is in this context that the need has been felt to evolve a National Health Policy.

Our Heritage

2. India has a rich, centuries-old heritage of medical and health sciences. The philosophy of Ayurveda and the surgical skills enunciated by Charaka and Shusharuta bear testimony to our ancient tradition in the scientific health care of our people. The approach of our ancient medical system was of a holistic nature, which took into account all aspects af human health and disease. Over the centuries, with the intrusion of foreign influences and mingling of cultures, various systems of medicine evolved and have continued to be practised widely. However, the allopathic system of medicine, has, in a relatively short period of time, made a major impact on the entire approach to health care and pattern of development of the health services infrastructure in the country.

Progress Achieved

3. During the last three decades and more, since the attainment of Independence, considerable progress has been achieved in the promotion of the health status of our people. Smallpox has been eliminated; plague is no longer a problem; mortality from cholera and related diseases has decreased and malaria brought under control to a considerable extent. The mortality rate per thousand of population has been reduced from 27.4 to 14.8 and the life expectancy at birth has increased from 32.7 to over 52. A fairly extensive network of dispensaries, hospitals and institutions providing specialised curative care has developed and a large stock of medical and health personnel, of various levels, has become available. Significant indigenous

UNIT 4 DISTRICT HEALTH ORGANISATION

Structure

4.8 OBJECTIVES

After going through this unit, you should be able to:

- describe the structure and functions of district health organisation;
- explain the concept, machinery and process of decentralised district planning for health and development; and
- discuss about the district health information system and its utility.

4.1 INTRODUCTION

District as you know is the vital link in the health care delivery system of the country as it is the focal point for management of health and family welfare programmes. The purpose of this unit is; thus, to give you an insight of the District Health Organisation.

In this unit you will learn about the set-up and functioning of District Health Office, decentralised planning process at the district level and about the district health information system.

4.2 DISTRICT HEALTH OFFICE

By now, you would have become conversant that for the delivery of health care services in the country, health infrastructure has been developed at different levels, which extends from the national/central level to the village level. A detailed description of the health care delivery system has been given in Unit 1 of this block. However, a broad picture of the total organisational structure for health and family welfare programmes is depicted in the chart given on page 88.

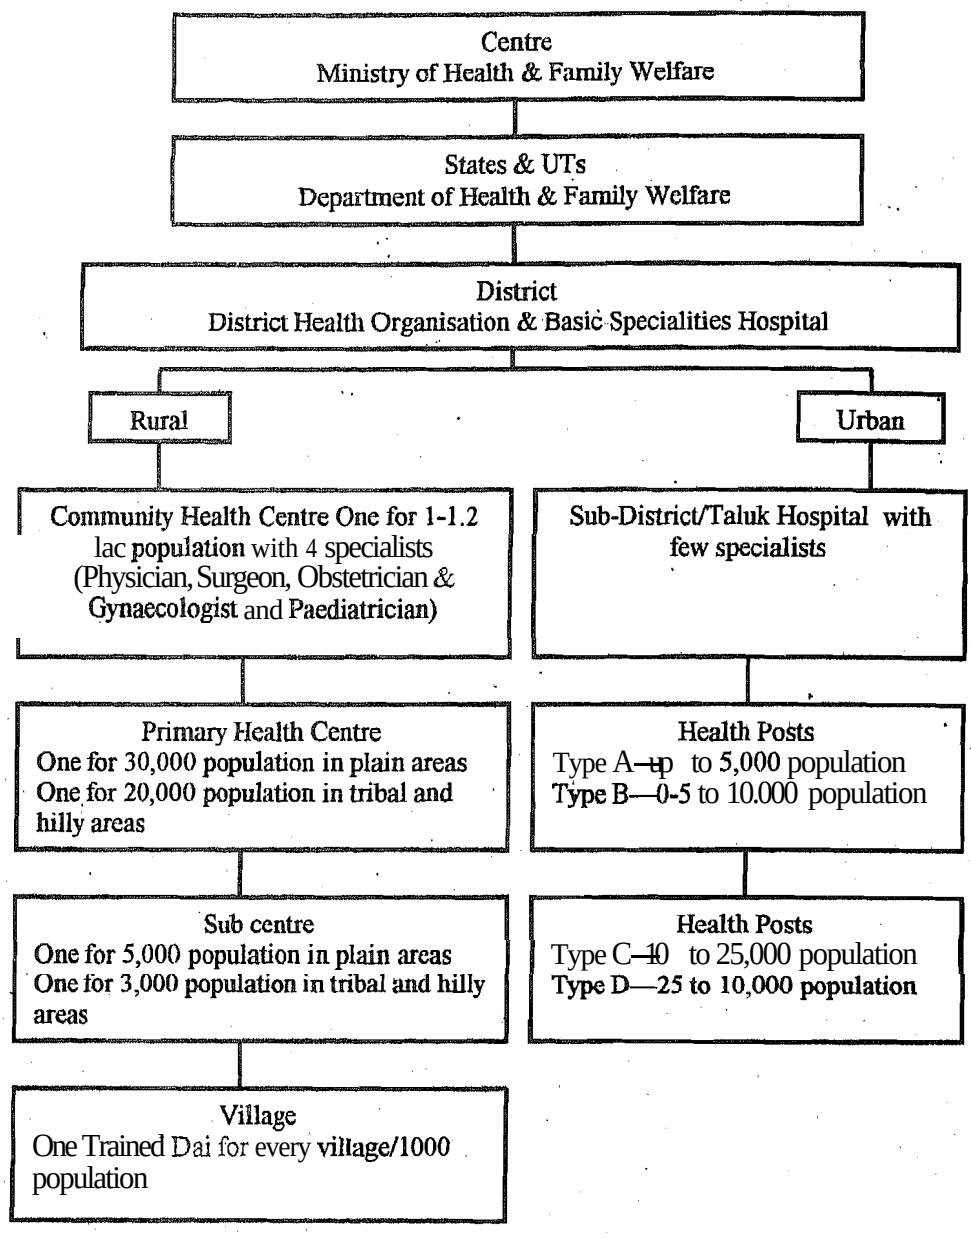

Chart 4.1: Organisational Structure for Health Care Delivery in India

4.2.1 Organisational Structure of Health Care System at District Level

The District level structure of the health care system is a middle level management organisation and it is a linkage between the state on one side and the peripheral level structures on the other side. With the implementation of multipurpose health workers scheme, a reorganisation of health care services structure has taken place. Consequently, all the health and family welfare programmes in the district have been brought under a unified charge. This district officer with the overall control is popularly known as the CMO (Chief Medical Officer). However, different nomenclatures are used in different states. Such a district officer may actually be designated as Chief Medical and Health Officer (CMHO) or District Medical and Health Officer (DMHO) or even Civil Surgeon. The district chief is assisted by Deputies/Programme Officers, whose numbers/specialisations and status in the cadre of state health services differ from state to state. Due to this, the span of control and hierarchy also varies from state to state. Since, health is a state subject; there is no uniform model of a district health organisation in India. However, each state has adopted this broad pattern with minor modifications, suiting its own requirement and also depending upon the availability of resources of men, money and material. Chart given on next page represents a general organizational structure at district level.

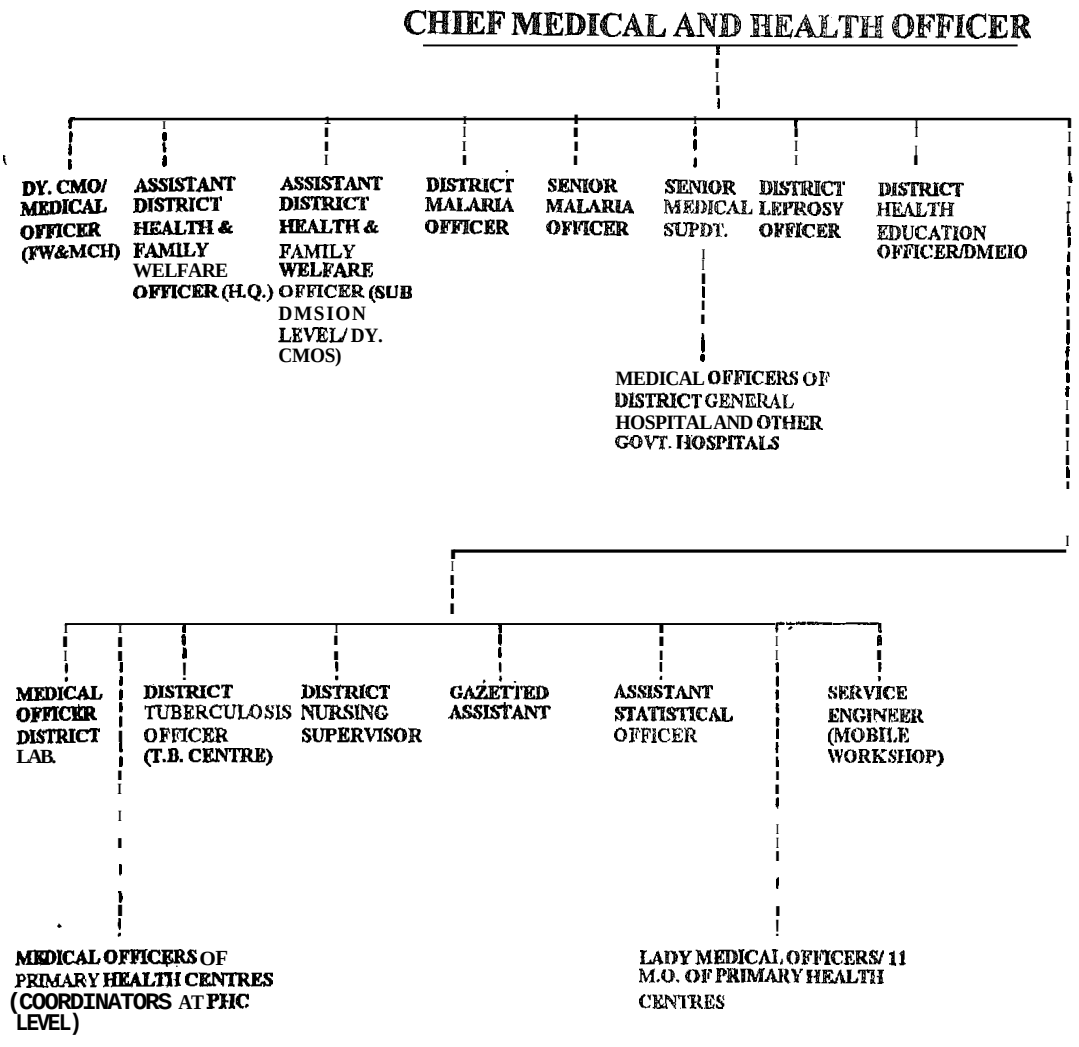

Chart 4.2: District Health Organisation

4.2.2 Functions of District Health *Office*

The Chief Medical Officer (CMO) being the supreme authority of district health care services structure who is expected to translate the broad health policies and programmes into action in the district. In doing so, the CMQ Is expected to provide direction and guidance to the peripheral health care structure in the district, Further, as a supreme authority of the district health services, the CMO is also expected to manage the structure of district as well as peripheral health care services. In addition, the CMO might also have other roles in the district development administration and its activities. Thus, the functions of CMO are several and these are inter-linked. In fulfilling his responsibilities, the CMO often delegates certain functions to other district health officials. With the adoption of multipurpose workers scheme, these deputies at the district health office have been relieved of their singular programme responsibilities and have been assigned responsibilities of supervising the activities of all the programmes in the specific areas of the district allocated to them.

The major functions of district health administration/office are to:

- arrange for the provision of health and family welfare services in the district adopting the comprehensive primary health care approach.

  integrate the preventive, promotive and curative activities prescribed under separate health programmes in a manner envisaged under the multipurpose workers scheme.

- incorporate the paradigm shift of the Reproductive and Child Health (RCH) programme by operationalising the Community Needs Assessment (CNA) approach in the district.
- make arrangements for the provision of services required statutorily e.g. medico-legal work, post-mortem, medical examination and certification, drug licensing, enforcement of Prevention of Food Adulteration (PFA) Act, registration of vital events etc.
- deal with the preventive, promotive, curative and rehabilitative activities related to natural calamities, disasters and epidemics.
- organise pre-service entry training for the para-professionals and paramedicals, and inservice training for health personnel working at different levels in the district.
- maintain liaison with Panchayati Raj Institutions, municipal bodies and other developmental and administrative departments of the district.

Check Your Progress 1

1) The chief of the District Health Organisation may be designated differently in different states viz. as .....

2) Tick the correct answer:

The deputies to the chief of the district are often given:

a) singular programme responsibilities

b) responsibilities of supervising activities of all the programmes in specific areas of the district.

4.3 DISTRICT LEVEL PLANNING AND MANAGEMENT

4.3.1 CMO's Role

In order to perform the functions assigned to the District Health Organisation in an efficient and effective manner, the chief of the district has to resort to decentralised district level planning and management. As a manager of the District Health Care Delivery System, the CMO has to perform three broad roles. These are:

1) **Interpersonal Contact Role**

a) ***Figurehead:*** By the status of their office, CMOs are required to carry out a variety of social, legal and ceremonial roles e.g. make opening remarks at meetings, signs various government forms and make themselves available to VIPs.

b) ***Leader:*** The role *that* describes CMO's interpersonal relations with his subordinates. CMOs need to motivate staff of work and give them responsibility according to *staff* competence.

c) ***Liaison:*** CMOs are responsible for relations/dealings with people outside the district health organisation. CMOs develop a network of contacts with other development sectors, district collector, local political representatives and leaders in the community.

2) **Information Processing Role**

a) ***Monitor:*** CMOs continually seek and receive information about their organisation and its services.

b) ***Disseminator:*** CMOs share information with subordinates according to what they need.

3) **Decision Maker Role**

a) ***Innovator:*** CMOs adopt innovative alternate approaches to the delivery of services and bring about changes in their organisation. CMOs anticipate problems and take initiative to solve them.

b) ***Disturbance Handler:*** CMOs take charge when the normal routine is disturbed e.g. during disaster, during intensive health campaigns, when employees strike, or when there is a breakdown of the supply line.

c) ***Resource Allocator:*** CMOs determine who will get what in their organisation and plan the distribution of health organisation resources.

d) ***Negotiator:*** CMOs may enter into negotiations with any one that affect the delivery of health services in the district.

In general, activities related to interpersonal contact, information processing and decision making are inseparable in CMO's day-today work.

Another way to look at CMO's role as district manager is:

- Planner
- Coordinator

  Facilitator
- Information processor
- Decision maker

  Supervisor
- Monitor

  Promoter of inter-personal interactions among individuals, between groups, and within the community

  Evaluator

  Communicator
- Innovator

  Motivator
- Resource provider

  Community contact maker

  Team leader

In playing his role, a CMO needs to have such qualities of leadership such as social . acceptance, empathy, capacity to inspire and motivate others particularly colleagues, subordinates, influential community groups and opinion leaders and to mobilise their commitment, ability to communicate, courage to take calculated risks and make bold decisions, take initiative and demonstrate faith in people's capabilities. He has to maintain an optimal concern for both the task as well as for the people with whom and for whom he works.

4.3.2 Decentralised District Planning: Concept and Machinery

There has been a growing recognition of the fact that there is a need to supplement the national and state health plans with a more detailed examination of the problems, resource and potentials of local areas, so that investment plans and

programmes tailored to the particular needs of each district; could be formulated and implemented. Apart from that, there has been an increasing emphasis on the involvement of people and their elected representatives in the formulation of district plan; so that such plans reflect the aspirations of the people and also fulfil the basic health needs.

In the field of health care, the district is the most peripheral unit that has comprehensive powers and responsibilities. Thus, district as a basic administrative unit, serves as a normal meeting point for bottom up community planning and top down central and state planning. In contrast to national or state level plans, the district plans present a multisectoral package of area specificity.

District planning generates a popular enthusiasm for innovation and experimentation to ameliorate the local problems. Further, it brings about involvement of people's representatives not only in the formulation of schemes but also in implementation and its follow-up, thereby ensuring a participative commitment.

District Planning Board has emerged as an effective organisation to formulate schemes and getting them implemented. It provides a forum for all sectors and organisations engaged in development work including panchayats to pool their, efforts and assist in evolving a well-coordinated and participatory approach to planning.

The District Planning Board is broad based and highly representative in character. The District Collector is its vice-chairman and the president of Zilla Panchayat as its co-vice-chairman. A Minister of the State Government is the chairman. There are 15 other categories of members consisting of lady members of Zilla Parishad, Presidents of Taluka/Block Panchayat, MPs, MLAs, Mayors of municipal bodies; officials like District Development Officer, Chief Medical Officer, etc. Associate members include representatives of voluntary organisations, Khadi Gram-udyog, Schedule Tribe Development Corporation, Deputy Collectors of the district etc.

The District Planning Board generally meets every three months and has powers to formulate and sanction schemes. The Board also has at its disposal the 'united funds' allocated by the state for 'Decentralised District Planning'. About one-third of total outlay under plan is allocated to district level schemes to be implemented through heads of departments of different sectors. There is also a special outlay for development of identified backward areas.

With the enactment of Panchayati Raj Act, the process of decentralisation has got strengthened further. There is provision for transfer of powers, functions and devolution of funds to the representatives of people. The Panchayati Raj institutions are a three-tier organisation viz. Zilla Panchayat at the district level, Taluk Panchayat at the taluk/block level and gram panchayat at the village level. The physical jurisdiction of Zilla Panchayat covers the entire district, barring the urban areas and town municipalities. In terms of activities, barring law and order, almost all other developmental activities come within its scope. It is the local government at the district level and 22 departments involved in developmental activities ideally fall within the governance of Panchayats. The Zilla Panchayat functions through various committees and the health committee is one of the important committees to work for health development. Thus, Panchayati Raj Institutions are expected to play a pivotal role in the decentralised district planning for health and development.

4.3.3 Designing the District Health Plan

A *plan* is a blue print for taking action. Planning needs to be done to prepare such a print for action. This by itself is a process. Thus, *health planning* can *be* defined as an orderly process of defining community health problems, identifying unmet needs; surveying the resources to meet them, establishing priority goals that are realistic

and feasible, and projecting administrative action to accomplish the purpose of the proposed plan.

The purpose of health planning is to:

- match the limited resources with many problems to be tackled.
- eliminate wasteful or duplication of expenditure, and
- develop the best course of action to accomplish a defined objective.

It has also been recognised that the vertical district plans for different sectors are less meaningful. Health of the people reflects on the success of all developmental efforts being undertaken in the district. Similarly, development has a bearing on health too e.g. greater availability of nutritious food through organised developmental efforts have a bearing on health of the people. In turn, healthy people can contribute more effectively towards developmental efforts.
Districts are now recognising the need to strengthen their planning system. However, the actions required would differ depending upon the context of various programmes. One may being with simplified programme for major activities and gradually refine them into detailed co-ordinated plan. Generally, the areas that support planning system have inherent weaknesses in them. These relate to:

a) ***Data*** System ***and its*** Use: District ***has*** a weak data system and at the same time it is used only in a limited way.

b) Planning ***Capabilities:*** The managers at different levels need to have skills in planning. As Panchayati Raj Institutions are expected to play a pivotal role in designing the district plan for health and development, not only the skills of health managers need to be increased, but also the planning skills of Panchayat members need to be strengthened.

The above considerations of weakness imply that health and health related sectors would have to develop an appropriate formalised planning system. Broadly there are three types of programmes from the planning point of view. The modes of planning vary to some extent in all of the three.

In Supply-oriented programmes, the planners are concerned with provision of goods and services. The demand is assumed to exist. The success of the programme depends upon the extent to which accessible, efficient and qualitative services *can* be provided in view of the existing demand. Maternal and Child Health (MCH) services may follow supply-oriented planning, as there is a fairly wide acceptance of these services.

In Strategically managed programmes, the planners are concerned with both creating demand, supply and services. The demand creation activities such as information, education and communication (IEC) and willingness to learn about the response to local needs are extremely important. Consequently the process of planning rather than the plan becomes more important. Programmes related to family planning may have to be strategically *managed.*

In ***Community centred programmes,*** the ***health*** services are seen as an integral part of overall developmental activities and are borne out of community needs, Here the programme operations have to be very flexible and the community participates actively in operational planning. The tuberculosis programme could be community centred.

Thus, the district may have to incorporate a mix of the above three planning modes at the same ***time.*** The planning process is a continuous cycle and it has typically five stages, namely, planning, execution, monitoring and control, evaluation and replanning. The basic steps needed for designing a district plan relate ***to*** answering a few key questions as reflected in Chart 4.3.

Basic Steps	Key Questions
1) Situational analysis 2) Projection/prediction of health status 3) Identification and definition of problems	When are we now?
4) Selection of priorities 5) Establishment of goals and objectives	Where do we want to reach?
6) Listing key alternative strategies 7) Try/Examine strategies in relation to resources 8) Selection of feasible strategy/choosing options 9) Listing of activities 10) Making an implementation plan	How will we reach?
11) Monitoring and control of operations 12) Evaluation 13) Replanning	Are we going in the right direction? Have we reached?

Chart 4.3: Steps for District Health Planning

Each of the steps have been briefly described below:

1) Situational Analysis

As a first step it is very necessary for a planner to know the health status of the community, factors promoting good health and the risk factors associated with ill health. Thus, for making a proper situational analysis, bath, the community as well the health aspects need to be looked into.

a) ***Community*** Aspects

i) ***Demographic Profile:*** Total population of the district, its distribution, age-sex composition, etc.

ii) ***Socioeconomic Conditions:*** Per capita income, housing conditions, major occupation etc.

iii) ***Socio-cultural Aspects:*** Attitudes ***and*** beliefs of community.

iv) ***Education*** Related: Literacy rate, institutions for imparting education etc.

b) ***Health Aspects***

i) ***Health Status:*** Morbidity (incidence and prevalence of various diseases), mortality pattern, etc.

ii) ***Health Facilities:*** Governmental, Voluntary ***as*** well as Private.

iii) ***Resources:*** Human Resources, financial resources, material resources, community resources.

iv) ***Training Centres:*** Location, numbers being trained, their capabilities for imparting training etc.

2) Projection/Prediction of Health Status

After making a community diagnosis through a situational analysis, it also needs to be deliberated as to what would be the likely situation in future for which planning needs to be done e.g. expected increase of population, migration of people, increase in HIV positivity etc.

3) Identification and Definition of Problems

The first two steps would yield in identification and definition of health problems in the district for which planning needs to be done.

4) Selection of Priorities

It may not be possible to redress all the problems at one go. In such a situation, health problems need to be tackled on a priority basis depending upon the:

i) Number of affected and severity of the problem.

ii) Diseases which are prevalent in the weaker sections of the community.

iii) Health problems with which the vulnerable groups of the community are associated e.g. mothers and children.

iv) Problems which have serious social and economic consequences, e.g. leprosy, tuberculosis, blindness.

5) **Establishment of Gods and Objectives**

It is very necessary to determine the ultimate state that is desired. The objectives set forth should be realistic to achieve and in measurable terms e.g. reduction in infant mortality rate from 75 to 70 in a period of two years.

6) 7) 8) Strategies

There could be various ways to resolve the problem. However, one has to adopt a strategy that is feasible and matches the available resources e.g. for control of diarrhoea there could be different alternatives like health education, water supply and sanitation, medical care including ORT etc.

9) Listing of Activities

The activities could be categorised under preventive, promotive, curative and rehabilitative aspects. Besides that, the activities to be undertaken at various level also need to be defined.

10) **Making an Implementation Plan**

Once the activities have been listed out (i.e., what needs to be done), for a proper implementation it is necessary to spell out as to how would it be done, where would it be done, who would do it and when it is required to be undertaken e.g. orientation of PHC Medical Officers in an activity for which working out the total numbers and batches is important, the place (may be SIHFW) where it needs to be imparted by whom and within what time frame would the whole thing be completed for the district.

11) Monitoring and Control of Operations

This is a continuous process of observing, recording and reporting of various activities in order to measure the level of performance, identify deviations if any, and taking corrective measures.

12) Evaluation

Evaluation is in terms of what has been set forth to achieve. Periodic and mid-term reviews are part of it and this has to be done at different levels in the district. Ideally evaluation should include aspects such as accessibility, coverage, community participation, intra and inter-sectoral coordination, cost and quality of services etc.

13) Replanning

Planning is a continuous learning experience. Objectives and activities need to be constantly reviewed as health problems get modified, new opportunities may evolve for optimisation of resources and there may occur a shift in priorities.

A good District Health Plan document should thus have:

- Background and situational analysis (including health needs and problems being tackled).
- Clearly specified objectives (along with outputs required to meet the objectives).
- Strategies and the resources required (including the ways to get the resources).
- Activities to be performed (along with setting out responsibility for the activities).
- Monitorable time-table (and if possible, specification of foreseeable constraints and risks).

3) The first step for planning is .....

4.4 DISTRICT WEALTH INFORMATION SYSTEM

By now it would have become clear to you that information is vital for the district level managers for working a situational analysis and eventually preparing a plan of action. Health information is thus a basic tool of management and a key input for bringing about an improvement in community health. A health information system is defined as "a ***mechanism for the collection, processing, analysis and transmission of information required for organising and operating health services, and also for research and training***"

The primary objective of a health information system is to provide reliable, relevant, up-to-date, adequate, timely and reasonably complete information for health managers at all levels and to assist planners in studying their current functioning and trends in demand and workload.

4.4.1 Sources of Health Information

As already indicated in the earlier section of this unit, the district has a weak data system. Still it is very difficult to get the information where it matters most, i.e., at the community level. Service statistics and beneficiary records are usually the basis for planning. If couple or household registers are accurately maintained by the health workers and are suitably analysed, then they can be useful for segmenting beneficiary population, exercising selectivity in activities and sequencing programme planning.

A district health planner has to identify all the sources of information. There are two sources of information: programme and non-programme. Both the sources are essential and in a way, complementary to each other. Information collected through non-programme machinery, in the form of assessment surveys and studies, help in

filling the gaps found in the information collected through the first source and has a long lasting impact.

The various sources of health information are briefly described below:

1) Census: The census is an important source of health information. The census is conducted in India at the end of first quarter of the first year in each decade. Census Commissioner and Registrar General of India directs, guides and operates the census. Without census data, it is not possible to obtain quantified health, demographic and socio-economic indicators. However, district-wise figures take sometime to be made available to district authorities.

2) Civil Registration System: Whereas census is an intermittent counting of population, registration of vital events (e.g. births, deaths) keeps a continuous check on demographic changes. Registration agencies vary from state to state e.g., (i) health agency in Kerala and West Bengal, (ii) panchayat agency in Uttar Pradesh, Rajasthan, Bihar and Madhya Pradesh, (iii) Police agency in Haryana, Punjab, Madhya Pradesh, Jammu & Kashmir and Assam; and (iv) Revenue agency in Gujarat, Maharashtra, Andhra Pradesh, Karnataka and Tamil Nadu. The extent of under registration makes this system as not too reliable a system for district health managers.

3) Sample Registration System: Since civil registration system is deficient in India, a Sample Registration System (SRS) is being operationalised by the Registrar General of India, to provide reliable estimates of birth rate, death rate and infant mortality rate.

4) Survey of Causes of Death: The Registrar General of India also undertakes survey of causes of death.

5) Notification of Diseases: List of notifiable diseases vary within the country, between the states and between urban and rural areas. However, it has serious limitations as it covers only a small part of total sickness and at the same time accuracy of diagnosis is also questionable.

6) Hospital and Health Centre Records: The main drawback is that such records only constitute a tip of the iceberg. Such sources could be governmental as well as non-governmental.

7) Epidemiological Surveillance: As part of the national health programmes, surveillance system are often set-up (e.g. malaria) to report the occurrence of new cases and on efforts to control diseases (e.g. spraying done).

8) Survey Data: In India, the Central Statistical Organisation (CSO) and National Sample Surveys Organisation (NSSO) conduct various surveys, which also include certain aspects related to health

4.4.2 Flow of Routine Health Information

The Government of India has set-up National Informatics Centre (NIC) to promote informatics culture in the government departments and to develop computer based management information system for decision support at various levels. NIC has set up a nation-wide satellite based computer communication network (NICNET) covering all the districts, state capitals and the centre, in order to facilitate the development of District Information System (DISNIC) at district level and essential data base for the states and central government departments.

A computer compatible version of Health Management Information System (HMIS version 2.0) has been developed for implementation all over the country. This version consists of the following data input in the district computer system.

i) PHC Report,

ii) District/Sub-district/Special Hospital Report,

iii) Private Hospital/Nursing Home Report, and

iv) Camp Information Report.

The District Computer System processes the data and produces the decided output reports.

For the compilation of PHC report, the health worker (male) and health worker (female) fill in the sub-centre form for the respective month and submit it to PHC Computor/Compiler. The PHC Computòr/Compiler aggregates the sub-centre data and also collects the PHC clinic and laboratory data to be reflected in the PHC format.

The PHC reports are sent to District Health Statistical Cell. The District Statistical Assistant feeds the PHC data in the NIC computer available at the District Collectorate Office. In addition. he also feeds data related to hospitals, nursing homes and camp activities.

Once the data entry is completed, the output table is made available to the district programme managers. Further, the transmission of information to the state headquarters and national level is through the NICNET. The information flow is depicted in the figure below:

4.5 LET US SUM *UP*

In this unit you have learnt about the district health organisation with details about the organisational structure and functions of the district health office. It would have become evident to you that district is the basic unit of administration in the country and how vital it is for the chief medical officer to play the role of a district level planner and a manager. You would have also got an insight into the procedure for developing a decentralised district health plan and the importance of a proper health information for the purpose. A district chief of health organisation (CMO) does not have to bank only on the programme sources of health information, but also on the non-programme sources.

UNIT 5 REGIONALISATION OF HEALTH CARE

Structure

5.0 OBJECTIVES

After going through this unit, you should be able to:

- describe the concept of regionalisation;
- list the points in favour of demarcation of a region;
- describe the basis of hierarchy within the region;

  list the problems in implementation; and
- explain the overall benefits of regionalisation.

5.1 INTRODUCTION

In the earlier units of this block you have learnt about health care delivery system in the country and also the district health organisation. In this unit you will learn about another concept of health care delivery system which aims at providing comprehensive health care services in a defined geographical area and this is known as regionalisation.

This unit will help you to understand the concept of regionalisation as it applies to health care. It explains the basis and purpose of regionalisation and also considers the other elements which have to be given weightage in regionalisation. The advantages and disadvantages of regionalisation have also been discussed briefly.

UNIT 5 REGIONALISATION OF HEALTH CARE

Structure

5.0 OBJECTIVES

After going through this unit, you should be able to:

- describe the concept of regionalisation;
- list the points in favour of demarcation of a region;
- describe the basis of hierarchy within the region;
- list the problems in implementation; and
- explain the overall benefits of regionalisation.

5.1 INTRODUCTION

In the earlier units of this block you have learnt about health care delivery system in the country and also the district health organisation. In this unit you will learn about another concept of health care delivery system which aims at providing comprehensive health care services in a defined geographical area and this is known as regionalisation.

This unit will help you to understand the concept of regionalisation as it applies to health care. It explains the basis and purpose of regionalisation and also considers the other elements which have to be given weightage in regionalisation. The advantages and disadvantages of regionalisation have also been discussed briefly.

In this unit you will also learn about the basis of evolving of a region, the level of services provided within the region and also about the hierarchy of services necessary to ensure free flow of information and services both up and down.

5.2 CONCEPT AND HISTORY OF REGIONALISATION

You must have studied in Geography that a country, a state or even a district may be divided into regions which are homogeneous areas. The same concept is applied to the provisions of health care. This process of regionalisation of health care in a region helps in assessing the requirements of health care in the region and then based on this a system is evolved, for providing the required health services considering the available resources too. It is of course necessary to exercise the greatest economy on the resources, as they are limited and should, therefore, be used optimally.

In the provision of health care, the District level is often taken as a region as it is administratively, functionally, structurally, generally and geographically too a distinct entity. Since Independence we have tried out many methods of bringing health care to the people who need it most and the three tiered system of the Gram Panchayat, Taluk Panchayat (block level) and the Zilla Parishad has proved to be the best working system that has stood the test of time so far.

You will also appreciate that vertical health programmes did not meet with the success which was expected over a period of time. This was because health is a matter which is closely linked with many other associated disciplines or departments. It is linked to food, water supply, forestry, environment, poverty removal, employment and so on. Many of these areas are handled by diverse departments. It has generally been found that the District is the region where all these departments and their activities interface. You must be knowing that the Zilla Parishad is the top tier of the Panchayat Raj Institutions (PRIs). This therefore forms a good homogeneous platform from which a region can be formed and controlled as all the lines of communication are established ones.

As a region, a district provides good scope for coordination and integration of services. This of course refers not only to health services but to all the allied services too. It is an established system and delivery of health care should also conform to these lives for effective, economical and successful implementation.

The concept of regionalisation of health care follows closely in the footsteps of the regionalisation process which took place in general administration. You must have heard the saying that India lives in its villages. This was true hundreds of years ago and is true even today. The village Panchayat originally consisted of five members but that has been subject to change, in numbers, depending on the size of the village.

For a while after Independence there was a great deal of centralisation of power and therefore all the decisions were taken at high levels. Plans were announced and implemented at the National level and at the State level. The implementation of many of these plans left much to be desired as the man in the village, the actual beneficiary was left out of the decision making process. This realisation dawned on the planners when the expected results did not materialise out of so called well planned and well financed programmes. The basis for most of the early schemes on health planning as you know is the Health Survey and Development Committee Report (Bhore Committee) of 1946. The Community Development Programme was launched on 2nd October, 1952 and it was planned to set up a Primary Health Centre in every Community Development Block. The Mudaliar Committee in 1961 recommended the reduction in the population covered by each PHC, among other things. In 1964 the Govt. of India reviewed the functioning of the PHC and

strengthened the staff therein, while integrating Maternal and Child Health into the health services. Subsequently health care infrastructure was strengthened based on the recommendations of various committees constituted from time to time and you have already learnt about this in the first unit of this block.

The first idea of local self-government was with the government resolution of Lord Rippon (1882). We have come a long way since then. Being a newly Independent country we have had to find the system which was most suitable to our setting and so we have taken some time to establish this. As stated earlier, the concept of regionalisation of health care followed closely on the heels of regionalisation of the administrative machinery.

A change of Government in the centre in 1977 brought about a renewed interest in Panchayat Raj. However it was only in 1992 that the Constitution (73rd Amendment) Act, was enacted. This act envisages the establishment of panchayats as units of self-government. The gram panchayat was to be the foundation of the system and the three tier system was built on this is the Gram Panchayat (GP), the Taluk (Block), Panchayat (TP), and the Zilla Parishad (ZP). The GP, TP and the ZP, constitute the backbone of the Panchayat Raj Institutions (PRIs) in the country.

You must have also seen how the concept of the Panchayat Raj is historical reality and how the concept of the Panchayat Raj and Panchayat Raj Institution (PRIs) has been brought back into the administrative machinery and working through the 73rd and 74th Amendments. The 73rd Amendment brought in the formalised concept of the Panchayats as units of self administration and the 74th Amendment brought in the concept of working of the District Planning Committee (DPC). These two processes really formalised the understanding and the application of the concept of regionalisation with the District as the nodal point for the region. Since the panchayats and DPCs had elected representatives of the people, the schemes were user friendly. The DPC and the various panchayats within the district were to monitor the progress of the various schemes and programmes within their area of responsibility and health care was one of them. This has the distinct advantage of promoting coordination between the different departments which are involved in overlapping and mutually beneficial schemes.

So over a period of almost 50 years we have come to realise that the District is a strong and viable unit of decentralisation of the administrative system and also the health care. It is at this level that there is an integration of services and also the coordination. The TP and GP are viable for local administration but lack the funds and resources for implementation of programmes with a larger perspective. Regionalisation then is a viable and positive step taken to fulfil the objectives that we had in various programmes that authorities have conceived for the benefit of the villagers. Regionalisation also makes the plans more implementable from the point of view of the health worker too.

It was envisaged that adequate powers and responsibilities would be devolved upon these panchayats at the appropriate level to enable them to prepare and implement schemes for economic development and social justice.

The gram sabha or the village council has been envisaged as the foundation of the panchayat raj system. There shall be three tiers of panchayats at the village, intermediate and district levels, All seats are to be filled by direct elections from territorial constituencies, with the ratio between the population and the number of seats being the same throughout the panchayat area. SC/ST reservation in proportion to their population in the panchayat—women 1/3rd of the seats for a term of 5 years.

A new schedule called the Eleventh schedule comprising 29 items has been added to provide an effective role to the PHs (Panchayat Raj Institutions) in the planning and implementation of works of local significance ranging from drinking water,

agriculture, land and water conservation to communications, poverty alleviation programmes, family welfare, education, libraries, cultural activities etc.

Fill in the blanks:

a) The concept of regionalisation of health care closely follows the regionalisation of .....

b) The concept of regionalisation of health care and administration are based on the .....System.

c) The Panchayat raj system is a ..... tier system, with the ..... as the foundation and the ..... as the intermediate level and the ..... as the top level.

5.3 ELEMENTS OF REGIONALISATION

In this section you will learn about various elements of regionalisation, namely, structure, demarcation of a region and hierarchy.

5.3.1 Structure

The structure of regionalisation consists of three basic components:

i) the demarcation of a region;

ii) presence of a graded hierarchy of services; and

iii) ensuring coordination of services through an integrated authority system.

The structure should also ensure that there are no hindrances to the process and that the flow of information and services up and down the system is smooth and continuous. The elements of regionalisation are the levels and as mentioned earlier there are three levels and these are the GP, TP and the ZP in the region of the District, Based on the information that was given in the previous section you now know the history and the concept of regionalisation and you will now be able to correlate that with the structure of a region. This will help you to get an overall view of the concept and the elements as they would appear in a region. The district has been chosen as the region as it is so in actual practice and you can relate the information given to your district where you live and work and this will help you to understand the concept and the structure better. You will be able to conceptualise the principle of regionalisation of health care better if you relate it to the district that you know while going through the unit.

5.3.2 Demarcation of a Region

This is the first step and should be a very carefully thought out and weighted decision. Each area should be capable of a level of autonomy both in resources and personnel. There should also be a homogeneity in the region.

Demarcation of the region could be done by time tested criteria of geography, economy, culture, ecology, and being a nodal centre. Since we are considering a district as a region for the purpose of delivery of health care and also for administrative purposes, most often the demarcation has already been done and generally the demarcation conforms to one or more of the principles enunciated above. However, in recent times there have been times when political

considerations have been overriding in the formation of a district. These are generally the exceptions and are bound to create problems.

Most of the older and geographically determined districts have an inherent homogeneity and are culturally and economically uniform too. In these districts and regions it is easy to implement a new programme once the local population has been taken into confidence. The cultural and ecological homogeneity makes for easier implementation. Such regions are also capable of functioning in a self contained way.

Some regions are nodal regions i.e. it is based on the headquarters being a communication centre and thereby the region around grows under its influence. This generally happens when the district is built around a large city or large commercial centre and all the surrounding area is dependent on and subsidiary to the centre. Such centres and regions often produce a lot of employment and facilitate establishment of high-tech centres for medical and health care too.

Where a region does not conform to the above mentioned characteristics the region could be considered as a planning artifact which has been created to meet certain other needs. However, it has been found that even such dissimilar regions when brought under a uniform authority tend to become homogeneous over a period of time.

A region should be large enough to be self-sufficient in providing a broad range of services. Besides the size the population also is an important determining factor in provision of health facilities. Provision of highly specialised services require a population base for establishment. For example, it is generally believed that for establishment of neurosurgery or open heart surgery a population of one million is the minimum per unit. This could then be established only in the third tier of the system that is at the district headquarter hospital if such a requirement is visualised.

Transportation is another important determining factor in establishment of medical and health care services. Travel time has become a more accurate measure than distance in kilometers, as it takes into account of state of available transport and road conditions in addition to the distance itself. Then is the index to be used when expansion of health care facilities in a region are contemplated.

Demarcation of the region is fundamental to the success of the region as an administrative unit. Each region should have a degree of autonomy both in resources and in personnel. This happens automatically when the district or region is carefully planned. Most of the districts have also a certain homogeneity which is also essential for the smooth functioning of the machinery. A district headquarter is the hub of activity and hence there should be a smooth flow of information and resources out from it and of information and patients and patient related activity to it. Culturally and economically too there is this homogeneity in a district. However, in newly formed districts which have been created for political or economic reasons this homogeneity takes considerable time and efforts to develop. Most district headquarters are geographically homogenous too, this makes for ease of transportation and interaction between the functionaries at different levels. Some district headquarters are demarcated because they are nodal centres, this also makes sense as they have come up as commercial or communication centres and so they automatically assume the function of being in the hub or centre of the region. The broad principle of primary care at the village level and secondary care at the taluk or panchayat level and tertiary care at the district hospital level is a smooth and time tested system which works well.

Population and transport facilities within the region also need to be studied carefully before the demarcation of a new district is made.

.....

.....

.....

.....

.....

.....

2) Name the **factors** which are essential for a region to be self contained.

.....

.....

.....

.....

5.3.3 Hierarchy of Services

Now, you will learn about the hierarchy of services. Once regionalisation has been decided upon, it is essential that the region functions as a cohesive and coordinated unit. This implies that information and services and statistics should flow smoothly up and down within the region. By up and down we mean that it should follow the natural flow of administrative channels. In any administrative set-up there is always a hierarchy. The dictionary defines the word hierarchy as "A body classified in successively subordinate grades". In our application it **means** the step ladder type of levels that we have established in the system for optimal function.

You **have** already learnt about the three tier system of **structure** in Health Care. This consists of the Primary Health Centre (PHC); Community Health Centre (CHC) and the District Hospital. These three levels roughly coincide with the three administrative levels of control, the Gram Panchayat (GP), the **Taluk** Panchayat **(TP)** and the Zilla **Parishad** (ZP). The PHC being population based may not coincide with every village level, however the other levels would coincide. The level of care provided at these three levels are known **as** primary, secondary and **tertiary.**

Location Level	**Administrative Level**	**Health Care Level**	**Type of Health Care**
District Headquarters	Zilla **Parishad**	**District** Hospital	Tertiary.
Taluk/Block Headquarters	**Taluka Panchayat** or Panchayat Samiti	Community Health Centre	Secondary
Village	Gram **Panchayat**	**Primary** Health **Centre/Sub** Centre	**Primary**

The above table explains the hierarchical system in health **care**. It **may** however be subject to minor **modifications depending** on geographical, topographical and communication line locations. The administrative levels are based on the Karnataka model which **has shown** a good degree of success.

The hierarchical system whether in health care or in administration are generally based on population figures. Population is the **overriding** deciding factor **as** it determines the resources available and the type of services that could and need to be

provided. Complex, costly and infrequently used facilities should be made available at a place where the catchment area is large and where the facilities would be adequately utilised. For example, complex surgeries and investigative facilities would be better utilised at the tertiary level hospital in the District Headquarters. Quite often this may be associated with a Medical college too which would enhance the provision and utilisation of these facilities.

In any large organisation it is necessary to lay down a hierarchy of services. You have learnt about the hierarchy of services as it exists in health care at district level, panchayat level and at the level of the village. You have also learnt of the three tiered system of the District Hospital, the Community Health Centre and the Primary Health Centre, and how these three levels are complimentary to each other. Cooperation and coordination between these three levels is essential and integral to the success of the entire process and will also ensure smooth and uninterrupted flow of information up and down the three levels. This will help to coordinate flow of patients for referral from the PHC to the CHC and then on to the District Hospital if necessary and then back to his village with the necessary follow up notes. You have also learnt how the structuring of authority and rceponsibility takes place between these levels. You have also touched upon the type of differencesthat could arise in such a system if total cooperation and coordination is not present between the different levels and if the person at the helm of affairs does not have the necessary authority, or if this has been delegated to persons who are unable to implement them.

You will agree to that health care administrative set up closely follows that of the district hierarchy itself. The District Medical Officer or the District Health Officer is located in the headquarters where the District Collector or Commissioner is also located. This hierarchical ladder goes right down to the village level where the functionaries arc at the same level too. The care afforded to the patient is also in the same hierarchical pattern depending on the facilities available. Tertiary care being available at lower levels, secondary carc is provided at the CHC and primary care at the village level in the PHC.

5.3.4 Primary Level

These services generally constitute the first contact of a patient with the health care facility and organisation. The PHC and the Sub Centres (SCs) cater to the needs of the villagers and need to be given due attention. They should be adequately staffed and also properly equipped to carry out the necessary function. It is planned to give the three tiers greater autonomy in order that their functioning is not interfered with in any way.

You would be visiting a Primary Health Centre as a part of practical activities. You should take this as an opportunity to see for yourself the working of the PHC and make an assessment of the level of regionalisation. Find out if the PHC has gained any degree of autonomy after 1993. Has there been any difference in the function of the centre? Has the staffing and the equipment position improved and is the PHC doing all that it is capable of?

Health programme management at a micro level is done by the Gram Panchayat. Are the members of the GP capable of this? Health programmes have to be managed judiciously and with care. At times GPs are staffed by illiterates, neoliterates or even first-time-ever-office bearers and this often causes a bit of stagnation in the process and lack of progress. You should be able to assess this and if you think that this requires to be rectified then you should suggest corrective steps. Do you think that the members of the GPs should go through some sort of training? Should they be introduced to the health programmes and the functioning of the PRI (Panchayat Raj Institutions)? These questions need to be answered by you in your assessment of the programme.

5.3.5 Secondary Level

Here we are dealing with the Taluk Panchayat as it is called in Karnataka and in many other states, It is also referred to as the Panchayat Samiti in some states. This is the middle level and generally the medical facility available here is the Community Health Centre of the Community Hospital. The effect of the concept of Regionalisation of health care could be felt here. There should be enough staff and equipment here for the patient to receive secondary level of treatment. If this centre or hospital is well equipped and staffed it would take the load off the District Hospital. At present due to poor staffing and equipment often it is seen that the patient goes from the PHC directly to the District Hospital and thereby puts a strain on the system of tertiary care which that centre is meant to provide.

5.3.6 Tertiary Level

The tertiary level services are provided at the tertiary level hospital, that is the District Hospital. Here there is a concentration of the more specialised services like sophisticated laboratory and investigative facilities, here there are better facilities for treatment too. More complicated and high tech operations and treatment of a higher order are offered. This is the apex of the pyramid of regional care as has been earlier started. Cases are referred from the Primary Health Centre at the village level to the Community Health Centre at the block of Taluk level and then from there, the more complicated cases are referred to the District Hospital.

Manning of these centres by technical personnel is also dependent on the level of technical expertise expected of them. In the concept of regionalisation it will be seen that the more highly trained manpower is required at the tertiary level and medium trained persons at the middle level and basic training is imparted to the personnel at the primary level. This is true of all technical manpower. Doctors also follow the same pattern, an MBBS doctor in the PHC and possibly a new post graduate at the CHC and an experienced post graduate with higher specialisation at the District Hospital. This fits in with the overall concept of regionalisation as you have understood it too.

Check Your Progress 3

.....

.....

.....

.....

3) Where would you expect the highest level of we, and where would you expect the most modest type of care within district?

.....

.....

.....

.....

5.4 STRUCTURING OF AUTHORITY AND RESPONSIBLITY

In the previous sections of this unit you have learnt of the three tier system of health care division and how this works. It works well because it is structured in lines with the administrative set-up. If these PRIs (Panchayat Raj Institutions) are to work well, then there should be a smooth structure in their authority and responsibility. Empowerment of the PRIs will hasten the decentralisation or the regionalisation process. You must have heard of decentralisation which is basically another term for regionalisation.

The concept of decentralisation or regionalisation implies delegating authority and responsibility from the central (National level) to the regional level. Within a region there is again delegation of responsibility and authority to the local level to the extent possible. The region is seen as the logical and desirable level for the planning and administration of health services.

"Midway between the local level—where highly technical problems cannot be solved, and the national level—where sometimes a theoretical equilibrium is sought—the region is the platform *on* which the public health plan can be fashioned, far enough from local contingencies to regard them with detachment, but near enough to appreciate their importance; far enough from the central authorities for objectivity, but near enough to influence them."

You will realise from the above that while control of the region is exercised from the centre of the region, in our case the District Headquarters, there has to be a sense of participation from the local level. The largest user of the services is the man at the local level and therefore it is imperative that he or his representative take part in the decision making process in so far as it deals with the local level of the region. This is where the gram panchayat as elected representatives come into play and have a say in the type of care that is provided. This of course would depend on the finances that are available. All this has to be planned at the District level. It is in this process of empowerment of the PRIs that the 74th Constitutional Amendment was passed.

Constitution for the District Planning Committee (DPC)

In accordance with the provisions of the 74th Constitutional Amendment, a District Planning Committee is envisaged in each District to prepare and consolidate the plans prepared by the Panchayats and the municipalities in the district and to generate a draft development plan for the district as a whole. While preparing the district plan, the DPC is expected to note the locational aspect of project, care for integrated development of infrastructure and environmental conservation and evolve criteria for sharing of the natural and financial resources. However, the composition of the DPC has been left to the discretion of the state, but it has been stipulated that 80% of the members shall be those elected to panchayats and municipalities.

5.5 DISTURBING VARIABLES

Regionalisation has not always been easy to implement. There have been instances where a "well planned" system has gone away because the so *called* "well planned" system was not actually well planned. There have been instances where for lack of involvement of the right persons the scheme has failed. When you try to study the working in your PHC, TP and ZP, you should also see how the scheme is working and whether there are hindrances.

A few bureaucratic hurdles that were encountered in one district where one N W had decided to try and implement the scheme of regionalisation on a small scale. These are only examples and there could tie many more such bottlenecks.

There could be many more such factors and they could differ from place to place. It would not be possible to list them all. They have to be looked for and tackled on a day-today basis. You must look for these in your PHC, TP, ZP. It has quite often been seen that projects fail, not due to lack of funds as is commonly thought, but due to bad planning and poor implementation and also lack of involvement of the grass-root level workers and beneficiaries.

Well documented schemes which failed listed some of the reasons as below:

a) The State authorities did not feel it necessary to be involved in a district scheme which was being planned by an NGO.

b) District Health Officers who were to oversee the working of the scheme were transferred frequently.

c) Panchayat members were not involved and the state authorities had expressed a degree of caution by noting that "Elected members vary in caliber and attitudes, Consult the District Health Officer before involving them". This sort of negative suggestion with a frequently transferred District Health Officer, left the whole programme without an impetus.

d) Dynamic leadership was lacking as *seen* by the fact that even when workshops were held and suggestions made they were not implemented for very trivial bureaucratic reasons. Repairs to vehicles were not carried out though funds were available, but the procedure for releasing funds was long. Contingency funds were not given to the PHC. Drugs available in the stores did not reach the sub-centre.

e) Passing of bills related to travel expenditure was delegated to the Taluk officers but most of these posts were vacant and hence these bills remained unpassed.

Implementation of any programme or concept always needs careful planning and motivated and dedicated personnel. It is necessary that time should be spent on familiarising worker at all the three levels on the benefit of regionalisation and to explain how this system works to the benefit of all levels.

Problems crop up in *the* system when functionaries at different levels are not sure *of* their duties or assume duties of other levels.

Problems *can* occur in the smooth flow of patients from the PHC to the CHC and then on to the District Hospital. This should be looked into and any obstacles) cleared, like transport, staffing (drives) and *so* on. For this purpose you need to check what happens to the patient when he is discharged from the District Hospital, Does he come back in an organized manner? Does he have notes for the PHC Doctor on the follow up of his clinical condition? All these are to be built into the system or regionalisation if it to *succeed.*

Assigning of responsibilities in implementation of the National programme at the grassroot level also causes problems. All these need to be looked into. A common sense approach with an open mind generally yields simple and practical solutions to most of these problems of implementation. It is also best to involve the functionaries affected in the decision making process or at least to consult him/her before a final decision is taken, otherwise some simple hurdles are missed out when these are discussed in higher levels. Taking decision making to the periphery and to the concerned person, pays great dividends. In fact this itself is the basis for regionalisation.

5.6 THE REGIONALISATION PROCESS

The process of regionalisation has been introduced to effect better efficiency in the system and if this has to work as planned, then there should be a free flow of information and of patients within the region. This includes referral of patients from the periphery to the centre that is from the PHC to the CHC and then on to the District Hospital. After the necessary treatment these patients should be able to go back to their villages with the necessary feedback on the treatment given and also the diagnosis and treatment for necessary follow up of the treatment.

5.6.1 Coordination within the Region

For the regionalisation or decentralisation process to be successful, it is necessary that there should be cooperation between all the levels of the three tiered system and its agencies. The district level is the most crucial in the chain of command of the various departments of the district. This is so for the Public Health Department and also for the affiliated departments which are concerned with the general welfare of the people of the district and the taluks and the villages. Coordination does not take place spontaneously. It will also not take place if the process of coordination is left to one of the agencies involved. "There has to be a carefully designed administrative structure which will oversee the function of coordinating the various departments and particularly the large areas where there is an overlap of the functions of these departments, so that the common man may benefit the maximum through optimal utilisation of resources. The coordination mechanisms itself will entail costs. However, these will be offset by improved functioning and eliminating duplication of effort and resources."

5.6.2 Monitoring

Any system which involves the participation and the cooperation of three different levels of functionaries and also keeping open channels of communication between all these levels should also be carefully monitored so that mid-stream corrections can be applied so that the scheme has the right impact on the people who are to be the beneficiaries, that is the last villager should feel the impact of the scheme. Monitoring is better done by an agent independent of the functioning of the scheme itself as otherwise there is a tendency for bias in the interpretation of the results, distribution of resources, funds etc.

5.6.3 Basis of Regionalisation

You also learnt that the district serves very well as the nodal centre for the regionalisation process. It occupies a central place in the three tiered system from both sides. It is at the bottom of the three tiered system when you consider the three tiers of the Centre, State and District. It is at the top of the regionalisation three tiers, that is the District, the Taluk and the Village. This unique feature gives the concept of regionalisation and has various advantages. Principal among these is the fact that the entire governmental administrative machinery too is district based. It is ideal, therefore, that the health care machinery too follow the same system. This makes coordination between the various departments which are closely associated with health care, like food, water supply, environment, poverty removal and so on smooth and easy.

5.6.4 Panchayat Raj

We have also seen how the concept of the Panchayat Raj is historical reality and how the concept of the Panchayat Raj and Panchayat Raj Institutions (PRIs) has been brought back into the administrative machinery and working through the 73rd

and 74th Amendments. The 73rd Amendment brought in the formalised concept of the Panchayats as units of self administration and the 74th Amendment brought in the concept of the working of the District Planning Committee. These two processes really formalised the understanding and the application of the concept of regionalisation with the District as the nodal point for the region. Since the panchayats and DPCs had elected representatives of the people, the schemes were user friendly. The DPC and the various panchayats within the district were to monitor the progress of the various schemes and programmes within their area of responsibility and health care was one of them. This has the distinct advantage of promoting coordination between the different departments which are involved in overlapping and mutually beneficial schemes.

It has been amply demonstrated that a well organised and coordinated three tiered hierarchy of the Zilla Parishad and the Panchayat Samithi and the Village Panchayat and their corresponding Panchayat Raj Institutions of District Hospitals, Community Health Centres and the Primary Health Centres, are currently the best institutions for providing health care at the various levels. This concept and practice of regionalisation has been seen to work well and smoothly where there is good coordination at all levels and between the functionaries of the different levels. Since elected bodies are involved in their implementation, it ensures involvement of the beneficiaries through their elected representatives too. The process of regionalisation of Health Care which closely follows the regionalisation of administrative machinery is therefore a successful step towards the provision of health care.

5.7 LET US SUM UP

In this unit you have learnt about the concept and process of regionalisation. The concept came up when it was realised that concentrating all the administrative, financial and such other powers in the centre and taking all the decisions there, did not take into account the needs and felt needs of the last beneficiaries that is the villagers for whom the health care activities were meant.

You have also learnt about the basis of evolving of a region, the level of services provided within the region and also about the hierarchy of services within the region. Further you learnt that district serves a nodal point for the regionalisation process and it occupies a central place in the three tiered system from both sides. Subsequently you learnt how the concept of panchayat raj and panchayati raj institutions (PRIs) has brought back into administrative machinery and working through 73rd and 74th amendments.

Towards the end you learnt about the problems/disturbing variables in implementation of the regionalisation process as well as the monitoring and coordination within the region.

5.8 ANSWERS TO CHECK YOUR PROGRESS

Check Your Progress 1

a) general administration.

b) Panchayati Raj

c) three, Gram Panchayat, Taluka Panchayat, Zila Parishad

Check Your Progress 2

1) • geography,

- economy,
- ecology,
- culture, and
- nodal centre

2)
- cultural homogeneity
- ecological homogeneity

Check Your Progress 3

1) The dictionary defines the world hierarchy as "a body classified in successively subordinate grades." In our application it means the step ladder type of levels that we have established in the system for optimal function.

2) Primary level—PHCs and Sub-centres

   Secondary level—CHCs

   Tertiary level—District Hospital

3) Highest level of care is available at district hospital.

   Most modest type of care is available at PHCs and Sub-centres.

UNIT 1 PROGRAMMES RELATED TO COMMUNICABLE DISEASES

Structure

1 . OBJECTIVES

After going through this unit, you should be able to:

- explain the evolutional background of programmes related to select communicable diseases;
- identify major strategic components of those programmes; and
- outline the organisational structure of select programmes.

1.1 INTRODUCTION

In the preceding block you have learnt about the health system in India. Under various units in that block, you have learnt about an overview of: health care delivery system; alternate system of medicine, including indigenous system; health policy and strategies; district health organisation; and regionalisation of heal* care.

In the present block you will learn about various ongoing national health programmes. For the convenience of understanding, these programmes have been classified into four categories: programmes related to communicable diseases; programmes related to non-communicable diseases; reproductive and child health programme; and other programmes. Through the opening unit of this block, you will be learning in brief about some important health programmes related to communicable diseases.

Since your learning needs are related to management, the focal points of discussion will be about evolutionary, strategic and organisational features of these programmes instead of details of technical (bio-medical) aspects. In this unit you will learn about the salient features in historical evolution, strategic components and organisational structure of the programmes directed towards vector-borne diseases, tuberculosis, leprosy, AIDS and STDs, and guinea worm disease in India.

1.2 PROGRAMMES AGAINST MALARIA AND OTHER VECTOR-BORNE DISEASES

In this section you will learn about the programmes related to vector borne diseases. You will appreciate that, development of malaria control activities in India can be taken as a specimen to understand the development of health care in India in many regards. You can realize it by briefly reviewing the evolution of anti-malaria programme in our country.

1.2.1 National Anti-Malaria Programme (NAMP)

Most of you must be aware of that the first systematic anti-malaria activity started in India under National Malaria Control Programme (NMCP) which was launched in 1953. It was a result of one of the recommendations of Bhore Committee (1946) that was endorsed by Planning Commission in 1951. The main NMCP strategies were:

- Residual insecticide spray of human dwellings and cattle sheds.
- Survey and monitoring of malaria incidence by malaria control teams under state anti-malaria organisation.
- Provision of anti-malarial drugs for patients reporting to health facilities.

This strategy appeared to work and significant progress in malaria control with regard to morbidity and mortality was observed all across the country. So were the experiences in several other countries as well, creating an optimistic sentiment among the policy makers world over. In 1955, World Health Assembly reflected this sentiment by recommending a shift from control to eradication of malaria. India responded to this shift by starting National Malaria Eradication Programme (NMEP) in 1958. The objective was to eradicate malaria in next 7-9 years. Outstanding achievements followed and India reported zero death in 1965.

Setbacks in malaria eradication started from 1968 onwards. It was realized that urban areas could not receive adequate attention. Urban Malaria Scheme was launched in 1971 with source reduction and anti-larval measures as its main strategic components but the resurgence of malaria could not be stopped. Burden of malaria attained huge proportions by 1976. The approach of malaria eradication was reviewed and a Modified Plan of Operation (MPO) was adopted in 1977, with following objectives:

- Prevention of malaria deaths.
- Reduction in malaria morbidity.
  Maintenance of industrial growth and green revolution through freedom from malaria.
- Consolidation of achievement gained so far.

Following major activities were undertaken during this phase:

- Insecticide spray during the transmission period in rural areas having Annual Parasite Incidence (API) ≥ 2.
- Active surveillance by fortnightly domiciliary visits and blood smear collection.
- Presumptive and radical treatment.
- Decentralization of laboratory services to PHC level.
- Establishment of Drug Distribution Centre (DDC) and Fever Treatment Depots (FTDs).
- Control of *Plasmodium falciparum* and checking its spread through *Plasmodium falciparum* Containment Programme (*Pf*CP).

Malaria Action Plan (MAP)

Till early nineties, the MPO was able to control malaria problem but since 1994 many areas have shown proneness to outbreaks of epidemic proportions with high mortality. The programme has been reviewed again by an expert committee and proposed Malaria Action Plan is in the process of implementation, The expert committee also deliberated on evolving paradigms of malaria in the country and identified five problem areas:

- Hard-core (Tribal) areas
- Epidemic prone areas
- Project areas
- Triple insecticide resistance areas
- Urban areas

This new action plan has following objectives:

- Management of serious and complicated malaria cases.
- Prevention of mortality with particular reference to high risk groups.
- Reduction in morbidity.
- control of outbreaks/epidemics.
- Reduction in *Plasmodium falciparum* resistance and containment of drug resistant malaria.
- Maintenance of low incidence status.

For seven North-Eastem states, malaria control has been made 100% centrally sponsored since 1994. Besides this, Enhanced Malaria Control Project (1997) is providing additional resources to several other malaria prone states.

Enhanced Malaria Control Project **(EMCP)**

This project has been planned to cover problematic Primary Health Centres where:

- API is >2 for last 3 years,
- *Pf* cases are >30% of the total malaria cases,
- >25% of the population is tribal, and
- The area has been reporting deaths due to malaria and has the flexibility of directing resources to other areas during outbreaks.

Besides benefiting core tribal populations in seven states, EMCP will strengthen anti-malaria activities all over the country through augmented IEC, training and management.

In the year 1999, NMEP has been redesignated as National Anti-Malaria Programme (NAMP).

Organisational Structure of NAMP

Integration of a national health programme with general health care system is best visible in NAMP. In fact, the history of development of NMEP (now NAMP) correlates with the history of development of primary health care in India. So much so that many experts say that the problem of malaria can be used as a concurrent indicator of primary health care in the area. Since vector-borne diseases have a very high epidemic potential, integration of their control activities with primary health care is very essential, at least for surveillance and chemotherapy.

Modified Plan of Operation (1977) made a big leap forward in this regard and the trend continues. Responsibility of case detection and treatment rests with the PHC staff, Health Worker (Male) carries out active surveillance and administers presumptive and radical treatment under the supervision of Health Assistant (Male). Laboratory Technician at PHC examines all blood films collected from the area. Medical Officer at PHC is the overall in-charge of anti-malaria activities in his area, besides taking care of serious fever cases. At the district level, a team lead by District Health Officer (DHO) and District Malaria Officer (DMO) is responsible for implementation of the programme in whole district. District Malaria Officer supervises the operational and evaluational components and is assisted by an Assistant Malaria Officer, who arranges and coordinates insecticide spray operations in various PHC areas of the district through a group of insecticide spray teams.

At the state level there is a State Malaria Officer, who coordinates between Regional and District Malaria Officers along with Urban Malaria Units in his state. State Malaria Officer is

also assisted by an Entomologist and his team. Directorate of NMEP/NAMP at the central level is the nodal agency for planning, implementation, review and evaluation of the programme.

1.2.2 National Filaria Control Programme (NFCP)

This programme was started in India in 1955 with three major components:

- Delimitation surveys.
- Recurrent anti-larval measures in urban areas.
- Anti-parasitic treatment to clinical cases and microfilaria carriers.

Operational components of NFCP have been merged with Urban Malaria Scheme since 1978. Training and research components continue to be with National Institute of Communicable Diseases (NICD).

Filariasis was generally considered to be more associated with urbanization. Now it is rapidly establishing itself as a major endemic in several rural areas as well. Now the filaria control activities are being tried to get integrated with primary care system. In this regard, peripheral health workers and volunteers are going to be key persons for training and involvement in anti-larval activities in the rural areas.

1.2.3 Kala Azar Control Programme

In our country the main burden of *leishmaniasis* or Kala Azar is confined to three states: Bihar (northern areas), West Bengal and Uttar Pradesh (some parts). It has re-emerged as a significant public health problem in these areas. The assistance for the programme is borne by the budgetary provisions of National Anti-Malaria Programme (NAMP). However, some additional resources are now being channelized to sustain planned activities against Kala Azar in the affected areas. These activities include:

- Vector reduction by indoor fesidual insecticidal spray, twice a year.
- Early diagnosis and complete treatment of Kala Azar cases.
- Health education for community participation.

1.2.4 Japanese Encephalitis Control Programme

Japanese encephalitis (JE) has rapidly spread to various parts of our country making several newer areas prone to outbreaks. Programme to control JE does not have separate budget of its own but gets assistance from National Anti-Malaria Programme (NAMP) for investigation and containment of epidemics in affected states. Following measures are taken to prevent and control the JE outbreaks:

- Vector control by aerial or ground fogging with the ultra-low volume insecticides.
- Prevention of man-mosquito contact.
- Prevention of animal reservoir-mosquito contact.

Health education.

1.3 NATIONAL TUBERCULOSIS CONTROL PROGRAMME

In this section you will learn about another important national programme i.e. Tuberculosis Control Programmes.

You must be knowing that Tuberculosis is today's global health emergency. Further, in our country, this problem has acquired threatening proportions inspite of four decades of programmed efforts to control it.

National Tuberculosis Control Programme was started in India in 1962. It has always been given due priority in health sector. Central Government financially supported the states on

50:50 basis. District was identified as the key unit for tuberculosis control activities and the District Tuberculosis Centres (DTCs) were established to develop District Tuberculosis Progamme (DTP). DTCs were assisted and strengthened by state level organisation. Main strategic components of the programme were:

- Early detection and treatment for converting infectious cases to non-infectious.
- Preventing non-infectious cases from becoming infectious with complete treatment.
- Diagnosis through radiology and sputum microscopy.
- Free domiciliary care through primary health care.
- Establishing District Tuberculosis Centres (DTCs) in every district.
- Extending coverage under Short Course Chemotherapy (SCC).
- Strengthen State TB Training and Demonstration Centres.

Revised National Tuberculosis Control Programme (RNTCP)

Though the National Tuberculosis Control Programme was very successful in creating an infrastructure for tuberculosis control throughout the country, it could not achieve the desired results in actual control of disease. Because of this reason and in consideration of changing situation and emerging threats in tuberculosis, the programme was comprehensively reviewed in 1992. As a result of this exercise Government of India adopted a new strategy in the form of Directly Observed Treatment, Short-course (popularly known by thk acronym DOTS) in 1993. The programme that has adopted DOTS strategy is known as Revised National Tuberculosis Control Programme (RNTCP). DOTS is a systematic strategy and has five major components in it:

a) Political and Administrative Commitment: Appreciation of the gravity of problem and giving it due priority.

b) Good Quality Diagnosis: Improvement in the quality of sputum microscopy. All the subjects having cough for ≥ 3 weeks will be subjected to sputum microscopy.

c) Good Quality Drugs: An uninterrupted supply of good quality anti-TB medicines to be made available. For every registered patient a box of medicines for the entire treatment is earmarked. So that the treatment will never fail for lack of drugs.

d) Right Treatment, Given in the Right Way: The heart of DOTS strategy is the component of 'directly observed treatment' in which a health worker or another trained person, who is not a family member watches as the patient swallows the daily dose of anti-TB medicines in his presence.

e) Systematic Monitoring and Accountability: Cure rate and other key indicators are monitored at every level.

In the RNTCP, the responsibility for cure has been shifted from the patient to the health care system.

Organisational Structure of NTCP

At the peripheral level, tuberculosis control activities are conducted through Primary Health Centres/Community Health Centres in the rural areas. For every 5 lakh rural population, there is a TB Unit situated at one of the CHCs. Medical Officer (TB control) is also working at sub-district level. There are TB Centres and Chest Clinics for urban areas.

At district level, a District Tuberculosis Centre (DTC) works under District Tuberculosis Qfficer as a nodal body for planning, organisation and implementation of TB control activities in the entire district. There are separate Tuberculosis Officers for metropolitan cities,

Besides the national TB institutions, State TB Training and Demonstration Centres are also strengthening the programme. The overall supervision of the programme is done by Deputy Director General (TB) at the national level.

1.4 NATIONAL LEPROSY ERADICATION PROGRAMME

In this section you will learn about another important national health programme related to a .chronic disease which is leprosy.

In 1955, National Leprosy Control Programme was started. Early detection of cases and depsone monotherapy were the mainstays of the programme. But, due to very long duration of treatment and irregular compliance, it could not register much success. After the successful piloting of multi-drug therapy (MDT) in two districts of our country, the programme was redesignated as National Leprosy Eradication Programme (NLEP) in 1983 with the objective to eliminate leprosy as a public health problem by 2000 AD. MDT has shown good results and the prevalence of leprosy has declined from 5.711000 population in 1981 to 0.5911 000 population in 1996.

The broad strategy of NLEP has two major components:

- Interruption of transmission through early detection and prompt and adequate treatment using MDT.
- Case holding and surveillance.

Strategy for Endemic Districts with Complete Vertical Set-up

There is a separate cadre of health functionaries in the districts with prevalence of ≥ 5 per 1000 population. It works with following strategic components:

- Strengthening of leprosy control infrashucture in the district.
- Adequate training of staff in MDT operations.
- Rapid surveys to enlist undetected cases.
- Screening of all cases to delete cured, left, died cases; categorizing others as multibacillary or paucibacillary cases; and preparing individual case cards.

Strategy for Endemic Districts with Inadequate Infrastructure

In the districts where vertical set-up is yet to be established, a modified approach for MDT has been adopted. It differs from the vertical programme in following areas:

- District Leprosy Unit worksunder the overall charge of District Medical Officer.
- Leprosy control activities are done by primary health care staff, when separate cadre of health workers is not available.
- MDT operations are under the charge of Medical Officer of the PHC.

Strategy for Districts which have Completed ≥ 7 Years with MDT

- Half of the paramedics from the separate vertical cadre are redistributed to make them a part of PHC.
- District Leprosy Unit is retained at district level.
- Infrastructure created under leprosy is retained. In addition to NLEP, it starts sharing some work for tuberculosis control.

Strategy for Next Phase

- Bringing modified MDT districts under regular vertical MDT for 5 years by hiring extra manpower.
- Introducing modified MDT in moderately endemic districts having prevalence between 2 to 5 per 1000.
- Introducing MDT in endemic pockets of remaining low endemic districts.
- Establishing zonal set-up to cover endemic pockets cutting across several districts.
- Establishing IEC cell at national headquarter to coordinate health education activities.

Organisational Structure of NLEP

The programme is headed by National Leprosy Eradication Board and Leprosy Division of the Directorate General of Health Services at the central level. This leadership is augmented by central and regional Leprosy Training and Research Centres and a number of voluntary organisations. At the state level, there is a State Leprosy Officer under the Directorate of Health Services of the respective state.

At the district level, tlie programme is supervised by the District Leprosy Officer who coordinates the activities of Leprosy Control Units (LCU) in the district. His/Her efforts are assisted by following other leprosy control facilities at district level:

- Leprosy Training Centres
- Urban Leprosy Centres
- Teniporary Hospitalisation Wards
- Reconstructive Surgery Units
- Sample Survey with Assessment Unit
- Leprosy Rehabilitation Promotion Unit
- Mobile Leprosy Treatment Units

Leprosy Control Units function as the key agencies in conducting programme activities. It is staffed by a medical officer with his team of non-medical supervisors, trained leprosy paramedics, laboratory technicians, physiotherapist, health educator and statistical assistant. In the rural areas with prevalence 1-511000, there is provision of Survey Education and Treatment (SET) Centres. One SET centre covers 25000 population. It is staffed by a trained leprosy paramedic and is attached to a PHC.

1.5 PROGRAMMES AGAINST AIDS AND STDs

You must already be knowing that infection with Human Immuno-deficiency Virus (HIV) is a world-wide problem and has been reported from all parts of our country. There has been a considerable rise in the seropositivity rate during last two decades. The burden of Sexually Transmitted Diseases (STDs) is an old problem with us and we have been tackling it through one of our oldest health programmes. In both of these diseases, risk behaviour is similar and unsafe sex plays a very important role in transmission and maintenance of pool of infection in population. Moreover, presence of STDs facilitates both acquisition and transntission of HIV infection. These considerations create a need for development of an approach that tackles both of these problems under a unified or integrated programme. Efforts have already began to achieve this integration at both, national and primary care levels.

1.5.1 National AIDS Control Programme

The HIV infection is spreading from high risk to low risk groups and from urban to rural areas. Today, there are over 7000 identified cases of AIDS in India and the probable source of infection in three fourth of them is heterosexual contact. The overall seropositivity rate in our country is 24.61 per 1000 persons screened.

A concerted activity to contain the spread of this terminally fatal disease started in 1987 when National AIDS Control Programme was initiated with following objectives:

- To prevent infection with HIV.
  To reduce the personal and social impact of HIV infection.
  To mobilize and unify national and international efforts against AIDS.

The plan of action consists of following strategic components:

Strengthening of Programme Management: The salient features of this component have been described under the organisational structure of NACP.

Surveillance: HIV/AIDS surveillance is being done through I-IIV sentinel surveillance at selected centres for specific population groups e.g. STD clinic attenders, injecting drug users and also pregnant women at certain centres; and surveillance of AIDS cases through all medical institutions.

Information, Education and Communication (IEC): For the dissemination of correct and consistent messages through interpersonal channels, health workers, group activities, and mass communication.

Targeted Interventions: Specifically designed for specific high risk groups with an aim of behavioural modification.

Control of Sexually Transmitted Diseases (STDs): STD control activities are being integrated with AIDS control programme. You should also go through the sub-section on National STD Control Programme at the end of this section,

Cohdom Programming: To ensure easy access for people to good quality, acceptable and affordable condoms and providing the right and adequate information about safe sex and condoms to people,

Blood Safety Programme: To ensure safety of blood and blood products. This programme was started in 1989-90. Now it has become an integral part of NACP. National Blood Transfusion Council, established in 1996, looks after this progranune.

Organisational Structure

National AIDS Committee and a Multisectoral Committee have been constituted at the national level to create intersectoral collaboration. National AIDS Committee is the highest body to give policy direction and supervise programme performance. It has representatives from various ministries, non-government, private and voluntary organisations and is chaired by the Union Minister of Health and Family Welfare.

Three more bodies have been set-up at national level, under the National AIDS Committee: National AIDS Control Board (NACB), National AIDS Control Organisation (NACO) and Technical Advisory Committee (TAC). National AIDS Control Board works under the chairmanship of secretary (health). Its functions arc to approve the NACO policies, expedite financial sanctions, approve procurcment and to undertake and award contracts to private bodies. NACO was established under Ministry of Health and Family Welfare for effective implementation and monitoring of the programme. The TAC works as an advisory body to NACO, and has eight sub-committees to cover key programme areas.

At the state level, State AIDS Cells, Empowered Committees and State Technical Advisory Committees supervise the programme activities and coordinate with the national bodies.

1.5.2 National STDs Control Programme

Started in 1949, it is one of the oldest health programmes in India. I-lowever, in today's reality, the STD control has been integrated with AIDS control activities considering the relationship between HIV and STD. To accomplish this integration STD Programme Officers have been appointed in the NACO at national level and in the State AIDS Cells at state level. Syndromic approach has been adopted as the main strategic component in treating STDs at peripheral level.

The syndromic approach has substantively simplified the treatment of STDs even at a place where proper diagnostic facilities for STDs are not available. In this approach, a combined treatment is given for all pathogens that can create a particular clinical picture (syndrome). Treatment prescribed is the one which is simple, short and still very effective. Most of the time STDs manifest as one of the following syndromes:

- Genital ulcer
- Urethral discharge
- Vaginal discharge
- Inguinal swelling
- Lower abdominal pain

A flow chart, with recommended treatment regimens, has been developed against each of these syndromes that helps in clinical decision making and in the selection of a suitable prescription for the patient.

1.6 NATIONAL GUINEA WORM ERADICATION PROGRAMME

After small pox, guinea worm is the next disease that has been virtually eradicated from India through deliberate human intervention. The last case of guinea worm in India was reported in August, 1996. This is a result of concerted activities through a quickly established eradication programme. In 1980, approximately 45000 guinea worm patients from seven states of our country (Rajasthan, Gujarat, Madhya Pradesh, Maharashtra, Andhra Pradesh, Karnataka, and Tamil Nadu) were estimated. Most of the cases were coming from rural areas. Ours was the first country to launch a National Guinea Worm Eradication Programme in

1983-84. It is a centrally sponsored programme which adopted following eradication. strategies:

- Case detection through three active case search operations during April, June and December every year followed by inter-search surveillance and regular monthly reporting.
- Case management.
- Vector (Cyclops) control by treatment of unsafe drinking water sources with Temephos, eight times a year along with use of fine mesh nylon/double layered cloth strainers to filterthe drinking water.
- Health education and community involvement.
- Continued training for manpower development for eradication activities.
- Provision and maintenance of safe drinking water supply on priority in endemic villages.
- Concurrent evaluation and operational research for efficiency and effectiveness of the programme.

Organisational Structure of **NGWEP**

GWEP activities have been integrated with the primary health care system of endemic states, and have been implemented by respective State Health Directorates. Each endemic state has a GWEP-Officer who is assisted by a Technical Officer. The District Medical Officer and PHC Medical Officer are responsible for local planning, implementation and monitoring of eradication activities.

1.7 LET US SUM UP

In this unit you have learnt about the historical evolution, strategic components and organisational structure of the programmes related to vector-borne diseases, tuberculosis, leprosy, AIDS & STDs, and guinea worm disease in India.

You have also learnt that how the history of development of a programme against one particular communicable disease (malaria) correlates with the history of development of primary health care in India. And also that the control activities targeted to other vector-borne diseases like filaria, kala-azar and JE are closely associated with NMEP/NAMP. Similarly AIDS control activities work in tandem with STD control activities. You have also learnt about the strategic shift in Revised National Tuberculosis Control Programme as it is applying the DOTS. The change brought by MDT in our approach towards leprosy control and distinctive organisational features in NLEP have been highlighted. The strategies and achievements of National Guinea Worm Eradication Programme have also been outlined.

It was also highlighted that most of the national health programmes need to be integrated with primary care system to be effective and sustainable.

In the next unit you will learn about the programmes related to non-communicable diseases.

11.8 KEY WORDS

Annual Parasite Incidence (API) : A measurement of malaria incidence calculated by the formula: (Confirmed cases in one year ÷ Population under surveillance × 1000.

Presumptive treatment *(in malaria)* : Antimalarial treatment given on assumption that all fever cases are due to malaria. It is administered before the blood film is examined.

Radical treatment *(in malaria)* : Anti-malarial treatment given to blood film positive cases during follow-up visit, It is definitive treatment to ensure complete cure and make the patient non-infective.

Reservoir *(of infection)* : Any part of living or inanimate environment which harbours the pathogenic organisms capable of being transmitted to humans or animals.

Syndrome : A group of symptoms creating a clinical picture. Standard definition of the term 'syndrome' is: *the aggregate of signs, symptoms or other manifestations considered to constitute the characteristics of a morbid entity.*

Veotor *(in infective diseases)* : An animal, commonly an arthropod, capable of transmitting an infective organism from one host to another.

1.9 ANSWERS TO CHECK YOUR PROGRESS

Check Your Progress 1

1)
- Insecticide spray during the transmission period in rural areas having Annual Parasite Incidence (API) ≥ 2.
- Active surveillance by fortnightly domiciliary visits and blood smear collection.
- Presumptive and radical treatment.
- Decentralization of laboratory services to PHC level.
- Establishment of Drug Distribution Centre (DDCs) and Fever Treatment Depots (FTDs).
- Control of *Plasmodium falciparum* and checking its spread through ***Plasmodium falciparum Containment Programme*** (*Pf*CP).

2)
- Hard-core (Tribal) areas
- Epidemic prone areas
- Project aregs
- Triple insecticide resistance areas
- Urban areas

3) Because of a comprehensively review of National Tuberculosis Control Programme in 1992. Government of India adopted a new strategy in the form of Directly Observed Treatment, Short-course (DOTS) in 1993. The programme is redesignated as Revised National Tuberculosis Control Programme (RNTCP), The responsibility for cure has been shifted from the patient to the health care system. In DOTS strategy, an uninterrupted supply of good quality anti-TB medicines is ensured and the patient swallows the daily dose of anti-TB medicines in the presence of a health worker or another trained person, who is not a family member.

4)
- Political and administrative commitment
- Good quality diagnosis
- Good quality drugs

- Right treatment given in the right way
- Systematic monitoring and accountability

5)
- Interruption of transmission througth early detection and prompt and adquate treatment with MDT
- Case holding and surveillance.

6)

UNIT 2 PROGRAMMES RELATED TO NON-COMMUNICABLE DISEASES

Structure

2.0 OBJECTIVES

After going through this unit, you should be able to:

- explain the importance of control programmes for non-communicable diseases;
- describe the historical aspects, objectives, infrastructure and activities of various National Health Programmes for control of non-communicable diseases;
- describe the indicators for monitoring of these programmes; and
- explain the role and responsibilities of community health administrators and hospital administrators in these national programmes.

2.1 INTRODUCTION

Non-CommunicableDiseases are likely to become a major future public health problems in the country due to changing life-styles, increasing stress and tensions due to changes in social and cultural systems in the society. Other factors like increase in life expectancy, resulting primarily from decline in child mortality, control of infectious diseases, extensive use of antibiotics, improvement in nutritional standards and access to health services etc. have contributed to increase life expectancy in the population. With increase in the number of aged people, there will be higher incidence and prevalence of diseases like Hypertension, IHD, Diabetes, Cancers and the whole range of geriatrics problems. The percentage of elderly (60 years and above) is projected to increase from 6 per cent to 12 per cent by 2025. This demographic transition would result in an ageing society, with elderly people having multiple illnesses, loss of vision, loss of hearing, impaired mobility, social isolation, mental stress, loneliness, depression, etc. in this age group.

The estimated number of cancer cases in India are 2 millions and every year 7 lakh cases are detected and 3 lakh die due to cancer in the country. The prevalence of mental disorders is estimated to be 15-20 per thousand population. Various studies put the prevalence of diabetes to be ranging from 0.95 per cent to 3.8 per cent in urban areas and 0.6 to 1.93 per cent in rural areas of the country. About 40 millions are estimated to suffer from coronary vascular diseases. The prevalence of IHD is estimated to be varying from 4.6 to 14.1 per 1000 population.

Besides, there are approximately 12.5 millions economically blind in India and 80 per cent of this blindness is due to cataract. Nearly 60 millions have endemic goitre and an estimated 8.8 millions have mental or psychomotor handicap due to iodine deficiency.

In this unit, you will leam about various national health programmes related to these non-communicable diseases. You will learn about the importance, historical development objectives, infrastructure activities of five important national health programmes viz. blindness control, Iodine deficiency control mental health, cancer control and diabetes control. You will also learn about the indicators for monitoring these progrmme. Towards the end of this unit you will learn about the role of health and hospital management in these programmes.

2.2 NATIONAL PROGRAMME FOR CONTROL OF BLINDNESS

2.2.1 Importance

Of the total estimated 30 million blind persons in the world, 6 million are in India. In India, as per the National Survey results, it is estimated that there are more than 12 million economically blind persons. Of the total 80 per cent are blind due to cataract, 7.35 per cent due to refractive errors, 1.70 per cent glaucoma, 1.52 per cent due to central corneal opacities, 0.39 per cent trachoma and the remaining 4.35 per cent suffer from other causes.

2.2.2 Historical Development

The Government of India established a Trachoma Control Pilot Project in 1956. From the survey on prevalence of infection it was noted that the States could be classified in three groups according to the trachoma endemicity:

Group I: Highly endemic having trachoma prevalence above 50 per cent, comprising the States of the Punjab (74.3 per cent), Uttar Pradesh (68.1 per cent) and Gujarat (56.0 per cent).

Group II: Moderately endemic with prevalence between 50.20 per cent comprising the States of Madhya Pradesh (41.3 per cent), Bihar 35.0 per cent, Assam (25.2 per cent) and Mysore (22.6 per cent).

Group III: Low endemicity with prevalence under 20 per cent were the State of Jammu and Kashmir (16.8 per cent), Maharashtra (11.3 per cent), Kerala (8.7 per cent), Andhra Pradesh (5.3 per cent), Tamil Nadu (4.6 per cent), Orissa (2.7 per cent), and West Bengal (0.5 per cent).

In the launching of the National Trachoma Control Programme priority was given to the high endemic areas where the prevalence was over 50 per cent. By the end of December 1973, a total of 81.07 million population from the 16 States had been brought under the control activities covering 968 Community Development Blocks/Primary Health Centres. Stress was laid on the control measures in the most vulnerable age group i.e. children up to 10 years of age.

In 1973-75, after the Indian Council of Medical Research Survey results were received and the causes of blindness came into focus, the thrust of the strategies of the programme underwent extensive modifications. The Central Council of Health and Family Welfare, at its meeting held in 1975, resolved that one of the basic human rights was the right to see. National Blindness Control Programme was launched in the year 1976 as a 100 percent centrally sponsored programme.

2.2.3 Objectives of the Programme

To reduce the prevalence rate ofblindness from 1.49 per cent to 0.3 per cent by the year 2000 AD.

2.2.4 Programme Strategies, Infrastructure and Activities

Strategy

The four pronged strategy of the programme is:

- strengthening service delivery,
- developing human resources for eye care,
- promoting outreach activities and public awareness,
- developing institutional capacity.

Strengthening Service Delivery

The programme aims to improve the physical, teclinical, and managerial capabilities of medical colleges, district hospitals, community health centres, primary health centres and selected non-profit institutions to provide high quality cataract treatment in institutions or through camps. The programme is implemented through a combination of service delivery models: medical colleges, camps in fixed facilities; camps in iniprovised facilities, (in exceptional case) and if necessary in private facilities, in collaboration between the Central Government, the State Governments, Non-Government organisations.

Strengthening of service delivery is ensured through:

- adhering to the norms for service delivery,
- increasing the output of resources allocated,
- regularisation of organisation of camps,
- involvement of NGOs and private sector, and
- expansion of coverage to tribal and remote rural areas.

4

Development of Human Resources

This component intends to strengthen medical colleges and Regional Institutes of Ophthalmology (RIOs) to train ophthalmologists and selected health personnel on cataract diagnosis, screening, surgery and follow up care as required, and these also provide management training for Central and State Project Managers, District Society Members, Project Co-ordinators and other project staff requiring managerial and administrative skills. training.

Promoting Outreach Activities and Public Awareness: Beneficiary assessment have revealed a variety of factors deterring potential patients from seeking surgery in the different areas. The component aims to generate patient demand for surgery through outreach camps and promotional campaigns.

Infrastructure at Tertiary Level: At the tertiary level of ophthalmic care there are Regional Institutes of Ophthalmology including the Apex institute Dr. R. P. Centre in the All India Institute of Medical Sciences, New Delhi. These centres have been established as centre of excellence in the field of eye care.

In addition, 82 medical colleges have been upgraded under NPCB.

There are 39 medical colleges which have been designated as training centres for Paramedical Ophthaimic Assistants.

Eye banks have been developed in government and non-government sector for promotion of eye donation and collection of eye for corneal transplantation.

Infrastructure at Secondary Level: Districts Hospitals have been equipped for ophthalmic services under NPCB. These districts have been given ophthalmic equipment and requisite manpower have been posted. Central mobile units have also been formed.

Recently, the District Blindness Control Societies scheme has been extended to cover the entire country. These societies have multi-disciplinary structure in which representatives of Government, non-government and private sector.

The concept of District Blindness Control Society (DBCS) is to de-centralise management of ophthalmic services and evolve a partnership among Government, non-government and private sector.

As many as 497 District Blindness Control Societies have been formed till date.

Infrastructure at Primary Level: The problem of blindness in rural areas and hence the programme has tried to expand accessibility of ophthalmic services.

There are 80 central mobile units (attached to medical colleges) and 316 district mobile units which cater mobile eye camps for eye care in general and performance of cataract surgery in particular. These units have a vehicle, ophthalmic surgeon and other para-medical staff. Most of the cataract operations in rural population are conducted through these mobile camps.

Primary health centres are the basic units in the rural areas. Primary health centres have been equipped with ophthalmic equipment and by posting para-medical ophthalmic assistants (PMOA's).

District Blindness Control Society

The society acts under the chairmanship of District Magistrate together with other medical personnel and NGOs with funds directly from the centre.

The objectives for these societies are as follows:

- Providing comprehensive eye care, including school eye screening programme, and rehabilitation of the blind.
- Developing institutional capability for eye care management at the Central, State and District levels.
- Developing collaborating mechanisms for co-operation between the Government and the private/voluntary sector.
- Introducing, monitoring and feedback mechanisms to facilitate implementation and maintain quality control.
- Building institutional capacity for human resources development.

Various activities of the programmes are:

- establishment of Regional Institutes of Ophthalmology,
- up-gradation of medical colleges and district hospitals,
- development of mobile eye units,
- recruitment of required ophthalmic manpower, and
- provision of various ophthalmic services.

Under the IX Plan

The National Blindness Co-ordination Committee recommended the following schemes for implementation for the IX Plan (1997 – 2002).

- Strengthening of the existing infrastructure for eye care, including voluntary sector.
- Strengthening management of eye care programmes through the establishment of the National Eye Care Resource Centre and strengthening Central and State management Cells and DBCSs.
- The school eye screening programme to be extended to all the blocks in the country.
- A policy shift from camp approach to Base Hospital is envisaged to ensure quality of eye care.
- Introduction of comprehensive services for the other major causes of blindness and ocular morbidity in India in addition to cataract.

2.3 NATIONAL IODINE DEFICIENCY DISORDERS CONTROL PROGRAMME (NIDDCP)

2.3.1 Importance

Iodine, as you know is a micro-nutrient which is required in the amount of 100-150 micro-grams daily for normal human growth and development. Its deficiency results in abortion, still-birth, mental retardation, deaf-mutism, squint, dwarfism, goitre in all ages; neuro-motor defects etc. Iodine deficiency thus directly affects the "Human Resource Development" which in turn greatly affects the human productivity as well as country's development.

It is estimated about 200 million people are in our country are at risk of developing Iodine Deficiency Disorders (IDD), There is an increasing evidence of wide-spread occurrence of environmental iodine deficiency not only in the Himalayan Tarai areas, but also in river-line areas and even the coastal regions. Surveys conducted by the Central and State Health

Directorates, ICMR and medical institutes have clearly demonstrated that not even a single State/UT is free from the problem of IDD. Sample surveys have been conducted in 25 States and 4 Union Territories of the country which revealed that out of 275 districts surveyed, so far, IDD is a major public health problem in 235 districts where prevalence is more that 10per cent.

In India it is estimated that 71 million population are suffering from endemic goitre and other IDDs.

2.3.2 Historical Development

In India the classical goitre belt extended from Kashmir in North West to Naga Hills in the North East, a stretch of 2400 km. Between 1956-62 Iodised salt was used in the Kangra Valley for mass prophylaxis of goitre and the success of the experiment led to the initiation of the 100 per cent centrally sponsored National Goitre Control Programme in 1962 by the Government of India. The strategy followed was supply of Iodised salt to the endemic areas.

In 1984 the Government of India adopted the policy of Universal Iodisation of salt in the whole country and accordingly modified the organisation and management of National Goitre Control Programme.

The Prevention of Food Adulteration Act was amended in 1988 and as per this the Iodised Salt was to contain 30 ppm Iodine at production level and 15 ppm at retail level.

The Government of India changed the nomenclature of the Goitre Control Programme to National Iodine Deficiency Disorders Control Programme in 1992 to ernphasise the wider implications of Iodine deficiency. The focus centred around the fact that universal iodisation of salt was the most effective measure in terms of human resource development with a cast benefit ratio of 1:8.

2.3.3 Objectives of the Programme

The main objective of the programme is to eliminate IDD to less than 10 per cent by the year 2000.

2.3.4 Programme Strategies, Infrastructure and Activities

Strategies

Programme strategies include:

- use of iodised salt in place of common salt.
- monitoring and surveillance.
- manpower training.
- mass communication.

Programme Infrastructure and Activities

- The policy of iodated salt production has been liberalised and thrown open to private sector. 641 private manufacturers have been licensed by the Salt Commissioner. Annual production capacity of iodated salt is more than 60 lakh metric tones for the entire country.
- The Salt Commissioner in consultation with the Ministry of Railways arranged for the transportation of iodated salt from the production centres to the consuming States under priority category 'B' which is second to that for defence.
- In order to ensure use to only iodated salt, 27 States /UTs have completely banned the sale of salt other than iodised salt while two other State viz. Andhra Pradesh and Maharashtra have issued partial ban.
- For effective monitoring and proper implementation of NIDDCP the States/UTs have been advised to set up IDD Control Cell in the State Health Directorates and Central Government provides cash grants for this purpose. Provides 26 States/UTs have established such cells.

- A National Reference Lab for monitoring of IDD has been set up at the National Institute of Communicable Diseases, New Delhi for training both medical and para-medical personnel and monitoring'iodine content in salt and in urine samples.
- For ensuring the quality control of iodated salt at cansumption level testing kits for on the spot qualitative testing have been developed and distributed to all district health officers in endemic States for awareness.
- It has been proposed to set up district level IDD monitoring labs in all the States who have issued ban notification for iodine. The content of salt and urinary iodine excretion are the most effective tools for proper monitoring of implementation of IDD Control Programme. An allocation of Rs. 75,000 per lab have been provided for this purpose.
- Cash grants are provided by the Central Government for conducting surveys/resurveys of IDD and to carry out Health Education and Publicity campaigns to promote the consumption of iodated salt.
- Realising the importance of control of iodine deficiency in relation to Human Resource Development, NIDDCP has been included in 20 Point Programme.
- The standards for iodated salt have been laid down under PFA Act, 1954. These stipulated the iodine content of salt at the production and consumption level to be at least 30 and 15 Parts Per Millions (ppm) respectively.

2.4 NATIONAL MENTAL HEALTH PROGRAMME

2.4.1 Importance

In various morbidity surveys, mental illness in India are estimated to vary from 18-20 per thousand population, which is not less than that in developed countries. Mental health as you know is not only related to relations between persons, but also to individuals' relations with community, social institutions, the way of living and working.

2.4.2 Historical Development

The National Mental Health Programme was initiated into the Central Scheme in 1982 considering the magnitude of the problem in the country. As had been recommended by the Central Council of Health and Family Welfare in October 1995, the District Mental Health Programme with a community based approach was launched in four districts, one each in the states of Andhra Pradesh, Assam, Rajasthan and Tamil Nadu in 1996-97 on a pilot basis under the National Mental Health Programme.

The District Mental Health Programme was further ektended to seven more districts in 1997-98 covering one district each in the states of Arunachal Pradesh, Haryana, Himachal Pradesh, Madhya Pradesh, Maharashtra, Punjab and Uttar Pradesh. During 1998-99 it was further extended to five more districts in the country.

The annual meeting of the Central Mental Health Authority was held in December 1998 and reviewed the implementation of Mental Health Act, 1987. The authority also reviewed the

implications arising of inclusion of mental illness as a disability in the persons with Disabilities Act, 1995.

2.4.3 Objectives of the Programme

The objectives of the National Programme for Mental Health are:

- To ensure availability and accessibility of minimum mental health care for all in future.
- To encourage applications of mental health knowledge in general health care.
- To promote community participation in mental health services.

2.4.4 Programme Strategies, Infrastructure and Activities

Strategies

Strategies for the programme include

- Training of all workers in the mental health team at identified nodal institutions.
- Health education to increase public awareness and to reduce social stigma
- Services for care of mentally ill patients in OPDs and indoors.
- Collection of related data for future planning, monitoring and research.

Infrastructure and Activities

Following infrastructure and activities have been envisaged in the programmes

- Village health guide at village level identifies and refers/follow-up the case.
- Health worker at Sub-centre level provides first aid and refers/follow up.
- Health assistants help in early detection and management of such cases under the supervision of medical officers.
- Medical officers of Primary Health Centres have overall responsibility of organising and supervising the primary level mental health care.

Various services provided under this programme are:

- Treatment of cases of Schizophrenia, psychosis, paranoid reactions, dementia, anxiety, hysteria, neurotic depression etc.
- Rehabilitation by opening community, district and higher level rehabilitation centres.
- Health education activities to increase awareness.

2.5 NATIONAL CANCER CONTROL PROGRAMME

2.5.1 Importance

Cancer has become one of the ten leading causes of death in India. In India it is estimated that there are nearly 1.5 – 2 million cancer cases at a given point of time. Over 7 lakh new cases of cancer and 3 lakh deaths occur annually due to cancer. Nearly 15 lakh patients

require facilities for diagnosis treatment and follow up at a given time. Data frompopulation based registries under National Cancer Registry Programme indicate that the leading sites of cancer have remained unchanged over the years, namely oral cavity, lung, oesophagus and stomach amongst men and cervix, breast and oral cavity amongst women. Cancers namely those of head and neck in males, and cervix and breast in females account for over 50per cent of all cancer deaths in India. WHO has estimated that 91 per cent of oral cancers in South-East Asia are directly attributable to the use of tobacco and this is the leading cause of oral cavity and lung cancer in India.

Cancer usually occurs in the later years of life and with increase in the life expectancy to more than 60 years, an estimate shows that the total cancer burden in India for all sites will increase from 7 lakh new cases per year to 14 lakh.

2.5.2 Historical Development

The Government of India, considering the gigantic problem of cancer, launched the National Cancer Control Programme in 1975-76, but at that time priorities were given for equipping the premier cancer hospital/institutions. Central assistance at the rate of Rs. 2.50 lakhs was given to each institution for purchase of cobalt therapy units.

A total of Rs. 19.34 crores was released by the Government for the implementation of the programme during the VIIth Plan period. At the same time ten major institutions were recognised as Regional Cancer Centres which received financial assistance from the Government.

However, it was realised soon that facilities for cancer control in the country at that time were grossly inadequate. The ten regional cancer centres covered only 10per cent of the population for treatment purposes. Some screening programmes were being carried out in a haphazard manner for common cancers e.g. cancer cervix. Public awareness about cancers and measures for tobacco control were patchy. The measures taken so far had been mainly directed towards treatment in advanced stages when it is least effective.

The strategy was revised in 1984-85 and the Cancer Control Programme was made a National Programme.

2.5.3 Objectives of the Programme

The objectives of the programme are:

Primary prevention of cancers by health education regarding hazards of tobacco consumption and necessity of genital health for prevention of cervical cancer.

- Secondary prevention i.e. early detection and diagnosis cancers, for example, cancer of cervix, breast cancer and of the oropharynageal cancer by screening methods and patients' education on self examination methods.
- Strengthening of existing therapeutical services.
- Palliative care in terminal cancers.

2.5.4 Programme Strategies, Infrastructure and Activities

The strategies, infrastructure and activities under this programme include:

Development of Oncology Wings in Medical **Colleges/Hospitals:** This scheme had been initiated to fill up the geographical gaps in the availability of cancer treatment facilities in the country. Central assistance was provided for purchase of equipment which included one cobalt unit. The civil works and manpower were provided by the concerned State Government/Institution. The quantum of central assistance was increased from Rs. 1 crore to Rs. 1.50 crore per institution under the scheme.

Scheme for **District** Projects: It is known that a large number of cancer cases can be prevented with suitable health education and the cases detected early are curable without much expensive treatment. Accordingly the scheme for district projects, preventive health education, early detection and pain relief measures was started. Under the scheme one time

financial assistance of Rs. 15.00 lakh is provided to the concerned State Government for each district project selected under the scheme with a provision of Rs. 10.00 lakh per year for each district for the remaining four years of the project period. The project is linked with a Regional Cancer Centre or an institution having good facilities for treatment of cancer patients. The patients are provided treatment at the conce ned Regional Cancer Centre or the nodal institution.

Financial Assistance to Voluntary Organisations: Under the scheme financial assistance upto Rs. 5.00 lakh is provided to the registered voluntary organisations recommended by the State Government for undertaking health education and early detection activities in cancer.

Cobalt Therapy Installation: To strengthen the treatment facilities the financial assistance has been raised to 1 crore from 1994-95 per unit, and other radio therapy equipment were also bought under the scheme.

Development and Dissemination of Health Education Materials: Health education materials for education of the public not to take tobacco and improve the general hygiene especially of the genitalia to prevent cervical cancers and how to palpate the breast i.e. self exaniination is advocated. For oral cancers people can examine themselves by opening the mouth and seeing in the mirror. Any abnormality if found by this can be further checked by the health workers and senior health officials.

Procurement, Supply and Distribution of Pain Relief Medicines: Under the Cancer Control Programme, Government of India is trying to procure oral morphine tablets for needy cancer patients to relieve their pain?So far it is being given to the Regional Cancer Centres recognisedby the Government of India and to some of the teaching medical colleges which have been recognised under the development of Oncology wing. Wherever the district programme is going on, Regional Cancer Centre are helping them if morphine tablets are needed in those areas.

Assistance for Regional Research and Treatment Centres: There are 12 Regional Research and Treatment Centres recognised by Government of India and recurrent expenditure to the tune of Rs. 50 lakhs is being given to these Regional Cancer Centres.

Role of Regional Cancer Centres

The functions of the regional centres are:

- diagnosis treatment and follow up,
- surveys of mortality and morbidity,
- training of personnel both medical and para-medical,
- preventive measures with emphasis on mass examination, health education and industrial hygiene, and
- research fundamental and applied.

National Cancer Registry Programme (NCRP)

It was realised way back in 1964 that authentic data on cancer was lacking in the country. So, the first Indian Cancer Registry was set up in Bombai. Subsequently the National Cancer Registry Programme was established in 1981-82 by the Indian Council of Medical Research (ICMR) to provide information for the National Cancer Control Programme in India. A need; therefore, was recognised for organisation of cancer registries in different regions of the country and strengthening of the existing cancer registry at Bombai.

The main objectives of NCRP are:

- to generate authentic data on the magnitude af the cancer problem,
- to undertake epidemiological investigations and advice control measures, and
- to develop human resource for research in cancer epidemiology.

The original network of NCRP consisted of three population based cancer registries at Bangalore, Bomb9 and Chennai and three hospital cancer registries in the Chandigarh,

Dibrugarh and Trivandrum. Later on, hospital cancer registries at Bangalore, Bombai and Chennai were strengthened. The network was subsequently expanded by addition of three population-based cancer registries one each at Delhi and Bhopal and a rural registry at Barshi (Maharashtra).

2.6 NATIONAL DIABETES CONTROL PROGRAMME

2.6.1 Importance

Epidemiological studies show 1-2 per cent prevalence of diabetes mellitus in India. The multicentric study conducted by ICMR shows that in persons over 15 years of age, the overall prevalence rate of 1.73 per cent. In urban population it is between 0.95-3.8 per cent and for rural population it varies between 0.6 to 1:93 per cent.

2.6.2 Historical Development

An Expert Committee was constituted by the Government of India in 1986 to formulate a national plan of action for the implementation of the National Diabetes Control Programme during the Seventh Five Year Plan.

2.6.3 Objectives of the Programme

The objectives of the National Diabetes Control Programme are:

- identification of high risk subject at an early stage, and imparting appropriate health education with focus on primary prevention.
- early diagnosis of disease and institution of appropriate management so as to reduce morbidity and mortality.
- prevention, arrest or slowing of acute metabolic as well as chronic cardio-vascular-renal complications of the disease,
- identification of subject with partial or total physical handicaps due to the disease, and to ensure their rehabilitation with emphasis on optimal organ or body function.

2.6.4 Programme Strategies, Infrastructure and Activities

It is envisaged to implement the programme at three levels.

- Level one is early identification of the cases by health workers, doctors at PHC, CHC and hospital specialist doctors through surveillance.
- Level two is case detection at hospital level through specialists and manpower training,.
- Monitoring and evaluation at national level by All India Institute of Medical Science,(' Department of Medicine.

A Steering Committee was constituted, to annually review the progress during the Eight Five Year Plan. The committee recommended that a National Diabetes Documentation Centre should be established in conjunction with the Co-ordination and Monitoring Centre located at the AIIMS, New Delhi.

The National Diabetes Documentation Centre is given the responsibility to collate and distribute all available information on the prevalence management and control of diabetes mellitus.

2.7 ROLE OF HOSPITAL AND DISTRICT HEALTH MANAGERS

Hospital Managers

The National Programmes or Control of non-communicable diseases are based on Hospital based facilities to a large extent. A hospital manager can help in these programmes by way of:

- Training of manpower (medical and other technical support manpower) in clinical and diagnostic aspects of non-communicable diseases.
- Carrying out of surveys and screening programmes in the communities for early detection of these disorders.
- Providing Sentinel Surveillance for these diseases for the cases reporting at Hospitals.
- Ensuring adequate care of case referred from peripheral institutions for diagnosis and treatment and proper feedback.
- Organisation of health education activities in hospital areas such as OPDs and Indoors.
- Rehabilitation services for disability due to these non-communicable diseases.

District Health Managers

The District Health Managers also have a crucial role to play in the implementation of the National Health Programmes including the programmes for control of non-communicable diseases.

Being mid-level managers in the hierarchy, they have to ensure optimal allocation of resources provided to them in the district for programme activities.

They need to develop'suitable monitoring parameters/indicators based on:

- Field visits reports
- Meetings and review of reports generated from the peripheral institutions
- Special surveys carried out in area.

The basic steps are as follows:

Defining an Indicator for Monitoring

An indicator as you know has a numerator, a denominator and is multiplied by a suitable constant. The various types of monitoring indicators may be:

Input Indictors

These are related to inputs or resources. Some of the examples of input ind'icators are:

- Manpower sanctioned for various categories of personnel as per the suggested norms and number of persons actually available in various categories for services under the programme.
- Amount of money required, sanctioned, released and actually used during# year for the programme activities.
- Cost per service delivered under the programme in the district.
- Equipment availability as per the suggested norm under the programme
- Equipment in working order
- Use co-efficient for the equipment. This is given by number of hours an equipment is actually used during the given period divided by the total hours when equipment is available for use.

Process Indicators

These are related to various processes and procedure involved in a progranune. These include percentage of processes and procedures done during a period as per the standard/ suggested norm for various activities under the programme.

Output Indicators

These are related to performance and include the number and types activities performed under the programme during the given period per unit persons or per unit institution in the given district.

Outcome Indicators

These are related to the ultimate effect on impact of the programmes. Some of the examples of outcome indicators are:

1)
   - Degree to which the objectives of the programme have been achieved.
   - Decrease in Morbidity or Mortality in the area.
   - Increase in awareness among clients/beneficiaries/community.
   - New cases detected, diagnosed, and treated.

2) Measure the performance level on these parameters for the programme to be monitored.

3) Compare the performance level with the standards or norms and find out the deviation if any.

4) Find out the causes for deviation and possible solutions.

5) Select the best or optimal solution and implement that solution.

2.8 LET US SUM UP .

In this unit you have learnt that Non-Communicable Diseases are likely to become a major future Public Health Problems in the country due to changing life-styles, increasing stress and tensions due to changes in social and cultural system in the society.

You have also learnt about the magnitude of problem of various non-communicable diseases which include blindness, IDD, mental illness, cancer and diabetes. Government of India has launched various national health programmes for control of these non-communicable diseases.

The estimated number of cancer cases in India are 2 millions and every year 7 lakh new cases are detected and 3 lakhs die due to cancer in the country. The prevalence of mental disorders in estimated to be 15-20 per thousand population. Various studies put the prevalence of diabetes to be ranging from 0.95 to 3.8 per cent *in* urban areas and 0.6 to 1.93 per cent in rural areas of the country.

You have been apprised about the importance, objectives and strategies for control of these. disease under respective national health programmes. Towards the end, you have learnt about the role of hospital and health managers.

Besides, there are approximately 12.5 millions economically blind in India and 80 per cent of this blindness is due to cataract. Nearly 60 millions have endemic goitre and an estimated 8.8 millions have mental or psychomotor handicap due to iodine deficiency.

2.9 ANSWERS TO CHECK YOUR PROGRESS

Check Your Progress 1

1) 6 million

.2) To reduce the prevalence rate of blindness from 1.49 per cent to 0.3 per cent by the year 2000 AD.

3)
- strengthening service delivery,
- developing human resources for eye care,
- promoting outreach activities and public awareness,
- developing institutional capacity.

4)
- Providing comprehensive eye care, including school eye screening programme, and rehabilitationof the blind.
- Developing institutional capability for eye care management at the Central, State and District levels.
- Developing collaborating mechanisms for co-operation between the Government and the private/voluntary sector.
- Introducing, monitoring and feedback mechanisms to facilitate implementation and maintain quality control.
- Building institutional capacity for human resources development.

Check Your Progress **2**

1) 200 million people are at risk.

2) To eliminate IDD to less than 10 per cent by the year 2000.

3)
- use of iodised salt in place of common salt.
- monitoring and surveillance.
- manpower training.
- mass communication.

Check Your Progress **3**

1) 18-20 per thousand population.

2)
- To ensure availability and accessibility of minimum mental health care for all in future.
- To encourage applications of mental health knowledge in general health care.
- To promote community participation in mental health services.

3)
- Training of all workers in the mental health team at identified nodal institutions.
- Health education to increase public awareness and to reduce social stigma
- Services for care of mentally ill patients in OPDs and indoors.
- Collection of related data for future planning, monitoring and research.

Check Your Progress **4**

1) 1.5-2 million.

2)
- Primary prevention of cancers by health education regarding hazards of tobacco consumption and necessity of genital health for prevention of cervical cancer.
- Secondary prevention i.e. early detection and diagnosis cancers, for example, cancer of cervix, breast cancer and of the oropharynageal cancer by screening methods and patients' education on self examination methods.
- Strengthening of existing therapeutical services.
- Palliative care in terminal cancers.

3)
- Development of oncology wings in medical colleges/hospitals.
- Scheme for district projects,
- Financial assistance to voluntary organisations.
- Cobalt therapy installation.
- Development and dissemination of health education materials.
- Procurement, supply and distribution of pain reliefmedicines.
- Assistance for regional research and treatment centres.

4)
- diagnosis treatment and follow up,
- surveys of mortality and morbidity,
- training of personnel both medical and para-medical,
- preventive measures with emphasis on mass examination, health education and industrial hygiene, and
- research fundamental and applied.

Check Your Progress **5**

1) 1-2 per cent.

2)
- identification of high risk subject at an early stage, and imparting appropriate health education with focus on primary prevention.
- early diagnosis of disease and institution of appropriate management so as to reduce morbidity and mortality.

- prevention, arrest or slowing of acute metabolic as well as chronic cardio-vascular-renal coniplications of the disease.
- identification of subject with partial or total physical handicaps due to the disease, and to ensure their rehabilitation with emphasis on optimal organ or body function.

3)
- Level one is early identification of the cases by health workers, doctors at PHC, CHC and hospital specialist doctors through surveillance.
- Level two is case detection at hospital level through specialists and manpower training.
- Monitoring and evaluation at national level by All India Institute of Medical Science, Department of Medicine.

Check Your Progress 6

1)
- Training of manpower (medical and other technical support manpower) in clinical and diagnostic aspects of non-communicable diseases.
- Carrying out of surveys and screening programmes in the communities for early detection of these disorders.
- Providing Sentinel Surveillance for these diseases for the cases reporting at Hospitals.
- Ensuring adequate care of case referred from peripheral institutions for diagnosis and treatment and proper feedback.
- Organisation of health education activities in hospital areas such as OPDs and Indoors.
- Rehabilitation services for disability due to these non-communicable diseases.

2)
- To ensure optimal allocation of resources provided to them in the district for programme activities.
- To develop suitable monitoring parameters/indicators based on field visit reports, meetings and review of reports and special surveys.

3)
- Input
- Process
- Output
- Outcome

UNIT 3 REPRODUCTIVE AND CHILD HEALTH PROGRAMME

Structure

3.0 OBJECTIVES

After going through this unit, you should be able to:

- describe briefly the evolution of RCH programme in India;
- explain the paradigm shift in the programme;
- describe components of the programme and packages of services under the each component;
- explain the role of hospitals in the implementation of the programme;
- explain various programme management dimensions; and
- list measures for improving the quality of services under the programme.

3.1 INTRODUCTION

In this unit you will learn about the genesis and components as well as service packages in relation to one of the most important national programmes, viz. Reproductive and Child Health (RCII) Programme. You will also learn the organisational set-up and infrastructural facilities for delivery of services under the programme. In addition, you will also be briefly oriented to some of the special projects and facilities envisaged under the programme. Further, you will learn about the role of hospitals in implementing the RCH programme. Towards the end you will learn about the specific managerial dimensions of the programme as well as measures to be taken for improving the quality of RCH services so as to ensure client satisfaction with the services.

3.2 EVOLUTION OF THE RCH PROGRAMME

3.2.1 Transition from MCW and FP to Family Welfare CSSM Programme

Poor health status in terms of high mortality and morbidity among women and children in India had been a major concem for public health professionals even before attainment of independence. Efforts to provide services to this vulnerable section of the population were initiated under Maternal and Child Health (MCH) services. Major hospitals in urban areas as well as Primary Health Centres (PHCs) in the rural areas were responsible to render these services since independence. The rapidly growing population of the country and its social and economic consequences on development and quality of life of people was another concern for the socio-economic development planners. The result was the launching of the National Family Planning Programme since the first five year plan period. With the advancement of technology, various other interventions for the improvement of the health of this section of population could be possible and during the seventies, programmes/schemes like imrnunisation against vaccine preventable diseases, nutritional interventions like iron and folic acid supplementation, vitamin A supplementation ctc. were initiated.

Even though the family planning programme and MCH programme were being implemented in a vertical manner, it was understood that fertility regulation was extremely important for maintenance of health of the mother and child. Similarly, it was also appreciated that couples will accept contraceptive services to prevent pregnancy, only if survival of their existing children is ensured. This realisation of the close inter-relationship between family planning and MCH programmes led to the government's major policy decision to integrate family planning with MCH and nutrition services.

Later during the seventh five year plan period, separate programmes were also initiated towards controlling two major killer diseases among children. These were Oral Rehydration Therapy for preventing deaths among children due to dehydration from diarrhoea and acute respiratory infection control programme to control morbidity and mortality due to pneumonia. Objectives of all these programmes were convergent and aimed at improving the health of mothers and young children and to provide them facilities for prevention and treatment of

major disease conditions. These programmes were implemented in the country separately, though concurrently. While all the above mentioned programmes did have beneficial results, the separate identity of each programme was causing problems for their effective management and their impact on health status of women and children could not be as visible as expected. Therefore, during the 8th five year plan period, all these programmes and services viz. antenatal, intranatal and postnatal care; child health services including immunisation, management of diarrhoea, and ARI were all integrated under the Child Survival and Safe Motherhood (CSSM) Programme which was implemented since 1992.

3.2.2 Need for Holistic Approach towards Women's Development

Even though CSSM programme was implemented all over the country with equal emphasis, the position regarding its performance and achievements was not uniform throughout the country. States like U.P., M.P., Bihar, Rajasthan, Orissa and J&K which showed performance at much lower level than the national level were also those which were more populous and hence, unless performance in these states did not improve, the national level performance also would have remained depressed. Integrated efforts towards improvement of the health status of women and children with infrastructural strengthening and resource inputs commensurate with the specific needs of the states/region became essential with a holistic approach towards overall socio-economic development and in particular for women's empowerment.

3.2.3 International Conference on Population and Development (ICPD) and Programme of Action (POA)

In the context of evolving a holistic approach to child survival and safe motherhood as explained above, the International Conference on Population and Development (ICPD) which was 3rd in the series of decadal population conferences, held in Cairo in 1994, came at an opportune time. At this conference, representatives of about 180 countries reached a new consensus about how world population issues should be approached. It was agreed that population policies should address social development beyond family planning, especially the advancement of women, and that family planning should be provided in the context of comprehensive reproductive health care. The Cairo Programme of Action (POA) defined reproductive liealth in a comprehensive fashion for the first time.

The definition states that *"reproductive health is a state of complete physical, mental and social well being and not merely the absence of disease or infirmity in all matters relating to the reproductive system and to its functions and processes".*

Reproductive health therefore implies that people are able to have a satisfying and safe sex life and that they have the capability to reproduce and the freedom to decide if, when and how often to do so. Implicit in this last condition are the right of men and women to be informed and to have access to safe, effective, affordable and acceptable methods of family planning of their choice, as well as other methods of their choice for regulation of fertility which are not against the law, and the right of access to appropriate health care services that will enable women to go safely through pregnancy and child birth and provide couples with best chance of having healthy infant. In line with this definition, *reproductive health should broadly include family planning; safe pregnancy and delivery services; prevention and treatment of RTIs and STIs; information and counseling on sexuality; and other women's health services.*

3.2.4 India's Commitment towards XCPD, POA and Launching of RCW Programme

Even though the sustained efforts in implementing the family welfare programme had benefited large number of people, over the years, it has been increasingly realised that more need to be to completely address the health needs of women and children. It has also been felt that the workload has been not set for the functionaries in accordance with the actual needs of the population. In response to these needs, government had decided to reorient the programme. At this juncture, the international consensus developed in the

ICPD, Cairo 1994, for a holistic approach to reproductive health also helped the country to develop the Reproductive and Child Health Programme in India. The RCH programme was formally launched on 15th October, 1997 in India.

.....

2) What was the major cqnsensus arrived at ICPD Conference in Cairo in 1994?

.....

.....

.....

3) When was the RCH programme formally launched in India?

.....

.....

.....

3.3 OBJECTIVES OF RCW PROGRAMME

Objectives of the RCH programme are:

1) Nationwide improved quality, coverage, and effectiveness of RCH services;
2) Improved management performance by:
   i) expanding existing monitoring system and decentralised participatory planning
   ii) institutional strengthening
   iii) enhanced programme management capacity
3) Local capacity enhancement.

3.4 PARADIGM SHIFT IN THE RCH PROGRAMME

The reproductive health approach extends beyond the narrow limits of family planning to encompass all aspects of human sexuality and reproductive health needs during various stages of life cycle. A paradigm shift is needed for operationalising the reproductive health programme. A change in focus from the population control approach of reducing numbers to a client based approach of addressing the reproductive needs of individuals, couples, and families is necessary.

An ideological shift is needed which in turn would necessitate a change in the existing culture of programme from one that focuses on achievements of targets to one that aims at providing a range of good quality services. It means that instead of remaining responsible for reducing the rate of population growth, reproductive health programme becomes responsible for reducing the burden of unwanted and unplanned child bearing and related morbidity and mortality.

It is important to note that RCH programme is a more sharply defined form of family welfare programme. It does not seek either to disband earlier programmes or to bring into a wholly new programme in a vacuum. *The* RCH *programme only seeks to fine tune the earlier programmes in an incremental manner with addition of certain service components and giving special emphasis on certain other service components already being provided. It seeks to bring about a holistic approach to programme*

implementation so that health functionaries are constantly conscious of whether good quality services are reaching the people to meet their needs.

3.4.1 Target-free Programme Based on Community Needs Assessment

Being a signatory to the ICPD Programme of Action ratified at Cairo in 1994, some major programme and policy initiatives had already been taken earlier since 1994, to give shape to the concept of reproductive health. In April 1996, even before the formal launching of RCH programme, Government of India took a landmark decision to withdraw the system of estimating workload and work allotment as well as monitoring the programme, based on centrally deteimined, method-specific contraceptive targets. Instead, it adopted a Community Needs Assessment (CNA) based; bottom up approach, where self-estimated workload/goals were used by the health personnel themselves.

3.4.2 Decentralised Participatory Planning

Planning for the services actually begins at grass-root level with members of panchayat and Mahila Swasthya Sangh (MSS) and other villagers closely interacting with the ANM and male health worker for deciding about the actual requirement of various family welfare services. This improves the sustainability of the programme on one hand, by generating a sense of involvement and ownership among the community towards the programme thereby increasing utilisation of services as well as on the other hand, by ensuring sense of responsibility and accountability among the workers. The plans prepared for tlie subcentres by the local health workers which are aggregated lo make the PHC plan in turn are aggregated at the district level to prepare the district plan.

3.4.3 Integrated RCH Package

The process of integration of various related programmes for improving health of women and children had been seriously attempted with the implementation of CSSM programme. However, with the implementation of RCH programme, this has taken a step further. It is also highly desirable to have an integrated approach since it would not only be more acceptable to the community, but would also help in reducing the cost inputs to some extent because overlapping of expenditure will not be necessary and integrated implementation would optimise outcome at the field level. This integrated package includes essential RCH package which gives basic minimum model framework of RCH services at different levels in the district viz. community, subcentre, PHC, FRU and district hospital. The essential components are:

- prevention and management of unwanted pregnancy;
- maternal care including antenatal, intranatal and postnatal as well as safe abortion services;
- child survival services including care of new born;
- management of RTI/STI.

3.4.4 State/District Specific RCW Strategy

The main focus of RCH programme is, implementation based on actual needs of people. Considering the variations in regard to different parameters/indicators of RCH and corresponding service needs among states and districts in the country, area specific approach has been worked out separately for different groups of states and districts. States and districts are classified based on indicators like, Crude Birth Rate (CBR), Total Fertility Rate (TFR), female literacy level, percentage women registered for antenatal care, percentage of hospital deliveries, percentage delivered by untrained attendant etc. For backward districts which have additional needs, additional resource inputs as per requirement are envisaged to be provided.

3.4.5 Greater Emphasis on Quality of Care

Provision of good quality care is the crux of RCH programme. Good quality care is difficult to be defined. However, a working definition of quality may be evolved incorporating few elements related to services i.e. choice of service, information provided

to clients, technical competence of service providers, interpersonal relation between service provider and clients, mechanism to ensure continuity of care etc. It may be assumed that good quality care would increase client satisfaction which is one of the major goals of the programme. This in turn would be expected to increase the service utilisation and thereby would enable achievement of the programme goals and may determine the success of the programme.

3.4.6 Comprehensive Integrated Training with District as Coordinator

In-service training of health personnel with due focus on practical clinical, managerial and communication skills is a major input under the programme towards improvement of quality of services. An important feature of the training in future would be involvement of the field functionaries and the Anganwadi workers as well as functionaries from other health related development sectors. Planning and management of the training programmes will be the responsibility of the district health authorities. Central and state governments are to support the district in training of trainers and in producing training materials,

3.4.7 Involvement of Panchayati Raj System

Panchayati raj system is expected to play a significant role in planning for RCH services particularly for identification of needs of local population for RCH services. The system is also to play a role in the implementation, particularly, financial support and transport support for referral of women to hospitals for obstetric services. In addition, for evaluation of the programme, the panchayat system is expected to extend support in assessing the client satisfaction from services. Therefore special efforts to provide RCH awareness to panchayat members are envisaged.

3.4.8 Iucreased Involvement of NGOs and Private and Corporate Sector

The programme envisages to involve personnel from NGO and private and corporate sectors in delivery of RCH services as well as in undertaking various types of training activities.

3.4.9 Area Specific IEC Campaigns

Information, Education, and Communication (IEC) activities have to play a major role in RCH programme for demystifying the RCH and population issues among public. Therefore, the Department of Family Welfare has been implementing a large IEC programme involving various government departments, NGOs and private agencies. While there is an attempt to evolve a national IEC strategy for RCH, emphasis is placed on development of local area – specific communication strategies to create more demand for RCH services and to promote informed decision making on health matters. Thus health personnel are trained in IEC skills to motivate people to use the right kind of services for meeting their needs. Special emphasis is also placed on interpersonal communication (IPC) and use of local traditional media for increasing acceptance and understanding of messages and thereby their effect and impact through behaviour change.

3.4.10 Gender Concerns

All efforts are being made to make the programme as gender sensitive as possible. Women's groups are involved in its planning and monitoring. In addition, the government has already initiated efforts which trigger changes in societal attitudes towards women. Women's empowerment and awareness about gender issues in relation to various developmental projects and programmes among all concerned are to be promoted.

3.4.11 Increased Male Participation in the Programme

Need for increased male participation in the RCH programme and on all issues related to reproductive health is being increasingly recognised. More responsibility in child rearing practices by males i.e. more responsible parenthood among males, increased acceptance of contraception by males as an evidence for acceptance of increased responsibility towards fertility regulation, informed decision making jointly by male and female partners on

reproductive health issues, male participation in RCH service provision etc. are very important.

Check Your Progress 2

1) What was the major policy decision taken by GOI before launching the RCH programme for giving shape to RCH concept?

.....

.....

.....

2) Why do we say that there is a paradigm shift in the RCH programme?

.....

.....

.....

3.5 (COMPONENTS AND PACKAGES OF SERVICES UNDER RCW PROGRAMME

Reproductive health approach means that:

- people have the ability to reproduce and regulate their fertility;
- women can go through pregnancy and childbirth safely;
- the outcome of pregnancy is successful in terms of maternal and infant health and well being; and
- couples can have sexual relations free of fear of pregnancy and of contracting disease.

3.5.1 Recommended Package of Services under RCH Programme

The RCH programme incorporates the components covered under CSSM programme and includes two additional components, one relating to reproductive tract infection and the other one relating to sexually transmitted infections. As there are enormous diversities in India, among regions and states, as well as between rural and urban areas, no single package of services can be recommended for nationwide implementation. Basically there are two types of packages:

1) A comprehensive package which at present would have limited application.

2) An essential package which is recommended for nationwide implementation.

Even if the facilities for implementing the comprehensive package are inadequate in most parts of the country, the goal should be to expand the implementation of services incrementally and in a phased manner, by utilising the lessons learnt from programme experience.

The following services are included in a comprehensive reproductive health service package:

- prevention and management of unwanted pregnancy
- services to promote safe motherhood
- services to promote child survival
- nutritional services for vulnerable groups
- prevention and treatment of reproductive tract infections and sexually transmitted diseases
- prevention and treatment of gynaecological problems
- screening and treatment of breast and cervical/uterine cancer
- reproductive health services for adolescents

- health, sexuality and gender information, education and counseling
- establishment of effective referral systems

The essential reproductive health package however excludes the management of gynaecological problems as well as screening and management of cancers.

3.5.2 Programme Interventions

The RCH programme is implemented in India based on a differential approach. Inputs in all districts have not been kept uniform because efficient delivery will depend upon the capability of the health system in a district. Therefore, basic facilities are proposed to be strengthened and streamlined specially in the weaker districts as the better-off districts already have such facilities and the more sophisticated facilities are proposed for the relatively advanced districts which have acquired the capability to make use of them effectively. All the districts have been categorised into A (best performance), B (medium performance), and C (poor performance) on the basis of CBR, and female literacy rate which reasonably reflect the RCH status of the district.

Following are the interventions in all the districts:

- Child survival interventions (as available under CSSM programme)
- Safe motherhood interventions (as available under CSSM programme)
- Facilitation for operationalisation of target-free approach
- Institutional development
- Integrated training package
- Modified Management Information System
- IEC activities and counseling on health, sexuality and gender
- Urban and tribal areas RCH package
- District subprojects under local capacity enhancement
- RTI/STI clinics at district hospitals where not already available
- Facility for safe abortions at PHC by providing equipment, contractual doctors etc.
- Enhanced community participation through panchayats, women's groups and NGOs
- Minor civil works
- Provision of lab technicians for lab diagnosis of RTI/STI and for EOC
- Adolescent health and reproductive hygiene.

3.5.3 Safe Motherhood Components

Some of the programme components are briefly described below:

1) Antenatal Care

All pregnant women should get registered with the health facility and should receive routine care and timely screening for identification of risk factors through at least three check up. Each pregnant woman should also receive two doses of Tetanus toxoid immunisation at interval of at least one month. In addition, special emphasis is given on control of anaemia among pregnant women through promoting consumption of Iron and Folic Acid (IFA) tablets and also by educating women regarding consumption of iron rich food. All pregnant women are expected to consume prophylactic dose of IFA and when found anaemic on screening through haemoglobin estimation, therapeutic dose of IFA is to be consumed.

2) Natal Care

One of the essential requirements for preventing maternal mortality and morbidity is to ensure safe delivery by every pregnant woman. It is safest to deliver babies in a health institution/hospital under care by trained personnel. In case it is not possible, it is to be ensured that deliveries at home take place under safe and hygienic surroundings and are assisted by trained personnel, preferably by ANM/LHV or at least by trained birth attendants. Delivery by relatives and friends and untrained dais are not safe and are to be discouraged. In case of any complications, referrals should be made to the First Referral

Units (FRU) for management of obstetric emergencies. Thus under RCH programme, these services are ensured under "essential obstetric care".

3) Essential Obstetric Care

Essential obstetric care includes those items of obstetric care which any pregnant woman requires if there is no complication during pregnancy or delivery. These items basically include:

- registration of pregnancy in the first 12-16 weeks of pregnancy
- at least three prenatal check ups by ANM or in dispensary or other health facility for providing check up for essential body parameters through blood pressure checks, routine investigations like urine, haemoglobin etc.
- counseling
- detection of complications of pregnancy if any
- referral to PHCIFRU in case of pregnancy complications
- assistance during delivery and three postnatal check ups
- detection of complications during delivery and referral.

4) Emergency Obstetric Care

Emergency obstetric care is an intervention for preventing maternal mortality and morbidity. The complications of pregnancy such as anaemia, haemorrhage, obstructed labour, and sepsis are major causes of maternal mortality and morbidity. If these complications are detected early and managed appropriately, maternal mortality and morbidity can be reduced substantially. If three check ups by ANM at antenatal and three at postnatal stage are ensured by competent supervision, most of such complications can be detected and managed before they become life threatening. The ANM is expected to refer the cases with complications during pregnancy or delivery to PHCIFRU. For ensuring effective emergency obstetric care under RCH programme, the FRUs are strengthened through supply of equipment kits, emergency obstetric care drug kits, provision of consultant anaesthetist etc.

5) Postnatal Care

Postnatal period which starts from delivery of placenta upto 42 days from delivery also requires special attention for preventing maternal mortality and morbidity. Postpartum haemorrhage and puerperal infection are major causes of maternal mortality. At least three postnatal check ups are to be ensured for each pregnant woman.

3.5.4 Child Survival Components

Ensuring survival and proper growth and development of every new born baby is extremely important. Inspite of various efforts made in the past and achievement of reduction in infant mortality in India, mortality and morbidity among children are still major concerns for health care providers and administrators.

Major causes of infant and child mortality and morbidity include:

- prematurity,
- respiratory infections,
- diarrhoea1 diseases,
- umbilical cord infection in the new born babies,
- birthinjuries,
- congenital malformations,
- nutritional deficiencies, and
- certain vaccine preventable infections etc.

Accordingly, the strategies for improving child survival and development include:

- strengthening essential new born care,
- appropriate management of diarrhoea,

- appropriate management of ARI,
- sustaining high levels of immunisation coverage,
- nutritional interventions like nutrition supplementation e.g. vitamin A prophylaxis, supplementaiy feeding etc.
- improved maternal care, and
- promotion of birth spacing.

1) Essential New Born Care

Inspite of decline in infant mortality, neonatal mortality still contributes to a major proportion of infant deaths. High incidence of low birth weight among babies is a common contributory factor in neonatal deaths. Major causes of neonatal mortalitv have been identified as hypothermia, asphyxia and infections. Simple cost effective indigenous technology is available to provide essential new born care at the field level to manage the direct causes of neonatal mortality. Provision of essential new born care will thus not only improve overall quality of services provided by peripheral health facilities but also contribute to decreasing neonatal mortality and morbidity.

Emphasis is placed on the following:

- Ensure five cleans i.e. clean hands, clean surface, clean razor blade, clean cord tie, clean cord stump (no applications).
- Eye care.
- Cleaning new born by wiping with soft and clean clothes and not by bathing to avoid hypothermia.
- Assessment of birth weight to identify low birth weight babies who need special attention.

  Resuscitation of new born baby who does not cry soon after birth.
- Early breast feeding initiation and exclusive breast feeding for initial 3-4 months
- Prevention of infection through clean hygienic practices.
- Immunisation against vaccine preventable diseases.

2) Control of Diarrhoea

Diarrhoea is a major cause of mortality and morbidity among young children. Dehydration caused by loss of fluids from the body is the main cause of death and hence under the programme, efforts are made to ensure prcvcntion and correction of dehydration in children through Oral Rehydration Therapy (ORT). Through health education to mothers, messages regarding need for cleanliness during handling of food as well as on how to manage diarrhoea at home by mothers and when to seek help from health personnel are also disseminated.

3) Control of Vitamin A Deficiency

Vitamin A deficiency is responsible for night blindness and in certain cases, irreversible blindness among children. Deficiency of vitamin A also can increase the risk of death among children particularly when they are suffering from measles or diarrhoea. Prevention and management of vitamin A deficiency is an important intervention under RCH programme.Every child between the age of 9 months and 3 years is given 5 doses of vitamin A concentrate i.e. first dose of 100,000 International Units (IU) at the age of nine months, second dose of 200,000 IU at the age of 16 months and thereafter 3 more doses of 200,000 IU each at six monthly intervals. Nutrition education regarding use of colostrum, use of vitamin A rich food etc. are also ensured.

4) Acute Respiratory Infection (ARI) Control

Acute Respiratory Infection (ARI) is a major cause of morbidity among young children. Majority of ARI are self-limiting. However, pneumonia, a serious manifestation of ARI is a major cause of mortality also. Timely and correct diagnosis, treatment and referral can save most children with pneumonia. Therefore, prevention and management of ARI has been

included as another important intervention under the RCH programme. The primary health care personnel should detect the case of pneumonia among children based on guidelines on signs and symptoms and provide treatment with effective antibiotics viz. Cotrimoxazole as per guidelines for doses. Serious cases of pneumonia should be identified and timely referral be made to save children's lives.

5) **Immunisation Services**

In addition to the routine imrnunisation services expected to be provided to all infants and young children as per approved schedule, the Government of India have accepted the goal of achieving eradication of poliomyelitis and elimination of neonatal tetanus from this country. The strategy adopted for polio eradication is through pulse polio programme being implemented all over the country. Importance is also given on surveillance of vaccine preventable diseases.

3.5.5 Safe Abortion Services

As you might be already knowing, complications of abortions performed under unhealthy surroundings using unhealthy and crude procedures is one of the major causes of maternal mortality and morbidity. Medical Termination of Pregnancy (MTP) is therefore made possible under certain conditions laid down under the MTP Act (1971). However, MTP should not be considered as a mechanism for restricting family size or as method of contraception for avoiding unwanted births in a routine. In India, it has been observed that often MTPs are still performed in unauthorised places where the required essential facilities are not available and sometimes even the person performing is also neither qualified nor experienced and thus cause maternal deaths and morbidity on a much larger scale. Under RCH programme specific emphasis is given on ensuring women's access to safe abortion services by increasing improved facilities and trained manpower for provision of MTP services.

3.5.6 Contraceptive Services for Eligible Couples

Since couples have to be assisted in deciding about the right time for having children, they have to be informed and have access to safe, effective, affordable and acceptable methods of contraception of their choice. Thus provision of contraception services is an important intervention under RCI-I programme. There is a growing concern among policy decision makers and planners in India that the overemphasis laid on females as the main target groups for accepting contraception services, particularly sterilisation services, in the past, is not likely to achieve the desired demographic goal. Hence more emphasis is now being placed on increasing method choice including reversible contraceptive methods both for females and males. For increasing male participation in acceptance of contraception, facilities for providing Non Scalpel Vasectomy (NSV) are also being expanded. Added importance is also being given to strengthen sexuality and gender information, edqcation and counseling with the aim of ensuring informed choice of methods by clients. Supportive counseling and follow up services are also being organised for acceptors.

3.5.7 Prevention and Management of RTIs and STIs

RTIs and STIs form a major group of infections which cause considerable extent of morbidity among both males and females and prevention and appropriate clinical management of these conditions have been included as important components under RCH programme. RTIs include a variety of bacterial, viral and protozoal infections in thereproductive tract. Some of these RTIs are sexually transmitted and pose threat to lives of both sex, particularly for women. RTIs may result from unhygienic procedures related to delivery and abortions and infections due to overgrowth of organisms normally found in genital tract, in addition to sexually transmitted infections.

Screening/diagnosis of RTIs/ STIs is based on identifying groups of easily recognised signs and symptoms (syndrome). Even though some men and many women remain asymptomatic, common signs and symptoms observed are:

- vaginal discharge in women which look and smell differently from normal discharge.
- genital ulcers in both men and women,

- lower abdominal pain in women.
- scrota1 swelling when testis is affected.
- enlarged, inflamed inguinal lymph glands in men and women.
- neonatal conjunctivitis.

Apart from individual suffering, RTI/STI can also lead to complications and long-term sequelae like:

- infertility;
- ectopic pregnancy;
- irregular menstruation;
- cancer of anus and genitals;
- abortion and stillbirth;
- infections in new born; and
- increased risk of transmission of HIV infection.

Provision of services for prevention and management of RTI/STI has been included as an important intervention under RCH programme by increasing facilities for diagnosis and management as well as through health education and counseling.

3.5.8 Adolescent Health Services

The adolescent period is important for several reasons. Not only that they are the future parents who need to be prepared for future parenthood, because of the practice of marriage of very young girls in many parts of the country, adolescent girls are exposed to hazards of pregnancy when they are not emotionally and physically ready for child bearing. Health programme for the adolescent girls have special significance because their effects are not only on the health and nutrition of the adolescent girls themselves, but also have long-term intergenerational effects by reducing the risks of low birth weight and minimising child mortality. It is felt that integrated p r o g r a m s for family life and reproductive as well as general health, education, employment and other related services need to be provided for, this hitherto neglected some segment of population.

3.5.9 Special Care Components – Cancer and Infertility Services

1) Screening and Treatment for Cervical Cancer and Breast Cancer

Cancer is one of the important causes of morbidity and mortality in both developed and developing countries. Most common among cancers of reproductive system in developing countries is cervical cancer and breast cancer is also not uncommon. Cervical cancer screening is one important intervention for prevention but at present, limited screening facilities are available for Indian women. Facilities for breast cancer also are inadequate except advice for self-examination by women as well as routine examination by professional and auxiliary personnel in different health institutions,

2) Prevention and Treatment of Infertility

Since child bearing is highly valued and can have serious social consequences in Indian women, infertility is perceived to be a very serious problem. Since infertility could be a sequel of STIs, interventions for management of STIs would be helpful in tackling infertility. Diagnosis and management of infertility due to major causes require sophisticated facilities and therefore services for treating infertility can be provided only in limited health facilities in India,

3.6 ORGANISATION AND INFRASTRUCTURAL FACILITIES FOR IMPLEMENTATION OF RCH PROGRAMME

3.6.1 Organisational Set-up for Delivery of RCH Programme

Even though the family welfare programme has been reoriented with a new name and new focus as already explained, the machinery for implementation of the programme remains more or less the same except that there are few changes in terms of the nature of support and assistance from Central Government to the State Governments. Further, the focus is also on more active involvement of the community and local panchayat with the aim of decentralised approach to the programme planning and implementation. The major inputs under the RCH progrmme will be directed more towards improving the already existing facilities and services to bring them within easy reach of the community, and the traditional items for creation of additional posts in health institutions and construction of new buildings will be only minimal.

At the national level, the programme is being steered by the Department of Family Welfare. The major responsibility of implementing the programme lies with state governments under tlie Directorate of Health and Family Welfare and Department of Family Welfare, specifically, with programme management responsibility assigned to the State Director of Family Welfare and State RCH Officer. It is also realised that for seeking larger and faster improvement in RCH indicators, it is important to treat districts as units of implementation. This is because, in most states the RCH service needs as well as implementation situation differ from district to district. Further, the emphasis on decentralised programme planning and management also necessitates this special focus on districts.

Tlie district health administration system with the District Civil Surgeon/Chief Medical and Health Officer assisted by the District RCH Officer is responsible for planning, implementation and monitoring of these services with the active participation of the panchayati raj system.

3.6.2 Infrastructural Facilities for Delivery of RCH Services

The national health policy of India (1983) clearly indicated that goal of Health For All (HFA) in this country is to be achieved through comprehensive primary health care approach. RCH services are no exception to this. The health infrastructure for delivery of primary health care in rural areas of the country is responsible for delivery of RCH services (as one component of priniary health care) to the rural population through the vast network of Primary Health Centres (PHCs), Subcentres, Community Healtli Centres (CHCs) as well as FRUs established over the years.

While general obstetric and child care will be provided by medical, paramedical and auxiliary personnel viz. Medical Officers, LHVs, ANMs, male health workers and male supervisors, Lab technicians etc. at tlie level of PI-IC and subcentres, specialised care from obstetricians and paediatricians will be available from the CHCs/FRUs onwards. The Anganwadi worker under the ICDS scheme also plays a very iniportant role in rendering tlie ECH services, particularly the nutrition component, through growth monitoring of children and supplementary feeding to children and pregnant and lactating mothers.

The next higher level of specialised services are available at the district level from district hospital specialists. MTP services are envisaged to be made available froni PHCs and efforts are being initiated to strengthen the existing facilities with additional inputs at these levels of institutions to fulfil the prescribed criteria according to MTP Act, for ensuring that adequate, good quality services are available to tlie needy. Referral of suspected cases of RTI/STI by the ANMs is supported by diagnosis and management by Medical officers with assistance of laboratory technicians at the PHCs. Specialised facility for RTI/STI will be made available in all district hospitals and even in some of the subdivisional hospitals.

In addition, the NGOs medical system will be involved in providing many RCH services and facilities. The Indian Systems of Medicine and Homeopathy (ISM and H) which are known to be efficacious will also be used in a substantial manner in providing RCH services. With regard to contraceptive services, the PHC and CHC functionaries and medical officers will render all possible services. The postpartum units at the sub-district and district levels will also participate in rendering these services. Special teams will be prepared with appropriate training and additional facilities (equipment and other supplies) for undertaking sterilisation operations, both laparoscopic and minilap, for females and NSV for males.

In the urban areas, due to the availability of big hospitals with adequate general and specialised facilities, RCH services are available to the majority of population within easy reach. However, the slum dwellers in urban areas, whose number is gradually increasing in India, are at a disadvantageous position regarding RCH services and special efforts are required for making services available to then;. Urban Health Posts under the Urban Revamping Scheme and the Urban MCH & FW Centres are expected to render these services with referral support from the urban hospitals. Due to the inadequacies in their functioning, special schemes are being envisaged to be initiated for the urban slums.

Similar schemes are also envisaged for the tribal population, which again constitutes a sizeable segment in India and are often not sufficiently covered by the existing health care delivery system.

3.6.3 Special Facilities and Projects under RCH Programme

In order to ensure availability of specific services and facilities to all under theprogramme, special efforts are made to give special support on selected components to certain needy and backward areas. Some of these are briefly described below.

1) Twcnty-four Hour **Delivery** Scrviccs at PHC

One of the major causes of maternal mortality and morbidity is lack ofattention by trained hands at the time delivery in the rural areas. This is particularly so in the case of deliveries taking place during night time when trained personnel like ANM or Medical officers are not available at PHC. It has been a major criticism that health personnel posted at PHCs and subcentres do not have their night halts at these institutions, and usually they stay somewhere away from these institutions. Under the RCI-I programme institutional deliveries are encouraged and attempt is being made to set up 24 hour delivery services in CHCs/PHCs in as many districts as feasible.

The arrangement in this regard would involve a mechanism for a doctor to be available on call, a nurse being available beyond normal working hours in the CHC/PHC and cleanliness service being available beyond normal working hours. The latter two can be arranged on contract basis or by appointing some recently retired persons available in the same locality. There is provision for payment of honorarium to the doctor of CHCIPHC at the rate of Rs. 200/- per delivery conducted between 8 p.m. and 7 a.m. on duty and also to the contractual nurse.

2) Referral System and Transport to Indigent **Families** through **Panchayats**

, Lack of timely and appropriate referral services has been one major responsible factor for high maternal mortality in rural areas, and many cases requiring such referral, fail to receive specialised care when needed. Therefore, under the RCH programme, strengthening of the FRUs has been taken up as priority activity. A total of 1748 FRUs were identified and equipped under CSSM programme, but many of them have not become fully functional because of shortage of specialists, equipment and drugs. Under **RCH** programme, FRUs are being strengthened through:

- supply of drugs and medicines.
- provision for appointment of contractual staff.
- provision of laparoscopes.
- provision for providing emergency obstetric care, and for those requiring surgical interventions, blood transfusion and anaesthesia.
- provision for consultant anaesthetist for emergency obstetric care etc.

The weakly performing states and particularly of the C category districts, the communication infrastructure is weak and the economic status of many families is also very low. Because of this, even when women are referred for delivery to higher specialised institutions away from the village, often they don't avail this service and deliveries get conducted by untrained hands available in the village which often end in undesirable outcomes for the mother and the baby. In order to overcome this problem, under **RCH** programme, provision is made to make available some fixed amount with the local panchayat in selected subcentre areas through District Family Welfare officers, so that arrangements for referral of women from indigent families can be made. This assistance is to be used only for procuring and paying for the transport for carrying the women to CHC/PHC for delivery.

3) Additional Programme for Urban Slums

With the increasing number of slums in the urban areas, and with the realisation that health status of women and children in these slums is paorer than even the national average due to poor sanitary and health facilities, special efforts are being taken to improve the RCH

At the national level, the programme is being steered by the Department of Family Welfare. The major responsibility of implementing the programme lies with state governments under the Directorate of Health and Family Welfare and Department of Family Welfare, specifically, with programme management responsibility assigned to the State Director of Family Welfare and State RCH Officer. It is also realised that for seeking larger and faster improvement in RCH indicators, it is important to treat districts as units of implementation. This is because, in most states the RCH service needs as well as implementation situation differ from district to district. Further, the emphasis on decentralised programme planning and management also necessitates this special focus on districts.

The district health administration system with the District Civil Surgeon/Chief Medical and Health Officer assisted by the District RCH Officer is responsible for planning, implementation and monitoring of these services with the active participation of the panchayati raj system.

3.6.2 Infrastructural Facilities for Delivery of RCH Services

The national health policy of India (1983) clearly indicated that goal of Health For All (HFA) in this country is to be achieved through comprehensive primary health care approach. RCH services are no exception to this. The health infrastructure for delivery of primary health care in rural areas of the country is responsible for delivery of RCH services (as one component of primary health care) to the rural population through the vast network of Primary Health Centres (PHCs), Subcentres, Community Health Centres (CHCs) as well as FRUs established over the years.

While general obstetric and child care will be provided by medical, paramedical and auxiliary personnel viz. Medical Officers, LHVs, ANMs, male health workers and male supervisors, Lab technicians etc. at the level of PI-IC and subcentres, specialised care from obstetricians and paediatricians will be available from the CHCs/FRUs onwards. The Anganwadi worker under the ICDS scheme also plays a very important role in rendering the ECH services, particularly the nutrition component, through growth monitoring of children and supplementary feeding to children and pregnant and lactating mothers.

The next higher level of specialised services are available at the district level from district hospital specialists. MTP services are envisaged to be made available from PHCs and efforts are being initiated to strengthen the existing facilities with additional inputs at these levels of institutions to fulfil the prescribed criteria according to MTP Act, for ensuring that adequate, good quality services are available to the needy. Referral of suspected cases of RTI/STI by the ANMs is supported by diagnosis and management by Medical officers with assistance of laboratory technicians at the PHCs. Specialised facility for RTI/STI will be made available in all district hospitals and even in some of the subdivisional hospitals.

In addition, the NGOs medical system will be involved in providing many RCH services and facilities. The Indian Systems of Medicine and Homeopathy (ISM and H) which are known to be efficacious will also be used in a substantial manner in providing RCH services. With regard to contraceptive services, the PHC and CHC functionaries and medical officers will render all possible services. The postpartum units at the sub-district and district levels will also participate in rendering these services. Special teams will be prepared with appropriate training and additional facilities (equipment and other supplies) for undertaking sterilisation operations, both laparoscopic and minilap, for females and NSV for males.

In the urban areas, due to the availability of big hospitals with adequate general and specialised facilities; RCI-I services are available to the majority of population within easy reach. However, the slum dwellers in urban areas, whose number is gradually increasing in India, are at a disadvantageous position regarding RCH services and special efforts are required for making services available to then;. Urban Health Posts under the Urban Revamping Scheme and the Urban MCH & FW Centres are expected to render these services with referral support from the urban hospitals. Due to the inadequacies in their functioning, special schemes are being envisaged to be initiated for the urban slums.

Similar schemes are also envisaged for the tribal population, which again constitutes a sizeable segment in India and are often not sufficiently covered by the existing health care delivery system.

3.6.3 Special Facilities and Projects under RCH Programme

In order to ensure availability of specific services and facilities to all under the programme, special efforts are made to give special support on selected components to certain needy and backward areas. Some of these are briefly described below.

1) Twenty-four Hour Delivery Services at PHC

One of the major causes of maternal mortality and morbidity is lack of attention by trained hands at the time delivery in the rural areas. This is particularly so in the case of deliveries taking place during night time when trained personnel like ANM or Medical officers are not available at PHC. It has been a major criticism that health personnel posted at PHCs and subcentres do not have their night halts at these institutions, and usually they stay somewhere away from these institutions. Under the RCH programme institutional deliveries are encouraged and attempt is being made to set up 24 hour delivery services in CHCs/PHCs in as many districts as feasible.

The arrangement in this regard would involve a mechanism for a doctor to be available on call, a nurse being available beyond normal working hours in the CHCIPHC and cleanliness service being available beyond normal working hours. The latter two can be arranged on contract basis or by appointing some recently retired persons available in the same locality. There is provision for payment of honorarium to the doctor of CHCIPHC at the rate of Rs. 2001- per delivery conducted between 8 p.m. and 7 a.m. on duty and also to the contractual nurse.

2) Referral System and Transport to Indigent Families through Panchayats

, Lack of timely and appropriate referral services has been one major responsible factor for high maternal mortality in rural areas, and many cases requiring such referral, fail to receive specialised care when needed. Therefore, under the RCH programme, strengthening of the FRUs has been taken up as priority activity. A total of 1748 FRUs were identified and equipped under CSSM programme, but many of them have not become fully functional because of shortage of specialists, equipment and drugs. Under RCH programme, FRUs are being strengthened through:

- supply of drugs and medicines.
- provision for appointment of contractual staff.
- provision of laparoscopes.
- provision for providing emergency obstetric care, and for those requiring surgical interventions, blood transfusion and anaesthesia.
- provision for consultant anaesthetist for emergency obstetric care etc.

The weakly performing states and particularly of the C category districts, the communication infrastructure is weak and the economic status of many families is also very low. Because of this, even when women are referred for delivery to higher specialised institutions away from the village, often they don't avail this service and deliveries get conducted by untrained hands available in the village which often end in undesirable outcomes for the mother and the baby. In order to overcome this problem, under RCH programme, provision is made to make available some fixed amount with the local panchayat in selected subcentre areas through District Family Welfare officers, so that arrangements for referral of women from indigent families can be made. This assistance is to be used only for procuring and paying for the transport for carrying the women to CHCIPHC for delivery.

3) Additional Programme for Urban Slums

With the increasing number of slums in the urban areas, and with the realisation that health status of women and children in these slums is poorer than even the national average due to poor sanitary and health facilities, special efforts are being taken to improve the RCH

services in these areas. The Urban Health Posts and Urban Health and Family Welfare Centres are expected to provide comprehensive integrated services of MCH and family planning to the slum dwellers. They are also supposed to function in close coordination with the Urban ICDS projects. However, since their functioning has been found to be unsatisfactory, a special committee was appointed to examine the situation and give suggestions for improvement. The following have been recommended:

i) A primary health centre for each slum with population of 15,000 having a doctor and 2-3 paramedics to provide outdoor services. These would be set up and managed by the concerned urban local body on a project basis.

ii) For clusters of slums having smaller population, a mobile clinic to be sanctioned to medical NGO and having facilities at par with a centre mentioned above and it will visit each slum on a fixed day during fixed hours to provide primary health care services.

iii) Some selected health NGOs may be assisted if they set up maternity clinics in or near urban slums.

State governments are requested to submit project proposals prepared in this regard for each city for consideration for sanction by GOI.

4) Special Programme for Tribal Areas

Because of the poor communication, low literacy status, as well as poor socio-economic conditions, despite having basic health infrastructure in place in most part of the tribal areas in the country, the situation regarding reproductive health of the tribal population is generally poor. Hence, under the RCH programme, special RCH care package is envisaged to be provided to this population group. A special committee was appointed to examine the situation and make recommendations for the provision of services to the tribal population.

Major recommendations of the conunittee are:

i) Despite having infrastructure like CHC/PHC etc. many staff positions in these institutions remain'vacant due to want of accommodation. Also availability of drugs and consumables is poor in these institutions. Thus, the programme would provide for financing construction of housing for staff and also for provision of drugs in these institutions.

ii) The state government will authorise committees at district level under chairmanship of District Magistrate, to advertise locally and appoint doctors and other staff on contract basis against vacancies till regular appointments are made.

iii) Due to the communication gap between the tribal population and the government staff, tribal population do not generally avail the available services. In order to bridge this gap, district level committees are envisaged to assist local NGOs to engage tribal youth after training to work with local community for promoting RCH information and to act as link between the health infrastructure and the community.

5) Special Programmes for Adolescents

Adolescents (10-19 years) constitute a large segment of the population (21.4% of the total estimated population) of India which is of special significance for whom reproductive health programme should be designed and implemented. Teenage pregnancy poses serious health hazard for both mother and child. Further, in the context of increasing prevalence of STIs and HIV infection, it is important that adolescents and youth are adequately informed about safe sex and sexuality. It is important to remember that the reproductive health needs of married and unmarried adolescents are different, which are mostly unmet needs and also that the adolescents' behaviour gets influenced seriously by various types of messages from different media, which are often conflicting and confusing.

Programmes directed to address the above mentioned problems of adolescents are almost nonexistent except some programmes by certain NGOs. These cover HIV/AIDS education and sexuality for youth as well as on reproductive and sexual health programme for women including adolescent girls. However, government has initiated some activities like ICDS

scheme which has recently extended its activities to include adolescent girls, particularly out of school girls who cannot be reached through the school health activities. Training is the major component for adolescent girls in the prograinme under ICDS, which focuses on motherhood skills such as nursing, first-aid, child health and nutrition care. Fresh packages of services for this group are under consideration. A draft policy on youth/adolescent issues is under debate which proposes measures to ensure young people to have access to all information and services including reproductive health and to promote social environment that prevents diseases/problems like HIV/AIDS, substance abuse etc. Under the RCH programme, specialised counseling and IEC materials are envisaged to be provided by NGOs and proposals are being invited from NGOs in this regard.

3.6.4 Role of Hospitals in Implementation of RCH Programme

Hospitals are important component of the health care delivery system which may be classified into different categories. This grouping may be based on size of hospital in terms of number of beds available; types of services'provided (generallspecialised); by location (urban/rural); according to the system of medicine practised (Allopathy/Ayurveda/ Homoeopathy); by ownership (public/private/NGO/corporate) etc. Irrespective of the type of a hospital, it is involved in providing outpatient and inpatient services and provide generally promotive, preventive and curative, and in some cases rehabilitative services also. Hospitals generally can play very important roles in implementation of various national health programmesincluding RCH programme.

Hospitals form important element of the referral system wherein the referred cases from the primary care facilities can get consultative as well as curative services from specialists from the hospitals. Obstetric and paediatric cases referred from peripheral institutions are treated on general or emergency basis at hospitals.

Hospitals having enough clinical cases and competent clinical experts in different specialities, can be actively involved in providing clinical skill based training to various health care personnel. Under RCM programme, training in integrated RCH service for primary health care personnel, MTP, laparoscopic sterilisation. minilap, NSV, IUD insertion etc. can be provided from hospitals.

Details of information on births and deaths that take place in the hospitals including reliable data on causes of deaths are expected to be reported to the health administrative authorities regularly. This information is very valuable for preparing action plan for RCH services in districts.

Patients suffering from various epidemic prone diseases attend the hospitals for medical care. Hospitals can play a very important role in preventing the epidemic by sending timely information about unusually increased number of cases to the health authorities in the district.

Hospitals can play an important role in surveillance of important diseases i.e. routine reporting of selected disease conditions even when not an epidemic. Certain hospitals have been identified as sentinel surveillance centres for specific diseases. For example, vaccine preventable diseases, diarrhoeal diseases, HIV infection etc.

I-Iospitals can also be involved in rendering health education/IEC/counseling to patients, relatives etc.

Hospitals can also contribute to the improvement of service components under RCH programme through conducting clinical and operational research.

3.7 MANAGERIAL DIMENSIONS OF RCH PROGRAMME

The RCH programme is being implemented all over the country by the different health institutions and personnel of the health care delivery system at various levels in the hierarchy. As already mentioned, there has been a major paradigm shift in the programme which needs to be understood by all concerned with its implementation. Health and hospital managers who are responsible for implementing the programme have to perform number of management functions. In view of the objectives of the programme as well as the paradigm shift in the programme and approach, it becomes clear that special attention needs to be placed on programme management at different levels. The major managerial dimensions include:

- participatory, decentralised, community needs assessment based programme planning.
- organising special programmes/schemes/projects under RCH.
- resource procurement and their management.
- ensuring quality of care.
- management information system.
- monitoring and supervision etc.

3.7.1 Community Needs Assessment Based Decentralised Planning

From 1st April, 1996, the Family Welfare Programme was implemented all over India based on Target Free Approach (TFA). Till then, the workload under the programme at different levels in the health care delivery system and the achievements of the programme were assessed on the basis of targets given from the central government for different individual contraceptive methods. This led to a situation where, achievement of contraceptive targets in pure numbers became an end in themselves. Not only that this top-down approach did not consider the clients' felt needs and choices, it also undermined the importance of quality of services and even forced many health personnel to over-report their achievements and inflate their performance. It is under this background that the GOI stopped the practice of fixing targets for services from above. It is important to understand that TFA does not mean the license to do no work. The population goals still remain the same as before and after targets from above

are withdrawn, the health workers are expected to consult families and local communities in the beginning of every year in order to assess their needs and preferences and then work out for themselves the workload and activity plan for the coming year. This is to be done by the ANM with the help of Male health worker, through consultation by her with the Anganwadi worker, TBA, members of the Mahila Swasthya Sangh, as well as local panchayat members. The ANM is to work out the requirements for each service, based on estimates made by her, using the data on various local relevant events like births, deaths, etc.

For example, to estimate the probable number of pregnancies that may occur in any area, the following formula may be used:

Probable Number of Pregnancies = Population of the Area × Birth rate of the area (district/state)

Once the probable number of pregnancies is estimated, this also will be the probable number of deliveries that an ANM can expect in her area. The number of antenatal registrations to be expected would be the probable number ofpregnancies with an additional 10% of that number to account for abortions.

The workload of different ANMs under one PHC when added up along with appropriate addition ofrequirements for specific activities bf the PHC also like MTP, institutional deliveries at PHC, would determine the workload or requirement for that PHC. Similarly, requirement at district level would be worked out by adding up the requirements for all PHCs along with requirements for specific activities undertaken at district level institutions like district hospitals etc.

After implementing the TFA approach for about 18 months, the experience was reviewed and based on the feed-back and deliberations among experts, certain modifications to improve the approach were made and it was renamed as Community Needs Assessment (CNA) Approach and the manual provided for helping the ANM in her performance was also accordingly modified and renamed.

A number of forms are prescribed under the programme, for enabling the preparation of action plan at different levels in which the reports must be made by the ANM for the subcentre plan, in-charge medical officer for the PHC, by incharge doctor for the FRU/ subdistrict hospital, and by incharge medical officers at the district hospitals, and by District Family Welfare Officer for the whole district, which ultimately will be sent to the state government and Department of Family Welfare, GOI.

After identifying the needs and resource requirements for meeting the identified needs, an activity plan needs to be developed wherein the persons responsible for various activities are identified and a logical framework indicating sequence of activities as well as indicators of achievement along with means of verifying the indicators are spelt out.

3.7.2 Human Resource Development and Capacity Building

For implementing RCH programme, a large number and categories of health personnel at different levels in the hierarchy are involved. One of the major responsibilities of the offtcials responsible for implementing RCH programme is to manage the human resource involved and ensure their professional capacity developnlent. One essential component of human resource management is to equip them with appropriate knowledge and skills for enabling them to perform their job responsibilities most efficiently through training and retraining.

Even though most of these personnel are trained in the past for providing health care to women and children, there are wide variations in the quantity a'nd quality of training received by them. Moreover, mostly these training efforts were vertical in nature concentrating on individual/compartmental service components and hence lacked in a comprehensive and integrated approach. With the introduction of RCH programme, it is important that all health personnel involved are reoriented to the change/shift in emphasis in the programme as well as to the new additional components of services. It has also been felt that a deviation from the previous knowledge based training to a more skill/competency based training is necessary for ensuring delivery of good quality services to the clients to achieve their satisfaction.

Accordingly, major investment is envisaged to be made on proper in-service training of the health personnel with special focus on skill/competency development through practical hands-on training. Because of the large number of personnel to be trained and in view of the complexity of the programme, a need for coordinated efforts for the whole country is felt. Hence, instead of leaving this responsibility entirely to the state health and family welfare department, the GOI have designed a separate training management system for RCH.

This system is to be made functional through the already existing network of training infrastructure in the country. The National Institute of Health and Family Welfare (NIHFW) an autonomous institution in New Delhi has been appointed by the GOI as the National Nodal Agency for coordination of the training activities all over the country. The nodal agency is supported in this activity by 16 Collaborating Training Institutions (CTIs) located in different parts of the country, belonging to both government and non-government sectors. At the peripheral level, various training institutions of health personnel including ANM/LHV training schools, Health and Family Welfare Training Centres (HFWTCs), District Training Teams/Bureau etc. are expected to provide training to the different categories of health personnel.

Under RCH Programme, the training of health personnel should minimally cover the following areas:

1) Reproductive health concepts, components, and new focus in the health programme.
2) Technical knowledge and skills for providing various services related to components of RCH i.e. maternal health, child health, contraception, RTIISTI management etc.
3) Communication skills, especially for communicating with clients for service, community members/panchayat members, functionaries from other health related sectors, adolescents and also for mobilising community resources for RCH etc.
4) Management skills required for planning based on community needs, material resource management like drugs, vaccines, equipment, etc. maintaining records and reports etc.

Accordingly, the different types of training activities envisaged under RCH programme include:

1) Awareness generation training for health functionaries, functionaries from health related sectors including panchayati raj system at grass-root, district and state levels.
2) Skill development training courses which are of four types viz.
   - integrated foundation skill based course for primary health care functionaries to render integrated RCH services as part of primary health care at ANMILHV schools/ HFWTCs;
   - specialised skill development courses like MTP, Laparoscopic sterilisation, minilap sterilisation, NSV for doctors and IUD insertion for ANM/LHV at identified training institutions/hospitals;
   - specialised management training for the state, divisional and district level programme managers at identified management training institutions; and
   - specialised training in communication for skill upgradation among IEC personnel of central, state and district levels at identified communication training institutions.

For integrated training in RCH or primary health care personnel, while the NIHFW will train the master trainers from faculty of CTIs, the CTIs in turn will train trainers from peripheral training institutions who will train the peripheral health functionaries on RCH service components.

Role of Health Administrators in Training under RCH

As already described regarding paradigm shift in the RCH programme, under the new approach adopted for implementation of the programme, it is envisaged to have

comprehensive, integrated training with district as the organiser/coordinator/implementor with support from centre and state. The district is to function as the basic unit and district based training plans are to be prepared for all types of training activities according to the actual training needs. The district authorities are to be assisted by the CTIs in this regard. These plans are to be approved by the State RCH Co-ordination Committee and sent to the national nodal agency, NIHFW for release of funds for implementing the training. The District FW Officer, assisted by the district training centres will coordinate with the training institutions to ensure that the health personnel of the district are nominated and relieved for the training regularly. The DFWO will also coordinate with the related departments and Panchayati Raj system in the district to organise awareness generation training for functionaries from health related sectors.

3.7.3 Management of Material Resources

One other major managerial responsibility of health personnel is that of managing the different types of material resources like drugs, vaccines, other supplies like cotton, linen, lab. reagents, contraceptives, equipment, IEC materials etc. so that effective and efficient services can be provided to the clients. This includes estimating the requirement for these items for a specific period (one year/one month/a quarter of a year) based on the service1 activity load; timely procurement of these items from their sources; their appropriate storage/ distribution to different levels of care as per the needs; maintaining proper records for effective monitoring of their use; appropriate maintenance of equipment; proper disposal of waste materials etc.

Under the RCH programme, there are specific drugs and equipment kits supplied to the subcentre, PHC, CHC/FRU levels based on the types of activities expected at these levels. Some of these are drug kits, equipment kits, surgical sets, IUD insertion kit, normal delivery kit, equipment for anaesthesia, equipment for neonatal resuscitation, blood transfusion set, laboratory diagnosis kit etc. With regard to supply of these kits, in order to enable the institutions to obtain these items issued as per their requirement, system is set up at divisional level (one divisional supply depot for a cluster of 6-10 districts) where suppliers will supply each individual item in reasonably large packing. The district/FRU/PHC can get individual items issued to them as per their entitlement under the scheme in any number of installments throughout the year. This arrangement is expected to minimise wastage of the items.

For supporting immunisation programme, cold chain has been created covering all PHCs. Based on actual requirement, deep freezers and ILRs are also being provided. For repair of cold chain there is provision for Rs. 500 per PHC per year.

For support to emergency obstetric care and MTP, where some cases may require blood transfusion, under the RCH programnle, pilot projects are being initiated with financial support from European Commission to set up regular and reliable blood supply to PHCs and CHCs by linking them with nearest district blood bank.

For essential new born care needed equipment is being provided to all district hospitals1 CHCs/FRUs and PHCs at block level.

In order to make safe abortion services available to the needy, under the RCH programme, MTP equipment is made available at institutions i.e. district hospitals/CHCs and PHCs wherever medical officers are trained and operation theatres are available.

Change in Procurement Procedures

Since the RCH programme has major component funded under World Bank RCH project, many items of procurement under the programme are funded out of this project. In order to obtain reimbursement from World Bank, specific procedural guidelines are to be followed. Accordingly, the procurement capacity would be strengthened by appointing consultants to serve as Procurement Support Agencies (PSAs) at the national and state level to assist MOHFW or state to procure equipment, drugs and materials.

3.7.4 Funding and Reimbursement Procedures under RCH Programme

In order to ensure smooth and timely flow of funds under the programme, funding to the states is being routed through state level registered societies named State Committees of Voluntary Action (SCOVA) with the exception of few states for which funds are provided through the State Budget. All states/UTs and societies, project directors at state, district and city and society level would be required to maintain an identifiable account of project funds and expenditure along with activity-wise expenditure clearly differentiating funds from different sources. All states are required to open a budget head for RCH programme with two subheads viz. National component and District sub-project component irrespective of whether funds are routed through SCOVA or state budget.

3.7.5 Management Information System (MIS)

As already mentioned, the initiation of CNA approach to RCH planning involves collection/ generation of huge volume of data and their use for participatory planning with involvement of stakeholders (women and men). Further, the items of performance to be reported on regular basis for monitoring of the complex and extensive programme have also changed. Accordingly, the MIS also has been modified and strengthened as per needs. This system should also provide relevant information on client satisfaction and the impact of the programme on health status of women and children.

The sources from where relevant data for demographic and vital statistical indicators can be obtained include decennial census, National Family Health Survey conducted all over the country in 1992-93, and Sample Registration Scheme.

For other selected information the sources include routine reporting and district surveys.

Routine reports on prescribed formats are regularly to be submitted by the ANM on prescribed dates to the PHC and PHC in turn is to send the consolidated report to the district. The district after consolidating performance reports from all health institutions submit the report to the state and central government authorities.

District surveys in half the districts on yearly basis is conducted using sample survey methods for generation of information on selected RCH and population indicators including programme process indicators. These surveys are co-ordinated by an identified national level organisation i.e. International Institute of Population Studies (IIPS) and surveys are undertaken by regional level institutions identified for this purpose.

In addition, for assessing the actual availability and utilisation of the RCH facilities from subcentre to district hospital, concurrent evaluation of the programme is also being undertaken regularly at least one district per month. These surveys would also.ascertain quality of services and community satisfaction. For this, information from families in at least 2 villages and one urban ward will be collected through interviews. Introduction of quality and impact indicators for monitoring and evaluation of the programme as well as the initiation of the rapid evaluation procedures are major deviations from the previous monitoring system for the programme.

3.7.6 Monitoring of RCH Programme

Monitoring is the process of measuring and observing changes during implementation of the programme. Monitoring is also a process of assessing progress in implementation in relation to the planned schedule.

The observations/measurements during monitoring may be positive or negative and may relate to resources, activities, outputs and outcome, Thus monitoring will indicate whether,

- the required resources have been provided or not.
- available resources are being optimally utilised or not.
- planned activities are being implemented as scheduled or are in progress.
- expecred results are being achieved or not,
- o any unplanned or unforeseen occurrences have taken place.

The measurement of these changes is based on certain predetermined indicators. An indicator is an indirect measure of an event or a condition. For example, an indicator to measure reduction in neonatal tetanus incidence will be the proportion of births attended by trained personnel.

Indicators could be for inputs (resources), processes (activities), outputs (performance achievements), or outcomes (effect/impact) e.g.:

- health worker population ratio is an input indicator
- frequency of antenatal clinics is a process indicator
- percentage of children receiving measles immunisation is an output indicator
- incidence of neonatal tetanus is an impact indicator

These indicators can be worked out based on data collected regularly through the management information system. As already mentioned, the MIS has been modified to meet the requirements of the programme and emphasis is more on quality aspect of the programme. Information also need to be collected on the additional components of services under RCH programme e.g.. RTI and STI control.

Examples of few RCH indicators are given below:

Service Delivery Indicators

- Percentage of eligible couples having access to contraceptive services
- Percentage of pregnant women who had received antenatal care
- percentage of new borns receiving care
- Percentage of children suffering from pneumonia who received treatment with antibiotics
- percentage of IUD users who are screened for RTIs

Indicators of Quality of Care

- Percentage of pregnant women who had at least three antenatal check ups
- Percentage of laparoscopic sterilisation done adhering to the prescribed protocol
- Percentage of ANMs who have undergone skill based training in IUD insertion
- Percentage males and females with knowledge regarding uses and side effects of cohtraceptive methods
- Percentage of users of oral contraceptives receiving follow up visits from health worker.

Outcome Indicators

- Low birth weight babies11000 live births
- Incidence of neonatal tetanus cases
- Incidence of anaemia in pregnant women
- Proportion of deliveries among mothers less than 19 years old

Monitoring can be undertaken with the help of reviewing the MIS regularly and studying the indicators based on the data. In addition, supervisory visits to service institutions can also be used for monitoring during which supervisor can identify the deviations if any, from the expected and can give appropriate suggestions. Interviews with the community members in the field can also help in monitoring the programme activities when the community's reaction to the services can be understood and if there are any drawbacks in the services they can point them out. Such interviews could be conducted also as a participatory process involving various stakeholders to obtain feed-back on clients' satisfaction with services.

3.7.7 Partnership Development – Intersectoral Cooperation and Involvement of NGOs

As already mentioned under paradigm shift in the programme, the GOI is increasingly involving the NGOs in both service delivery and in training of health personnel under RCH programme. The major strength of the NGOs is the flexibility in their procedures which is different from the restrictions of need for strict adherence to rules and regulations in the government system. Further, they also enjoy better rapport and credibility among the people. GOI expects NGOs to undertake various innovative efforts through special projects in finding solutions to many problems in RCH service provision of best quality. Such projects are funded by the GOI.

The involvement of NGOs in the programme has been done through a decentralised manner. While small NGOs all over the country are being involved in counseling, advocacy and for increasing awareness among people about RCH, mother NGOs identified at regional level extend assistance to these small NGOs. At the same time, national level NGOs are identified which will meticulously evaluate the mother NGOs before they are sanctioned to undertake the different innovative projects. Not only that the NGOs are recognised as partners in RCH programme implementation, for success of the programme there is also need to have close cooperation and coordination between health sector and other related sectors in the government. For example, the Women and Child development department, Rural Development department, the Panchayati Raj system, Department of Education etc. are a few of them which have a major complementary role to play in the effective implementation of RCH programme. RCH administrators have to devise different mechanisms to ensure support from these sectors. Similarly effective implementation can contribute to the health and development of children and mothers empowerment.

3.8 IMPROVING QUALITY OF SERVICES

The RCH programme's main emphasis is on provision of clients' need based services and ensuring clients' satisfaction. Therefore, an important requirement for effective implementation of the programme is to ensure that the quality of services is improved. Various efforts have been initiated to ensure quality of services under the RCH programme. Some such initiatives are described below:

- For various service components/procedures, standards have been developed which need to be ensured/complied with by service providers e.g. standards for male and female sterilisation, IUD insertion, Oral contraceptives and MTP services, midwifery practices etc.
- A well designed training strategy which is competency/skill based has been evolved for various health care providers. One essential step introduced in this training is introduction of requirement of proficiency certification for the trainees from trainers after ensuring that the trainee has actually acquired the skills to perform the service activity1 procedure.
- Improved logistics management is another essential effort initiated for ensuring quality of services so that right type of supplies are available of right quantity and quality at the right time. It is envisaged to have a project which has its components like setting up an autonomous corporation at state level with state and regional level warehouses for improved storage and distribution, use of private transport facilities for transporting supplies at regular intervals, development of a logistics management information system which will help tracking supplies and forecasting requirements and training in logistics management.
- Monitoring and evaluation of the programme has also focus on quality with a participatory approach involving all stakeholders and incorporating quality indicators for assessment, particularly focusing on clients' satisfaction.
- Supportive counseling and follow-up services are essential elements of the programme designed to provide quality care. This is particularly so for MTP acceptors, contraceptive acceptors, low birth weight babies etc. Follow-up contacts provide good opportunity for continuing counseling and education and for discussing related reproductive health issues.
- IEC efforts to make the community well informed about various aspects of reproductive health do contribute to enable the clients to make informed choice of services as per their needs which would add to the quality of care.

What steps have been initiated for improving the quality of care under RCH programme?

.....

.....

3.9 LET US SUM UP

In this unit, you have learnt that the Government of India have launched the Reproductive and Child Health Programme with a view to adopt a conlprehensive and integrated approach to the population issues and also towards ensuring women's development. The major paradigm shift in the programme which needs to be understood by all concerned with implementation of the programme has also been described in this unit.

While describing the components and service packages under the programme, you have been apprised that, a differential approach is adopted in the programme in terms of cornprehensivelessential components of RCH being implemented in different districts in the country based on their RCH status. You have also been introduced to the organisational and infrastructural set-up for implementing the programme with special emphasis on the various specific schemes and projects under the programme.

You have learnt about certain specific managerial responsibilities including the Community needs based decentralised participatory planning, modified procedures for management of material and finance resources as well as human resource management with special focus on competency based training under the programme. You have also been familiarised with tlie modified MIS and its use in monitoring the programme.

As you have understood, the RCH programme focuses on increasing the coverage and improving the quality of services and thereby ensuring clients' satisfaction and you have learnt about the various efforts initiated by the government in achieving this goal.

3.10 ANSWERS TO CHECK YOUR PROGRESS

Check Your Progress 1

1) Integrated approach is desirable because,
   - couples will accept contraceptive services only if survival of their children already bdrn is ensured;
   - separate identity of each programme component led to problems in their effective management;
   - integrated approach would increase service acceptance by community/clients; and
   - overlapping and additional expenditure can be avoided.

2) Major consensus arrived at ICPD conference in 1994 "that population policies should address social development beyond family planning, especially the advancement of women and that family planning should be provided in the context of comprehensive reproductive health care".

3) RCH programme was launched in India on 15th October, 1997.

Check Your Progress 2

1) The policy decision before implementing the RCH programme was to withdraw the system ofestimating workload and work allotment as well as monitoring the family welfare programme based on centrally determined method-specific contraceptive targets and instead, introducing a community needs assessment based, bottom up approach for the same.

2) There is paradigm shift in the programme because,
   - shift from focus on achievement of target to provision of range of quality services;
   - shift from reducing population in numbers to services to meet reproductive needs of individuals and community;
   - shift from compartmental to an integrated approach to service delivery as well as training;

- shift towards increased involvement of community. non health sector, NGOs etc.; and
- focus on gender issues and increased male responsibility and participation towards reproductive health matters.

Check Your Progress 3

1) Comprehensive reproductive health package includes:
   - prevention and management of unwanted pregnancy,
   - services to promote safe motherhood,
   - services to promote child survival,
   - nutritional services for vulnerable groups,

     prevention and treatment of RTIs and STIs,
   - prevention and treatment of gynaecological problems,

     screening and treatment of breast and cervical/ uterine cancer,
   - reproductive health services for adolescents,
   - health, sexuality and gender.information, education and counseling, and
   - establishment ofeffcctive referral system.

2) Reason for classification of districts for RCH services are:
   - services are to be commensurate with the needs and facilities.
   - interdistrict variations exist in terms of RCH indicators like CBR, female literacy rate etc.

     Poorly performing districts with inadequate facilities need priority attention for resource allocation.

3) Components of essential obstetric care include:
   - early registration of pregnancy,
   - at least.3 prenatal check up by trained personnel at appropriate intervals,
   - antenatal care should include blood pressure check, haemoglobin estimation, urine examination etc. regularly,
   - counseling,
   - detection of complications ofpregnancy if any,
   - referral to PHC/ FRU for complications,
   - assistance during delivery,
   - ensure 3 postnatal check up, and
   - detection of complications during delivery, and referral.

4) Special inputs for Emergency obstetric care include strengthening of FRUs through:
   - supply of drugs and medicines,
   - provision for appointment of contractual staff,
   - provision of laparoscope,

     provision for providing emergency care requiring surgical interventions, blood transfusion and anaesthesis, and

     provision for consultant anaesthetist for emergency obstetric care etc.

5) Major causes of maternal mortality are:
   - anaemia,
   - haemorrhage,
   - obstructed labour,
   - sepsis,
   - eclampsia, etc.

6) Major causes of mortality among infants and children are:
   - prematurity,
   - respiratory infections,
   - diarrhoeal diseases,
   - umbilical cord infections in new born baby,
   - birth injuries,
   - congenital malformations,
   - severe malnutrition, etc.

7) The important components of child survival service package are:
   - essential new born care,
   - prevention and management of diarrhoea,
   - appropriate management of ARI,
   - sustaining high level of immunisation coverage,
   - nutritional interventions, etc.

8) Major signs and symptoms of RTI/STI are:
   - abnormal vaginal discharge in women,
   - urethral discharge in men,
   - genital ulcers in men and women,
   - lower abdominal pain in women,
   - scrotal swelling,
   - enlarged, inflamed inguinal lymph glands,
   - neonatal conjunctivitis etc.

9) Hazards of pregnancy when the adolescent girls are not physically and emotionally not ready for child bearing.

Check Your Progress 4

1) PHC and its subcentres, CHC, FRU, and their medical and paramedical personnel, Anganwadi and anganwadi worker, district and subdivisional hospital.

2) Doctor on call, nurse and cleanliness service available beyond normal working hours through contract service, provision of payment of honorarium for deliveries conducted between 8 p.m. and 7 a.m. on duty and to the contractual nurse.

3) Payment of fixed amount to local panchayat in selected subcentre areas for arranging transport for referral of women to CHC/PHC for delivery,

4) Services through urban health posts, urban MCH and FW centres, urban ICDS projects, referral hospitals, PHCs in slums (proposed) maternity homes and mobile clinics by NGOs etc.

5)
- Referral services,
- clinical skill-based training to health personnel,
- providing information on births and deaths including causes of deaths,
- providing timely information on epidemics, surveillance of selected diseases,
- health education in hospitals,
- research etc.

Check Your Progress 5

1)
- maternal health,
- child health,
- management, and
- communication.

2) i) Awareness generation training for personnel from health and non-health sectors

ii) Integrated skill-based training for primary health care personnel

iii) Specialised clinical skill training on MTP, Laparoscopic sterilisation, Minilap sterilisation, NSV etc. for doctors

iv) IUD training for ANM/LHV

v) Management skill based training for RCH programme managers

vi) Communication skill based training for IEC personnel

3) i) Preparation of district training plans and getting approval

ii) procurement and management of funds.

iii) nomination and deputing staff for training

iv) nionitoring training

v) coordination with health and related sectors for training staff.

4) Sources of data for RCH service management include:

- Decennial census,
- SRS,
- NFHS,
- District surveys, and
- Routine service records and reports.

5) Monitoring is a management function which measures the changes during the implementataion of a programime and it checks the progress to see if activities take place as scheduled/planned. If changes seen are of negative nature then corrective steps can be initiated.

6)
- Review of reports and records
- Supervisory visits
- Interviews and discussions with community

7) Indicator is an indirect measure of an event or condition which can help in measuring the changes.

Check Your Progress 6

Steps for improving quality of RCH services include:

- development of standards for various service components arid ndherence to them,
- appropriate competency-based training for health personnel,
- development of procedures for proficiency certification and adherence to them to ensure acquirement of skills after training,'

- improved logistics management,
- close supervision and monitoring,
- counseling and follow-up services for clients, and
- need-based information, education and communication services.

UNIT 4 HEALTH RELATED PROGRAMMES

Structure

4.0 OBJECTIVES

After going through this unit, you should be able to:

- enumerate various ongoing national programmes related to health;
- list the objectives, services and organisation of ICDS scheme;
- describe the salient features of the rural water and sanitary programme;
- list the various components of minimum need programme; and
- enumerate the national norms under Minimum Need Programme.

4.1 INTRODUCTION

In the earlier three units of this block you have learnt about the national programme for communicable diseases, non-communicable diseases and reproductive and child health care.

In this unit, you will learn about the health related national programmes. To begin with you will learn about the objectives, services and organisation of ICDS scheme which is an important multisectoral programme. Thereafter you will learn about the rural sanitation and waste programme. Towards the end of this unit you will learn about another very important programme namely minimum need programme which was initiated in the fifth five year plan. You will learn about its components and various norms for establishment of rural health care infrastructure.

UNIT 4 HEALTH RELATED PROGRAMMES

Structure

4.0 OBJECTIVES

After going through this unit, you should be able to:

- enumerate various ongoing national programmes related to health;
- list the objectives, services and organisation of ICDS scheme;
- describe the salient features of the rural water and sanitary programme;
- list the various components of minimum need programme; and
- enumerate the national norms under Minimum Need Programme.

4.1 INTRODUCTION

In the earlier three units of this block you have learnt about the national programme for communicable diseases, non-communicable diseases and reproductive and child health care.

In this unit, you will learn about the health related national programmes, To begin with you will learn about the objectives, services and organisation of ICDS scheme which is an important multisectoral programme. Thereafter you will learn about the rural sanitation and waste programme. Towards the end of this unit you will learn about another very important programme namely minimum need programme which was initiated in the fifth five year plan. You will learn about its components and various norms for establishmeni of rural health care infrastructure.

4.2 INTEGRATED CHILD DEVELOPMENT SCHEME

The children population is around 17% in India and constitutes an important national asset. This asset in its formative period of life is threatened by a number of preventable diseases of childhood, poor nutrition, lack of education and poor growth and development. The Government of India in the year 1974 adopted a national policy for children from the time before the birth till completion of childhood, so that they will have full physical, mental and social development. Integrated Child Development Services (ICDS) scheme was launched on 2nd October, 1975 in pursuance of National Policy for children in 33 experimental blocks. Success of the scheme led to its expansion to 2996 projects by the end of March, 1993.

ICDS is a multisectoral programme and involves several government departments. The primary responsibilty for the implementation of programme is with the Department of Women and Child Development Ministry of Human Resource Development at the centre and the nodal departments at the states, which may be social welfare, rural development, tribal welfare, health and family welfare or women and child development department.

4.2.1 Aims and Objectives

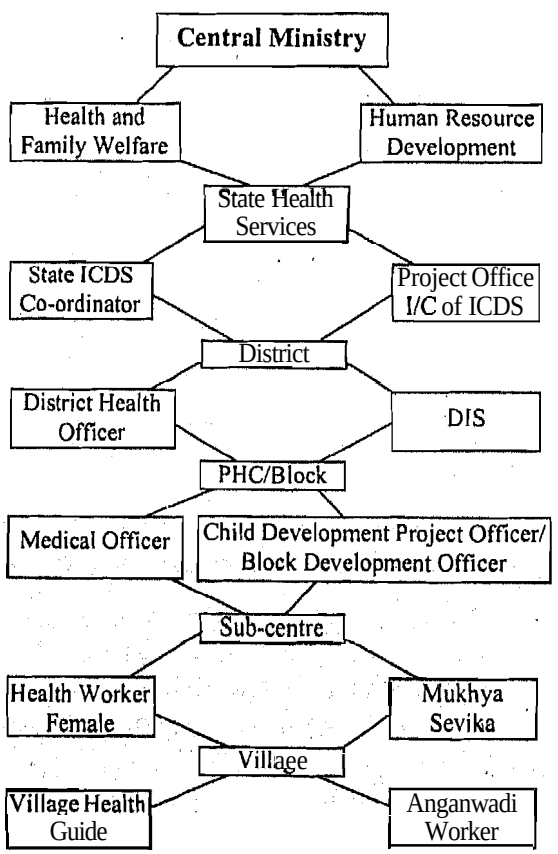
The aims and objectives of ICDS are:

- To improve nutritional health status of 0-6 year age children for proper physical, social and psychological development.
- To reduce the incidence of malnutrition, morbidity, mortality and school drop-outs.
- To achieve inter-departmental co-ordination for effective implementation of policy aiming at child development
- paternal education regarding health and nutritional needs of children.

Towards achieving these objectives, a package of services is provided through the Anganwadi workers at the village centre called "Anganwadi". The supportive supervision is done by the functionaries of the nodal and health departments.

4.2.2 Organisation

The following flow chart depicts the organisation of ICDS and linkages among various functionaries.



4.2.3 Services Rendered

The ICDS package of services includes:

- Supplementary nutrition, Vitamin 'A', Iron and Folic acid
- Immunisation
- Health checkup
- Referral Services
- Treatment of minor illness
- Nutrition and health education to women
- Pre-school education to children in age group of 3-6 years
- Convergence of other supportive services like water supply, sanitation etc.

4.2.4 Beneficiaries

Following are the beneficiaries under the scheme:

- Children below six years of age,
- Expectant and nursing mothers,
- Women in reproductive age group.
- Adolescent girls.

Service Delivery System

An "Anganwadi" is the focal point for the delivery of the services to the children and mothers at their doorsteps and population covered by anganwadi is:

- 1000 in both rural and urban areas, and
- 700 in tribal areas.

But the number of anganwadis in any project can be increased according to local needs on the basis of population, topography, number of villages etc. Services at the Anganwadis are delivered by:

i) Anganwadi Worker: The anganwadi worker, is a part time honorary worker and receives an honorarium. She is assisted by a helper.

ii) Helper: Helper assisted the Anganwadi worker who is also a local woman and is paid an honorarium.

iii) Mukhya Sevikas (MS): The work of Anganwadi workers is supervised by full time workers, the Mukhya Sevikas (MS). They are appointed at the proportion of one for 25, 20 and 17 anganwadi in urban, rural and tribal projects respectively.

iv) Child Development Project Officer (CDPO): For one project there is one CDPO which covers one community development block having a population of 80,000 to 1,20,000 CDPO, coordinates and guides the work of entire ICDS project as an incharge and provide supervision to 4-5 Mukhya Sevikas. CDPO is assisted by one assistant CDPO.

4.2.5 Staff of the ICDS Under Health Department

The following staff from health side monitors the functioning and delivery of services under the scheme.

i) State Co-ordinator: Director in chief or Director health services or Director family welfare and MCH is designated as honorary state co-ordinator of ICDS.

ii) Senior Advisor: A senior officer of the health and family welfare department is appointed as senior advisor.

iii) Officer-in-Charge Data Analysis Cell: Health family welfare department may be appointed to this post of the recommendation of the state co-ordinator.

iv) Divisional Advisor: He/She is a deputy director. or joint director, or additional director who review ICDS programme implementation, co-ordinate with district officials, programme officials and organise meetings.

v) Chief District Advisor: He/She is the head of the medical and health department at the district (CMO) who organises and supervises all activities at district.

vi) District Advisor: He/She is a deputy CMO, additional CMO, district TB, malaria or leprosy officer who supervises one of the 3-4 ICDS projects of the district.

vii) Project Advisor: He/She is the official incharge of the community health centre who supervises and coordinates the continuing education with other medical officers.

viii) Sectoral Advisor: Each ICDS project PHC/CHC is divided into sectors corresponding to the area of one MS, one medical officer is made incharge of one sector, and is designated as sectoral advisor.

4.2.6 Criteria for Project Site

Areas which are tribal/backward, drought/flood prone, predominantly scheduled castes, nutritionally poor, underdeveloped social services, slum population are selected for project site:

- A community development block in the rural areas.
- A tribal development block in the tribal areas.
- A group of slum in urban areas.

Thus, you have learnt that ICDS is a multisectoral programme and involves several governmental departments and the coordination machinery has been set up at all levels of management. You have also learnt that the scheme was launched on 2nd October, 1975 in pursuance of the national policy for children in 33 experimental blocks: Success of the scheme led to its expansion to 2996 projects by the end of March, 1993.

Although scheme is being implemented successfully, there are some drawbacks also:

- There is irregular and inferior supply of supplementary nutrition.
- Children are visiting Anganwadi only at the time of food distribution, which indicate that no other activity of the ICDS scheme is carried out.
- Referral system and home visits are not practical properly and adequately.
- There is hardly serviced coverage of children in the age group of 0-3 years, which is the most vulnerable group.

4.3 WATER SUPPLY AND SANITATION

In this section you will learn about the importance of safe water supply and sanitation, and also about the Water-borne diseases and water safety procedures and standards have been explained.

4.3.1 Importance of Water and Sanitation

Safe drinking water supply and basic sanitation as you know are essential coniponents of human health and development. As per WHO estimate, 80% of all diseases in developing countries, including India are related to unsafe drinking water and poor sanitation.

Diseases, the common cause of deaths are gastroenteritis, typhoid, cholera, hepatitis, amoebiasis, schistosomiasis and vectors borne diseases like guinea worm, yellow fever, malaria etc.

Emphasising the significance of drinking water supply and sanitation services, the United Nations Water Conference (1977) made a distinction between drinking water and sanitation, and other water issues. The conference reconunended that each country should develop national plans and programmes for community water supply and sanitation, thereafter the national water supply and sanitation programme was launched in 1954. The UN declared 1980-90 as the "International Drinking Water Supply and Sanitation decade". The targets were fixed by the Indian Government for the decade:

- One hundred per cent urban and rural water supply
- 50% urban sanitation
- 25% rural sanitation

In 1987 the National Water Policy was announced that has given high priority to drinking water. Rural sanitation was taken up by the minimum needs programme.

4.3.2 Sources of Water Supply

Selection of source of drinking water, a number of factors may influence the health of consumers. In particular, attention must be given to possible future developments that may influence the continued suitability of the source. Important considerations include:

a) Quantity (Source Capacity)

It is the quantity of water available at the source sufficient to meet continuing water demands, taking into account daily and seasonal variations and projects growth in the size of the community being served'?

b) Quality

It is the raw water quality such that, with appropriate treatment, water can be supplied that meets or exceeds the quality specified in the drinking water standards.

c) **Protection**

The water source should bc protected from pollution with human excreta, industrial discharges and agriculture run off.

d) **Feasibilty**

It is the source available at reasonable cost both in absolute terms and in comparison with possible alternative sources of supply.

e) **Treatability**

It is treating water adequately under locally prevailing conditions.

4.3.3 classification of Water-borne Diseases

Various water-borne diseases which can effect humen beings can be classified as follows:

1) Diseases Caused by the Presence of an Infective Agent

   a) ***Viral:*** Viral hepatitis ***A,*** Hepatitis E, Poliomyelitis, Rotavirus, diarrhoea in infants.

   b) ***Bacterial:*** Typhoid and paratyphoid fever, bacillary dysentery, Esch. coli, diarrhoea, cholera.

   c) ***Protozoal:*** Amoebiasis, giardiasis.

   d) ***Helminthic:*** Round worm, threadworm, hydatid disease.

   e) ***Leptospiral:*** Weil's diseases.

2) Diseases Due to the Presence of an **Aquatic Host**

   a) ***Snail:*** Schistosomiasis

   b) ***Cyclops:*** Guineaworm, fish tape worm

4.3.4 Safe Drinking Water

The WHO has published in 1993 vol. 1 and in 1996 vol. 2 of second edition of Guidelines for Drinking Water Quality intended for use by countries as basis for the development of standards, which is properly implemented will ensure the safety of drinking water supplies.

In developing national drinking water standards based on these guidelines, it will be necessary to take account of variety of local geographical, socio-economic, dietary and industrial conditions. This may lead to national standards that differ appreciably from the guideline values.

The guidelines for drinking water quality recommended by **WHO** (1993 and 1996) related to the following variables:

i) Acceptability aspects

ii) Micro-biological aspects

iii) Chemical aspects

iv) Radiological aspects

Safe Drinking Water at Community Level

i) **Storage:** Storage provides reserve of water from which further pollution is excluded. As a result of storage a very condiderable amount of purification takes place.

ii) Filtration: Impurities and 98-99% of the bacteria removed by filtration. Two types of filters are in use.

- Slow sand or Biological filters.
- Rapid sand or mechanical filters.

iii) Disinfection: Effective disinfection can be done by:

- Chlorination
- Ozonation
- Ultra-violet Irradiation

Chlorination: The disinfecting action of chlorine is mainly due to the hypochlorous acid for proper chlorination:

- All the water should be clear and free from turbidity.
- Chlorine demand for water should be estimated.
- Contact period of free residual chlorine should be at least one hour.
- Minimum recommended concentration of free chlorine is 0.5 mg/1 for one hour.

Ozonation: Ozone is a relatively unstable gas. It is a powerful oxidising agent. It eliminates undesirable odour, taste and colour and removes all chlorine from water. The drawback of ozone is that after it has done its job, it decomposes and disappears.

Ultra-violet Irradiation: Germicidal property of UV rays effective against most micro-organisms known to contaminate water supplies including viruses.

Safe Drinking Water at Household Level

Following three methods are generally available for purifying water on an individual or domestic level:

i) Boiling .

ii) Chemical disinfection

- Bleach powder
- Chlorine solution
- High test hypochloride
- Chlorine tablets
- Iodine
- Potassium permagnate

iii) Filtration

Criteria for Potable Water and Quality of Drinking Water

Following table shows the physical and chemical criteria of potable water and quality of drinking water:

Physical Qualities of Water

Characteristics	Level	Remarks
Turbidity	5 Units	Intcrfcrc with chlornatiers
Colour	5 Units	Caused by dissolved impurities
Odour	Agrceablc	Fishy by uroglenopsis and aromatic by asterionella
Taste	Agrceablc	By putrefaction and by algac

Chemical Qualities of Water

Fluorides	0.5-0.8 ppm	Excess leads to dental, skeletal fluorosis and less to dental caricr deflurodation by SSD carbon
Chlorides	200 ppm	From organic pollution and salt suspect pollution of suddenly increase or decrease
Free Salirie Ammonia	0.5 ppm	From decomposing organic matter by action of ferrous salt or nitrate
Albuminoid Ammonia	0.1 ppm	Indicate organic matter yet to be decomposed
Nitrites	Absent	From decomposing organic matter. In deep well due to action of ferrous salts or nitrates. Indicatcs active decomposition and recent current pollution

Nitrates	1ppm	Give past history of organic pollution cxccss cause mcthacnioglobinaemiain infants
O_2 absorbed	1ppm at 3hrs & 37°C	Indicate amount of organic matter yet to bc decomposed
O_2 dissolved	5ppm	If less indicates bacterial arc still actively reducing organic matter arsenic cyanide lead
Assenic Cyanide Lead	0.65	—

4.3.5 Concept of Total Environmental Sanitation

Under the seventh five year plan, the concept of "total environmental sanitation" was absent only construction of latrine is not enough. There is poor sewerage and lack of waste treatment facilities. In actual implementation of water supply, poor and backward classes of population were often neglected. There was a wide'gap between provisions for safe disposal of waste water and drinking water supply in urban areas. Billing and collection mechánism for water tariff needed considerable improvement. There is a great water wastage and leakage.

Under the eighth five year plan in rural areas, highest priority was to be given to those remaining hard core 3000 problem villages (the one which does not have water within 1,6 km. radius/15 minutes walking distance/a height of 100 meters/depth of 15 meters and water source is biologically or chemically contaminated). Ensure supply of 40 litres of water per capita per day (1pcd). Ensure supply of water to weaker sections of the society. At least one hand pump set/spot-source for every 250 persons in problem villages. Achieve zero incidence of Guinea worm diseases hy 1993 and total eradication by 1995, improving water quality and controlling fluorides, salinity and iron content. Improving sanitation in rural areas through IEC programmes, and introducing the concept of total environmental sanitation. Converting all existing dry latrines to low cost sanitary latrines.

Under the eighth five year plan in urban areas there should be 100% coverage with safe drinking water supply by the turn of this century. 125 litres of water per capita per day (lpcd) where piped and underground sewerage system are available, 70 pcd where underground sewerage system does not exist. Priority to small town for water supply with providing financial support. Converting all existing dry latrines to sanitary latrines. Recycling the treated effluents for horticulture, irrigation and other non-domestic purpose. Developing collection and transport system for solid waste disposal.

4.3.6 Rural Sanitation

Rural sanitation was included as an integral part of the national water supply and sanitation programmes under the first and second five year plans. Simple latrines which require no special servicing were considered suitable. The aim was to provide latrines in each house and only an absolute minimum by way of public sanitary conveniences.

The third plan stated that an effort should be made in each community development block to introduce the use of sanitary latrines in schools and group of houses.

The sixth plan admitted that little attention had been paid to the problem of rural sanitation. Even by the end of sixth plan less than one percent of the rural population is reported to have been covered.

The main element of the strategy in the seventh plan to tackle the problem of rural sanitation included the following:

i) Promotion of total concept of sanitation among the people. This will include environmental sanitation personnel, home and food hygenic solid waste disposal and wastewater disposal.

ii) Intensive programme of rural sanitation in certain selected districts initially which could later be replicated to other areas.

iii) Development of delivery system which is prime importance, and giving high priority to software than hardware. Once the rural masses understand the importance of sanitation through motivational and educational efforts there is not likely to be much difficulty in accepting the hardware provided,

iv) Creation of sanitation cell at the stage, district as well as block levels.

Progress in the implementation of the rural sanitation programme has been slow with the major shortfalls in physical and financial targets.

4.3.7 Organisational Structure

At the central governmental level, the departmental of rural development in the ministry of agriculture has been allocated responsibility for rural water supply and sanitation. In the field of rural drinking water supply the major task are being performed by the technology mission.

The department of rural development collaborates with other ministries, and organisations such as the department of science and technology, ministry of health and family welfare.

The management and organisation of urban and rural water supply and sanitation schemes rests primarily with state governments. But the department/agency dealing with tlie programme varies from state to state.

4.3.8 Water Testing

Now you will learn about various steps of water testing:

Collection

Water samples collected depending upon tlie need or as a routine periodic activity and sample can be collected from public or private sources of water supply.

Physical **and Chemical Examination** of Water Sample

Two litres of water should,be collected in inert glass bottle with stopper and before collecting sample bottle should be rinse it thoroughly with water to be sampled. Stopper it, seal it, label it and indicate area, source, purpose, time, and date of collection etc.

Bacteriological Examinations of **Water Sample**

Collect the sample in 250 nil sterile Mecartney bottle made of neutrol ground glass with stopper rim outstructural. In case such bottles are not available sterile cap bottle can be used.

Sample Collected from ATAP

Tap in regular use – allow the water to run for a couple of minutes. So that the impurities, may get washed out. The leaking tap should be sterilised from outside and no water running on outer surface should enter sample bottle.

The tap in case not in regular use then ignile, its inner and outer surface by spirit swap. Allow the water to run and cool the tap and then collect the sample water.

In case the sample is to be collected from stream, river or tank, collect it from the near centre. At the banks it is likely the water get disturbed. Tie a string to the neck of bottle, and slowly immerse the bottle in the water allow it to fill and take out leave the empty space within bottle then seat it. Each time allow empty air space in sample bottle.

After sealing, label it properly indicating source of water date, place and time of collection of sample quality, collected status of'chlorination and type of examination required.

Bacteriological Examination of Water

1) *Objectives of Examination*

a) Detection of faecal pollution.

b) As certain effects of rainfall drought purification system on water bodies:

c) As certain qualities of the recreational water like swimming pool water.

d) As certain quality of commercial use of water like for aerated water, ice, ice-cream, dairy, dairy products, breweries etc.

2) *Indicators of Faecal Pollution*

Coliform organisms are taken as indicator of fecal pollution of water. E. coli group I are chosen because:

a) They are excreted in abundance of human intestine about 1 lakhs to 1 million per ml of faeces.

b) They cannot survive outside human intestine for long periods, but survive longer than pathogens, and hence their presence is the stongest possibility of presence of pathos of faecal origin.

c) They are easy to detect and culture in laboratory.

d) They are always foreign to natural water fecal streptococci and the claustridium pertringens are the indicators of pollution.

4.4 MINIMUM NEED PROGRAMMES

The Minimum Need Programme (MNP) was introduced in the first year of fifth five plan (1974-78). The objective of the programme is to provide certain basic minimum needs and thereby improve the living standards of the people in term of social and economic development of the community particulary the underprivileged and undergeneral population.

4.4.1 Components

Programme includes the following components:

- Elementary education and adult education
- Rural health service
- Rural water supply
- Rural roads
- Rural electrification
- Housing assistance to rural landless labourers

- Environmental improvement of urban slums
- Nutrition
- Rural domestic cooking energy
- Public distribution system
- Rural sanitation

4.4.2 'Rural Health Services

The main component of MNP is deliveryof rural health services. Delivery of health and family welfare services to rural community through three tier system was adopted Sub-centre, Primary Health Centre and Conlmunity Health Centre.

Consolidation and operationalisation of the network of subcentres, PHCs and CHCs so that their performance is optionalised.

- Strengthening of physical facilities
- Essential equipment supply
- Filling up all vacant post
- Ensuring essential drugs, dressing and other material,

Monitor the progress of implementation of minimum need primary at the district, state and national level, a health information management.system development,

Rural Health Infrastructure

Targets were completed regarding setting up of sub-centre, PHCs, CHCs on the basis of population norm according to the priority area, rural tribal and difficult terrain.

Sub-centre

It is manned by MPW male and one female CMPW female/ANM. There are 1,37,271 sub-centre functioning in the country (June 1999) and majority of them funded by minimum need programme.

Primary Health Centre (PHC)

PHC is the first contact point between villagers and medical officer. It is manned by a medical office (MO), and supported by 14 paramedical and other staff. It act as a referral unit for sub-centres. There are 22,975 PHCs functioning in the country (June, 1999).

Community Health Centre **(CHC)**

It is manned by four medical specialist i.e. surgeon, physical gynaecologist and pediatrician supported by 21 paramedical and other staff. It has 30 indoor beds with one operation theatre, X-rays, labour room, and lab. facilities. It serves as a referral centre for PHCs. There are 2935 CHCs functioning in thecountry (June 1999).

4.4.3 Other Components

The other components of MNP include:

Environmental Improvement *of* Urban Slums

This programme is applicable to improve slums in all urban areas and-aims at provision of basic amenities like water supply, services, storm water drains, community baths and latrines etc.

Rurnl Housing

This programme provides housing plot and construction assistance including Schedule Caste and Schedule Tribe.

Rural Sanitation

A centrally sponsored Rural Sanitation Programme (CRSP) was launched in 1986.

Panchayat and local bodies made responsible for all activities related to rural sanitation. NGOs and women groups were also invplved in the implementation of programme in eigth plan.

Rural Water Supply

Highest priority was given to those hard-core problems villages (approximately 3000) that does not have safewater supply or where water is available more than 40 litres per person or available at a walking distance of more than 1.6 km or elevation difference of 100 meters in hilly areas. At least one hand pump/spot sources for every 250 person was provided.

Rural Electrification

Rural electrification is one of the main assets for rural development. During eigth five year plan it was proposed to electrified around 50,000 villages which included 10000 in remote areas.

Nutrition

In the field of nutrition, the objectives are (a) to extend nutrition support to 11 million eligible persons (b) to expand "Special nutrition programme" to all the ICDS projects and. (c) to consolidate the midday meal programme and link it to health, potable water sanitation.

Health Facilities in India

In the field rural health the objectives to be achieved by the end of eighth five year plan, under the minimum need programme are: One PHC for 30,000 population in plains and 20,000 population in tribal and hilly areas. One sub-centre for a population of 5,000 people in the plains and 3,000 in tribal and hilly areas and one community health centre (rural hospital) for a population of one lakh or one C.D. Black by the year 2000.

Rural Health Infrastructure: Norms and Level of Achievements

Indicator	Nationnl Norms		Achievements
1) Rural Population (1991) covcrcd by a	General	Tribal	
• Sub-centre	5000	3000	4579
• Primary Health Centre (PHC)	30000	20000	27364
• Community Health Centre (CHC)	120000	80000	2.14 lakhs
2) Number of Sub Centres per PHC	6		5.97
3) Number of PHCs per CHC	4		7.82
4) Rural Population (1991) covered by a:			
• MPW (F)	5000	3000	4688
• MPW (M)	5000	3000	8573
5) Ratio of HA (M) to MPW (M)	1 : 6.0		1 : 3.3
6) Ration of HA (F) to MPW (F)	1 : 6.0		1 : 6.9
7) Avcragc Rural Area (Sq. Km) covcrcd by a:			
• Sub Centre	—		22.81
• PHC	—		136.31
• CHC	—		1067.10
8) Average Radial Distance (Kms) covered by a:			
• Sub Centre	—		2.69
• PHC	—		6.58
• CHC	—		18.42
9) Average Number of Villages covered by a:			
• Sub Centre	—		4.27
• PHC	—		25.55
• CHC	—		200.07

4.5 LET US SUM UP

In this unit you have learnt about three important health related national programme. To begin with you have learnt about the multisectoral programme of ICDS which is providing various preventive and promotive services to vulnerable section of community i.e. mothers and children. Thereafter. you learnt about water and sanitation programme which aims at providing safe drinking water both in rural and urban areas as well.

You also learnt about the concept of total environmental sanitation and the organisational structure. Towards the end you learnt about various components of MNR which was launching in fifth five year plan and also about the health care infrastructure norms laid down under the programme.

4.6 ANSWERS TO CHECK YOUR PROGRESS

Check Your Progress 1 ,

1) • To improve nutritional health status of 0-6 year age children for proper physical, social and psychological development.
   • To reduce the incidence of malnutrition, morbidity, mortality and school drop-outs.
   • . To achieve inter-departmental co-ordination for effective implementation of policy aiming at child development
   • Maternal education regarding health and nutritional needs of children.

2) • Supplementary nutrition, Vitamin 'A', Iron and Folic acid
   • Immunisation
   • Health checkup
   • Referral Services
   • Treatment of minor illness
   • Nutrition and health education to women
   • Pre-school education to children in age group of 3-6 years
   • Convergence of other supportive services like water supply, sanitation etc.

3) i) Anganwadi Worker
   ii) Helper
   iii) Mukhya Sevikas
   iv) Child Development Project Officer

Check Your Progress 2

1) • One hundred per cent urban and rural water supply.
   • 50 per cent urban sanitation.
   • 25 per cent rural sanitation.

2) i) Acceptability aspects
   ii) Micro-biological aspects
   iii) Chemical aspects
   iv) Radiological aspects

3) a) Detection of faecal pollution.'
   b) As certain effects of rainfall drought purification system on water bodies.
   c) As certain qualities of the recreational water like swimming pool water.
   d) As certain quality of commercial use of water like for aerated water, ice, ice-cream, dairy, dairy products, breweries etc.

Check Your Progress 3

1) The objective of the programme is to provide certain basic minimum needs and thereby improve the living standards of the people in term of social and economic development of the community particulary the underprivileged and undergeneral population.

2) • Elementary education and adult education
   • Rural health service
   • Rural water supply
   Rural roads
   • Rural electrification
   • Housing assistance to rural landless labourers
   • Environmental improvement of urban slums
   • Nutrition
   • Rural domestic cooking energy
   • Public distribution system
   • Rural sanitation

3) a) Sub-centre
   b) **PHC**
   c) CHC

Academy of Hospital Administration
(Established in 1987)

Mission of AHA

"Developing and maintaining quality training, consultancy and research activities in health care/hospital sector through active involvement of health care organizations and providers, to attain a leading role in continuously improving the performance of health care services in the country."

For one year PG Diploma Programme in Hospital and Health Management. Apart from conducting Seminar/Workshop/Symposia, we are looking forward to spread our message to South Asian and other countries.

UNIT 1 GUIDELINES FOR VISIT TO SUB-CENTRES, PHC, CHC AND DISTRICT HEALTH CENTRE

Structure

1.0 OBJECTIVES

After going through this unit, you should be able to:

- know the infrastructural facilities and functioning of rural health care facilitieslstitutions relevant aspects of health centres for assessment of structure of the establishments and their functioning;

  identify the problem/bottlenecks in functioning of these facilities/institutions; and

- suggest the remedial measures for improving their efficiency and effectiveness.

1.1 INTRODUCTION

In the theory blocks of this course you have learnt about health system management and you may have developed a clear picture of the health care delivery system in the country. In this unit you will be preparing yourself for a visit to health establishments at all levels and carry out study to assess the strengths and weaknesses in the system and thereafter prepare a study report.

1.2 PREPARATION FOR FIELD VISITS

In order to understand the functioning of the institutions/facilities providing Maternal and Child Health Care, you are expected to visit these institutions and acquire first hand infoimation about them and record your observations.

Your Academic Counsellors are expected to perform following functions for facilitating the field visits and making them more meaningful learning experiences:

a) Scheduling of the field visits;

b) Making necessary logistics arrangements for conduction of these field visits including correspondence with concerned authorities and arrangements of transport;

c) Explaining the objectives of field visits to you;

d) Provide the checklist to you for studying the organisation and functioning of various units and recording these in your workbook; and

e) Evaluating and providing feedback to you on the records maintained by you for field visits.

In case you feel confident about making your own arrangements for visting these institutions/facilities, you feel free to visit these of your own and record your observations1 findings as per guidelines given in this manual. You are also expected to inform your academic counsellors about this in advanee and take his approval,

1.3 VISITS TO VARIOUS RURAL WEALTH UNITS

You have already leamt in theory blocks of this course about the delivery of Rural Health Care delivery at various levels, i.e., sub-centres, Primary Health Centre . Community Health Centre and district level. You have also learnt about the staffing pattern and types of activities being carried out at these levels. Now you will learn yourself the operational aspects of these institutions/facilities by making a visit to these places. You have to visit the following places to observe the ongoing activities:

- Sub-centre
- Primary Health Centre (PHC)
- Community Health Centre (CHC)
- District Health Office/CMO Office

At eachplace you should see:

- Organisational set up
- Population coverage
- Range of MCH services being provided
- Staffing pattern
- Drugs, logistics and equipment available for MCH care
- Schedule of activities
- Records and Returns
- Problems being faced in implementation of MCH schemes and programmes
- Referral system.

In the end you must be able to critically analyse the functioning at each level and suggest remedial measures.

You can achieve this by:

- Observation of various activities at each level
- Study of records maintained at each level
- Interaction/discussions with available personnel at various levels.

You must record the findings of the visits and get it signed by the concerned academic counsellor.

1.4 LET US SUM UP

After making visits to the various health units engaged in delivery of primary healtli care services you must have appreciated the capabilities and limitations in their organisational set-up, functioning and activities being carried out by them. You must have also gained an insight into some of the problem areas requiring immediate attention. This practical activity will help you in improving the co-ordination with these institutions in you set-up in furtherence of quality in delivery of health care services.

UNIT 2 INVESTIGATION OF AN OUTBREAK

Structure

2.0 OBJECTIVES

At the end of this unit, you should be able to:

- identify the presence of an outbreak;
- apply the steps of investigation of an outbreak;
- find out the causes of the outbreak and prevent future epidemics; and
- send report of investigation of the outbreak.

2.1 INTRODUCTION

You have already learnt about general principles of epidemiology, applied aspects of health statistics, 'at risk' approach and screening and surveillance and monitoring in Unit 3 of Block 1 of this Course. In this unit you will learn about the identification of an epidemic as well as the usual steps followed in an investigation of an outbreak. Epidemics can occur in many communicable diseases like infective diarrhoeas, respiratory infections, exanthematous fevers (viz. measles, chickenpox) etc. Out of all diseases causing epidemic, some diseases can be prevented by the available vaccines. Other containment measures during epidemic like isolation, disinfection, chemoprophylaxis etc. have to be undertaken in addition to immunoprophylaxis for prevention of further spread of the disease. You will be able to investigate an outbreak if you follow the epidemiological principles for control and prevention of the 'diseases.

2.2 STEPS OF INVESTIGATION OF AN OUTBREAK

You will appreciate that whenever there is an epidemic, investigation of the epidemic or outbreak is very important from the point of view of containment measures, finding out

underlying causes of the epidemic and application of appropriate preventive measures for controlling the spread of the disease. There are well established, well accepted steps of investigation of an epidemic. In every situation, the sequence of these steps may not be taken as incorporated in this text, but may vary according to the given situation. Very often the investigator has to undertake many steps concurrently and not one after the other. While data related to causation and time, place, person is being collected, management of affected individuals should be simultaneously undertaken. If investigation is undertaken after the peak of the epidemic is over, the investigation is mainly retrospective.

It is desired to have a scientific procedure, to achieve the ultimate purpose of epidemiological investigation i.e., to control the health problem in the community.

An epidemiological investigation is usually undertaken by following steps.

2.2.1 Ensure the Existence of Outbreak

The first step in investigation of an epidemic outbreak is to ensure the existence of outbreak. For this purpose repeated cases with similar symptoms and signs start appearing in well defined geographical area must be identified. In the unusual occurrence of many cases of same/similar illness causes concern in the public. When you observe such an occurrence of unusually large number of cases in the community, you suspect an outbreak of epidemic and must bring it to the notice of health authorities.

Sometimes you may not be aware of any such phenomenon but routine records and returns show a sudden rise in the number of cases due to particular disease. This should draw your attention and also of all those who are dealing with these statistics right from the grass-root level worker to the health authorities.

Increase in number of cases beyond expected number in case of those diseases, which are endemic can be considered as an outbreak. For those diseases which do not occur in the concerned geographical area, like Yellow Fever in India, even one indigenous case of yellow fever can be considered as an epidemic. The diseases which were endemic earlier but are now controlled due to good vaccine coverage like Polio, are considered on similar lines. Where vaccine coverage is very high, even a single case of paralytic poliomyelitis should be considered as an epidemic. For ensuring the existence of an epidemic, baseline information about occurrence of various diseases in different geographical regions is essential. Comparison of current figures with the existing figures for corresponding months over a period of time will tell you whether epidemic situation is present or not.

2.2.2 Confirm Diagnosis

When there are large number of cases occurring simultaneously in the community, it may not be possible to take a detailed history and clinical examination for each and every case. Since signs and symptoms of the disease are similar 'a working case definition' can be made based on symptomatology and clinical signs of the disease.

Symptoms as you know are subjective criteria and are based on what the patient feels or experiences, e.g. pain in abdomen or vomiting. On the other hand, clinical signs and laboratory studies give objective criteria for diagnosis.

There can be other conditions producing symptoms and signs observed in an epidemic situation to some extent. Laboratory investigations will give you the exact estimation of the number of persons affected by the disease under consideration. Depending upon the underlying diseases under consideration, the relevant samples will have to be collected for sending to the appropriate public health laboratory. Samples are subjected to microbiological, pathological and chemical investigations as per suspected provisional diagnosis of the disease causing epidemic.

During an epidemic there could be many individuals affected or only a few individuals affected. If number of cases is small, each and every case can be examined thoroughly and laboratory investigations undertaken for all of them. But if the number of affected persons is few thousands, it is not possible, and also not essential to undertake laboratory investigations for each ahd every individual, Investigations on a representative and

sufficiently large sample of affected cases is enough to confirm the diagnosis and find out the important information related to agent, host and environment as well as the mode of transmission of the disease.

Once the organisms are isolated you can know about the agent factors like toxigenicity, different strains, their resistance to antimicrobials, etc.

2.2.3 Estimate the Number of Cases

Using the 'working case definition' estimate the number of persons affected. Collect relevant data such as age, sex, place of residence of the cases, history of travel, exposure to a suspected case and a detailed history about the symptoms. This information may be collected on 'epidemiological case sheet', from cases as well as from persons apparently exposed but unaffected.

To know the-total population exposed to the risk of infection, sometimes it is necessary to carry out a house-to-housesurvey. This will help in further analysis like calculating the 'attack rate'.

During an epidemic there can be some overt cases and some sub-clinical cases also. Identification of these subclinical cases or carriers is important from the point of view of the spread of the disease. Estimating clinical cases as well as sub-clinical cases is thus an important step in the investigation of an epidemic.

2.2.4 Orient the Data in Terns of Time, Place and Person

Prepare the 'epidemic curve', which is a clear, simple y a y to show the relationship between the occurrence of cases and their time of onset. The occurrence of cases in the area/region affected can be best shown on the "spot map". The spot map may help to show that the cases occurred close to a sewage treatment plant or its outflow or around a factory letting out toxic fumes/gases.

Calculate the attack rate of the infection. This can be done by considering the population at risk as the denominator and those individuals affected as the numerator. Also calculate the attack rates/case fatality rates for those exposed and those not exposed.

You have already learnt in Unit 1 of this block that the descriptive epidemiology giving information as to when did the epidemic start. You will also agree that knowing about the number of cases occurred in relation to time is important. Seasonal and cyclical trend of a disease can also be studied (Fig. 2.1). Where did the epidemic take place and the distribution

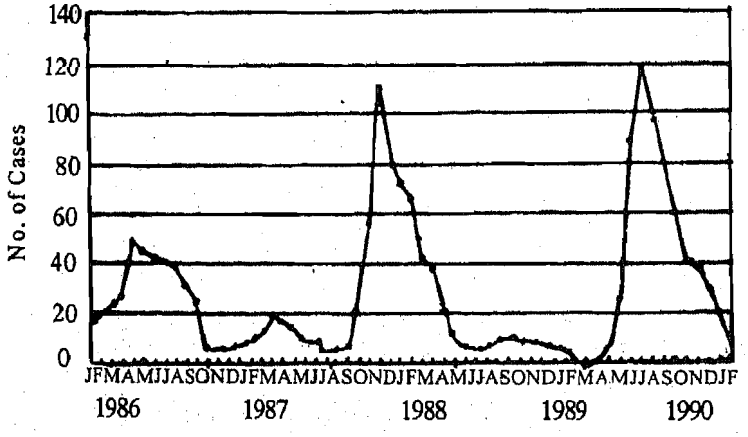

Fig. 2.1 : Epidemic pattern and seasonal variation of measles

of cases in well definedgeographicalarea will give us distributionin space (Fig. 2.2). Similar characteristics of the persons affected in relation to age, sex, occupation etc, will give us an idea about the susceptible population. Children below five years are at a higher risk of getting measles. Epidemic occur both in urban and rural area. Epidemics of measles are common in India during winter and early spring (January to April).

Fig. 2.2: Mapping of Cases of Measies in **a** Health Centre Area

2.2.5 Determine who is 'At Risk' of Contracting the Disease

It is very important to determine the population at risk because when the rates are calculated, those with the disease are taken as numerator and those exposed to the risk of disease are taken as denominator. If the disease is such which occurs in the entire population like in case of water borne diseases, when the water supply of the area is contaminated, all the population receiving water from the contaminated source is at risk. Out of this population group, those persons with the disease under consideration can be identified. These values of numerator (people with the disease) and denominator (total population at risk) are essential for calculating incidence rate prevalence rate and attack rate. When the outbreak is limited to certain population groups like food poisoning among those who attended a marriage party or feast or gastroenteritis in a particular residential institute, the investigations can be'focussed on these restricted population groups at risk.

2.2.6 Develop an Explanatory Hypothesis

Compare the attack rates among those at risk with these who or not. Compare the food-specific attack rates in case of suspected food borne outbreaks. With the help of all the data collected so far and after its analysis, now, formulate a hypothesis and explain the possible sources, causative agent, mode of its spread and the environmental factors favouring its spread.

It was John Snow who hypothesised in 1854 that cholera spread through the water supply. He observed that death rate from cholera was very high in a particular area of London i.e., in Broad Street Golden Square. This area was supplied by two water supply companies viz. Lambeth Company and Southwark and Vauxhall Company. Both these companies drew their water from the Thames River at a point which was highly polluted with sewage. Then between 1849 and 1854, the Lambeth Company changed its source to a point of the Thames River, which was quite free from sewage pollution. Thereafter, the rates of cholera declined drastically in those areas of the city supplied by the Lambeth Company, while there was no change in those areas receiving water from the Southwark and Vauxhall Company,

Table 2.1: Death Rates from Cholera in London, 1853-54 According to Water Company Supplying Actual House

Water company	Number of houses	Deaths from cholera	Deaths per 10,000 houses
Southwark and Vauxhall	40046	1263	315
Lambeth	26107	98	37
Rest of London	256423	1422	59

These data provided Snow with convincing evidence that water supplied by the Southwark and Vauxhall company was responsible for the out-break of cholera in London. With the help of the distribution of cholera cases, he formulated the hypothesis that the disease was spread through the water supply. This is a classical example of how an explanatory hypothesis can help in clinching the source of epidemic and arriving at some conclusions.

2.2.7 Compare the Hypothesis with the Established Facts

The hypothesis formulation should take into consideration all the facts known about the disease such as the causative agent, source of infection, mode of spread, clinical features, etc. If the hypothesis and the known facts are not coherent, then go through the medical records once again, and repeat different calculations. Repeat the interviews with case subjects, collect additional laboratory specimens for more detailed laboratory tests.

The epidemics of gastroenteritis have been occurring usually during summer and raining months in India. In your area, if you encounter a sudden increase of cases during this gastroenteritis period, suspect an epidemic of gastroenteritis. Thus compare your observe facts with the established ones to a logical conclusion.

If cases start occurring among previously immunised individuals then it calls for more detailed study, Theoretically immunised individuals are immune to attack. Hence, in such instances, vaccine potency tests, cold chain maintenance, take of the vaccine have to be studied.

2.2.8 Plan a More Systematic Study

After the initial study and formulation of a hypothesis, plan a more detailed systematic study such as a case control study. It requires more often additional information which dan be collected by surveying the population at risk. a serological survey or carrying out other biological and chemical tests.

For example, if a large number of paralytic poliomyelitis among vaccinated population is encountered, this has to be further investigated. Different aspects of the disease causation should be looked into. Future epidemics could be prevented by improvements in the immunisation services based on the results of the investigation.

The rate of occurrence of polio cases among immunised and unimmunised population can be studied and Vaccine Efficacy Rate can be calculated. So also the development of immunity after oral polio vaccine can be studied by estimation of serum antibodies.

2.2.9 Prepare a Written Report

This will form the basis of action by health officials. The report should be complete comprising of the background information, methodology of investigation, analysis and interpretation of data such as agent, host and environmental factors, mode of spread of the disease, etc. Many a times, such a report will bring out a new fact about the disease. It may also form a basis for reallocation of resources in future.

It was by such a study that John Snow in England, in his classical investigation of cholera epidemic in 1854, showed that cholera was a water-borne disease, long before the birth of bacteriology.

2.2.10 Proposed Measures for Control and Prevention

No investigation of an epidemic is complete without containment measures. While the data are being collected and the causes are being investigated, working definition of cases is made and provision of treatment of the cases is undertaken on war footing.

The aim of any epidemiological investigation should be the ultimate control of the disease problem in question. The study should propose the methods of control of the epidemic both in terms of short and long term measures.

2.3 CASE STUDY

In the preceding sections of this unit, you have learnt the theoretical aspects of investigation of an epidemic outbreak. In this section you are going to learn practical aspects of investigation of an outbreak.

You already know that investigation is an examination for the purpose of finding out something. You will also appreciate that the investigation of an epidemic is of limited duration for some already existing problem. This existing problem or an outbreak is an extraordinary situation due to shift of balance between agent, host and environment. You have also learnt the steps in the investigation of an outbreak. These steps can be recapitulated.

- Ensure the existence of an epidemic
- Confirm the diagnosis

  Estimate the number of cases
- Orient the data in terms of time, place and person
- Deteimine who is at risk of having the health probelm
- Develop an explanatory hypothesis
- Compare the hypothesis with the established facts
- Plan a more systematic study
- Prepare a written report and purpose measures for control and prevention

Now you will go through a case study of gastro-intestinal epidemic which will give you an insight of application of various steps in investigation of an epedemic

2.3.1 Case Study of an Epidemic Outbreak

On 3rd May 1995, it was observed that there were many cases of nausea, vomiting, diarrhoea and abdominal pain in one of the villages of PHC Shivapur area. Cases started occurring on the night of 2nd May till the early morning of 3rd May. All the cases gave history of having attended the marriage party on 2nd May evening. A total of 75 persons attended the marriage party, out of whom 48 persons suffered from gastro-intestinal illness.

Question may be arising in your mind that what makes this an outbreak? Yes you have rightly thought that there was a sudden increase in the number of cases with similar signs and symptoms in the said village, constituting an outbreak.

Next question coming to your mind may be that which diseases could possibly cause an outbreak of such illness?

Clinically, illness consisted of nausea, vomiting, diarrhoea and abdominal pain. None had fever. The illness was of acute onset. The conditions causing such gastro-intestinal illness are:

1) Food poisoning due to Staphylococci, Salmonella, Cl. perfringens or B. cereus
2) Chemical poisoning such as arsenic, heavy metals, etc.
3) Diarrhoea diseases like Cholera, Shigella, E. coli and Campylobacter

Pause for a moment and think what more information is required at this stage ? Yes you have rightly throught of:

- List of those who attended the part
- Items of foods served in the party

Chronological occurrence of cases

Table 2.1 gives information on the age and sex of the persons attended, time of food consumption, onset of symptoms and food items eaten in the party. From this table you will also notice that the earliest case occurred on 2nd May evening at 9.00 p.m. and the latest case occurred at 3.30 a.m. on 3rd May.

Now if you draw a graph of cases by onset of illness using appropriate time periods (epidemiccurve), you will observe from the graph that the epidemic was a single source explosive epidemic without any secondary cases (Fig. 2.3).

Now can you calculate the incubation period from available data and determine the median incubation period and the range?

You will see that in the present instance, the incubation period is the time interval between consumption of food and the onset of symptoms. The shortest incubation period was 3 hrs and longest was 7 hrs (range 3-7 hrs).

Now you arrange the incubation period of the cases in an ascending order starting from 3 hrs onwards, the incubation period of the middle case will be the median incubation period which is 4 hrs.

Table 2.2 and 2.3 are showing agewise and sexwise distribution of cases.

Now you can calculate the attack rate by age and sex'from available data?

For this first you need to classify the people according to their age group. In each age group make male and female columns. Then in each column make tally mark according to their age.

Table 2.1 : **People at Marriage Party**

Y = Yes (indicates consumption of food item.)

N = No (indicates non-consumption of food item.)

Unk = Unknown

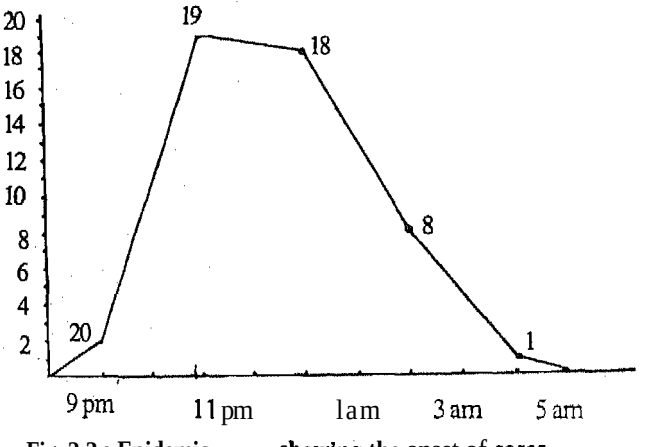

Fig. 2.3 : Epidemic curve showing the onset of cases

and condition after consuming food Go on making one vertical tally mark for each person in the respective category. Make a cross tally mark for every 5th person which will make it easier for counting (Table 2.3). Calculate the attack rate in each age group for male and female separately. Add up both row wise and column wise.

Table 2.2 : Sexwise Attack Rate of illness

Age in Years	Male Total	Male Ill	Male A.R.	Female Total	Female Ill	Female A.R.	Total Total	Total Ill	Total A.R.
0-9	II	II		I	0		III	II	
10-19	~~IIII~~ II	II		~~IIII~~ rm	~~IIII~~ II		~~IIII~~ ~~IIII~~ I	&a- m	
20-29	~~IIII~~	II		I	I		~~IIII~~ I	III	
30-39	IIII	III		~~IIII~~ IIII	~~IIII~~ I		~~IIII~~ ~~IIII~~ IIII	~~IIII~~ IIII	
40-49	I	0		IIII	IIII		~~IIII~~	IIII	
50-59	III	I		~~IIII~~ II	~~IIII~~		~~IIII~~ ~~IIII~~	~~IIII~~ I	
60+	~~IIII~~ ~~IIII~~ m	~~IIII~~ IIII		~~IIII~~ III	~~IIII~~ II		~~IIII~~ ~~IIII~~	~~IIII~~ ~~IIII~~ ~~IIII~~	

Table 2.3: Sexwlse Attack Rate of Illness

Age in Years	Male Total	Male Ill	Male A.R	Female Total	Female Ill	Female A.R	Total Total	Total Ill	Total A.R
0-9	2	2	100.00	1	0	0.00	3	2	66.67
10-19	7	2	28.57	9	7	77.78	16	9	56.25
20-29	5	2	40.00	1	1	100.00	6	3	50.00
30-39	4	3	75.00	9	6	66.67	13	9	69.23
40-49	1	0	0.00	4	4	100.00	5	4	80.00
50-59	3	1	33.33	7	5	71.43	10	6	60.00
60 +	13	9	61.54	8	7	77.78	22	15	68.18
All	35	18	51.43	40	30	75.00	75	48	64.00

You will notice that the total attack rate among those who attended the party was 64, i.e., out of 75 persons who consumed food, 64% became ill, The attack rates among males and females were 51.43% and 75.00% respectively.

Now does the information on incubation period, combined with clinical symptom help in the differential diagnosis ?

From your previous knowledge you can make the differential diagnosis of food poisoning which includes:

a) Salmonella food poisoning

Incubation period : *12* to 48 hours
Source : Contaminated meat, milk, milk products, custard, eggs and egg products
Symptoms : Sudden onset fever, chills, nausea, vomiting and profuse watery diarrhoea

b) Staphylococcal food poisoning

Incubntion period : 1 to 6 hours
Source : Salads, custards, milk, and milk products.
Symptoms : Sudden onset, vomiting, abdominal cramps and diarrhoea

c) Cl. perfringens food poisoning

Incubation period : *12* to 24 hours
Source : Cooked meat and poultry
Symptoms : Diarrhoea, abdominal cramps

d) B. cereus

Incubation period : Emetic form — 1 to 6 hours
Diarrhoea1form — 12 to 24 hours
Source : Cooked rice, dried potatoes
Symptoms : Diarrhoea, abdominal pain

e) Cholera

Incubation period : few hours to 5 days
Source : Contaminated food and water
Symptoms : Onset with purging, projectile vomiting, copious rice watery diarrhoea, and Dehydration.

In the above case the median incubation period is 4 hours and the symptoms were nausea, vomiting, diarrhoea, and abdominal pain. These are suggestive of staphylococcal food poisoning or B. cereus.

Now let us tabulate the specific items of food as consumed by ill and healthy persons and calculate the food specific attack rate.

Table 2.4 : Consumption of Different Food Items and Condition of Health Status

Food Items	Consumed			Not Consumed		
	Total	Ill	A.R.	Total	Ill	A.R.
Rice	38	21	55.26	37	27	72.97
Chapati	36	19	52.78	39	29	74.36
Dal	35	17	48.57	40	31	77.50
Bundi Ladu	28	10	35.71	47	38	80.85
Kheer	46	43	93.48	29	5	17.24
Bhaji	33	11	33.33	42	37	88.10
Chutney	27	12	44.44	48	36	78.00
Water	41	23	56.10	34	25	73.53

From Table 2.4 it can be observed that the highest food specific attack rate among consumed was observed for Kheer (93.48%); and the lowest attack rate among not consumed was observed for Kheer (17.24%).

Given below is a table containing the consumption of Kheer and condition of Health Status of 75 person who attended the marriage party :

Table 2.5 : Consumption of Kheer and Condition of Health Status

	Consumed	Did not Consumed	Total
Ill	43	5	48
Well	3	24	27
Total	46	29	75

From the above table, it is seen that for the item Kheer the attack rate is 93.48% among consumed and 17.24% among not consumed which is significant statistically also. Therefore, it is concluded from the table that Kheer was responsible for the outbreak of food poisoning.

Now can you outline the further investigations needed ?

Further you need to take the food samples from the left over food have to send for laboratory examination. The vomitus and stool samples of the symptomatic cases also have to be sent for laboratory examination. The food handlers, kitchen employees have to be examined thoroughly and nasal swab, throat swabs from the food handlers have to be collected for laboratory examination. The procedure of food preparation and storage has also to be studied.

Now based upon the information and knowledge can you identify a vehicle or common vehicle or common vehicle of infection ?

You will see that from the data given, it is clear that there is a common history of consumption of food in the marriage party. All the cases started experiencing symptoms after that food consumption, From the food specific attack rates it can be concluded that Kheer was the food item responsible for the outbreak of food poisoning.
Lastly what is your hypothesis and conclusion ?

In order to make any further conclusions, you are being provided with following additional information, half of the Kheer was prepared by Mr. A during the early hours of 2nd May and the remaining half was prepared by him on 2nd May mid-morning. Both the preparations were later mixed and kept in a big vessel, which was covered. During preparation and storage they were presumably not touched by anyone.

Bacteriological examination of left over Kheer indicated large number of staphylococcus aurcus.

All the food handlers were examined. Nose and throat cultures were taken from Mr. A who prepared the Kheer. The laboratory report showed staph aurcus in the isolate. He did not have skin lesions nor any symptom suggestive of acute respiratory infection. The Kheer was served with a clean spoon.

With this additional information, you may be able to draw following possible inference:

In this case it is possible that contamination of the kheer with staphylococci could have occurred while mixing the two parts of the kheer preparation. The temperature of this mixed Kheer could have been warm enough for survival rapid multiplication of the organism but not sufficient to kill the organism. Under favourable conditions when cooked food is allowed to cool slowly, sufficient enterotoxin can be produced within two to three hours. Between 30 to 37°C/staphy lococci multiply rapidly in milk and after 7 hours, there can be sufficient number of organisms producing enterotoxin food poisoning. In this case the Kheer was allowed to cool slowly and a lapse of more than seven hours was seen between possible contamination and consumption.

Considering all the information collected, it may appear to you that the outbreak could have been caused because of staphylococci food poisoning due to contamination of Kheer.

Conclusion

An outbreak of gastroenteritis associated with stapliylococcus aurcus occurred on 2nd May 1995 following a marriage party. A total of 48 persons were affected out of the total 75 people who consumed food. The main symptoms were nausea, vomiting, diarrhoea and abdominal pain. All these cases were admitted and given treatment. It was observed that, the Kheer had distinctly higher food specific attack rate, as compared to other food items suggesting that it was Kheer that was responsible for the outbreak. Positive nose and throat cultures in a food handler who prepared Kheer suggest that he might have been responsible for contaminating the food. On 3rd May, all the remaining food was discarded. No further cases occurred and the outbreak subsided on its own.

2.4 LET US SUM UP

In this unit of practical manual you have learnt about various steps in investigation of an epidemic outbreak. You have also gone through a case study which contains step by step analysis of this process of investigation of an outbreak of a gastroenteritis outbreak. After going through the case study you will also gain an insight as to how to apply the epidemiological principles and methods for investigation of an epidemic outbreak.

2.5 KEY WORDS

Attack Rate : An attack rate is an incidence rate, used when the population is exposed to risk for a limited period of time such as during an epidemic.

Endemic : It refers to the constant presence of a disease but at a low frequency within a given geographic area or population group, without importation from outside,

Epidemic : An epidemic is the occurrence in a community or region of a number of cases of a disease that is unusually large or unexpected for the given place and time.

Epidemic curve : It is a graph of the time distribution of epidemic cases,

Incidence : The number of new cases occurring in a defined population during a specified period of time,

Outbreak : The word outbreak is usually used for a smaller epidemic in the interest of minimising public alarm.

Prevalence : The term prevalence refers specifically to all current cases (old and new) existing at a given point in time in a given population.

Spot map : The spot map shows at a glance the areas of high or low frequency, the boundaries and patterns of disease distribution in a region.

PROJECT STUDY

PROJECT STUDY

Structure

1.0 OBJECTIVES

The purpose of this project work is to help you to apply the concepts and techniques learnt earlier to develop an action plan for improving the effectiveness of a selected area of an institution/hospital. The manual outlines a framework for integration of various concepts and provides guidelines for collection, analysis and interpretation of data of a particular health institution.

After going through the project guidelines, you should be able to:

- understand the meaning, characteristics and types of the project;
- apply the multidisciplinary concept, tools and techniques to solve hospital/health management practical problems.
- critically appraise the functioning of an institution providing medical care/health care services;
- identify the key problem areas; and
- suggest measures to improve the effectiveness of the selected institution.

1.1 INTRODUCTION

Throughout the various courses of this programme you have learnt that globalisation and liberalisation have made the organisations more competitive. You have also learnt that the focus has shifted from home turf to the international market, where the operating area for the organisations are not marked by boundaries of countries. For them it is open market or progressing towards open economy. Consequently the pressure on organisations is increasing to maintain a competitive edge in all areas of its operations. You will appreciate that competitive edge can be maintained only by the improvement of its processes and products and the onerous task of improving upon the processes and products requires a thorough study and careful examination of the issues involved. The multiple factors that influence these issues have to be viewed in correct perspective before assessing the influence by them as well as on them, A group of people from multiple disciplines are employed to study these multiple factors in a given time frame who examine and study the issues involved in detail to suggest a range of possible solutions. It is expected that after going through these guidelines you should be able to write a project report on a topic related to a hospital management on health service management.

1.2 WHAT IS A PROJECT?

Let us now try to understand, what is a project?

Various authors have defined project differently as per their own point of view depending

upon their particular field of activity. A very simple and explicit definition of project is as follows:

"A project is any task which has a definable beginning and definable end and requires the expenditure of one or more resources in each of the separate but interrelated and interdependent activities which must be completed in the given time frame to achieve the objectives for which the task (or project) was instituted."

From above definition you will see that a project has a definite aim to achieve in the given time frame and requires the firm commitment of resources to achieve the objective.

1.3 CHARACTERISTICS OF A PROJECT

A project has following characteristics:

- A project is an entity by itself.
- A project has a specific purpose that can be readily defined.
- It is made up of a collection of activities that are linked together because they all contribute to the desired result.
- It has identifiable end product.
- It is non-repetitive.
- It has clearly defined and agreed time constraints. It has to be completed in a given time frame.
- It involves high degree of uncertainty and risk at every step of the process and the management of the risks to sustain the focus on the desired results.
- It is complex because the work involves the commitment and coordination of resources in different departments and even on different sites.
- It has to be flexible to accommodate change as the work proceeds.
- It involves many unknowns both within the work itself and the external influences on the project.
- It has cost constraints, which must be clearly defined and understood to ensure the project remains viable at all times.
- It challenges the traditional lines of authority with perceived threats to tlie status quo.

1.4 WHAT IS PROJECT STUDY?

Having understood the definition and various characteristics of the project, it will be easier for you to understand what is meant by project study.

"Project Study is the method of study of all the variables involved in a given project by the application of various scientific principles, statistical and management techniques with the aim of arriving at a set of feasible and practical solutions, one of which provides the most optimum option to increase the effectiveness and efficiency of the ultimate aim involved for which the project study has been ordered."

In simple terms project study is the scientific examination of a problem and/or concerned issues, to assist the decision-makers arrive at conclusions with a sharper focus over a broad perspective. Project study involves the process of following a logical way to carry out the careful examination of multiple factors involved in a project, based on sound and time tested scientific principles and management techniques. The outcome of a project study must result into a "Project Report"

1.5 WHY PROJECT STUDY?

The advantages of doing a project study are:

a) It helps you to gain experience in the application of theoretical knowledge to real life management situations.

b) It helps you to increase your awareness of the need for synergy and teamwork in dealing with complex problems.

c) It helps you to examine real life problems critically, with a view to analyse them, formulate findings and recommendations and thereby improve system efficiency and cost effectiveness.

d) It helps you in exponential expansion of human knowledge, skill and aptitude.

1.6 TYPES OF PROJECT STUDIES

The project studies are initiated to help the decision-makers in choosing the most optimum solution depending upon his requirements after bringing forth all the relevant issues in sharper focus. The project studies are classified into different types depending upon their proposed utilisation. They are of following types:

a) Exploratory Studies

b) Problem Solving Studies

c) Designing, Refining or Modifying Systems

d) Designing Interventions

e) Evaluating Options

f) Validating Hypothesis

Exploratory Studies

This type of study is carried out to gather some specific information/facts about some management issue. The issue and its attributes are explored and analysed and a "cause-effect" relationship is established, based on which meaningful solutions are recommended for desirable changes.

Examples of such studies in Health and Hospital settings are:

- Project study on acceptance of family planning methods in some specific community
- Project study on motivation profile of health workers in public sector
- Project study on impact of National Health Programme on health status of population

Problem Solving Studies

This type of study is carried out to find solution for a specific problem confronting the organisation. Often the normal functioning in an organisation gets interrupted due to a problem, Problem solving technique involving broadly the following steps is used:

- Defining and diagnosing the problem
- Collection of information and its analysis
- Finding Alternatives
- Choice and evaluation of alternatives
- Selecting the most optimum alternative
- Recommending solution based on that alternative

Some of the examples of such study in health and hospital settings are:

- How to reduce the waiting time in OPD (Outdoor Patient Department) services.
- How to reduce the unnecessary laboratory investigations.

Designing, Refining **or Modifying** Systems

This type of study is carried out when new organisation components are evolved, or when new routines are introduced or when new norms are evolved. In such studies the existing issues are studied and based on the new requirements the appropriate solutions are designed or systems are recommended to be modified.

Few examples of such studies are:

- Study to evolve a uniform organisational structure in health departments for various states.
- Study on evolving staffing norms for a 400 bedded district hospital:

  Study on expansion of out door patient services of a hospital.
- Study on hospital information system.

Designing Interventions/Interventional Studies

This type of study is carried out when the decision maker is confronted with the situation where he seeks assistance to find ways and means for implementing a solution, i.e., how a particular intervention should be designed. So in this type of study the problem and its solution has already been identified, only the way the solution is to be implemented has to be designed.

Some of the examples of such type of studies are:

- Study to devise a method for administration of Oral Polio Vaccine to eliminate polio from India within a defined time frame (Pulse Polio Campaign).
- Study to design a method for distribution of nutritional supplements to school going children to reduce incidence of Kwashiorkor and Marasmus (Mid-day Meal Programme).

  Study to devise a methods for increasing the access of health services to rural population and people staying in remote areas (Mobile Clinics and Medical Camps) etc.

Evaluating Options

This type of study is required to be carried out when the decision-maker requires assistance in selecting the best option as per his requirement, out of a number of alternatives available to him. It may include even generating the alternatives and then selecting one out of them.

Examples of this kind of study are:

- Mechanical laundry versus conventional (manual) laundry services in a hospital.
- Developing hospital services in-house versus contracting out services.
- Evaluating drug distribution methods in pharmacy services.

Validating Hypothesis

Hypothesis as you know is an assumptive statement of facts made by an investigator health manager based on scientific facts after carrying out a study or research. At times the decision maker may be interested in knowing the degree of truthness or success of the hypothesis or idea, i.e., the validity of hypothesis. Under these circumstances such a study is required to validate hypothesis.

Examples of this type of study are:

- Study to test the hypothesis that improving OPD (Out Patient Department) services reduces the average length of stay of an indoor patient.
- Study to test the hypothesis that improving hygiene factors improve themotivation of workers.

1.7 PROCESS OF PROJECT STUDY

As already discussed, tlie type of project study depends upon its proposed utilisation. Therefore it is not correct to label a particular process, which can be followed for every type of project study. However general guidelines are described here which could be applied for conducting most of the project studies. The process of project study consists of essentially following steps:

- Selecting Aim, Objectives and Scope of study
- Methodology including tools of data collection
- Analysis of existing system

- Data collection

  Inference and Interpretation

- Discussion

  Conclusions and Recommendations

- Summary

1.7.1 Selecting Aim, Objectives and Scope of Study

Aim as you know is the ultimate end towards which all objectives are directed. In fact aim should define the solution to the problem or the issue or the "felt need". For example the felt need of the user for the construction of a multi-speciality hospital in terms of aim, can be defined as "To prepare a project report on planning of physical facilities, staffing, equipment and utilisation of a 300 bedded multi-speciality hospital in a metropolitan city"

Objectives are the important ends towards which all activities are directed. The list of objectives should cover the main issues. In selecting objectives, one should list out attributes, which when measured will provide the necessary analytical context of the subsequent work. Objectives should be verifiable and should state what is to be accomplished and when. Objectives should present a challenge and indicate priorities. A few important points to be kept in mind while formulating objectives are as follows:

- Do the objectives cover the main feature?
- Are the objectives expressed clearly?
- Are the objectives verifiable?
- Do the objectives indicate:
  - Quantity (how much)?
  - Quality (how well or specific characteristics)?
  - Time (when)?
  - Cost (at what cost)?
- Are the priorities assigned to the objectives?

  Are the assumptions underlying the objectives clearly identified?

- Are the objectives achievable within available resources.

After the objectives are formulated, it should also be decided how to quantify these objectives, meaning thereby that how the objectives contribute quantitatively towards achieving the aim of the study. A decision has to be made how to measure these objectives. The objectives 'cover lot of issues some small and others big, and dimensions and interrelationship of all these issues and attributes are required to be measured and identified. The physical attributes can be measured with the help of physical instruments but the measurement of psychological and social attributes does require a different set of instruments.

Scope or the limits of the study should also be clearly defined. It means what the study will include and what it will not. What considerations will be taken into account and what will be left out? The constraints of the study should be clearly spelt out in the scope.

1.7.2 Methodology

Methodology adopted to carry out these study varies with the type of study. It may involve retrospective study, present study or prospective study. Retrospective study is the one in which the past events are studied. The prospective is the forward-looking study for the future period. For example in case of a project like " Study of health practices of a given community and their impact on the existing health system with a view to plan for expansion of health care facilities in that community " may involve all the three types of studies mentioned above.

In certain projects, networking techniques like PERT (Programme Evaluation and Review Technique), CPM (Critical Path Method) may be required. For example projects concerning construction of a hospital, project like installing MRI (Magnetic Resonance Imaging)

facilities or expansion of a hospital, application of PERT/Cost techniques is very useful. You have already learnt in detail about these techniques in Block 1 of Course 1.

Certain projects may require the application of Operations Research techniques like Simulation, Linear programming, Work-study, Activity Sampling, Method Study, Distribution logistics etc. For example in a project study to work out the staffing norms for a hospital or its department will require the use of technique of "Work Measurement" or "Activity Sampling". You have been exposed to these operation research techniques in Course 1.

Besides the techniques mentioned above, there are other techniques like Quality Circles, Total Quality Management, Value Engineering, CAD/CAM (Computer Aided Designs/ Computer Aided Manufacturing) which can be applied in project studies.

The important aspects which has to be decided in methodology is, that What data is to be collected, how the data is to be measured and how it is to be collected ?

What is Data?

Data as you know is an organised collection of information, containing the values of the variables, obtained from a sample of the subjects, and which would be sequentially used to derive conclusions through the process of scientific analysis and reasoning. In all types of studies the process df making measurements obtains data.

Types of Data

In clinical and health research the data, which is generally collected, is of two types:

- Quantitative data
- Qualitative data

Quantitative data is when the information is collected in the form of mathematical figures and it is recorded in the form of numerals. For example, height, weight, length etc. It is also called 'Numerical data'. The statistical methods employed in analysis of such a data or mean, range, standard deviation, co-efficient of variation and co-relation co-efficient.

Qualitative data is when the information can not be recorded in the form of numbers, but according to some certain defined attributes. For example "Sex-Malememale", " Satisfaction level - Satisfactory/Unsatisfactory". The results of a qualitative data are always expressed as a ratio, proportion, percentage or a rate. The statistical methods commonly employed in analysis of such a data are standard error of proportion and Chi-square tests.
Data can also be classified according to the source:

- ***Primary Data*** which is collected for the first time and thus is original in character.
- ***Secondary Data*** is that which has already been collected by someone else and has already been statistically processed. It can be obtained from various sources such as hospital registers, reports and returns of health centres, published data of some research studies etc.

Measurement of Data

Measuring or quantifying of the data is very important step in any project study. The data or the attributes in a project study are measured with the help of indicators. Indicators as you know are the specific instruments in the form of questions, scales or devices by which respondent's knowledge, opinion, expectations or the other data being collected in the study is measured. There is seldom a perfect measure of an attribute. Therefore it is desirable to consider and use different measures to gauge the same dimension/attribute. At times it is necessary to develop an instrument for measuring a specific attribute or data under study. At times when we have several attributes of a concept resulting in multifarious measurements, it may become necessary to combine these measurements into a single index so that they can be related to the original concept in a comprehensive way. The method of 'scaling is used to quantify data.

Scaling

Scaling is the procedure for the assignment of numbers (or other symbols) to a property of

objects in order to impart some of the characteiistics of numbers to the properties in question. In physical sciences the numbers are assigned to the measurement of various parameters like length, time, mass and so on, but in social research the numbers assigned do not have the one and the same interpretation. The interpretation of the numbers assigned in scaling depends upon the levels of measurement. These four levels are:

a) Nominal Scale
b) Ordinal Scale
c) Interval Scale
d) Ratio Scale

Nominal Scale: The nominal scale is used to measure qualitative data. In nominal scale, an attribute is marked as being either present or absent. The number of objects are recorded either those which have the defined or the specific attribute or those which do not have the defined or the specific attribute. So nominal scales merely classify without indicating order, distance or unique origin. In nominal scaling the given sample/population is labeled into a predetermined class. Examples are:

a) Marital Status – Single, Married, Divorced.
b) Status – Member/Nonmember
c) Smoker – Yes/No

Ordinal Scale: The ordinal scale uses numerical symbols for recording the data, but these numbers do not have any meaningful mathematical relationship. Ordinal scales indicate magnitude relationships of "more than" or "less than". Ordinal numbers do not permit mathematical operations. Since the number of this scale have only a ranking meaning, the appropriate measure of central tendency is the median. Example of ordinal scale: the fever can be graded as Mild =1, Moderate =2, High Fever =3. So when ranking the degree of fever these numbers can be used for mild, moderate or high fever but these numbers 1, 2, and 3 do not have same mathematical relationship between them as in other mathematical operations.

Interval Scale: Interval Scale has the property of both the nominal as well as the ordinal scale. In addition the interval between numbers, on an interval scale represents equal distances in the variable being measured. The scale does not have a unique or absolute zero, but an arbitrary zero. For example Fahrenheit temperature scale.

Ratio Scale: This scale includes the features of nominal, ordinal and interval scales and in addition provides an absolute (non-arbitrary) zero point. Ratio scales represent actual amounts of variables. Measures of physical dimensions such as weight, height, distance. etc. are examples where ratio scales can be used. In project studies ratio scales are used to obtain stock levels, transit time etc. All the statistical techniques can be used with ratio scales and all the manipulations that one carries out with real numbers can also be carried out with ratio scale values.

Based on these rating scales and techniques a decision is made how to evolve criteria for analysis of existing system by applying these scales and techniques.

After a decision has been made which methodology is to be used for the project study, what data is to be collected, how it is to be collected, what measurement techniques are to be used, the next step in project study is to apply these decisions to the existing system.

Data Collection

Following methods are used to collect the primary data:

- Observation
- Interview
- Questionnaire
- Documents

Observations: In this method, the information is sought by way of investigator's own direct observation without asking anything from the respondent. While recording observations, the investigator should take care to rule out all kinds of bias. Care should also be taken that others do not become conscious of the fact that they are being observed, as this will not produce the correct data. Observations therefore should be recorded discretly. The

recording of observations should be carefully planned and proper checks and controls for validity and reliability of data should be made. Advantages of this method are that subjectivity is reduced and there is complete separation from past or future. Disadvantages of this method are that it is relatively costly, time consuming and provides limited information.

Interview: This method is used to collect data from the subjects who have the knowledge o: the subject under investigation. Interviews may be Personal Interviews or Telephonic Interviews. In personnel interviews, the information is collected by face to face physical presence of the interviewer and the respondent. But nowadays organisations are taking help of modern technological tools like video-conferencing, in which face to face interview is conducted but both interviewer and the respondent are located at a far of distance, but both can see each other as sitting face to face. In telephonic interviews, contacting respondents on telephone collects the information. Interviews can be Structured inteiviews, Semi-Sructured interviews and Unstructured Interviews.

In Structured *Interviews*, a set of questions related to the project under study are prepared and asked. The questions are so designed so as to provide specific information about the issues under study. The interviewer in structured interview follows a rigid procedure laid down, asking questions in form and order prescribed and recording of responses is also done in the form and order prescribed. Structured interviews require lesser skill on the part of interviewer. Structured interviews are usually used in descriptive studies.

In *Unstructured* Interview, the interviewer is allowed much greater freedom to ask supplementary questions or omit certain questions. He has greater freedom while recording responses to include some aspects and exclude others. Here the aim is to extract information about the issues, which are important from the point of view of person who is being interviewed. This gives an insight about the human behaviour of persons performing the job under study. Unstructured interviews demand greater skill and knowledge on the part of interviewer. Unstructured interviews are generally used in case of exploratory studies.

In *Semi-structured Interview*, the interviewer follows the interview guide or the set pattern, but in addition may asks other questions.

Interviews may be focussed interviews, clinical interviews and non-directive interviews. In focussed interview the aim is to focus attention on the given experience of the respondent and its effect. The main task of the interviewer is to confine the respondent to a discussion of issues with which he seeks conversance. Such interviews are used in the development of hypothesis.

The clinical interview is concerned with broad underlying feelings or motivations or with the course of individual's life experience. In case of non-directive interview, the interviewer's function is simply to encourage the respondent to talk about the given topic with bare minimum questioning.

Questionnaire: This method is used when large size inquiries are to be conducted. A number of questions, presented in a definite order on a specially designed form are administered to the subjects under study, either personally or through post or through telephone. It is important to structure the questionnaire and validate it through pilot survey. before presenting it to the subjects under study. Care should be taken that questions are short and simple. Questions may be of closed type (with 'yes' or 'no' type answer) or they may be of open type (inviting free response). They may be of the type where they provide fixed alternative responses.

Documents: In this method the data is collected from the records, documents, report and returns, research papers and recorded forms. Documents or records provide a reliable source of observation. They can also be used to verify the articulation of policies, rules and Standard Operating Procedures (SOPs).

1.7.3 Analysis of Existing System

The next step is to analyse the existing system. An analysis is made of the existing objectives, existing functions being performed, the different relationships including functional relationship, the existing expenditure or the costs involved, the effectiveness of the existing way of functioning, existing policies, rules bylaws and so on. This review of the

existing system may require visits, discussions, briefings and interactions with a wide variety of people both inside and outside the organisation. It may include the review of literature available on the subject. It includes, not only the study of the organisation for which the project study is being done, but also, the analysis of the external environment, that is, the similar projects/ industries outside, their profitability, su vival, success.

For example in case of a project of construction of a multidisciplinary hospital in a district, the review of existing systems will include:

- The present system of health care delivery in the district
- The present number of health care facilities, hospitals, hospital beds, general practitioners, Registered Medical Practitioners and alternative health care system facilities and their capabilities.

  Demographic profile of the dependent population of the district.

  The social, economic and educational status, the health practices and social customs and taboos.
- Common health problems and disease prevalence in the dependent population so that concerned departments in the hospital can be developed more.

The detailed examination of the system involves the following:

Enumeration and description of all the elements

- Appreciation of the policies governing the relationships amongst the elements
- Identification of the opportunity elements
- Task analysis of the opportunity elements

Opportunity Elements

When you enumerate and describe various elements of the system, look for the elements, which promise scope for improvement, These elements are called Opportunity elements. The focus should be kept on these elements, but the care should be taken that the focus does not become too narrowed. Therefore elements of associated system should also be included, but the study should remain manageable. The opportunity elements are perused for the task analysis

Task Analysis

It basically means getting details about the task elements of each opportunity element so that the focus can be emphasised on these elements, The aim is to control the specific parts of the operations.

Effectiveness **Criteria**

An effectiveness criteria is basically the degree to which the system achieves the designated task or function while operating in the specified environment. The cost of operation related to the effectiveness should also be measured.

The good review of the system helps in better appreciation of the task and enables the study team to arrive at a range of feasible options as well as the attendant consequences.

1.7.4 Data Collection

The data relevant to the project study should be collected applying the methodology and using the parameters and attributes, decided as per study plan. While recording the data due care need to be taken to rule out the observer and instrument error. The observations should be recorded carefully and all types of biases should be ruled out. Any deviation, if it is there, should be explained by logical, sound and scientific reasoning. The overall plan or design for the study and the time frame as decided earlier should be strictly followed and adhered to. How the data being collected will contribute to the aim and objective of the study should always be kept in mind to avoid wasting of time and money in collecting data irrelevant to the study. Facts, figures, observations and data so collected should be

arranged, tabulated and presented in a simple and easily understandable manner. All statements should be supported suitably by relevant facts and figure.

1.7.6 Inference and Interpretation

After the data has been collected, it is analysed to draw inferences. The purpose of collecting, collating and analysing information is to arrive at objective assessment of the selected attsibutes of the system under consideration. The information, available on the basis of the processed data, is to be utilised in drawing inferences about the status of the selected attributes on which data is collected. These inferences are to be interpreted in larger context to arrive at meaningful conclusion.

Inferences in simple terms mean estimation. Use of both qualitative and quantitative techniques is made. The qualitative technique used can be intuition based on the experience or past practices. The quantitative techniques used are:

- Hypothesis testing
- Chi-square test
- Analysis of Variance
- Regression Analysis
- Co-relation Analysis
- Trend Analysis

All these techniques come under Statistical Analysis and beyond the scope of this project works and, therefore, are not being described here. The inferences should be drawn objectively and should be restricted to the information procured from the available data. After drawing inferences correctly, the next step is to make correct interpretation. The 'Interpretation' is the process of establishing links within the inferences and possible cause-effect relationship within the sub-system as well as with the larger system. The inferences should also be linked with the other studies on the same or related subject.

1.7.7 Discussion

After the inferences have been drawn and an appraisal of the organisational system including its processes with specific reference to areas of interest has been made, brainstorming sessions are held with in the study team to threadbare various conclusions drawn. The nodal points of the system needing attention and further study are emphasised to find ways and means to provide effective solution to the problem. The possible approaches/techniques/concepts that can be employed are explored. The options are generated and shortlisted based on the criteria of feasibility from all aspects including their evaluation for cost and effectiveness. The discussions are also held with the important users and outside experts and different options are generated. The consequences of implementing various options are also discussed and recorded. Any specific preferences of the user/sponsorer for a particular set of options are noted and specific interventions if required are designed. This helps in finding solutions, appropriate to the organisation and also improves acceptability subsequently. If the circumstances permit, a limited trial on a small scale can also be conducted to give confidence to the sponsorer/user as regards to viability of the proposal. This will help the study team in collecting data on post implementation changes and modify the proposal, if necessary.

1.7.8 Recommendations

Recommendations form the most important part of the project study. While framing recommendations due care should be taken that they provide answer to the aim and all the objectives set forth in the study. The recommendations should cover all aspects of the problems/issues for which the sponsorer/user has requested the study.

1.8 PROJECT REPORT

After the study has been completed, it is necessary to reduce in writing the entire thought process as evolved during the study. All underlying assumptions and information on which

the recommendations were based and formed should be recorded in a logical sequence. The most well designed and conducted study and the most revealing findings are of little value unless they are communicated properly. The purpose of project study is served only when the findings and recommendations are made well known to all concerned. Writing of the report is basically an art and requires special skills. The important thing to be kept in mind while writing the project report is that the whole subject matter should be written logically and chronologically and all facts, figures and statements should be stated along with various options and the implications and consequences of implementing these options. The following format as a guideline is suggested for the project report:

Layout of a Project Study Report

1) Cover Page : It should contain the following:
   - Title of tlie project report
   - Organisation or project study team or individual's name who has conducted and prepared tlie project report

     The organisation for which the project report has been prepared
   - Date and year of project report
2) Table of Contents
3) List of Abbreviations
4) Project Report Summary
5) Details of project study as under:
   a) Introduction
   b) Aims, Objectives and Scope of project study
   c) Background material like review of literature
   d) Methodology
   e) Findings/observations including analysis
   f) Discussion giving details of inferences and interpretations
   g) Recommendations with detailed justifications.
6) Areas of further study
7) Acknowledgements
8) Appendices, Charts, Graphs, Sketches etc.

1.9 LET US SUM UP

In this project manual you have learnt that a project study is the scientific examination of a problem and/or concerned issues, to assist the decision-makers arrive at conclusions with a sharper focus over a broad perspective. Organisations, as you know, are increasingly requesting for project studies in order to maintain their competitive edge in this era of globalisation and liberalisation. You have also learnt that project studies help to examine real life problems critically, analyse them and provide solutions to improve system efficiency and cost effectiveness. You have also learnt about the classification of project studies which can be classified in to different types depending upon their proposed utilisation, These can be Exploratory, Problem solving, Designing or modifying systems, Interventional studies, Evaluating options and Validating hypothesis. You have learnt that the process of conducting project study which consists of various steps viz. selecting aim, objectives and scope, methodology, analysis of existing system, making observations and collecting data, making inference and interpretation, discussion, recommendations, and summary. You will appreciate that the purpose of project study is served only when the findings and recommendations are made well known to all concerned and this is best done with the help ofproject report,

ACTIVITY

You would be required to write dissertation/project on a topic related to hospital management or health services management or on health problems. A list of suggested topics for dissertation project is given here:

1) Study of OPD services of a district hospital.
2) Study of purchase system and management of medical and surgical stores in the hospital.
3) A study of Nursing service in a district hospital.
4) An evaluatory study of some of CGHS/ESI dispensaries in the station.
5) A study of hospital laboratory services of a district hospital.
6) A study of Blood Bank services in a district hospital.
7) A study of Radiological services in a district hospital.
8) A study of Dietary services in a district hospital.
9) A study of absentesm among class D employees.
10) A study of Disaster plan for a hospital.
11) Procurement, storage and consumption pattern of crystalloids at a district hospital.
12) A study of the problems in maintenance of hospital buildings and equipments.
13) Any other subject pertaining to General Administration, Personnel Management, Financial Management, Materials Management.

This list is suggestive in nature only but you may select any other suitable subject for study. The dissertation should be based on a practical field study carried out by the candidate.

You should identify and select an institution/hospital or an area which has about average performance. You may finalize the selection of institution/hospital in consultation with your academic counsellor at programme study centre.

After the selection of the institution; you must:

- introduce yourself to the head of institution
- explain him the purpose of your study
- seek his approval for carrying out the project work in the institution
- request him to provide you access to various records and reports available at his end
- develop rapport with head of institution and other staff members
- develop the tools for collection of data i.e., questionnaire, interview schedules and checklists for observational study.
