Routes of transmission of HIV in India 2011–2012 (Jan.)

Source : *(11)*

Patterns of HIV epidemic at national level *(12)*

At the national level, the overall HIV prevalence among different population groups in 2010–11 continues to portray the concentrated epidemic with high prevalence of HIV in high risk groups. Fig. 2 shows the percentage positivity of HIV in different population groups during the year 2010–11.

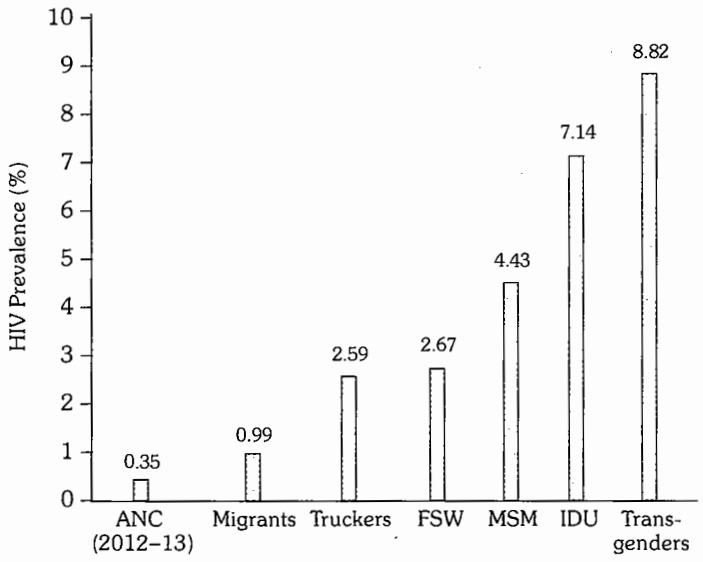

FIG. 2
HIV prevalence for ANC attendees and among different risk groups, India, 2010–11

Source : *(12)*

The primary drivers of HIV epidemic in India are unprotected paid sex/commercial female sex workers, unprotected sex between men, and injecting drug use. It is estimated that there are 8.68 lakh female sex workers, 3.13 lakh men who have sex with men with high-risk and 70,000 transgenders, 1.77 lakh injecting drug users in India and 110 lakh bridge population which includes 80 lakh migrants and 30 lakh truckers. Though sex workers account for 0.5 per cent of adult female population, they account for seven per cent of HIV infected females. Sex workers continues to act as the most important source of HIV infection in India due to the large size of clients that get infected from them. These men then transmit the infection to their wives affecting several low risk women in the society. Long-distance truckers and single male migrants constitute a significant proportion of clients of sex workers *(12)*.

The national adult (15–49 years) HIV prevalence is estimated at 0.27 per cent for the year 2011, 0.32 among males and 0.22 in females. There is a steady decline from 0.49 per cent in 2001. The prevalence among young population (15–24 years) at national level is estimated at 0.11 per cent for 2011, and equal among men and women at 0.11 per cent. There is stable decline in most states, while rising trends are noted in Jharkhand, Odisha, Tripura and Uttarakhand. India is estimated to have around 1.16 lakh annual new infections among adults and 14,500 among children. About 1.48 lakh people died of AIDS related causes in 2011. Deaths among HIV-infected children account for 7 per cent of all AIDS-related deaths. It is estimated that the scale up of free ART since 2004 has saved over 1.5 lakh lives in the country till 2011.

During 2010–11, none of the states have shown HIV prevalence of 1 per cent or more among ANC clinic attendees. While declining trends are noted at national level among general population, female sex workers, and men who have sex with men, stable trends are recorded among injecting drug users.

Impoverished, unemployed, under employed, mobile and migrant youth, and street children are particularly vulnerable to HIV, as they are less likely to have information about HIV or access to preventive measures, and they may face repeated risks of HIV infection.

EPIDEMIOLOGICAL FEATURES

1. Agent factors

(a) AGENT : When the virus was first identified it was called "lymphadenopathy–associated virus (LAV)" by the French scientists. Researchers in USA called it "human T–cell lymphotropic virus III (HTLV–III)". In May 1986, the International Committee on the Taxonomy gave it a new name : human immunodeficiency virus (HIV).

The virus is 1/10,000th of a millimetre in diameter. It is a protein capsule containing two short strands of genetic material (RNA) and enzymes. The virus replicates in actively dividing T4 lymphocytes and like other retroviruses can remain in lymphoid cells in a latent state that can be activated. The virus has the unique ability to destroy human T4 helper cells, a subset of the human T–lymphocytes. The virus is able to spread throughout the body. It can pass through the blood–brain barrier and can then destroy some brain cells. This may account for certain of the neurological and psychomotor abnormalities, observed in AIDS patients. HIV mutates rapidly, new strains are continually developing. There are two types of HIV – HIV 1 and HIV 2, which exceeds 50 per cent.

The virus is easily killed by heat. It is readily inactivated by ether, acetone, ethanol (20 per cent) and beta–propiolactone (1:400 dilution), but is relatively resistant to ionizing radiation and ultraviolet light *(13)*.

(b) RESERVOIR OF INFECTION : These are cases and carriers. Once a person is infected, the virus remains in the body life-long. The risk of developing AIDS increases with time. Since HIV infection can take years to manifest itself, the symptomless carrier can infect other people for years.

(c) SOURCE OF INFECTION : The virus has been found in greatest concentration in blood, semen and CSF. Lower concentrations have been detected in tears, saliva, breast milk, urine, and cervical and vaginal secretions. HIV has also been isolated in brain tissue, lymph nodes, bone marrow cells and skin *(14)*.

2. Host factors

(a) AGE : Most cases have occurred among sexually active persons aged 20–49 years. This group represents the most productive members of the society, and those responsible for child-bearing and child-rearing.

(b) SEX : In North America, Europe and Australia, about 51 per cent of cases are homosexual or bisexual men. In Africa, the picture is very different; the sex ratio is equal. Certain sexual practices increase the risk of infection more than others, e.g., multiple sexual partners, anal intercourse, and male homosexuality. Higher rate of HIV infection is found in prostitutes.

(c) HIGH-RISK GROUPS : Male homosexuals and bisexuals, heterosexual partners (including prostitutes), intravenous drug abusers, transfusion recipients of blood and blood products, haemophiliacs and clients of STD.

Immunology

The immune system disorders associated with HIV infection/AIDS are considered to occur primarily from the gradual depletion in a specialised group of white blood cells (lymphocytes) called T–helper or T–4 cells. The full name of T–helper cell is CD4 + T lymphocyte and is also commonly known as CD4 + cell. These cells play a key role in regulating the immune response.

HIV selectively infects T–helper cells apart from several other cells in the immune system such as B–cells, microphages and nerve cells. When the virus reproduces, the infected T–helper cells are destroyed. Consequently people with AIDS tend to have low overall white blood cell count *(15)*. Whereas healthy individuals have twice as many "helper" cells as "suppressor" cells, in the AIDS patients the ratio is reversed. A decreased ratio of T–helper to T–suppressor cells may be an indirect indicator of reduced cellular immunity. One of the most striking features of the immune system of patients with AIDS is profound lymphopenia, with a total lymphocyte count often below 500 cu. mm. It is the alteration in T–cell function that is responsible for the development of neoplasms, the development of opportunistic infections, or the inability to mount a delayed–type hypersensitivity response. The lack of an obvious immunological response by the host to the virus is one of the problems confronting scientists *(16)*. That is, those with antibodies to HIV, usually will have too few of HIV antibodies, and these antibodies are also ineffective against the virus.

Mode of transmission

The causative virus is transmitted from person-to-person, most frequently through sexual activity. The basic modes of transmission are :

(a) Sexual transmission

AIDS is first and foremost a sexually transmitted disease. Any vaginal, anal or oral sex can spread AIDS. Every single act of unprotected intercourse with an HIV–infected person exposes the uninfected partner to the risk of infection. The size of the risk is affected by a number of factors, including the presence of STD, the sex and age of the uninfected partner, the type of sexual act, the stage of illness of the infected partner, and the virulence of the HIV strain involved. A European study of heterosexual couples in which only one partner was infected at the start, suggests that chances of transmission of HIV infection from male to female is twice as likely as from female to male *(17)*. Generally, women are more vulnerable to HIV infection because a larger surface is exposed, and semen contains higher concentration of HIV than vaginal or cervical fluids.

Anal intercourse carries a higher risk of transmission than vaginal intercourse because it is more likely to injure tissues of the receptive partner. For all forms of sex, the risk of transmission is greater where there are abrasions of the skin or mucous membrane. For vaginal sex the risk is greater when woman is menstruating.

Exposed adolescent girls and women above 45 years of age are more prone to get HIV infection. In teenagers the cervix is thought to be less efficient barrier to HIV than in mature genital tract of adult women. The thinning of mucosa at menopause is believed to lessen the protective effect. The production of mucus in the genital tract of adolescent girls and in postmenopausal women is not as prolific as in women between these life stages and this may also enhance their susceptibility to HIV infection.

An STD in either the HIV–negative or the HIV–positive partner facilitates the transmission of HIV. The risk of transmission is 8-10 times higher. If an STD, such as syphilis, chancroid or herpes, causes ulceration in the genital or perineal region of the uninfected partner, it becomes far easier for HIV to pass into his or her tissues. An STD causes inflammation. T–cells and monocytes/macrophages, get concentrated in the genital area. In a person already infected with HIV, some of these key cells of the immune system will be carrying the virus – which magnifies the risk of transmission to the uninfected partner.

As for HIV–infected people, they are more infectious to others in the very early stages, before antibody production i.e. during the "window period", and when the infection is well advanced, because levels of virus in the blood at that time is higher than at other times.

(b) Blood contact

AIDS is also transmitted by contaminated blood – transfusion of whole blood cells, platelets and factors VIII and IX derived from human plasma. There is no evidence that transmission ever occurred through blood products such as albumin, immunoglobulins or hepatitis vaccines that meet WHO requirements *(13)*. Contaminated blood is highly infective when introduced in large quantities directly into the blood stream. The risk of contracting HIV infection from transfusion of a unit of infected blood is estimated to be over 95 per cent. Since the likelihood of HIV transmission through blood depends on the "dose" of virus injected, the risk of getting infected through a contaminated needle, syringe or any other skin–piercing instrument is very much lower than with transfusion. Nevertheless, among drug users who inject heroin, cocaine or other drugs, this route of transmission is significant because exposure is repeated so often, in some cases, several times a day. As a result, needle–sharing by drug users is a major cause of AIDS in many countries, both developed and developing, and in some it is the predominant cause. Any skin piercing (including injections, ear-piercing, tattooing, accupuncture or scarification) can transmit the virus, if the instruments used have not been sterilized and have previously been used on an infected person. It may be mentioned that transfusion of blood and blood products has played a minor role in the spread of AIDS in the developed countries.

(c) Maternal–foetal transmission : mother-to child transmission

HIV may pass from an infected mother to her foetus, through the placenta or to her infant during delivery or by breast-feeding. In the absence of any intervention, rates of this form of transmission can vary from 20–25 per cent. Transmission during the peripartum period accounts for one-third to two-thirds of overall numbers infected, depending on whether breast-feeding transmission occurs or not, and this period has, therefore, become a focus of prevention efforts. The risk of infection is higher if the mother is newly infected, or if she has already developed AIDS. HIV infected infants and children progress rapidly to AIDS.

Transmission of HIV from mother to child can be prevented almost entirely by anti-retroviral drug prophylaxis, elective caesarian section before onset of labour and rupture of membranes, and by refraining from breast-feeding. However, in economically poor countries, elective caesarian section is not a safe option. A substantial

efficacy of triple combination of drugs has been shown in industrialized countries, where the rate of transmission is now below 2 per cent in the absence of breast-feeding *(9)*.

There is no evidence that HIV is transmitted through mosquitoes or any other insect, casual social contact with infected persons including within households, or by food or water. There is no evidence of spread to health care workers in their professional contact with people with AIDS *(18)*.

Incubation period

While the natural history of HIV infection is not yet fully known, current data suggest that the incubation period is uncertain, (from a few months to 10 years or even more) from HIV infection to the development of AIDS. The virus can lie silent in the body for many years. The percentage of people infected with HIV, who will develop clinical disease remains uncertain – possibly 10–30 per cent will develop AIDS, and another 25–30 per cent will develop AIDS–related complex. However, it is estimated that 75 per cent of those infected with HIV will develop AIDS by the end of ten years *(19)*.

Clinical manifestations

The clinical features of HIV infection have been classified into four broad categories *(14)* :

I. Initial infection with the virus and development of antibodies
II. Asymptomatic carrier state
III. AIDS–related complex (ARC)
IV. AIDS.

(I) INITIAL INFECTION

Except for a generally mild illness (fever, sore throat and rash) which about 70 per cent of people experience a few weeks after initial infection with the virus, most HIV – infected people have no symptoms for the first five years or so. They look healthy and feel well although right from the start they can transmit the virus to others. Once infected, people are infected for life. Scientists have not found as yet, a way of curing them, or making them uninfectious to others.

HIV antibodies usually take between 2 to 12 weeks to appear in the blood-stream, though they have been known to take longer. The period before antibodies are produced is the "window period" during which, although the person is particularly infectious because of the high concentration of virus in the blood, he will test negative on the standard antibody blood test. Though the body's immune system reacts to the invasion of HIV by producing antibodies, these do not inactivate the virus in the usual way.

(II) ASYMPTOMATIC CARRIER STATE

Infected people have antibodies, but no overt signs of disease, except persistent generalized lymphadenopathy. It is not clear how long the asymptomatic carrier state lasts.

(III) AIDS-RELATED COMPLEX

A person with ARC has illnesses caused by damage to the immune system, but without the opportunistic infections (Fig. 3) and cancers associated with AIDS, they may exhibit one or more of the following clinical signs; unexplained diarrhoea lasting longer than a month, fatigue, malaise, loss of more than 10 per cent body weight, fever, night sweats, or other milder opportunistic infections such as oral thrush,

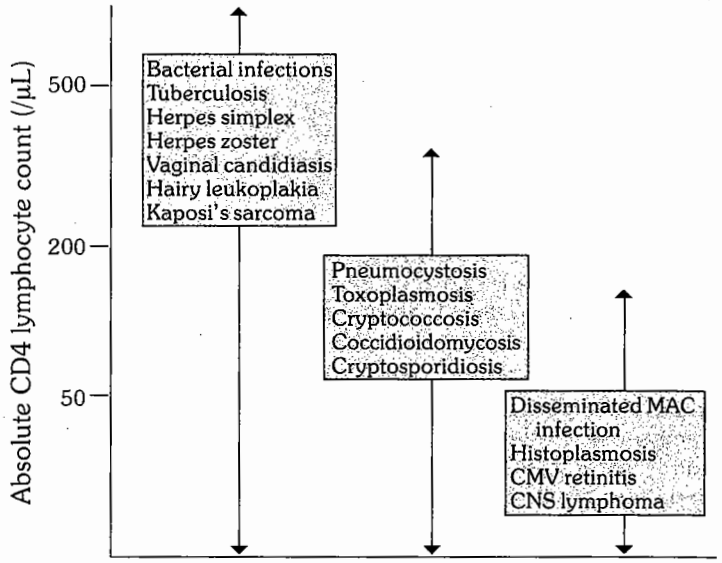

FIG. 3

Relationship of CD4 count to development of opportunistic infection

Source : *(20)*

generalized lymphadenopathy or enlarged spleen. Patients from high-risk groups who have two or more of these manifestations (typically including generalised lymphadenopathy), and who have a decreased number of T–helper lymphocytes are considered to have AIDS-related complex *(1)*. Some patients with AIDS-related complex, subsequently develop AIDS.

(IV) AIDS

AIDS is the end–stage of HIV infection. A number of opportunist infections commonly occur at this stage (Fig. 3), and/or cancers that occur in people with otherwise unexplained defects in immunity. Death is due to uncontrolled or untreatable infection. Tuberculosis and Kaposi sarcoma are usually seen relatively early. Serious fungal infections such as *Candida oesophagitis*, *Cryptococcus meningitis* and *penicillosis*, and parasitic infections such as *Pneumocystis carinni* pneumonia or *Toxoplasma gondii* encephalitis tend to occur, when T–helper cell count has dropped to around 100. People whose counts are below 50 have the late opportunistic infections such as *cytomegaloviral retinitis*.

Many people with AIDS are affected by a wasting syndrome that is known, especially in Africa, as "slim disease". It involves chronic diarrhoea and severe weight loss. Another condition, seen worldwide, is AIDS encephalopathy or AIDS dementia, which is caused by HIV crossing "blood–brain barrier". In its late stages, AIDS encephalopathy resembles senile dementia or Alzheimer's disease. AIDS dementia appears to result not from opportunistic infection, but from the action of the virus itself.

TUBERCULOSIS. An alarming factor in the AIDS epidemic is the increasing link between HIV infection and tuberculosis. In countries where tuberculosis is endemic, many people are infected in childhood. When the immune system breaks down, as in HIV infection, tuberculosis becomes active and the person becomes contagious to others. Studies in Rwanda, the USA, Zaire and Zambia found that HIV–positive individuals were 30–50 times more likely to develop active tuberculosis than HIV–negative people. As a consequence, AIDS is reviving an old problem

in developed countries e.g. in the USA, where there was sudden increase in tuberculosis cases. The situation in developing countries is still worst.

The emergence of drug resistance makes it essential that antibiotic sensitivity be performed on all positive cultures. Drug therapy should be individualized. Patients with multi drug resistance should receive atleast three drugs to which their organism is sensitive *(20)*.

PERSISTENT GENERALIZED LYMPHADENOPATHY. Lymph nodes are larger than one centimetre in diameter, in two or more sites other than the groin area for a period of at least three months.

KAPOSI SARCOMA. A tumour featuring reddish brown or purplish plaques or nodules on the skin and mucous membranes. Endemic in Africa prior to HIV, it used to affect mainly older men. With HIV infection it affects a wider age range and both sexes, and is characterized by lesions in the mouth or gut; or lesions are generalized (in two or more places) or rapidly progressive or invasive.

OROPHARYNGEAL CANDIDIASIS. Caused by a common yeast fungus, oral thrush presents with soreness and redness, with white plaques on the tongue, and in the mouth and throat; and sometimes a white fibrous layer covering the tonsils and back of the mouth. Infection of the oesophagus presents with pain behind the breastbone.

CYTOMEGALOVIRUS RETINITIS. Inflammation of the eye retina which may lead to blindness.

PNEUMOCYSTOSIS CARINII PNEUMONIA. Symptoms can include a dry, non-productive cough; inability to take a full breath and occasional pain on breathing; and weight loss and fever.

TOXOPLASMA ENCEPHALITIS. Protozoal infection in the central nervous system, presenting with focal neurological signs such as mild hemiplegia or stroke, resulting from damage to part of the brain, seizures or altered mental status.

HAIRY LEUKOPLAKIA. White patches on the sides of the tongue, in vertical folds resembling corrugations.

CRYPTOCOCCAL MENINGITIS. A fungal infection in the central nervous system which usually presents with fever, headache, vomiting and neck stiffness.

HERPES-ZOSTER OR SHINGLES. Viral inflammation of the central nervous system, presenting with localised pain and burning sensations, followed by vesicle eruption (skin blistering) and ulceration.

SEVERE PRURIGO OR PRURITIC DERMATITIS. Chronic skin inflammation in the form of a very itchy rash of small flat spots developing into blisters.

SEVERE OR RECURRENT SKIN INFECTIONS. Warts; dermatophytosis or ringworm; and folliculitis (inflammation of hair follicles).

DIAGNOSIS OF AIDS

CLINICAL

I. WHO case definition for AIDS surveillance

For the purposes of AIDS surveillance an adult or adolescent (>12 years of age) is considered to have AIDS if at least 2 of the following major signs are present in combination with at least 1 of the minor signs listed below, and if these signs are not known to be due to a condition unrelated to HIV infection *(21)*.

Major signs

- weight loss ≥ 10% of body weight
- chronic diarrhoea for more than 1 month
- prolonged fever for more than 1 month (intermittent or constant).

Minor signs

- persistent cough for more than 1 month[a, b]
- generalized pruritic dermatitis
- history of herpes zoster[b]
- oropharyngeal candidiasis
- chronic progressive or disseminated herpes simplex infection
- generalized lymphadenopathy.

The presence of either generalized Kaposi sarcoma or cryptococcal meningitis is sufficient for the diagnosis of AIDS for surveillance purposes.

a. For patients with tuberculosis, persistent cough for more than 1 month should not be considered as a minor sign
b. Indicates changes from the 1985 provisional WHO clinical case definition for AIDS ("Bangui definition")

The clinical definition is relatively *specific* (if used correctly), meaning that the vast majority of people diagnosed as having AIDS will have been correctly assessed. However, studies show that the definition is relatively *insensitive*, meaning that only half the patients who have severe illness related to HIV infection are included. This is because not all HIV–related opportunistic diseases are in the AIDS definition. Tuberculosis is widely recognized as the commonest opportunistic disease associated with HIV in Africa. But because TB causes wasting, cough and fever in most patients, the AIDS clinical case definition cannot reliably distinguish between HIV–positive and HIV–negative TB patients.

The clinical case definition was developed to enable reporting of the number of people with AIDS for the purposes of public health surveillance, rather than for patient care. However, for the purpose of individual case management, it is useful to be able to diagnose whether illnesses may be related to HIV infection (symptomatic HIV infection) because :

- clinical manifestations can be a reliable indicator of underlying HIV infection;
- over-use of HIV testing is avoided, testing is used to confirm suspected HIV infection, rather than as a diagnostic tool in the first instance;
- a patient with suspected HIV infection can be counselled about having an HIV test, the implications for them and their sexual partners, self-care and nutrition;
- many HIV–related illnesses can be treated, improving the patient's quality of life;
- certain drugs (such as thiacetazone) cause severe side effects in people with HIV infection, and should not be prescribed for them.

Children *(22)*

The case definition for AIDS is fulfilled if at least 2 major signs and 2 minor signs are present (if there is no other known cause of immunosuppression).

Major signs

- weight loss or abnormally slow growth
- chronic diarrhoea for more than 1 month
- prolonged fever for more than 1 month.

Minor signs

- generalized lymph node enlargement
- oropharyngeal candidiasis
- recurrent common infections, e.g. ear infection, pharyngitis
- persistent cough
- generalized rash

Confirmed HIV infection in the mother counts as a minor criterion.

The definition for children is not very specific, particularly in poor regions where childhood malnutrition and TB are common. Further, many children present with acute HIV-related illness such as *pneumocystis carinii pneumonia* without any clinical evidence of AIDS.

II. Expanded WHO case definition for AIDS surveillance

For the purposes of AIDS surveillance an adult or adolescent (>12 years of age) is considered to have AIDS if a test for HIV antibody gives a positive result, and one or more of the following conditions are present :

- ≥ 10% body weight loss or cachexia, with diarrhoea or fever, or both, intermittent or constant, for at least 1 month, not known to be due to a condition unrelated to HIV infection
- cryptococcal meningitis
- pulmonary or extra–pulmonary tuberculosis
- Kaposi sarcoma
- neurological impairment that is sufficient to prevent independent daily activities, not known to be due to a condition unrelated to HIV infection (for example, trauma or cerebrovascular accident)
- candidiasis of the oesophagus (which may be presumptively diagnosed based on the presence of oral candidiasis accompanied by dysphagia)
- clinically diagnosed life–threatening or recurrent episodes of pneumonia, with or without aetiological confirmation
- invasive cervical cancer.

Major features of this expanded surveillance case definition are that it requires an *HIV serological test,* and includes a broader spectrum of clinical manifestations of HIV such as tuberculosis, neurological impairment, pneumonia, and invasive cervical cancer. The expanded definition is simple to use and has a higher specificity *(21)*.

CLINICAL STAGING

WHO clinical staging system for HIV infection and HIV-related disease *(22)*

WHO has developed a clinical staging system (originally for prognosis), based on clinical criteria. The definition of symptoms, signs and diseases is according to clinical judgement. Clinical condition or performance score, whichever is the higher, determines whether a patient is at clinical stage 1, 2, 3, or 4 as shown in Table 2. Clinical stage is important as a criterion for starting antiretroviral (ARV) therapy.

TABLE 2
WHO clinical staging of HIV disease in adults and adolescents

Clinical stage 1
- Asymptomatic
- Persistent generalized lymphadenopathy

Clinical stage 2
- Moderate unexplained weight loss (under 10% of presumed or measured body weight)
- Recurrent respiratory tract infections (sinusitis, tonsillitis, otitis media, pharyngitis)
- Herpes zoster
- Angular cheilitis
- Recurrent oral ulcerations
- Papular pruritic eruptions
- Seborrhoeic dermatitis
- Fungal nail infections

Clinical stage 3
- Unexplained severe weight loss (over 10% of presumed or measured body weight)
- Unexplained chronic diarrhoea for longer than 1 month
- Unexplained persistent fever (intermittent or constant for longer than 1 month)
- Persistent oral candidiasis
- Oral hairy leukoplakia
- Pulmonary tuberculosis
- Severe bacterial infections (e.g. pneumonia, empyema, meningitis, pyomyositis, bone or joint infection, bacteraemia, severe pelvic inflammatory disease)
- Acute necrotizing ulcerative stomatitis, gingivitis or periodontitis
- Unexplained anaemia (below 8 g/dl), neutropenia (below 0.5 x 10^9/l) and/or chronic thrombocytopenia (below 50 x 10^9/l)

Clinical stage 4
- HIV wasting syndrome[a]
- Pneumocystis jiroveci pneumonia
- Recurrent severe bacterial pneumonia
- Chronic herpes simplex infection (orolabial, genital or anorectal of more than 1 month's duration or visceral at any site
- Oesophageal candidiasis (or candidiasis of trachea, bronchi or lungs)
- Extrapulmonary tuberculosis
- Kaposi sarcoma
- Cytomegalovirus disease (retinitis or infection of other organs, excluding liver, spleen and lymph nodes)
- Central nervous system toxoplasmosis
- HIV encephalopathy[b]
- Extrapulmonary cryptococcosis including meningitis
- Disseminated non-tuberculous mycobacteria infection
- Progressive multifocal leukoencephalopathy
- Chronic cryptosporidiosis
- Chronic isosporiasis
- Disseminated mycosis (histoplasmosis, coccidiomycosis)
- Recurrent septicaemia (including nontyphoidal Salmonella)
- Lymphoma (cerebral or B cell non-Hodgkin)
- Invasive cervical carcinoma
- Atypical disseminated leishmaniasis
- Symptomatic HIV-associated nephropathy or HIV-associated cardiomyopathy

[a] HIV wasting syndrome : weight loss > 10% of body weight, plus either unexplained diarrhoea for more than one month or chronic weakness, and unexplained fever for more than one month.

[b] HIV encephalopathy : clinical findings of disabling mental or motor dysfunction, interfering with activities of daily living, progressing over weeks and months, in the absence of a concurrent illness or condition other than HIV infection which could explain the findings.

Source : *(23)*

Children

WHO clinical staging system for HIV infection and related disease in children

Stage 1 : – Asymptomatic
– Persistent generalized lymphadenopathy

Stage 2 : – Unexplained chronic diarrhoea
– Severe persistent or recurrent candidiasis outside the neonatal period
– Weight loss or failure to thrive
– Persistent fever
– Recurrent severe bacterial infections

Stage 3 : – AIDS-defining opportunistic infections
– Severe failure to thrive
– Progressive encephalopathy
– Malignancy
– Recurrent septicaemia or meningitis.

Source : *(22)*

LABORATORY DIAGNOSIS

SCREENING TESTS : As antibodies to HIV are far easier to detect than the virus itself, their presence or absence in blood–stream is the basis for the most widely used test of HIV infection. A person whose blood contains HIV antibodies is said to be HIV–positive, or seropositive, meaning that he or she is infected with HIV. There is now a wide range of screening tests based on detection of HIV–antibodies. To be reliable, a screening test must be ***sensitive*** enough to identify all "true positives", while being ***specific*** enough to record few "false positives". The ideal test needs both the attributes.

At present, to ensure accuracy, two different tests are commonly applied. At first a sensitive test is used to detect the HIV–antibodies, while a second **confirmatory test** is used to weed out any false positive results. The first kind of test is normally the **ELISA**. The confirmatory test, usually a **Western Blot** is a highly specific test; it is based on detecting specific antibody to viral core protein (p24) and envelop glycoprotein (gp 41). This is a more difficult test to perform and requires trained and experienced laboratory workers to interpret the test.

VIRUS ISOLATION : A test for the virus itself would eliminate the painful uncertainty of AIDS infection. HIV can be recovered from cultured lymphocytes *(23)*. This type of testing is very expensive and requires extensive laboratory support.

The current trend in HIV–antibody tests is towards simple, cheap, reliable kits whose results can be read on the spot without much waiting and without the need for laboratory backup.

Non-specific laboratory findings with HIV infection may include anaemia, leukopenia (particularly lymphocytopenia) and thrombocytopenia in any combination, polyclonal hypergammaglobulinaemia. Cutaneous energy is frequent early in the course, and becomes universal as the disease progresses *(24)*.

Several laboratory markers are available to provide prognostic information and guide therapy decisions. The most widely used marker is the absolute CD4 lymphocyte count. As the count decreases, the risk of opportunistic infection increases. People with healthy immune system usually have more than 950 CD4 cells/μL of blood. The number falls over the course of HIV infection. People with AIDS usually have CD4 cell count below 200 (USA makes CD cell count below 200 in an HIV–infected person a definition of AIDS). The trend of the count is much more important than any single reading. The frequency of performance of counts depends on the patient's health system. Patients whose count is substantially above the threshold for antiviral therapy (500 cells/μL) should have count performed every 3 months. This is necessary for evaluating the efficacy of antiviral therapy and for initiating *P. carinii* prophylactic therapy, when the count falls below 200 cells/μL. Some studies suggest that the percentage of CD4 lymphocytes is more reliable indicator of prognosis than the absolute count because the percentage does not depend on calculating a manual differential. Risk of progression to AIDS is high with percentage of CD4 lymphocyte less than 20 *(24)*.

The laboratory tests and their significance are as summarized in Table 3.

TABLE 3

Laboratory findings with HIV infection

Test	Significance
HIV enzyme-linked immunosorbent assay (ELISA)	Screening test for HIV infection. Sensitivity > 99.9%; to avoid false-positive results, repeatedly reactive results must be confirmed with Western blot.
Western blot	Confirmatory test for HIV. Specificity when combined with ELISA>99.99%. Indeterminate results with early HIV infection, HIV-2 infection, autoimmune disease, pregnancy and recent tetanus toxoid administration.
CBC	Anaemia, neutropenia, and thrombocytopenia common with advanced HIV infection.
Absolute CD4 lymphocyte count	Most widely used predictor of HIV progression. Risk of progression to an AIDS opportunistic infection or malignancy is high with CD4 < 200 cells/μL.
CD4 lymphocyte percentage	Percentage may be more reliable than the CD4 count. Risk of progression to an AIDS opportunistic infection or malignancy is high with percentage < 14%.
HIV viral load tests	These tests measure the amount of actively replicating HIV virus. Correlates with disease progression and response to antiretroviral drugs.
B_2 - Microglobulin	Cell surface protein indicative of macrophage – monocyte stimulation. Levels >3.5 mg/dL associated with rapid progression of disease. Not useful with intravenous drug users.
p24 antigen	Indicates active HIV replication. Tends to be positive prior to seroconversion and with advanced disease.

Source : *(20)*

The WHO has pointed out the danger of compulsory testing programmes in their tendency to social rejection of HIV–carrier and the resulting social and psychological consequences. Diagnostic testing may be useful in gauging the magnitude and course of the epidemic.

Control of AIDS

There are four basic approaches to the control of AIDS :

1. Prevention

(a) EDUCATION

Until a vaccine or cure for AIDS is found, the only means at present available is health education to enable people to make life-saving choices (e.g., avoiding indiscriminate sex, using condoms). There is, however, no guarantee that the use of condoms will give full protection. One should also avoid the use of shared razors and toothbrushes. Intravenous drug users should be informed that the sharing of needles and syringes involves special risk. Women suffering from AIDS or who are at high risk of infection should avoid becoming pregnant, since infection can be transmitted to the unborn or newborn. Educational material and guidelines for prevention should be made widely available. All mass media channels should be involved in educating the people on AIDS, its nature, transmission and prevention; this includes international travellers.

(b) PREVENTION OF BLOOD-BORNE HIV TRANSMISSION

People in high-risk groups should be urged to refrain from donating blood, body organs, sperm or other tissues. All blood should be screened for HIV 1 & HIV 2 before transfusion. Transmission of infection to haemophiliacs can be reduced by introducing heat treatment of factors VIII and IX. Strict sterilization practices should be ensured in hospitals and clinics. Pre-sterilized disposable syringes and needles should be used as far as possible. One should avoid injections unless they are absolutely necessary.

2. Antiretroviral treatment

At present there is no vaccine or cure for treatment of HIV infection/AIDS. However, the development of drugs that suppress the HIV infection itself rather than its complications has been important development. These antiviral chemotherapy have proved to be useful in prolonging the life of severely ill patients.

The availability of agents in combination suppress HIV replication. It has a profound impact on the natural history of HIV infection. Patients who achieve excellent suppression of HIV generally have stabilization or improvement of their clinical course which results from partial immunologic reconstitution and a subsequent decrease in complications of immunosuppression. Concept about the timing of such therapy have changed considerably.

Classification of drugs used for ART *(24)*

The drugs used for ART are classified as :

Nucleoside reverse transcriptase inhibitors (NRTIs)
Abacavir (ABC)
Didanosine (ddI)
Emtricitabine (FTC)
Lamivudine (3TC)
Stavudine (d4T)
Zidovudine (AZT)
Nucleotide reverse transcriptase inhibitors (NtRTIs)
Tenofovir (TDF)
Non-nucleoside reverese transcriptase inhibitors (NNRTIs)
Efavirenz (EFV)
Etravirine (ETV)
Nevirapine (NVP)
Protease inhibitors (PIs)
Atazanavir + ritonavir (ATV/r)
Darunavir + ritonavir (DRV)r)
Fos-amprenavir + ritonavir (FPV/r)
Indinavir + ritonavir (IDV/r)
Lopinavir/ritonavir (LPV/r)
Saquinavir + ritonavir (SQV/r)
Integrase strand transfer inhibitors (INSTIs)
Raltegravir (RAL)

WHO recommended ARV treatment schedule (2013) *(25)*

WHO has been providing guidance on the use of ARV drugs since 2002, producing a range of guidelines on various aspects of HIV diagnosis, treatment and care. The 2013 guidelines aim to combine and harmonize new and existing recommendations, including updated recommendations from the 2010 guidelines on ART for adults, adolescents and children, and ARV treatment and prophylaxis for pregnant and breast-feeding women living with HIV. They also include existing WHO guidance on HIV testing and counselling. HIV prevention, general care for people living with HIV, managing common coinfections and other comorbidities and monitoring and managing drug toxicities.

The 2013 guidelines are based on a public health approach to further expanding the use of ARV drugs for HIV treatment and prevention, with a particular focus on resource-limited settings. The new clinical recommendations in the guidelines include :

1. treating adults, adolescents and older children earlier, starting ART in all individuals with a CD4 cell count of 500 cells/mm^3 or less and giving priority to individuals with severe or advanced HIV disease and those with a CD4 cell count of 350 cells/mm^3 or less;
2. starting ART at any CD4 count for certain populations with HIV, including people with active TB disease, people with hepatitis B virus (HBV) coinfection with severe chronic liver disease, HIV-positive partners in serodiscordant couples, pregnant and breast-feeding women and children younger than five years of age;
3. a new, preferred first-line ART regimen harmonized for adults, pregnant and breast-feeding women and children aged three years and older;
4. support to actively accelerate the phasing out of stavudine (d4T) in first-line ART regimens for adults and adolescents;
5. the use of viral load testing as the preferred approach to

monitoring the success of ART and diagnosing treatment failure in addition to clinical and CD4 monitoring of people receiving ART; and

6. community-based HIV testing and counselling, and HIV testing of adolescents to diagnose people with HIV earlier and link them to care and treatment.

The recommendations are summarized in Table 4, 5, 6, and 7.

TABLE 4

Preferred first line ART in treatment (2013)

Target population	Recommendations
First-line ART regimens for adults	• First-line ART should consist of two nucleoside reverse-transcriptase inhibitors (NRTIs) plus a non-nucleoside reverse-transcriptase inhibitor (NNRTI). • TDF + 3TC (or FTC) + EFV as a fixed-dose combination is recommended as the preferred option to initiate ART. • IF TDF + 3TC (or FTC) + EFV is contraindicated or not available, one of the following options is recommended : • AZT + 3TC + EFV • AZT + 3TC + NVP • TDF + 3TC (or FTC) + NVP • Countries should discontinue d4T use in first-line regimens because of its well-recognized metabolic toxicities.
First-line ART for pregnant and breastfeeding women and their infants	• A once-daily fixed-dose combination of TDF + 3TC (or FTC) + EFV is recommended as first-line ART in pregnant and breastfeeding women, including pregnant women in the first trimester of pregnancy and women of childbearing age. The recommendation applies both to lifelong treatment and to ART initiated for PMTCT and then stopped. • Infants of mothers who are receiving ART and are breastfeeding should receive six weeks of infant prophylaxis with daily NVP. If infants are receiving replacement feeding, they should be given four to six weeks of infant prophylaxis with daily NVP (or twice-daily AZT). Infant prophylaxis should begin at birth or when HIV exposure is recognized postpartum.
Fisrt-line ART for children younger than 3 years of age	• A LPV/r-based regimen should be used as first-line ART for all children infected with HIV younger than three years (36 months) of age, regardless of NNRTI exposure, if LPV/r is not feasible, treatment should be initiated with an NVP-based regimen. • Where viral load monitoring is available, consideration can be given to substituting LPV/r with an NNRTI after virological suppression is sustained. • For infants and children younger than three years infected with HIV, ABC + 3TC + AZT is recommended as an option for children who develop TB while on an ART regimen containing NVP or LPV/r. Once TB therapy has been completed, this regimen should be stopped and the initial regimen should be restarted. • For infants and children younger than three years infected with HIV, the NRTI backbone for an ART regimen should be ABC + 3TC or AZT + 3TC.
First-line ART for children 3 years of age and older (including adolescents)	• For children infected with HIV three years of age and older (including adolescents), EFV is the preferred NNRTI for first-line treatment and NVP is the alternative. • For children infected with HIV three years to less than 10 years old (and adolescents weighing less than 35 kg), the NRTI backbone for an ART regimen should be one of the following, in preferential order : • ABC + 3TC • AZT or TDF + 3TC (or FTC) • For adolescents infected with HIV (10 to 19 years old) weighing 35 kg or more, the NRTI backbone for an ART regimen should align with that of adults and be one of the following, in preferential order: • TDF + 3TC (or FTC) • AZT + 3TC • ABC + 3TC

Source : *(25)*

TABLE 5

Monitoring ART response and diagnosis of treatment failure

Population	Recommendations
All populations	• Viral load is recommended as the preferred monitoring approach to diagnose and confirm ARV treatment failure. • If viral load is not routinely available, CD4 count and clinical monitoring should be used to diagnose treatment failure.

Source : *(25)*

TABLE 6

Second-line ART

Population	Recommendations
What ARV regimen to switch to in adults and adolescents (includes pregnant and breastfeeding women)	• Second-line ART for adults should consist of two nucleoside reverse-transcriptase inhibitors (NRTIs) + a ritonavir-boosted protease inhibitor (PI). • The following sequence of second-line NRTI options is recommended : • After failure on a TDF + 3TC (or FTC)-based first-line regimen, use AZT + 3TC as the NRTI backbone in second-line regimens. • After failure on an AZT or d4T + 3TC-based first-line regimen, use TDF+3TC (or FTC) as the NRTI backbone in second-line regimens. • Use of NRTI backbones as a fixed-dose combination is recommended as the preferred approach. • Heat-stable fixed-dose combinations ATV/r and LPV/r are the preferred boosted PI options for second-line ART.
What ART regimen to switch to in children (including adolescents)	• After failure of a first-line NNRTI-based regimen, a boosted PI plus two NRTIs are recommended for second-line ART; LPV/r is the preferred boosted PI. • After failure of a first-line LPV/r-based regimen, children younger than 3 years should remain on their first-line regimen, and measures to improve adherence should be undertaken. • After failure of a first-line LPV/r-based regimen, children 3 years or older should switch to a second-line regimen containing an NNRTI plus two NRTIs; EFV is the preferred NNRTI. • After failure of a first-line regimen of ABC or TDF + 3TC (or FTC), the preferred NRTI backbone option for second-line ART is AZT + 3TC. • After failure of a first-line regimen containing AZT or d4T + 3TC (or FTC) the preferred NRTI backbone option for second-line ART is ABC or TDF + 3TC (or FTC).

Source : *(25)*

TABLE 7

Third-line ART

Population	Recommendations
All populations	• National programmes should develop policies for third-line ART. • Third-line regimens should include new drugs with minimal risk of cross-resistance to previously used regimens, such as integrase inhibitors and second-generation NNRTIs and PIs. • Patients on a failing second-line regimen with no new ARV options should continue with a tolerated regimen.
Special considerations for children	Strategies that balance the benefits and risks for children need to be explored when second-line treatment fails. For older children and adolescents who have more therapeutic options available to them, constructing third-line ARV regimens with novel drugs used in treating adults such as ETV, DRV and RAL may be possible. Children on a second-line regimen that is failing with no new ARV drug options should continue with a tolerated regimen. If ART is stopped, opportunistic infections still need to be prevented, symptoms relieved and pain managed.

Post-exposure prophylaxis (PEP) *(26)*

PEP for HIV consists of a comprehensive set of services to prevent infection developing in an exposed person, including : first aid care; counselling and risk assessment; HIV testing and counselling; and, depending on the risk assessment, the short term (28 day) provision of antiretroviral drugs, with support and follow-up.

Eligibility for post-exposure prophylaxis

1. Post-exposure prophylaxis should be offered, and initiated as early as possible, to all individuals with exposure that has the potential for HIV transmission, and ideally within 72 hours.
2. Assessment for eligibility should be based on the HIV status of the source whenever possible and may include consideration of background prevalence and local epidemiological patterns.
3. Exposures that may warrant post-exposure prophylaxis include :
   a. parenteral or mucous membrane exposure (sexual exposure and splashes to the eye, nose or oral cavity); and
   b. the following bodily fluids may pose a risk of HIV infection; blood, blood-stained saliva, breast-milk, genital secretions and cerebrospinal, amniotic, rectal, peritoneal, synovial, pericardial or pleural fluids.
4. Exposures that does not require post-exposure prophylaxis include :
   a. when the exposed individual is already HIV positive;
   b. when the source is established to be HIV negative; and
   c. exposure to bodily fluids that does not pose a significant risk: tears, non-blood-stained saliva, urine and sweat.

Assessment of the HIV status of the exposed individual should not be a barrier to initiating post-exposure prophylaxis. In emergency situations where HIV testing and

counselling is not readily available but the potential HIV risk is high or if the exposed person refuses initial testing, post-exposure prophylaxis should be initiated and HIV testing and counselling undertaken as soon as possible.

Tablt 8 summarizes the new WHO (2014) recommendations for post-exposure prophylaxis.

TABLE 8

Post-exposure prophylaxis for HIV (WHO 2014)

Number of antiretroviral drugs
An HIV post-exposure prophylaxis regimen with two antiretroviral drugs is effective, but three drugs are preferred.
Preferred antiretroviral regimen for adults and adolescents
TDF + 3TC (or FTC) is recommended as the preferred backbone regimen for HIV post-exposure prophylaxis among adults and adolescents.
LPV/r or ATV/r is recommended as the preferred third drug for HIV post-exposure prophylaxis among adults and adolescents.
Where available, RAL, DRV/r or EFV can be considered as alternative options.
Preferred antiretroviral regimen for children ≤ 10 years old
AZT + 3TC is recommended as the preferred backbone regimen for HIV post-exposure prophylaxis among children 10 years and younger.
ABC + 3TC or TDF + 3TC (or FTC) can be considered as alternative regimens.
LPV/r is recommended as the preferred third drug for HIV post-exposure prophylaxis among children younger than 10 years.
An age-appropriate alternative regimen can be identified among ATV/r, RAL, DRV, EFV and NVP.
Prescribing frequency
A 28-day prescription of antiretroviral drugs should be provided for HIV post-exposure prophylaxis following initial risk assessment.
Adherence support
Enhanced adherence counselling is suggested for all individuals initiating HIV post-exposure prophylaxis.

All individuals potentially exposed to HIV should be encouraged to undergo HIV testing 3 months following exposure. Further testing after this time should be in accordance with WHO guidelines. Individuals diagnosed with HIV following PEP should be linked to treatment and care services as soon as possible. Risk reduction counselling should form part of each consultation with the individual. Use of condoms and safe injecting practices to prevent secondary transmission should be discussed. Blood donation should be avoided while the individual is taking PEP following a possible HIV exposure and while still in the window period for HIV acquisition and testing *(26)*.

Use of co-trimoxazole prophylaxis for HIV-related infections *(26)*

Co-trimoxazole is a fixed dose combination of two antimicrobial drugs (sulfamethoxazole and trimethoprim) that covers a variety of bacterial, fungal and protozoan infections. The therapy is feasible, well tolerated and inexpensive intervention for people living with HIV to reduce HIV-related morbidity and mortality. The WHO recommendations (2014) for the use of co-trimoxazole is summarized in Table 9.

TABLE 9

Use of co-trimoxazole for HIV related infections, WHO (2014)

Adults (including pregnant women)
Co-trimoxazole prophylaxis is recommended for severe or advanced HIV clinical disease (WHO stage 3 or 4) and/or for a CD4 count ≤ 350 cells/mm^3.
– In settings where malaria and/or severe bacterial infections are highly prevalent, co-trimoxazole prophylaxis should be initiated regardless of CD4 cell count or WHO stage.
Co-trimoxazole prophylaxis may be discontinued in adults (including pregnant women) with HIV infection who are clinically stable on antiretroviral therapy, with evidence of immune recovery and viral suppression.
– In settings where malaria and/or severe bacterial infections are highly prevalent, co-trimoxazole prophylaxis should be continued regardless of CD4 cell count or WHO clinical stage.
Infants, children and adolescents
Co-trimoxazole prophylaxis is recommended for infants, children, and adolescents with HIV, irrespective of clinical and immune conditions. Priority should be given to all children younger than 5 years old regardless of CD4 cell count or clinical stage and to children with severe or advanced HIV clinical disease (WHO clinical stage 3 or 4) and/or those with CD4 ≤ 350 cells/mm^3.
– In settings with a high prevalence of malaria and/or severe bacterial infections, co-trimoxazole prophylaxis should be continued until adulthood irrespective of antiretroviral therapy provision.
– In settings with low prevalence for both malaria and bacterial infections, co-trimoxazole prophylaxis may be discontinued for children 5 years of age and older who are clinically stable and/or virally suppressed on antiretroviral therapy for at least 6 months and CD4 > 350 cells/mm^3.
HIV-exposed infants
Co-trimoxazole prophylaxis is recommended for HIV-exposed infants from 4–6 weeks of age and should be continued until HIV infection has been excluded by an age-appropriate HIV test to establish final diagnosis after complete cessation of breast-feeding.
LPV/r is recommended as the preferred third drug for HIV post-exposure prophylaxis among children younger than 10 years.
An age-appropriate alternative regimen can be identified among ATV/r, RAL, DRV, EFV and NVP.
HIV and TB coinfection
Routine co-trimoxazole prophylaxis should be administered to all HIV-infected people with active TB disease regardless of CD4 cell counts.

Monitoring the efficacy of ART

Efficacy is monitored by (21)

(a) clinical improvement
  - gain in body weight,
  - decrease in occurrence and severity of HIV-related diseases (infections and malignancies),

(b) increase in total lymphocyte count,

(c) improvement in biological markers of HIV (when available)
  - CD4 + T-lymphocyte counts,
  - plasma HIV RNA levels.

3. Specific prophylaxis

Until more effective antiviral therapy becomes available, the main aim of existing therapies will be to treat the

manifestations of AIDS. Primary prophylaxis against *P. carinii* pneumonia should be offered to patients with CD4 count below 200 cells/μL. The regimens available are trimethoprim – sulfamethoxazole, aerosolized pentamidine and dapsone. Patients who develop *P. carinii* infection on a particular prophylactic regimen should be switched to the other drug or should receive a combination regimen.

M. avium complex occurs in at least one-third of AIDS patients. Rifabutin has been shown in a randomized trial to decrease the incidence of disseminated *Mavium–intracellulare* in persons with less than 200 CD4 cell/μL. Clinicians should make certain that patients do not have active *M. tuberculosis* infection before starting Rifabutin. Prophylaxis against *M. tuberculosis* is 300 mg isoniazid daily for 9 months to one year. It should be given to all HIV–infected patients with positive PPD reactions (defined for HIV–infected patients as more than 5 mm in induration). Kaposi's sarcoma might be treated in some stage with interferon, chemotherapy or radiation. Cytomegalovirus retinitis can be controlled by ganciclovir, cryptococcal meningitis with fluconazole. Esophageal candidiasis or recurrent vaginal candidiasis can be treated by fluconazole or ketoconazole. Herpes simplex infection and herpes zoster can be treated with acyclovir or foscamet.

4. Primary health care

Because of its wide–ranging health implications, AIDS touches all aspects of primary health care, including mother and child health, family planning and education. It is important, therefore, that AIDS control programmes are not developed in isolation. Integration into country's primary health care system is essential.

National AIDS Control Programme

Refer to chapter 7, page 431 for details.

The WHO launched a "Global Programme on AIDS" on Feb. 1 1987 to provide global leadership and to support the development of national AIDS programmes.

EMERGING AND RE-EMERGING INFECTIOUS DISEASES

Today the world stands on the threshold of a new era in which hundreds of millions of people will be safe from some of the most terrible diseases. Soon poliomyelitis, neonatal tetanus, leprosy, guineaworm disease, river blindness, Chagas' disease will join smallpox as diseases of the past. On the other hand, the world also stands on the brink of a global crisis in infectious diseases. No country is safe from them and no country can afford to ignore their threat any longer. The optimism of a relatively few years ago that many of these diseases could easily be brought under control has led to a tragic complacency among the international community. This complacency is now costing millions of lives. Today the infectious diseases are not only a health issue; they have become a social problem with tremendous consequences for the well-being of the individual and the world we live in.

Some infectious diseases once thought to be all but conquered, have returned with a vengeance. Others have developed stubborn resistance to antibiotic drugs. New and previously unknown diseases continue to emerge (Table 1). Together, these trends amount to a crisis for today and a challenge for the future.

The factors responsible for emergence and re-emergence of infectious diseases are : (1) unplanned and under–planned urbanization; (2) overcrowding and rapid population growth; (3) poor sanitation; (4) inadequate public health infrastructure; (5) resistance to antibiotics; (6) increased exposure of humans to disease vectors and reservoirs of infection in nature; and (7) rapid and intense international travel.

Emerging diseases

During the past 30 years, at least 30 new diseases have emerged to threaten the health of hundreds of millions of people. For many of these diseases there is no treatment, cure or vaccine and the possibility of preventing or controlling them is limited.

Emerging infectious diseases are those whose incidence in humans has increased during the last two decades or which threaten to increase in the near future. The term also

refers to newly-appearing infectious diseases, or diseases that are spreading to new geographical areas – such as cholera in South America and yellow fever in Kenya.

The diseases in question involve all the major modes of transmission – they are spread either from person to person, by insects or animals, or through contaminated water or food. The most dramatic example of a new disease is AIDS, caused by the human immunodeficiency virus (HIV). The existence of the virus was unknown until 1983. Presently, estimated 2.3 million cases occur every year worldwide. For more details, please refer to page 343.

A new breed of deadly haemorrhagic fevers, of which **Ebola virus disease** (previously known as Ebola haemorrhagic fever) is the most notorious, has struck in Africa. Ebola appeared for the first time in Zaire and Sudan in 1976. Since then it has appeared periodically. Ebola virus is a member of Filoviridae family and comprises of 5 distinct species – Zaire ebolavirus; Reston ebolavirus; Sudan ebolavirus; Tai ebolavirus; and Bundibugyo ebolavirus. The recent epidemic started in December 2013 in Guinea and spread to South Africa. By 28th Sept. 2014, a total of 7,192 cases have been reported with 3,286 deaths. Case fatality rate may be as high as 70 per cent. Ebola has incubation period of 2–21 days, and is not infective during this period. Asymptomatic cases are also not infective. The virus is transmitted through direct contact with the blood, organs, body secretions or other body fluids of infected animals like chimpanzees, gorillas, monkeys, fruit bats etc. Human to human transmission is through blood or body fluids of an infected symptomatic person or through exposure to objects (such as needles) that have been contaminated with infected secretions. It is not transmitted through air, water or food. The illness is characterized by sudden onset of fever, intense weakness, muscle pain, headache, sore throat, vomiting, diarrhoea, rash, impaired kidney and liver functions and in some cases both internal and external bleeding. Currently there is no specific treatment for this disease. However, by intensive supportive care, the mortality can be reduced and spread of the disease can be prevented by instituting specific infection control measures. There is no vaccine against ebola *(1)*.

The United States has seen the emergence of hantavirus pulmonary syndrome, characterized by respiratory failure and a case fatality rate of over 50%. Since it was first recognized in 1993, this type of hantavirus infection has been detected in more than 20 states in that country, and has also surfaced in Argentina and Brazil. This hantavirus is carried by rodents, particularly deer mice. Other hantaviruses have been recognized for many years in Asia, where they cause haemorrhagic fever with renal involvement in humans.

Epidemics of foodborne and waterborne diseases due to new organisms such as cryptosporidium or new strains of bacteria such as *Escherichia coli* have hit industrialized and developing countries alike. The O157:H7 strain of *E.coli* was first reported in 1982 and has since then been implicated in many serious outbreaks of diarrhoeal illness, sometimes leading to kidney failure. The strain has been linked to undercooked hamburger beef and unpasteurized milk. A completely new strain of cholera, 0139, appeared in south-eastern India in 1992 and has since spread north and west to other areas of India, into western China, Thailand and other parts of South-East Asia.

The threat of a new global influenza pandemic is increasing. Major shifts in the make-up of influenza viruses occur every 20 years or so, triggering large epidemics in many parts of the world, and causing many thousands of deaths. The next such shift is expected to take place very soon. Epidemic strains of influenza viruses originate from China. The influenza virus is carried by ducks, chickens and pigs raised in close proximity to one another on farms. The exchange of genetic material between these viruses produces new strains, leading to epidemics of human influenza, each epidemic being due to a different strain. Currently avian H5N1 is the strain with pandemic potential, since it might adapt into a strain that is contagious among humans. Since 1997, 478 cases with 286 deaths have been reported to WHO. The first case was from Hong Kong. Other countries involved are Cambodia, Indonesia, Thailand and Viet Nam *(4)*. In late 2002, a new disease called SARS was reported from China with rapid spread to Hong Kong, Singapore, Viet Nam, Taiwan, and Toronto. During 2003, 8,422 SARS cases were reported from 30 countries with 916 fatalities *(5)*. More recently, pandemic due to influenza A (H1N1) 2009 strain is continuing worldwide involving 214 countries, already taking 18,156 lives. New strains such as those of cholera and influenza do not follow the usual pattern of being more common in younger people. They affect all age groups, since older people have not acquired immunity to them from previous infection.

Table 1 summarizes the aetiological agents and infectious diseases in humans and/or animals recognized since 1973. The year may differ from first appearance and first identification of cases.

Re-emerging diseases

The term re-emerging diseases refers to the diseases which were previously easily controlled by chemotherapy and antibiotics, but now they have developed antimicrobial resistance and are often appearing in epidemic form.

The emergence of drug-resistant strains of microorganisms or parasites is promoted by treatments that do not result in cure. The increasing use of antimicrobials worldwide, often in subtherapeutic doses and sometimes in counterfeit form, indicates that this problem will increase in the foreseeable future. Changes in lifestyle, behaviour (including injecting and non-injecting drug use) and cultural or social values are behind the emergence of some infectious diseases such as syphilis. Increases in the number of sexual partners have been the main factor in the spread of HIV infection and other sexually transmitted diseases. Travel, including tourism, also plays a role. The spread of syphilis in the 18th and 19th centuries was related to the movement of armies. Today, the introduction of HIV in many parts of the world is due to greatly increased human mobility. Studies show that whereas only a few generations ago most people in their lifetime travelled no further than 40 kilometres from their birthplace, many today go up to 1,000 times further, travelling the whole world.

The practices of modern medicine also contribute. The spread of viral hepatitis is related in part to techniques such as kidney dialysis and multiple blood transfusions, as well as to other forms of transmission. Relaxation in immunization practices can quickly result in the resurgence of diseases, as, for example, the recent spread of diphtheria in the Russian Federation and other former republics of the USSR.

New animal diseases pose potential foodborne risks to human health that are sometimes difficult to evaluate or predict. An example that has caused much public concern in

TABLE 1

New infectious diseases recognized since 1973

Year	Agent	Type	Disease/Comments
1973	Rotavirus	Virus	Major cause of infantile diarrhoea worldwide
1975	Parvovirus B19	Virus	Aplastic crisis in chronic haemolytic anaemia
1976	*Cryptosporidium parvum*	Parasite	Acute and chronic diarrhoea
1977	*Ebola virus*	Virus	Ebola haemorrhagic fever
1977	*Legionella pneumophila*	Bacterium	Legionnaires' disease
1977	Hantaan virus	Virus	Haemorrhagic fever with renal syndrome (HRFS)
1977	*Campylobacter jejuni*	Bacterium	Enteric pathogen distributed globally
1980	Human T-lymphotropic virus 1 (HTLV-1)	Virus	T-cell lymphoma-leukaemia
1981	Toxin-producing strains of *Staphylococcus aureus*	Bacterium	Toxic shock syndrome
1982	*Escherichia coli 0157:H7*	Bacterium	Haemorrhagic colitis; haemolytic uraemic syndrome
1982	*Borrelia burgdorferi*	Bacterium	Lyme disease
1982	HTLV-2	Virus	Hairy cell leukaemia
1983	Human immunodeficiency virus (HIV)	Virus	Acquired immunodeficiency syndrome (AIDS)
1983	*Helicobacter pylori*	Bacterium	Peptic ulcer disease
1985	*Enterocytozoon bieneusi*	Parasite	Persistent diarrhoea
1986	*Cyclospara cayetanensis*	Parasite	Persistent diarrhoea
1986	BSE agent?	Non-conventional agent	Bovine spongiform encephalopathy in cattle (Mad cow disease)
1988	Human herpes virus 6 (HHV-6)	Virus	Exanthem subitum
1988	*Hepatitis E virus*	Virus	Enterically transmitted non-A, non-B hepatitis
1989	Ehrlichia chaffeensis	Bacterium	Human ehrlichiosis
1989	*Hepatitis C virus*	Virus	Parenterally transmitted non-A, non-B liver hepatitis
1991	Guanarito virus	Virus	Venezuelan haemorrhagic fever
1991	*Encephalitozoon hellem*	Parasite	Conjunctivitis, disseminated disease
1991	*New species of Babesia*	Parasite	Atypical babesiosis
1992	*Vibrio cholerae 0139*	Bacterium	New strain associated with epidemic cholera
1992	*Bartonella henselae*	Bacterium	Cat-scratch disease; bacillary angiomatosis
1993	Sin Nambre virus	Virus	Hantavirus pulmonary syndrome
1993	*Encephalitozoon cuniculi*	Parasite	Disseminated disease
1994	Sabia virus	Virus	Brazilian haemorrhagic fever
1995	Human herpes virus 8	Virus	Associated with Kaposi's sarcoma in AIDS patients
1996	nvCJD Australian bat lyssavirus	Virus	–
1997	H5N1	Virus	Avian flu (Bird flu)

Europe is bovine spongiform encephalopathy ("mad cow disease"). Fears have grown that the infectious agent responsible may be passed through the food chain to cause a variant of the incurable Creutzfeldt–Jakob disease in humans, in which the brain is attacked. The British beef market has been seriously affected and stringent public health safeguards have been introduced.

The reasons for outbreaks of new diseases, or sharp increases in those once believed to be under control, are complex and still not fully understood. The fact is however, that national health has become an international challenge. An outbreak anywhere must now be seen as a threat to virtually all countries, especially those that serve as major hubs of international travel. Despite the emergence of new diseases in the last 30 years, there is still a lack of national and international political will and resources to develop and support the systems that are necessary to detect them and stop their spread. Without doubt diseases as yet unknown, but with the potential to be the AIDS of tomorrow, lurk in the shadows.

Antimicrobial resistance

Resistance by disease–causing organisms to antimicrobial drugs and other agents is a major public health problem worldwide. It is making a growing number of infections virtually untreatable, both in hospitals and in the general community. It is having a deadly impact on the control of diseases such as tuberculosis, malaria, cholera, dysentery and pneumonia.

Antimicrobial resistance is not a new problem, but it has worsened dramatically in the last decade. During that time, the pace of development of new antimicrobials has slowed down while the prevalence of resistance has grown at an alarming rate. The increase in the number of drug–resistant

bacteria is no longer matched by a parallel expansion in the arsenal of agents used to treat infections. There is strong evidence that a major cause of the current crisis in antimicrobial resistance is the uncontrolled and inappropriate use of antibiotic drugs, in both industrialized and developing countries. They are used by too many people to treat the wrong kind of infection, in the wrong dosage and for the wrong period of time. The implications are awesome : drugs that cost tens of millions of dollars to produce, and take perhaps 10 years to reach the market, have only a limited life span in which they are effective. As resistance spreads, the life span shrinks; as fewer new drugs appear, the gulf widens between infection and control. So far, the pattern of excessive or inappropriate use and the development of resistance has been repeated after the introduction of each new antimicrobial. The over-use of expensive drugs designed to cover a range of infections is a particularly serious problem in industrialized countries. In developing countries, the problem is compounded by the ready availability of over-the-counter drugs. This allows patients to treat themselves, either with the wrong medicine, or in quantities that are too small to be effective. Sub-standard and counterfeit drugs which lack adequate amounts of active ingredients further exacerbate the resistance problem.

The examples of bacterial resistance are as follows :

Strains of *M.tuberculosis* resistant to anti-tuberculosis drugs are widespread, although attention has recently focused on the alarming outbreaks of tuberculosis caused by multidrug-resistant strains in the United States. Drug resistance is the result of poor prescribing practices, or poor patient compliance with treatment. It is low in the few countries with effective tuberculosis programmes. The most dangerous form of the multidrug-resistant disease occurs when cases become virtually incurable and doctors face situations similar to those of the pre-antibiotic era.

Malaria presents a double resistance problem : resistance of the *Plasmodium* parasites, which cause the disease, to antimalarial drugs; and resistance of the *Anopheles* mosquitoes, the vectors of the disease, to insecticides. The arsenal of antimalarial drugs is limited. Most of them act by killing parasites when they are multiplying in the blood stream of the human host. Unfortunately, due to inadequate regimens, poor drug supply, and poor quality and misuse of drugs, rapid development of drug resistance has occurred in most areas of the world. Drug resistance is particularly important in falciparum malaria, the most severe form of the disease. Resistance to chloroquine, the most commonly used drug, has been found in all endemic countries except those of Central America and the Caribbean. Resistance to multiple drugs is common in South–East Asia. This serious obstacle to malaria control efforts is further complicated by mosquito resistance to insecticides. Many mosquitoes are reported to be resistant to the three classes of insecticides available for public health use, and some are becoming resistant to pyrethroids, widely promoted for bed-net and curtain impregnation.

Enterococci contribute to some of the most common infections acquired in hospitals, causing intra-abdominal abscesses, endocarditis, and infections of the urinary tract and soft tissues. In some countries, infections resulting from strains resistant to the main groups of antibiotics, such as the beta–lactams and the aminoglycosides, can only be treated with vancomycin, an expensive intravenous drug. Even resistance to vancomycin has developed in the last 10 years or so. Staphylococci, which can contribute to skin infections, endocarditis, osteomyelitis, food poisoning and other serious disorders, have developed resistance to all antibiotics except vancomycin. If vancomycin–resistant strains were to emerge, some of the most prevalent hospital–acquired infections would become virtually untreatable.

Streptococci have become increasingly resistant to some antibiotics. They are among the most common disease–causing bacteria, responsible for infections of the throat, middle ear, skin and wounds, and also necrotizing fasciitis and gangrene. Pneumococci and *Haemophilus influenzae* are the most common bacteria causing acute respiratory infections in children, particularly pneumonia. Both of these organisms are becoming more and more resistant to drugs. Strains of pneumococci, once uniformly susceptible to penicillin, are currently resistant to it in up to 18% of cases in the United States and, 40% in South Africa. In addition, they are becoming resistant to many other commonly used antibiotics, including cotrimoxazole, the drug recommended by WHO for treatment of pneumonia. The most virulent type of *Haemophilus influenzae* is today frequently resistant to ampicillin, and strains have been identified that are resistant to other drugs, including cotrimoxazole. In brief, doctors worldwide are losing some of the most useful and affordable antibiotics against the two bacteria which are the major cause of death in children.

Neisseria gonorrhoeae, cause of one of the most common sexually transmitted diseases, has acquired such resistance to penicillin and tetracyclines in most countries that the use of these antibiotics to treat it has become unacceptable and this infection now requires the use of much more expensive drugs which are often unavailable.

Shigella dysenteriae has been causing outbreaks of severe diarrhoeal disease in central and southern Africa in recent years, including those in refugee camps, with the epidemic strain acquiring increasing resistance to standard antibiotics. Epidemic dysentery caused by this strain results in the death of up to 15% of those infected. *Salmonella typhi,* the bacterium responsible for typhoid fever, has developed resistance to antibiotics commonly used in the past for treatment. Resistant strains have caused outbreaks of the disease in India and Pakistan. Without effective antibiotic treatment, typhoid fever kills almost 10% of those infected. In South–East Asia, 50% or more of the strains of the bacteria may already be resistant to several antibiotics.

More than half of the antibiotics produced worldwide are used in animals, largely in subtherapeutic concentrations which favour the onset of drug resistance. As a result, two important human pathogens of animal origin, *E.coli* and salmonellae, are today highly resistant to antibiotics in both industrialized and developing countries. For instance, in the United Kingdom, the increase of multidrug–resistant strains of *Salmonella typhimurium* isolated from cattle is paralleled by increasing resistance among strains of human origin. In Thailand, salmonellae isolated from food animals are also highly resistant to the common antibiotics. These bacteria cause diarrhoeal disease and can lead to life-threatening complications. Due to the globalization of food supply and international travel, antimicrobial resistance among animal bacteria can affect consumers anywhere in the world.

Together, these factors have created perhaps the richest opportunities ever for the spread of infections, many of which become global problems that make the first line of

defence – early recognition and adequate and timely response – essential.

Responding to epidemics

The process of response encompasses a multitude of activities including : diagnosis of the disease; investigation to understand the source of transmission; implementation of control strategies and programmes; research to develop adequate means to treat the disease and prevent its spread; and the production and distribution of the necessary drugs and vaccines.

The strategy for controlling re-emerging diseases is through available cost-effective interventions such as early diagnosis and prompt treatment, vector control measures and the prevention of epidemics, for malaria; and DOTS–directly observed treatment, short–course – for tuberculosis; by launching research initiatives for treatment regimens and improved diagnostics, drugs and vaccines; and above all by strengthening epidemiological surveillance and drug–resistance surveillance mechanisms and procedures with appropriate laboratory support for early detection, confirmation and communication.

The category of diseases – **"new diseases – new problems"**– such as Ebola and other viral haemorrhagic fevers, is probably the most frightening. The need, therefore, is for expanding research on infectious disease agents, their evolution, the vectors of disease spread and methods of controlling them, and vaccines and drug development. Much of this already applies to HIV/AIDS, one of the most serious diseases to emerge in recent decades.

HOSPITAL-ACQUIRED INFECTION

Hospital-acquired infection is cross infection of one patient by another or by doctors, nurses and other hospital staff, while in hospital. A high frequency of nosocomial infection is evidence of a poor quality of health service delivery. Many factors contribute to the frequency of nosocomial infections: hospitalized patients are often immunocompromised, they undergo invasive examinations and treatments, and patient care practices and the hospital environment may facilitate the transmission of microorganisms among patients. The selective pressure of intense antibiotic use promotes antibiotic resistance. While progress in the prevention of nosocomial infections has been made, changes in medical practice continually present new opportunities for development of infection.

Definition of nosocomial infections

Nosocomial infections, also called "hospital-acquired infections", are infections acquired during hospital care which are not present or incubating at admission. Infections occurring more than 48 hours after admission are usually considered nosocomial. Definitions to identify nosocomial infections have been developed for specific infection sites (e.g. urinary, pulmonary).

Nosocomial infections may also be considered either endemic or epidemic. Endemic infections are most common. Epidemic infections occur during outbreaks, defined as an unusual increase above the baseline of a specific infection or infecting organism.

Changes in health care delivery have resulted in shorter hospital stays and increased outpatient care. It has been suggested that the term nosocomial infections should encompass infections occurring in patients receiving treatment in any health care setting. Infections acquired by staff or visitors to the hospital or other health care setting may also be considered nosocomial infections.

Simplified definitions may be helpful for some facilities without access to full diagnostic techniques. Table 1 provides definitions for common infections that could be used for surveys in facilities with limited access to sophisticated diagnostic techniques.

TABLE 1

Simplified criteria for surveillance of nosocomial infections

Type of nosocomial infection	Simplified criteria
Surgical site infection	Any purulent discharge, abscess, or spreading cellulitis at the surgical site during the month after the operation.
Urinary infection	Positive urine culture (1 or 2 species) with at least 10^5 bacteria/ml, with or without clinical symptoms.
Repiratory infection	Respiratory symptoms with at least two of the following signs appearing during hospitalization : – cough – purulent sputum – new infiltrate on chest radiograph consistent with infection.
Vascular catheter infection	Inflammation, lymphangitis or purulent discharge at the insertion site of the catheter.
Septicaemia	Fever or rigors and at least one positive blood culture.

According to a French National Prevalence Survey the distribtution of sites of nosocomial infection are as shown in Fig. 1.

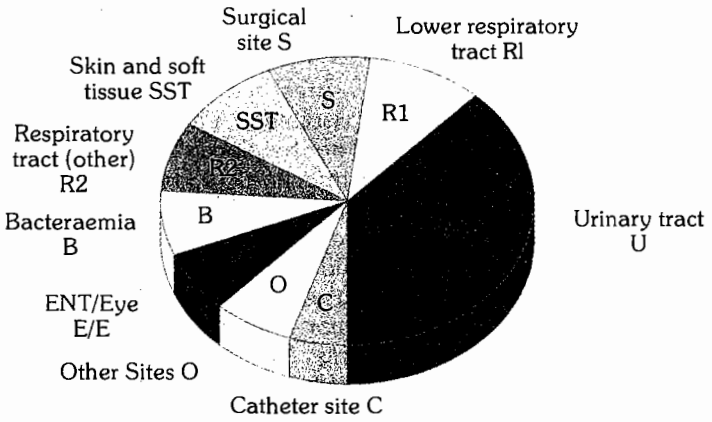

FIG. 1
Sites of the most common nosocomial infections

Source : *(1)*

Hospital–acquired infection may be considered from three angles :

1. Source
2. Routes of spread; and
3. Recipients.

1. Sources

The sources are patients, hospital staff and the environment. (a) PATIENTS : Patients suffering from infectious diseases are potential sources of infection. These cases may be certain **viral infections** (measles, german measles, influenza, viral hepatitis); **Skin infections** (discharging wounds, infected skin lesions, eczema, psoriasis, boils, bed sores); **respiratory infections** (sore throat, pulmonary tuberculosis, chest infection); and **urinary tract infection** (*B. coli* infection). All these are very common sources of hospital acquired infection. (b) STAFF: The hospital staff (viz doctors, nurses, ward boys) who come in close contact with patients may often be an important source of cross infection. For example, staphylococcus aureus is commonly carried in the nose or on the skin. *Haemolytic streptococci* may be carried in the throat and *salmonella* in the gut. (c) ENVIRONMENT : The hospital environment (viz. hospital dust, linen, bed clothes, furniture, sinks, basins, door handles and even the air) is laden with microorganisms, and is thus an important source of infection.

2. Routes of spread

The common routes of spread of cross infection are : (a) Direct contact, i.e. the organism may be transferred directly from the hands of a nurse or doctor to a susceptible patient; (b) Droplet infection, e.g. droplets released from nose and throat through coughing or sneezing; (c) Air-borne particles ; (d) Release of hospital dust into the air; (e) Through various hospital procedures, viz, catheterization, intravenous procedures, infected cat gut, dressings, sputum cups, bed pans, urinals etc.

3. Recipients

All patients in hospitals are potential recipients of cross infection. Some patients are more susceptible than others, especially those who are severely ill and those under corticosteroid therapy. Cross infection is greater in intensive care units, urological and geriatric wards and in special baby care units.

Preventive measures

The main preventive measures are : (a) Isolation : Infectious patients must be isolated. Patients who are susceptible to infection should not be placed in beds next to patients who are a source of infection. (b) Hospital staff : Those who are suffering from skin diseases, sore throat, common cold, ear infection, diarrhoea or dysentery and other infectious ailments should be kept away from work until completely cured. They should be careful about personal hygiene and in regular changes of aprons and outer clothing. (c) Hand-washing : The most common route of infection is *via* the hands. When dealing with patients, hand-washing must be thorough. When hand-washing with soap and water is not sufficient, a suitable alcohol-based disinfectant must be employed for hand-washing. In the year 2009, WHO developed guidelines for hand hygiene known as *"Clean Care is Safer Care"*. It should be followed to improve the standards of hand hygiene practices *(2)*. (d) Dust control : Hospital dust contains numerous bacteria and viruses. The dust is released during sweeping, dusting and bed making. Suppression of dust by wet dusting and vacuum cleaning are important control measures. (e) Disinfection : The articles used by the patient as well as patient's urine, faeces, sputum should be properly disinfected. Proper sterilization of instruments should be enforced. (f) Control of droplet infection : Use of face masks, proper bed spacing, prevention of overcrowding and ensuring adequate lighting and ventilation are important control measures. (g) Nursing techniques : Barrier nursing and task nursing have also been recommended to minimize cross infection. (h) Administrative measures : There should be a hospital "Control of Infection Committee" to formulate policies regarding admission of infectious cases, isolation facilities, disinfection procedures, and in fact all matters relating to control of hospital acquired infection.

The four most common nosocomial infections are urinary tract infections, surgical wound infections, pneumonia, and primary bloodstream infection. Each of these is associated with an invasive medical device or invasive procedure. Specific policies and practices to minimize these infections must be established, reviewed and updated regularly, and compliance monitored, as shown in Table 2.

Standard (routine) precautions

Standard precautions should be applied to the care of all patients. This includes limiting health care worker contact with all secretions or biological fluids; skin lesions, mucous membranes, and blood or body fluids. Health care workers must wear gloves for each contact which may lead to contamination, and also gown, mask and eye protection where contamination of clothes or the face is anticipated.

Considerations for protective clothing include :

- gown: should be of washable material, buttoned or tied at the back and protected, if necessary, by a plastic apron
- gloves: inexpensive plastic gloves are available and usually sufficient
- mask : surgical masks made of cloth or paper may be used to protect from splashes.

Standard precautions for all patients are as follows :

- Wash hands promptly after contact with infective material.
- Use no touch technique wherever possible.
- Wear gloves when in contact with blood, body fluids, secretions, excretions, mucous membranes and contaminated items.
- Wash hands immediately after removing gloves.
- All sharps should be handled with extreme care.
- Clean up spills of infective material promptly.
- Ensure that patient-care equipment, supplies and linen contaminated with infective material is either discarded, or disinfected or sterilized between each patient use.
- Ensure appropriate waste handling.
- If no washing machine is available for linen soiled with infective material, the linen can be boiled.

Health care workers are at risk of acquiring infection through occupational exposure. Hospital employees can also transmit infections to patients and other employees. Thus, a programme must be in place to prevent and manage

TABLE 2

Measures for prevention of infection

Infection	Proven effective	Proven not effective
Urinary tract infections	Limit duration of catheter Aseptic technique at insertion Maintain closed drainage	Systemic antibiotic prophylaxis Bladder irrigation or instillation of normal saline antiseptic or antibiotic Antiseptic added to drainage bag Antimicrobial-coated catheter Daily antiseptic perineal cleaning.
Surgical site infections	Surgical technique Clean operating environment Staff attire Limiting preoperative hospital stay Preoperative shower and local skin preparation of patient Optimal antibiotic prophylaxis Aseptic practice in operating room Surgical wound surveillance.	Fumigation Preoperative shaving
Pneumonia	Ventilator-associated Aseptic intubation and suctioning Limit duration Non-invasive ventilation Others Influenza vaccination for staff Isolation policy Sterile water for oxygen and aerosol therapy Prevention of *Legionella* and *Aspergillus* during renovations.	Digestive decontamination for all patients Changes of ventilator circuit every 48 or 72 hours
Vascular device infections	All catheters Closed system Limit duration Local skin preparation Aseptic technique at insertion Removal if infection suspected Central lines Surgical asepsis for insertion Limitation of frequency of dressing change Antibiotic-coated catheter for short term.	Antimicrobial creams for skin preparation

infections in hospital staff.

Employee's health should be reviewed at recruitment, including immunization history and previous exposure to communicable diseases (e.g. tuberculosis) and immune status. Some previous infections (e.g. varicella-zoster virus (VZV) may be assessed by serological tests.

Immunizations recommended for staff include: hepatitis A and B, yearly influenza, measles, mumps, rubella, tetanus, and diphtheria. Immunization against varicella may be considered in specific cases. The Mantoux skin test will document a previous tuberculosis infection and must be obtained as a base-line.

Specific postexposure policies must be developed, and compliance ensured for: human immunodeficiency virus (HIV), hepatitis A virus, hepatitis B virus, hepatitis C virus, Neisseria meningitidis, Mycobacterium tuberculosis, varicella-zoster virus, hepatitis E virus, corynebacterium *diphtheriae*, bordetella *pertussis*, and rabies.

6 Epidemiology of Chronic Non-communicable Diseases and Conditions

"While there are many diseases, there is, in a sense, only one health"

Chronic diseases and conditions have been variously defined. An EURO symposium in 1957 *(1)* gave the following definition :

> "An impairment of bodily structure and/or function that necessitates a modification of the patient's normal life, and has persisted over an extended period of time".

Another EURO symposium in 1965 *(2)* observed:

> "Upto now no widely acceptable definition (of acute or chronic patients) has been found. Some authors maintain that an acute illness usually consists of a simple episode of fairly short duration from which the patient returns to normal activity, whereas a chronic illness is one of long duration in which the patient is permanently incapacitated to a more or less marked degree. There is also the view that progress in the technology of resuscitation and haemobiology has blurred the borderline between acute and chronic conditions".

The Commission on Chronic Illness in USA *(3)* has defined "chronic diseases" as "comprising all impairments or deviations from normal, which have one or more of the following characteristics :

a. are permanent
b. leave residual disability
c. are caused by non-reversible pathological alteration
d. require special training of the patient for rehabilitation
e. may be expected to require a long period of supervision, observation or care''

In short, there is no international definition of what duration should be considered long-term *(4)*, although many consider that chronic conditions are generally those, that have had a duration of at least 3 months *(5)*. A practical definition should be established which will suit the particular conditions of the community *(4)*.

Non-communicable diseases (NCDs) include cardiovascular, renal, nervous and mental diseases, musculo-skeletal conditions such as arthritis and allied diseases, chronic non-specific respiratory diseases (e.g., chronic bronchitis, emphysema, asthma), permanent results of accidents, senility, blindness, cancer, diabetes, obesity and various other metabolic and degenerative diseases and chronic results of communicable diseases. Disorders of unknown cause and progressive course are often labelled "degenerative".

The problem

Chronic non-communicable diseases are assuming increasing importance among the adult population in both developed and developing countries. Cardiovascular diseases and cancer are at present the leading causes of death in developed countries. The prevalence of chronic disease is showing an upward trend in most countries, and for several reasons this trend is likely to increase. For one reason, life expectancy is increasing in most countries and a greater number of people are living to older ages, and are at greater risk to chronic diseases of various kinds. For another, the life-styles and behavioural patterns of people are changing rapidly, these being favourable to the onset of chronic diseases. Modern medical care is now enabling many with chronic diseases to survive. The impact of chronic diseases on the lives of people is serious when measured in terms of loss of life, disablement, family hardship and poverty, and economic loss to the country. Developing countries are now warned to take appropriate steps to avoid the "epidemics" of non-communicable diseases likely to come with socio-economic and health developments.

Of the 57 million global deaths in 2008, 36 million or 63 per cent were due to non-comunicable diseases (NCDs). By cause, cardiovascular diseases were responsible for the largest proportion of NCD deaths (47.9 per cent), followed by cancers (21 per cent), chronic respiratory diseases (11.72 per cent), digestive diseases (6.1 per cent), diabetes (3.5 per cent) and rest of the NCDs were responsible for 9.78 per cent of deaths *(6)*. As population will age, annual NCD deaths are projected to rise substantially, to 52 million in 2030. Annual cardiovascular disease mortality is projected to increase by 6 million and cancer mortality by 4 million. In low–and–middle income countries NCDs will be responsible for three times as many DALYs and nearly five times as many deaths as communicable disesases, maternal, perinatal and nutritional conditions combined *(6, 7)*.

India is experiencing a rapid health transition with a rising burden of NCDs causing significant morbidity and mortality, both in urban and rural population, with considerable loss in potentially productive years (age 35–64 years) of life. NCDs are estimated to account for about 53 per cent of all deaths. Fig. 1 shows the proportional mortality in the country.

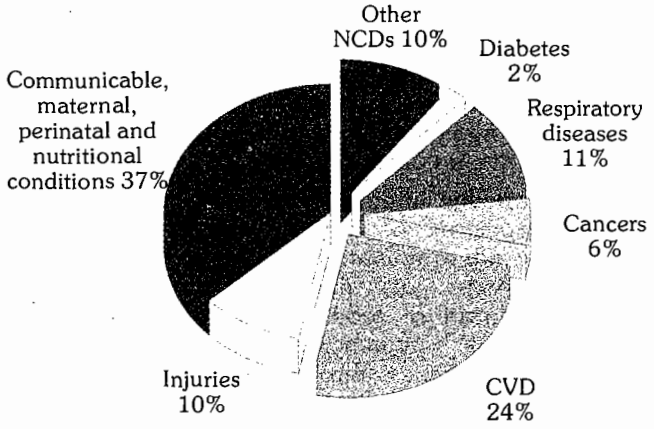

FIG. 1

Proportional mortality in India (% of total deaths, all ages)

Source : *(8)*

Non-communicable disease risk factors

Most epidemiologists accept that a sets of "risk factors" are responsible for a major share of adult non-communicable disease morbidity and premature mortality. A large percentage of NCDs are preventable through the changes in these factors. The influences of these risk factors and other underlying metabolic/physiological causes, on the non-communicable disease epidemic include *(6)* :

Tobacco : Almost 6 million people die from tobacco use each year, both from direct tobacco use and second–hand smoke. By 2020, this number will increase to 7.5 million, accounting for 10% of all deaths. Smoking is estimated to cause about 71% of lung cancer, 42% of chronic respiratory disease and nearly 10% of cardiovascular disease. The highest incidence of smoking among men is in lower-middle-income countries; for total population, smoking prevalence is highest among upper–middle–income countries.

Insufficient physical activity : Approximately 3.2 million people die each year due to physical inactivity. People who are insufficiently physically active have a 20% to 30% increased risk of all-cause mortality. Regular physical activity reduces the risk of cardiovascular disease, including high blood pressure, diabetes, breast and colon cancer and depression. Insufficient physical activity is highest in high-income countries, but very high levels are now also seen in some middle-income countries especially among women.

Harmful use of alcohol : Approximately 2.3 million die each year from the harmful use of alcohol, accounting for about 3.8% of all deaths in the world. More than half of these deaths occur from NCDs including cancers, cardiovascular disease and liver cirrhosis. While adult per capita consumption is highest in high-income countries, it is nearly as high in the populous upper-middle-income countries.

Unhealthy diet : Adequate consumption of fruit and vegetables reduces the risk for cardiovascular diseases, stomach cancer and colorectal cancer. Most populations consume much higher levels of salt than recommended by WHO for disease prevention; high salt consumption is an important determinant of high blood pressure and cardiovascular risk. High consumption of saturated fats and trans-fatty acids is linked to heart disease. Unhealthy diet is rising quickly in lower-resource settings. Available data suggest that fat intake has been rising rapidly in lower-middle-income countries since the 1980s.

Raised blood pressure : Raised blood pressure is estimated to cause 7.5 million deaths, about 12.8% of all deaths. It is a major risk factor for cardiovascular disease. The prevalence of raised blood pressure is similar across all income groups.

Overweight and obesity : At least 2.8 million people die each year as a result of being overweight or obese. Risks of heart disease, stroke and diabetes increase steadily with increasing body mass index (BMI). Raised BMI also increases the risk of certain cancers. The prevalence of overweight is highest in upper-middle-income countries, but very high levels are also reported from some lower-middle income countries.

Raised cholesterol : Raised cholesterol is estimated to cause 2.6 million deaths annually; it increases the risk of heart disease and stroke. Raised cholesterol is highest in high–income countries.

Cancer–associated infections : At least 2 million cancer cases per year, 18% of the global cancer burden, are attributable to a few specific chronic infections, and this fraction is substantially larger in low-income countries. The principal infectious agents are human papillomavirus, Hepatitis B virus, Hepatitis C virus and *Helicobacter pylori*. These infections are largely preventable through vaccinations and measures to avoid transmission, or treatable. For example, transmission of Hepatitis C virus has been largely stopped among high–income populations, but not in many low–resource countries.

Environmental risk factors : occupational hazards, air and water pollution, and possession of destructive weapons in case of injuries.

Gaps in natural history

There are many gaps in our knowledge about the natural history of chronic diseases. These gaps cause difficulties in aetiological investigations and research *(9)*. These are :–

1. Absence of a known agent

There is much to learn about the cause of chronic diseases. Whereas in some chronic diseases the cause is known (e.g., silica in silicosis, asbestos in mesothelioma), for many chronic diseases the causative agent is not known. The absence of a known agent makes both diagnosis and specific prevention difficult.

2. Multifactorial causation

Most chronic diseases are the result of multiple causes – rarely is there a simple one-to-one cause-effect relationship. In the absence of a known agent, the term "risk factor(s)" is used to describe certain factors in a person's background or life-style that make, the likelihood of the chronic condition more probable. Further, chronic diseases appear to result from the cumulative effects of multiple risk factors. These factors may be both environmental and behavioural, or constitutional. Epidemiology has contributed massively in the identification of risk factors of chronic diseases. Many more are yet to be identified and evaluated.

3. Long latent period

A further obstacle to our understanding of the natural history of chronic disease is the long latent (or incubation) period between the first exposure to "suspected cause" and the eventual development of disease (e.g., cervical cancer). This makes it difficult to link suspected causes (antecedent

events) with outcomes, e.g., the possible relation between oral contraceptives and the occurrence of cervical cancer. In an attempt to overcome this problem, a search has been made for precursor lesions in, for example, cancer cervix, oral cancer and gastric cancer. But this is not possible in all chronic diseases. However, it has now become increasingly evident that the factors favouring the development of chronic disease are often present early in life, preceding the appearance of chronic disease by many years. Examples include hypertension, diabetes, stroke, etc.

4. Indefinite onset

Most chronic diseases are slow in onset and development, and the distinction between diseased and non-diseased states may be difficult to establish (e.g., diabetes and hypertension). In many chronic diseases (e.g., cancer) the underlying pathological processes are well established long before the disease manifests itself. By the time the patient seeks medical advice, the damage already caused may be irreversible or difficult to treat.

Prevention

The preventive attack on chronic diseases is based on the knowledge that they are multifactorial in causation, so their prevention demands a complex mix of interventions. Previously only tertiary prevention seemed possible to prevent or delay the development of further disability or the occurrence of premature death. But, now, with the identification of risk factors, health promotion activities aimed at primary prevention are being increasingly applied in the control of chronic diseases. Some of the interventions that should be undertaken immediately to produce accelerated results in terms of lives saved, disease prevented and heavy cost avoided are as follows *(6)* :

1. Protecting people from tobacco smoke and banning smoking in public places, warning about the dangers of tobacco use, enforcing bans on tobacco advertising, promotion and sponsorships and raising taxes on tobacco;
2. Restricting access to retailed alcohol, enforcing bans on alcohol advertising and raising taxes on alcohol;
3. Reduce salt intake and salt content of food;
4. Replacing trans-fat in food with polyunsaturated fat; and
5. Promoting public awareness about diet and physical activity, including through mass media.

In addition, there are many other cost-effective and low-cost population-wide interventions that can reduce risk factors for NCDs. These include :

1. Nicotine dependence treatment;
2. Enforcing drink-driving laws;
3. Restrictions on marketing of foods and beverages high in salt, fats and sugar;
4. Food taxes and subsidies to promote healthy diets.
5. Healthy nutrition environments in schools;
6. Nutrition information and counselling in health care;
7. National physical activity guidelines (school based physical activity programmes for children and workplace programmes for physical activity and healthy diets).

There also are population-wide interventions that focus on cancer prevention, like vaccination against Hepatitis B, a major cause of liver cancer. Vaccination against human papillomavirus (HPV), the main cause of cervical cancer, is also recommended. Protection against environmental or occupational risk factors for cancer, such as aflatoxin, asbestos and contaminants in drinking-water can be included in effective prevention strategies.

Present knowledge indicates that the chronically ill require a wide spectrum of services – case finding through screening and health examination techniques; application of improved methods of diagnosis, treatment and rehabilitation; control of food, water and air pollution; reducing accidents; influencing patterns of human behaviour and life-styles through intensive education; upgrading standards of institutional care and developing and applying better methods of comprehensive medical care including primary health care. Political approaches are also needed as in the case of smoking control, control of alcohol and drug abuse. The approach should be holistic in handling the complex medical and social needs of the chronically ill and should always be considered in relation to the family and community.

Integrated approach

It is now felt that the principles of prevention of CHD can be applied also to other major non-communicable diseases (NCDs) because of common risk factors. A broader concept is emerging, that is, to develop an overall integrated programme for the **Prevention and Control of NCDs** as part of primary health care systems, simultaneously attacking several risk factors known to be implicated in the development of non-communicable diseases. Such concerted preventive action should reduce not only cardiovascular diseases but also other major NCDs, with an overall improvement in health and length of life *(10)*.

Recently, the WHO has developed a survey methodology known as *"the STEPS Non-communicable Disease Risk Factors Survey"* to help countries establish NCD surveillance system. Some surveys are conducted at the country level and others at the subnational level. The methodology prescribes three steps – questionnaire, physical measurements, and biochemical measurements. The core topics covered by most surveys are demographic, health status and health behaviours. These provide data on socio-economic risk factors and metabolic, nutritional and lifestyle risk factors. Details may differ from country to country and from year to year *(11)*.

In India the survey was conducted from April 2003 to March 2005 in 6 sites and again in 2007 in 7 states.

WHO Global Action Plan for the Prevention and Control of NCDs (2013–2020)

The Global Action Plan provides member states with a road map and menu of policy options which, when implemented collectively between 2013 and 2020, will contribute to progress on 9 global NCD targets including that of 25 per cent relative reduction in premature mortality from cardiovascular diseases, cancer, diabetes and chronic respiratory diseases by 2025. These four diseases make the largest contribution to mortality and morbidity due to NCDs. It will target four behavioural risk factors – tobacco use, unhealthy diet, physical inactivity and harmful use of alcohol. The voluntary global targets are *(12)* :

1. A 25 per cent relative reduction in risk of premature mortality from cardiovascular diseases, cancer, diabetes and chronic respiratory disease.

2. At least 10 per cent relative reduction in the harmful use of alcohol as appropriate within national context.
3. A 10 per cent relative reduction in prevalence of insufficient physical activity.
4. A 10 per cent relative reduction in mean population intake of salt/sodium.
5. A 30 per cent relative reduction in prevalence of current tobacco use in persons aged 15+ years.
6. A 25 per cent relative reduction in prevalence of raised blood pressure.
7. Halt the rise of diabetes and obesity.
8. At least 50 per cent of eligible people receive drug therapy and counselling (including glycaemic control) to prevent heart attacks and strokes.
9. An 80 per cent availability of the affordable basic technology and essential medicines including generics, required to treat major NCDs in both public and private facilities.

CARDIOVASCULAR DISEASES

Cardiovascular diseases (CVD) comprise of a group of diseases of the heart and the vascular system. The major conditions are ischaemic heart disease (IHD), hypertension, cerebrovascular disease (stroke) and congenital heart disease. Rheumatic heart disease (RHD) continues to be an important health problem in many developing countries.

Problem statement

WORLD

In today's world, most deaths are attributable to non-communicable diseases (36 million) and just over half of these (17 million) are as a result of CVD; more than one-third of these deaths occur in middle-aged adults. In developed countries, heart diseases and stroke are the first and second leading cause of death for adult men and women. These facts are familiar and hardly surprising, however, surprisingly in some of the developing countries, CVD have also become the first and second leading causes responsible for one-third of all deaths *(1)*.

Table 1 shows the global estimates of mortality due to cardiovascular disease for the year 2008 *(2)*.

TABLE 1
Mortality due to cardiovascular disease, global and regional estimates for 2008

Region	Deaths (000)	Per cent of total CVD deaths
Africa	1,254	7.23
SEAR	3,616	20.86
Americas	1,944	11.21
East Mediterranean	1,195	6.89
Europe	4,584	26.45
Western Pacific	4,735	27.32
World	17,327 (30.5 per cent of all deaths)	100

Source : *(2)*

Cardiovascular diseases are responsible for about 25 per cent of the DALYs lost due to non-communicable diseases in SEAR countries. Of these IHD accounts for about 40 per cent of DALYs lost, cerebrovascular diseases about 19 per cent, Rheumatic heart disease 6 per cent, inflammatory heart diseases about 6 per cent and other conditions about 29 per cent.

The incidence of CVD is greater in urban areas than in rural areas reflecting the acquisition of several risk factors such as tobacco consumption, lack of physical activity, unhealthy diet (today's fast food habits) and obesity. A peculiar cause of concern is the relative early age of CVD deaths in the developing countries. Ironically CVDs are now in decline in the industrialized countries first associated with them. They seem to have crossed the peak of the epidemic by now. The decline is largely a result of the success of primary prevention and to a lesser extent, treatment. The middle and low-income countries are at the mid-point of the emerging epidemic and will face its full impact in the coming years. These countries can be benefitted from the strategy of primary prevention.

INDIA

It is estimated that there were approximately 46.9 million patients with cardiovascular disease in India during the year 2010. An estimated 2.33 million people died of CVD during 2008. The mortality from common CVD are, about 1.2 million ischaemic heart disease and about 0.8 million stroke cases every year. Compared with all other countries India suffers the highest loss in potentially productive years of life, due to deaths from CVD in people aged 35–64 years. The prevalence of CVD is reported to be 2–3 times higher in the urban population as compared to the rural population. In one study, the prevalence of IHD among adults (based on clinical and ECG criteria) was estimated at 96.7 per 1000 population in the urban and 27.1 per cent in rural areas *(3)*.

Risk factors

The present mortality rates are the consequence of previous exposure to behavioural risk factors such as inappropriate nutrition, insufficient physical activity and increased tobacco consumption. It is called the "lag-time" effect of risk factors for CVD. Overweight, central obesity, high blood pressure, dyslipidaemia, diabetes and low cardio-respiratory fitness are among the biological factors contributing principally to increased risk.

It is now well established fact that a persistently high cholesterol level can almost certainly precipitate a cardiac event such as CHD. Still most people do not have an idea of nutritional requirements and a balanced diet. Unhealthy dietary practices include a high consumption of saturated fats, salt and refined carbohydrates, as well as a low consumption of vegetables and fruits and these tend to cluster together.

Some of the dietary measures, on the strength of evidence on lifestyle factors and risk of developing cardiovascular diseases, are summarized in Table 2.

TABLE 2

Summary of strength of evidence on lifestyle factors and risk of developing cardiovascular diseases

Evidence	Decreased risk	No relationship	Increased risk
Convincing	Regular physical activity Linoleic acid Fish and fish oils (EPA and DHA) Vegetables and fruits (including berries) Potassium Low to moderate alcohol intake (for coronary heart disease)	Viamin E supplements	Myristic and palmitic acids Trans fatty-acids High sodium intake Overweight High alcohol intake (for stroke)
Probable	α-Linolenic acid Oleic acid NSP Wholegrain cereals Nuts (unsalted) Plant sterols/stanols Folate	Stearic acid	Dietary cholesterol Unfiltered boiled coffee
Possible	Flavonoids Soy products		Fats rich in lauric acid Impaired fetal nutrition Beta-carotene supplements
Insufficient	Calcium Magnesium Vitamin C		Carbohydrates Iron

EPA, eicosapentaenoic acid: DHA, docosahexaenoic acid; NSP, non-starch polysaccharides.

Source : *(4)*

The dietary aspect of CVD has been discussed in detail in the chapter 10 "Nutrition and Health", under heading "Nutritional factors in selected diseases", and the recommended nutrient intake goals for prevention of CHD are shown in Annexure 7 of that chapter.

In summary, the major CVD risk factors of tobacco use, inappropriate diet and physical inactivity explain at least 75–85 per cent of new cases of coronary health disease. In the absence of elevation of these risk factors, CHD is a rare cause of death. Unfortunately, the vast majority of the populations in almost all countries are at risk of developing CVD because of higher than optimal levels of main risk factors.

CORONARY HEART DISEASE

Coronary heart disease (syn : ischaemic heart disease) has been defined as "impairment of heart function due to inadequate blood flow to the heart compared to its needs, caused by obstructive changes in the coronary circulation to the heart" *(1)*. It is the cause of 25–30 per cent of deaths in most industrialized countries. The WHO has drawn attention to the fact that CHD is our modern "epidemic", i.e., a disease that affects populations, not an unavoidable attribute of ageing. CHD may manifest itself in many presentations :

a. angina pectoris of effort
b. myocardial infarction
c. irregularities of the heart
d. cardiac failure
e. sudden death.

Myocardial infarction is specific to CHD; angina pectoris and sudden death are not. Rheumatic heart disease and cardiomyopathy are potential sources of diagnostic confusion *(2)*. The natural history of CHD is very variable. Death may occur in the first episode or after a long history of disease.

Measuring the burden of disease

The burden of CHD may be estimated in various ways, each illustrating a different aspect of the picture *(3)*.

(a) Proportional mortality ratio : The simplest measure is the proportional mortality ratio, i.e., the proportion of all deaths currently attributed to it. For example, CHD is held responsible for about 30 per cent of deaths in men and 25 per cent of deaths in women in most western countries.

(b) Loss of life expectancy : CHD cuts short the life expectancy. Calculations have been made *(4)* for the average gain in life expectation that would follow a complete elimination of all cardiovascular deaths if other mortality rates remain unchanged. The benefit would range for men from 3.4 years to 9.4 years, and even greater for women.

(c) CHD incidence rate: This is the sum of fatal and non-fatal attack rates *(5)*. Because of its different manifestations, accurate incidence of CHD rates are difficult to compute. Mortality rates can be used as a crude indicator of incidence.

(d) Age-specific death rates : When analysis is planned to throw light on aetiology, it is essential to study the age-specific rates. Age-specific death rates suggest a true increase in incidence.

(e) Prevalence rate : The prevalence of CHD can be estimated from cross-sectional surveys using ECG for evidence of infarction and history of prolonged chest pain. A useful publication to conduct such surveys is "Cardio-vascular Survey Methods" by Rose and Blackburn *(6)*.

(f) Case fatality rate : This is defined as the proportion of attacks that are fatal within 28 days of onset. The International Society and Federation of Cardiology has suggested that "sudden deaths" be defined to include deaths "occurring instantly or within an estimated 24 hours of the onset of acute symptoms or signs". Data collected in many industrialized countries indicate that 25–28 per cent of patients who suffer a heart attack die suddenly. In about 55 per cent of all cardiac deaths mortality occurs within the first hour *(7)*.

(g) Measurement of risk factor levels : These include measurement of levels of cigarette smoking, blood pressure, alcohol consumption and serum cholesterol in the community *(8)*.

(h) Medical care : Measurement of levels of medical care in the community are also pertinent.

Epidemicity

"Epidemics" of CHD began at different times in different countries. In United States, epidemics began in the early 1920s *(9)*; in Britain in the 1930s *(10)*; in several European countries, still later. And now the developing countries are catching up. Countries where the epidemic began earlier are now showing a decline. For example, in United States, where the epidemic began in early 1920s, a steady decline was evident by 1968, and a 25 per cent fall in mortality (not morbidity) by 1980 *(9)*. Substantial declines in mortality have also occurred in Australia, Canada and New Zealand.

The decline in CHD mortality in US and other countries has been attributed to changes in life-styles and related risk factors (e.g., diet and diet-dependent serum cholesterol, cigarette use and exercise habits) plus better control of hypertension *(11)*.

The reasons for the changing trends in CHD are not precisely known. The WHO has completed a project known as MONICA "(multinational monitoring of trends and determinants in cardiovascular diseases)" to elucidate this issue. Forty-one centres in 26 countries were participating in this project, which was planned to continue for a 10 year period ending in 1994 *(12)*.

When CHD emerged as the modern epidemic, it was the disease of the higher social classes in the most affluent societies. Fifty years later the situation is changing; there is a strong inverse relation between social class and CHD in developed countries *(13)*.

To summarize, in many developed countries, CHD still poses the largest public health problem. But even in those showing a decline, CHD is still the most frequent single cause of death among men under 65 *(13)*.

International variations

With 7.2 million deaths and 12.8 per cent of total deaths, CHD is a worldwide disease. Mortality rates vary widely in different parts of the world (Table 1).

TABLE 1

Mortality due to CHD, global estimates for 2008

Region	Deaths (000)	Per cent of total CHD deaths
Africa	374	5.15
SEAR	1,834	25.28
Americas	881	12.14
East Mediterranean	587	8.08
Europe	2,195	30.25
Western Pacific	1,383	19.06
World	1,254*	100

* 12.8 per cent of all deaths

Source : *(14)*

The highest coronary mortality is seen at present in the European Region followed by South-East Asia Region *(15)*. On the other hand rates in Americas and Eastern Mediterranean countries are much lower.

Coronary heart disease in India

Coronary heart disease is assuming serious dimension in developing countries. It is expected to be the single most important cause of death in India by the year 2015. There is a considerable increase in prevalence of CHD in urban areas in India during the last decade. Although there is increase in prevalence of CHD in rural areas also, but it is not that steep because life-style changes have affected people in urban areas more than in rural areas.

The pooled estimates from studies carried out in 1990s upto 2002 shows the prevalent rate of CHD in urban areas as 6.4 per cent and 2.5 per cent in rural areas. In urban areas the pooled estimate was 6.1 per cent for males and 6.7 per cent for females. In rural areas the estimate was 2.1 per cent for males and 2.7 per cent for females *(15)*. According to medical certification of cause of death data, 25.1 per cent of total deaths in urban areas are attributable to diseases of the circulatory system. Therefore, it was assumed that mortality rates due to CHD (which forms an important disease entity and the diseases of circulatory system) in rural areas are expected to be half of CHD specific mortality rates in urban areas. The projections of burden of disease due to CHD in India for the year 2004 are given in Table 2. The age specific prevalence rate derived from the studies are as shown in Table 3 *(15)*.

TABLE 2

Indices of burden of disease for CHD

Indices	Urban	Rural
Prevalence rate/1000	64.37	25.27
Death rate/1000	0.8	0.4
DALY per 100,000	2703.4	986.2

Taking urban population 30% and rural population 70% of total,
Prevalence rate (Urban+Rural)
= 64.37 (0.3) + 25.27 (0.7) = 37.0 per 1000

Source : *(15, 16)*

TABLE 3

Age-specific prevalence rate per 1000 for CHD derived from the selected studies 2004

Age group (in years)	Urban		Rural	
	Male	Female	Male	Female
20-24	8.00	6.80	17.54	10.47
25-29	19.65	26.24	13.67	14.42
30-34	17.05	22.96	12.39	10.75
35-39	43.18	48.44	18.79	15.99
40-44	47.25	65.85	17.94	23.23
45-49	83.26	105.35	20.72	38.78
50-54	93.07	111.88	31.11	49.86
55-59	162.44	152.75	26.68	50.91
60+	173.65	175.35	71.07	67.44

Risk factors

The aetiology of CHD is multifactorial. Apart from the obvious ones such as increasing age and male sex, studies have identified several important "risk" factors (i.e., factors that make the occurrence of the disease more probable). Some of the risk factors are modifiable, others immutable (Table 4). Presence of any one of the risk factors places an individual in a high-risk category for developing CHD. The greater the number of risk factors present, the more likely one is to develop CHD. The principal risk factors are discussed below:

TABLE 4
Risk factors for CHD

Not modifiable	Modifiable
Age	Cigarette smoking
Sex	High blood pressure
Family history	Elevated serum cholesterol
Genetic factors	Diabetes
Personality (?)	Obesity
	Sedentary habits
	Stress

1. Smoking

Some people commit suicide by drowning, but many by smoking. A uniquely human habit, smoking has been identified as a major CHD risk factor *(17, 18)* with several possible mechanisms – carbon monoxide induced atherogenesis; nicotine stimulation of adrenergic drive raising both blood pressure and myocardial oxygen demand; lipid metabolism with fall in "protective" high-density lipoproteins, etc.

It has been calculated that in countries where smoking has been a widespread habit, it is responsible for 25 per cent of CHD deaths under 65 years of age in men *(19)*. Cigarettes seem to be particularly important in causing sudden death from CHD especially in men under 50 years of age *(19)*.

The degree of risk of developing CHD is directly related to the number of cigarettes smoked per day *(21)*. Filter cigarettes are probably not protective *(22)*. There is evidence that the influence of smoking is not only independent of, but also synergistic with other risk factors such as hypertension and elevated serum cholesterol (Fig. 1). This means that the effects are more than additive *(19)*.

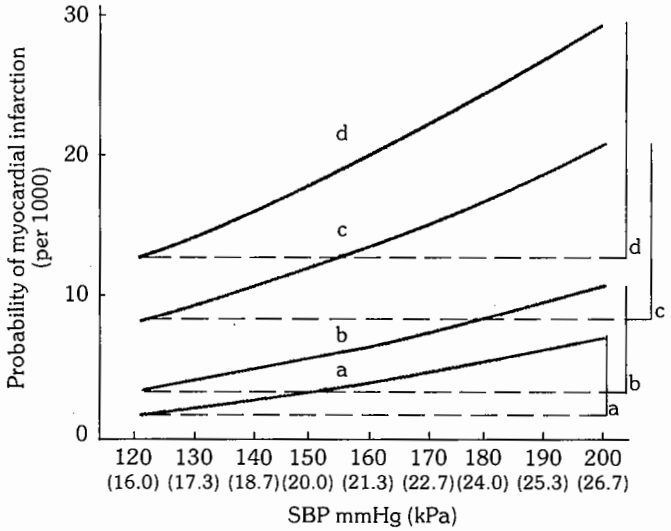

FIG. 1
The importance of risk-factor combinations, illustrated by the six-year risk of myocardial infarction at various levels of SBP and serum cholesterol in smokers and non-smokers

The vertical axis gives the probability of myocardial infarction occuring in the next 6 years per 1000 men with a given SBP.
Curve a : risk in the absence of smoking and elevated serum cholesterol.
Curve b : risk in smokers.
Curve c : risk with elevated serum cholesterol.
Curve d : risk with smoking and elevated serum cholesterol.
The vertical bars a–d show how the increment in the risk of myocardial infarction associated with a given SBP elevation depends on the various "constellations" (combinations) of risk factors. The ratios of the length of the bars provide a measure of the risk due to a particular risk-factor constellation.

Source : *(20)*

The risk of death from CHD decreases on cessation of smoking. The risk declines quite substantially within one year of stopping smoking and more gradually thereafter until, after 10–20 years, it is the same as that of non-smokers *(19)*. For those who have had a myocardial infarction, the risk of a fatal recurrence may be reduced by 50 per cent after giving up smoking *(19)*.

2. Hypertension

The blood pressure is the single most useful test for identifying individuals at a high risk of developing CHD. Hypertension accelerates the atherosclerotic process, especially if hyperlipidaemia is also present and contributes importantly to CHD. In the past, emphasis was placed on the importance of diastolic blood pressure. Many investigators feel that systolic blood pressure is a better predictor of CHD than is the diastolic. However, both components are significant risk factors. The risk role of "mild" hypertension is generally accepted *(13)*.

3. Serum cholesterol

It is nearly three decades since it became clear that elevation of serum cholesterol was one of the factors which carried an increased risk for the development of myocardial infarction. Today, there is a vast body of evidence showing a triangular relationship between habitual diet, blood cholesterol–lipoprotein levels and CHD, and that these relationships are judged to be causal *(1)*. There is no population, in which CHD is common, that does not also have a relatively high mean level of cholesterol (i.e. greater than 200 mg/dl in adults). This is illustrated in Fig. 2 *(1)* which shows the cultural differences in serum cholesterol levels between two countries, Japan and Finland – Japan having the lowest incidence and Finland the highest incidence of CHD.

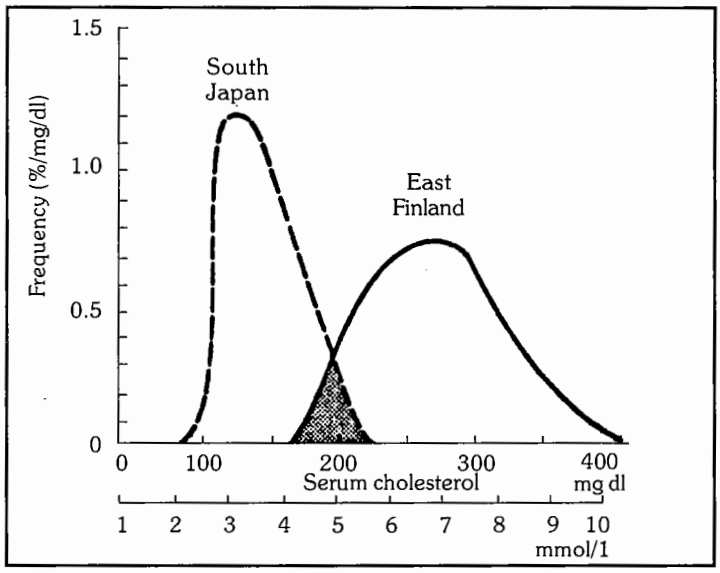

FIG. 2
Cultural differences in serum cholesterol levels

Fig. 3 shows that the risk of CHD rises steadily with the serum cholesterol concentration *(23)*. The 14-years experience of the Seven Countries Study *(24)* showed that serum cholesterol concentration is an important risk factor for the incidence of CHD at levels perhaps 220 mg/dl or more. This supports the notion of a "threshold level" of cholesterol, that is, a certain level beyond which there is an association.

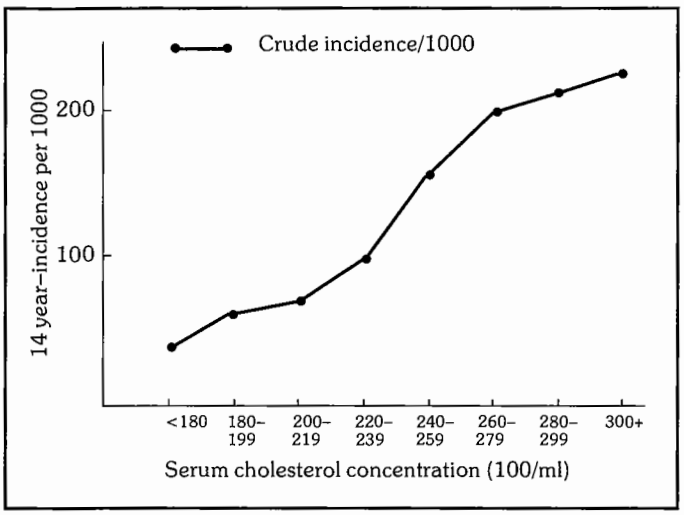

FIG. 3
The risk of CHD and serum cholesterol levels

The *strength* of the dietary-fat hypothesis is that observations in the Seven Countries Study (among others) fitted it well – that is, the Japanese had low fat diets, low serum cholesterol and low incidence of CHD while the East Fins were at the other extreme (Fig. 2). The weakness of the hypothesis is that studies of individuals have not shown such a relationship. This has been attributed to genetic and dietary intake differences between individuals *(1)*.

When we look at the various types of lipoproteins, it is the level of low-density lipoprotein (LDL) cholesterol that is most directly associated with CHD *(25)*. While very low-density lipoprotein (VLDL) has also been shown to be associated with premature atherosclerosis, it is more strongly associated with peripheral vascular disease (e.g., intermittent claudication) than with CHD. High-density lipoprotein (HDL) cholesterol is protective against the development of CHD – the higher its mean level in a group of individuals, the lower the incidence of infarction in that group *(25)*. HDL should be more than 40 mg/dl.

To further refine CHD risk prediction based on serum lipid levels, a total "cholesterol/HDL ratio" has been developed. A ratio of less than 3.5 has been recommended as a clinical goal for CHD prevention *(26)*.

With newer techniques, high-density and low-density lipoproteins have been further subdivided into sub-fractions. Recent evidence indicates that levels of plasma apolipoprotein–A–I (the major HDL protein) and apolipoprotein–B (the major LDL protein) are better predictors of CHD than HDL cholesterol or LDL cholesterol respectively. Therefore, measurement of apolipoproteins may replace lipoprotein cholesterol determinations in assessing the risk of CHD *(27)*.

4. Other risk factors

(i) Diabetes : The risk of CHD is 2–3 times higher in diabetics than in non-diabetics. CHD is responsible for 30 to 50 per cent of deaths in diabetics over the age of 40 years in industrialized countries *(28)*.

(ii) Genetic factors : A family history of CHD is known to increase the risk of premature death. Genetic factors are probably the most important determinants of a given individual's TC and LDL levels. However, the importance of genetic factors in the majority of cases is largely unknown.

(iii) Physical activity : Sedentary life-style is associated with a greater risk of the development of early CHD. There is evidence that regular physical exercise increases the concentration of HDL *(29)* and decreases both body weight and blood pressure which are beneficial to cardiovascular health.

(iv) Hormones : The pronounced difference in the mortality rates for CHD between male and female subjects (Table 3) suggests that the underlying factor may have a hormonal basis. It has been hypothesized that hyperestrogenemia may be the common underlying factor that leads both to atherosclerosis and its complications such as CHD, stroke and peripheral vascular disease *(30)*.

(v) Type A personality : Type A behaviour is associated with competitive drive, restlessness, hostility and a sense of urgency or impatience. Type–A individuals are more coronary prone to CHD than the calmer, more philosophical Type B individuals *(31)*.

(vi) Alcohol : High alcohol intake, defined as 75 g or more per day is an independent risk factor for CHD, hypertension and all cardiovascular diseases *(13)*. The evidence that moderate alcohol intake leads to a reduction in the risk of CHD is un-substantiated *(32)*.

(vii) Oral contraceptives : Women using oral contraceptives have higher systolic and diastolic blood pressure. The risk of myocardial infarction in women seems to be increased by oral contraceptives, and the risk is compounded by cigarette smoking *(33)*.

(viii) *Miscellaneous :* The possible role of dietary fibre, sucrose and soft water have been debated *(5)*. Dyspnoea on exertion and low vital capacity have also been cited as possible risk factors.

PREVENTION OF CHD

In the 1960s the issue was whether CHD could be prevented or not. Studies were launched, reported and debated. The accumulated evidence led to a broad consensus of expert opinion that CHD is preventable *(13)*. This is best expressed in a report of the WHO Expert Committee on the Prevention of CHD *(1)* which recommended the following strategies :

a. Population strategy
   (i) prevention in whole populations
   (ii) primordial prevention in whole populations
b. High risk strategy
c. Secondary prevention.

a. Population strategy

CHD is primarily a mass disease. The strategy should therefore be based on mass approach focusing mainly on the control of underlying causes (risk factors) in *whole populations*, not merely in individuals. This approach is based on the principle that small changes in risk factor levels in total populations can achieve the biggest reduction in mortality *(34)*. That is, the aim should be to shift the whole risk-factor distribution in the direction of "biological normality" *(1)*. This cannot obviously be done by medical means alone; it requires the mobilization and involvement of the whole community to alter its lifestyle practices that are associated with CHD.

Specific interventions

The population strategy centres round the following key areas:

1. Dietary changes : Dietary modification is the principal preventive strategy in the prevention of CHD. The WHO Expert Committee *(1)* considered the following dietary changes to be appropriate for high incidence populations :

- reduction of fat intake to 20–30 per cent of total energy intake
- consumption of saturated fats must be limited to less than 10 per cent of total energy intake; some of the reduction in saturated fat may be made up by mono and poly-unsaturated fats
- a reduction of dietary cholesterol to below 100 mg per 1000 kcal per day
- an increase in complex carbohydrate consumption (i.e., vegetables, fruits, whole grains and legumes)
- avoidance of alcohol consumption; reduction of salt intake to 5 g daily or less.

2. Smoking : As far as CHD is concerned, present evidence does not support promotion of the so-called "safer cigarette" *(13)*. The goal should be to achieve a smoke-free society, and several countries are progressing towards this goal.

To achieve the goal of a smoke-free society, a comprehensive health programme would be required which includes effective information and education activities, legislative restrictions, fiscal measures and smoking cessation programmes.

3. Blood pressure : It has been estimated that even a small reduction in the average blood pressure of the whole population by a mere 2 or 3 mm Hg would produce a large reduction in the incidence of cardiovascular complications *(35, 36)*. The goal of the population approach to high blood pressure would thus be to reduce mean population blood pressure levels. This involves a multifactorial approach based on a "prudent diet" (reduced salt intake and avoidance of a high alcohol intake), regular physical activity and weight control. The potential benefits and the safety and low cost of this advice would justify its implementation.

4. Physical activity : Regular physical activity should be a part of normal daily life. It is particularly important to encourage children to take up physical activities that they can continue throughout their lives *(1)*.

PRIMORDIAL PREVENTION

A novel approach to primary prevention of CHD is **primordial prevention** *(1)*. It involves preventing the emergence and spread of CHD risk factors and life-styles that have not yet appeared or become endemic. This applies to developing countries in particular. These countries should seek to preserve their traditional eating patterns and life-styles associated with low levels of CHD risk factors.

Since the aetiology of CHD is multifactorial the approach to prevention should be multifactorial aimed at controlling or modifying as many risk factors as possible. The aim should be to change the community as a whole, not the individual subjects living in it *(37)*.

Several well-planned risk factor intervention trials (e.g., The Multiple Risk Factor Intervention Trial (MRFIT) in the US *(38)*, The Stanford Heart Disease Prevention Programme in California *(39)*, and The North Kerelia Project in Finland *(40)* have demonstrated that primary prevention can achieve substantial reduction in the incidence of coronary heart disease. For detailed information, the reader is referred to references *38, 39* and *40*.

b. High risk strategy

(i) Identifying risk : High-risk intervention can only start once those at high risk have been identified. By means of simple tests such as blood pressure and serum cholesterol measurement it is possible to identify individuals at special risk *(1)*. Individuals at special risk also include those who smoke, those with a strong family history of CHD, diabetes and obesity and young women using oral contraceptives.

(ii) Specific advice : Having identified those at high risk, the next step will be to bring them under preventive care and motivate them to take positive action against all the identified risk factors, e.g., an elevated blood pressure should be treated; the patient should be helped to break the smoking habit permanently – nicotine chewing gum can be tried to wean patients from smoking *(41)*; serum cholesterol concentration should be reduced in those in whom it is raised, etc.

Several well planned high-risk intervention studies (e.g., Oslo Heart Study *(42)*, Lipid Research Clinics Study *(43)*, in US have shown that it is feasible to reduce the CHD risk factors.

From a methodological point of view, however, high-risk approach suffers from the disadvantage that the intervention (e.g., treatment) may be effective in reducing the disease in a high-risk group, but it may not reduce the disease to the same extent in the general population which consists of symptomatic, asymptomatic, high-risk, low-risk and healthy people *(44)*. Further, unfortunately, more than half of the CHD cases occur in those who are *not* apparently at special risk, and this is one limitation of the high-risk strategy *(1)*. Nevertheless, recognition and treatment of high-risk cases do make an important contribution to prevention *(1)*.

c. Secondary prevention

Secondary prevention must be seen as a continuation of primary prevention. It forms an important part of an overall strategy. The aim of secondary prevention is to prevent the recurrence and progression of CHD. Secondary prevention is a rapidly expanding field with much research in progress (e.g., drug trials, coronary surgery, use of pace makers).

The principles governing secondary prevention are the same as those already set out in the above sections, e.g., cessation of smoking, control of hypertension and diabetes, healthy nutrition, exercise promotion, etc. The most promising results to date have come from beta-blockers which appear to reduce the risk of CHD mortality in patients who have already suffered at least one infarct in the order of 25 per cent. None of the preventive measures discussed earlier lose their importance even after the first attack. For example, cessation of smoking is the most effective single means of intervention currently available in the management of patients after a heart attack. The risk of fatal infarction or sudden death is reduced by 20–50 per cent. If the patient does not stop smoking, nothing else is worth doing *(45)*.

Despite advances in treatment, the mortality of an acute heart attack is still high: among survivors, around 10 per cent in the first year, and 5 per cent yearly thereafter. Delay in reaching hospital is still considerable even in big cities in the West and may be as much as 3.5 hours. About 30 per cent of all deaths occur within 30 minutes of onset. This is one of the reasons why coronary care units have failed to make impact on the total coronary mortality in the community *(46, 47)*.

Each strategy – population strategy, high-risk strategy, secondary prevention – has its advantages and disadvantages, but the population strategy has the greatest potential.

Revascularization procedures for patients with angina pectoris *(48)*

The indications for coronary artery revascularization i.e. coronary artery bypass grafting (CABG) and percutaneous transluminal coronary angioplasty (PTCA) in patients with angina pectoris are often debated. There is general agreement that otherwise healthy patients in the following groups should undergo revascularization. (a) patients with unacceptable symptoms despite medical therapy to its tolerable limits; (b) patients with left main coronary artery stenosis greater than 50 per cent with or without symptoms; (c) patients with three-vessel disease with left ventricular dysfunction (ejection fraction <50 per cent or previous transmural infarction); (d) patients with unstable angina who after symptom control by medical therapy continue to exhibit ischaemia on exercise testing or monitoring; and (e) post-myocardial infarction patients with continuing angina or severe ischaemia on noninvasive testing.

CABG can be accomplished with a very low mortality rate (1–3 per cent) in otherwise healthy patients with preserved cardiac function. However, the mortality rate of this procedure rises to 4-8 per cent in older individuals and in patients who have had a prior CABG. Increasingly, younger individuals with focal lesions of one or more vessels are undergoing coronary angioplasty as the initial revascularization procedure, where coronary artery stenosis can be effectively dilated by inflation of a balloon under high pressure. PTCA is also possible but less successful in bypass graft stenosis.

The incidents of restenosis appears to be reduced with intracoronary stent placement and may be as low as 15–20 per cent. The number of PTCA and stent procedure now exceeds that of CABG operations. Several studies have shown PTCA to be superior to medical therapy for symptom relief but not in preventing infarction or death. In patients with no or only mild symptoms, aggressive lipid-lowering and anti-anginal therapy may be preferable to PTCA.

RISK FACTOR INTERVENTION TRIALS

Since 1951, one of the best known large prospective studies, the **Framingham Study,** has played a major role in establishing the nature of CHD risk factors and their relative importance *(49, 50)*. The major risk factors of CHD are elevated serum cholesterol, smoking, hypertension and sedentary habits. Accordingly, the four main possibilities of intervention in CHD prevention are: reduction of serum cholesterol, the cessation of smoking, control of hypertension and promotion of physical activity.

Risk factor trials can be "single factor" trials or "multi-factor" trials. Both the approaches are complementary and both are needed. Early trials of CHD prevention concentrated on one factor (e.g., dietary cholesterol). Later emphasis swung away from unifactorial to multifactorial approach.

The widely reported intervention trials are : (a) The Stanford Heart Disease Prevention Programme in California, (b) The North Kerelia Project in Finland, (c) The Oslo Study, (d) The Multiple Risk Factor Intervention Trial (MRFIT) in USA, and (e) The Lipid Research Clinics Study. A brief account of these trials is given below. For more details the reader is referred to the references cited in the text.

1. The Stanford–Three–Community Study *(39)*.

To determine whether community health education can reduce the risk of cardiovascular disease, a field experiment was undertaken in 1972 in three northern California towns with populations varying between 12,000 and 15,000. In two of these towns intensive mass education campaigns were conducted against cardiovascular risk factors over a period of 2 years. The third community served as a control. People from each community were interviewed and examined before the campaign began and one and two years afterwards to assess knowledge and behaviour related to cardiovascular diseases (e.g., diet and smoking) and also to measure physiological indicators of risk (e.g., blood pressure, serum cholesterol, relative weight). In the control community, the risk of cardiovascular disease increased over the two years, but in the intervention communities there was a substantial and sustained decrease in risk. The net difference in estimated total risk between control and intervention samples was 23–28 per cent.

2. The North Kerelia Project *(37, 40)*

North Kerelia is a county in the eastern part of Finland, where CHD is particularly common. Its 185,000 inhabitants work mostly in farming and forestry and live in the countryside.

A multiple risk factor intervention trial was started in 1972. The project had two aims : (a) to reduce the high levels of risk factors for cardiovascular disease (e.g., smoking, blood pressure and serum cholesterol), and (b) to promote the early diagnosis, treatment and rehabilitation of patients with CV disease. A control population was established in a neighbouring county which has similar CV mortality. The main strategy employed was mass community action against risk factors and advice on their avoidance.

Follow-up surveys at 5–years demonstrated a significant reduction in all three major risk factors. By 1979, mortality began to decline by 24 per cent in men and 51 per cent in women in North Kerelia, compared with 12 per cent in men and 26 per cent in women in rest of Finland. A further representative sample (8000) was studied in 1982. It exhibited its effect on CHD deaths – more than twice the reduction achieved in the rest of Finland during the same period. Thus it took 10 years (Rose's 10–year incubation period) to exhibit its effect on CHD deaths.

3. MRFIT *(38)*

The multiple risk factor intervention trial (MRFIT) carried out in USA was aimed at high risk adult males aged 35–57 years. A total of 12,866 men who showed no evidence of CHD either clinically or on ECG were enrolled for the study. Half the group was randomly allocated to an intensive intervention programme, being seen at least every four months to ensure adequate control of risk factors. The other half (control group) received a medical examination once yearly, and no specific advice was given to them about the control of risk factors. The intervention procedures included cessation of smoking, controlling blood pressure and altering diet to reduce hypercholesterolemia.

Over the 7 year follow-up period, IHD mortality was reduced by 22 per cent more in the intervention group but this was not statistically significant. This was because the control group had also changed their habits and lifestyle to a far greater extent than anticipated by the designers of the trial. The trial produced no significant changes at all in

mortality or risk factors in as much as the control group was not properly chosen.

4. Oslow diet/smoking Intervention Study *(42).*

This study began in 1973. 16,202 Norwegian men aged 40–49 years were screened for coronary risk factors; of these 1232 healthy normotensive men at high risk (total serum cholesterol 290–379 mg/dl; smoking) of CHD were selected for a 5 year randomized trial. The aim of the study was to determine whether lowering of serum lipids and cessation of smoking would reduce the incidence of first attack of CHD in males aged 40–50.

The intervention group underwent techniques designed to lower serum cholesterol level through dietary means (e.g., a polyunsaturated fat diet), and to decrease or eliminate smoking. At the end of 5 years, the incidence of myocardial infarction (fatal and nonfatal) was lower by 47 per cent in the intervention group than in the control group.

With this study, primary prevention of CHD entered the practical field of preventive medicine in an impressive manner.

5. Lipid Research Clinics Study *(43)*

This double-blind, randomized clinical trial involved 3806 asymptomatic "high-risk" American men aged 35–59 years with typeII hyperlipoproteinaemia. The trial was designed to test whether reducing serum cholesterol would prevent CHD events.

The men were randomized into two groups, one receiving cholestyramine and the other receiving a placebo. Both the groups were followed for an average of 7.4 years.

The treatment group had an 8.5 per cent and 12.6 per cent greater reduction in total cholesterol and LDL–cholesterol levels respectively than the placebo–treated group. This difference resulted in a 24 per cent reduction in death from definite CHD and a 19 per cent reduction in non-fatal myocardial infarction. The findings of this study have resulted in enthusiasm for the drug treatment of those men with considerably elevated serum cholesterol levels.

Secondary prevention trials

Secondary prevention trials are aimed at preventing a subsequent coronary attack or sudden death. A wide range of clinical trials have been performed with four main groups of drugs – anti-coagulants, lipid-lowering agents (e.g., clofibrate), anti-thrombotic agents (e.g., aspirin) and beta-blockers. The most promising results to date have come from beta blockers.

In general the above studies and similar others show that it is feasible through well-planned intervention programmes to reduce the risk factors in the populations studied. The primary and secondary prevention studies promise at present to be the main contribution of epidemiology to the conquest of chronic diseases.

HYPERTENSION

Hypertension is a chronic condition of concern due to its role in the causation of coronary heart disease, stroke and other vascular complications. It is the commonest cardiovascular disorder, posing a major public health challenge to population in socio-economic and epidemiological transition. It is one of the major risk factors for cardiovascular mortality, which accounts for 20–50 per cent of all deaths.

Definition of hypertension is difficult and, by necessity arbitrary. Sir George Peckering first fomulated a concept

that blood pressure in a population is distributed continuously as a bell-shaped curve with no real separation between normotension and hypertension *(1)*. There is also a direct relation between cardiovascular risk and blood pressure : the higher the blood pressure, the higher the risk of both stroke and coronary events *(1)*. As a consequence, the dividing line between normal and high blood pressure can be defined only in an operational way.

As intervention trials included only adults aged 18 years or older, definition and classification of hypertension refer to adults not taking anti-hypertensive drugs and not actually ill, and based on the average of two or more readings on two or more occasions after initial screening. Table 1 shows the classification of hypertension by blood pressure level.

TABLE 1
Classification of blood pressure measurements

Category	Systolic blood pressure (mm of Hg)		Diastolic blood pressure (mm of Hg)
Normal	< 120		< 80
Pre-hypertension	120–139	or	80–90
Hypertension			
Stage 1	140–159	or	90–99
Stage 2	≥160	or	≥100

Source : *(2)*

When systolic and diastolic blood pressure fall into different categories, the higher category should be selected to classify the individual's blood pressure. *"Isolated systolic hypertension"* is defined as a systolic blood pressure of 140 mm of Hg or more and a diastolic blood pressure of less than 90 mm of Hg.

Organ damage

Although the extent of organ damage often correlates with the level of blood pressure, it is not always the case. In addition the rate of progression of organ damage varies from one individual to another depending on many influences, most of which are incompletely understood. Therefore, blood pressure and organ impairment should be evaluated separately, since markedly high pressures may be seen without organ damage and, conversely, organ damage may be present with only moderate elevation of blood pressure. The presence of signs of organ damage confers an increased cardiovascular risk to any level of blood pressure.

Blood pressure measurement

Despite more than 75 years of experience with the measurement of blood pressure, discussion continues about its reliability and wide variability in individual subjects. Accurate measurements are essential under standardized conditions for valid comparison between persons or groups over time. Three sources of errors have been identified in the recording of blood pressure : *(a) Observer errors :* e.g., hearing acuity, interpretation of Korotkow sounds. *(b) Instrumental errors* : e.g., leaking valve, cuffs that do not encircle the arm. If the cuff is too small and fails to encircle the arm properly then too high a reading will be obtained; and *(c) Subject errors :* e.g., the circumstances of examination. These include the physical environment, the position of the subject, external stimuli such as fear, anxiety, and so on *(3)*.

A few salient points need be mentioned about measuring blood pressure. A WHO Study Group *(4)* recommended the sitting position than the supine position for recording blood pressure. In any clinic a uniform policy should be adopted, using either the right or left arm consistently. The pressure at which the sounds are first heard (phase I) is taken to indicate the systolic pressure. Near the diastolic pressure the sounds first become muffled (phase IV) and then disappear (phase V). Most of the studies have used phase V to measure diastolic blood pressure. The systolic and diastolic pressures should be measured at least three times over a period of at least 3 minutes and the lowest reading recorded. For reasons of comparability, the data should be recorded everywhere in a uniform way.

Classification

Hypertension is divided into primary (essential) and secondary. Hypertension is classified as "essential" when the causes are generally unknown. Essential hypertension is the most prevalent form of hypertension accounting for 90 per cent of all cases of hypertension. Hypertension is classified as "secondary" when some other disease process or abnormality is involved in its causation. Prominent among these are diseases of kidney (chronic glomerulo-nephritis and chronic pyelonephritis), tumours of the adrenal glands, congenital narrowing of the aorta and toxemias of pregnancy. Altogether, these are estimated to account for about 10 per cent or less of the cases of hypertension.

Magnitude of the problem

Although blood pressure is easily measured, it had taken several decades to realise that arterial hypertension is a frequent, worldwide health disorder *(5)*.

"Rule of halves"

Hypertension is an "iceberg" disease. It became evident in the early 1970s that only about half of the hypertensive subjects in the general population of most developed countries were aware of the condition, only about half of those aware of the problem were being treated, and only about half of those treated were considered adequately treated *(6)*. Fig. 1 illustrates this situation *(7)*. If this was the situation in countries with highly developed medical services, in the developing countries, the proportion treated would be far too less.

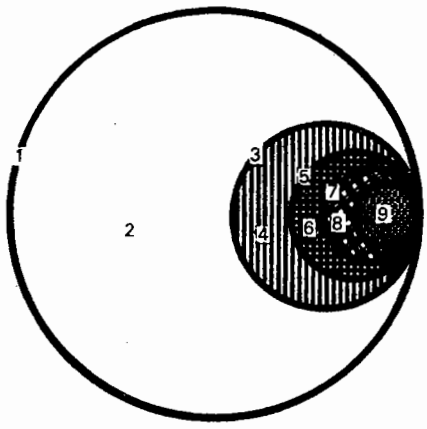

FIG. 1
Hypertension in the community

The areas of the circles shown in Fig. 1 correspond to the actual proportions observed in several population based studies and number-wise represent the following : *(6)*.

1. The whole community
2. Normotensive subjects
3. Hypertensive subjects
4. Undiagnosed hypertension
5. Diagnosed hypertension
6. Diagnosed but untreated
7. Diagnosed and treated
8. Inadequately treated
9. Adequately treated

INCIDENCE : The concept of incidence has limited value in hypertension because of the variability of consecutive readings in individuals, ambiguity of what is "normal" blood pressure and the insidious nature of the condition *(8)*.

Worldwide, raised blood pressure is estimated to cause 7.5 million deaths, about 12.8 per cent of the total of all annual deaths. This accounts for 57 million DALYs or 3.7 per cent of total DALYs. It is a major risk factor for coronary heart disease and ischaemic as well as haemorrhagic stroke. In some age groups, the risk of cardiovascular disease doubles for each incremental increase of 20/10 mm Hg of blood pressure. In addition, complication of raised blood pressure includes heart failure, peripheral vascular disease, renal impairment, retinal haemorrhage and visual impairment. Treating systolic and diastolic blood pressure so that they are below 140/90 mm Hg is associated with a reduction in cardiovascular complications *(9)*.

Globally, the overall prevalence of raised blood pressure in adults aged 25 years and over was around 40 per cent in 2008 *(9)*. The proportion of the world's population with high blood pressure, or uncontrolled hypertension, fell modestly between 1980 and 2008. However, because of population growth and ageing, the number of people with hypertension rose from 600 million in 1980 to 1 billion in 2008 *(9)*.

Across the income groups of countries, the prevalence of raised blood pressure was consistently high, with low, lower-middle and upper-middle-income countries all having rates of around 40% for both sexes. The prevalence in high-income countries was lower, at 35% for both sexes.

Prevalence in India

A community based survey was carried out by ICMR during 2007–08 to identify the risk factors for non-communicable diseases under state based Integrated Disease Surveillance Project Phase I. The survey was carried out in the states of Andhra Pradesh, Kerala, Madhya Pradesh, Maharashtra, Uttarakhand, Tamil Nadu and Mizoram.

According to the survey report, the prevalence of hypertension was varying from 17 to 21 per cent in all the states with marginal rural–urban differences. Overall pattern of prevalence was found increasing with age groups in all states. Though hypertension was prevalent in all educational levels, it was high in higher education levels of Uttarakhand, Mizoram and Madhya Pradesh. Hypertension was comparatively more prevalent in executive and service categories in all the states *(10)*.

"Tracking" of blood pressure

If blood pressure levels of individuals were followed up over a period of years from early childhood into adult life, then those individuals whose pressures were initially high in the distribution, would probably continue in the same "track" as adults. In other words, low blood pressure levels tend to remain low, and high levels tend to become higher as individuals grow older. This phenomenon of persistence of rank order of blood pressure has been described as "tracking" *(11)*. This knowledge can be applied in identifying children and adolescents "at risk" of developing hypertension at a future date.

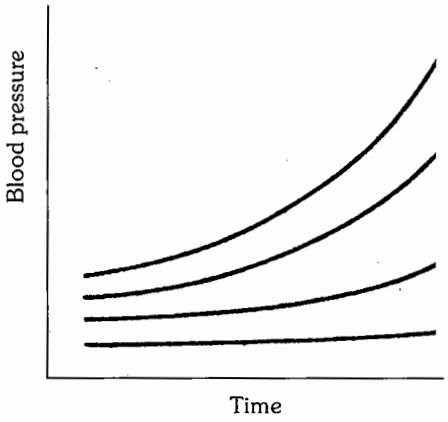

FIG. 2
Tracking of blood pressure

Risk factors for hypertension

Hypertension is not only one of the major risk factors for most forms of cardiovascular disease, but that it is a condition with its own risk factors. A WHO Scientific Group *(5)* has recently reviewed the risk factors for essential hypertension. These may be classified as :

1. Non-modifiable risk factors

(a) AGE : Blood pressure rises with age in both sexes and the rise is greater in those with higher initial blood pressure. Age probably represents an accumulation of environmental influences and the effects of genetically programmed senescence in body systems *(3)*. Some populations have now been identified whose mean blood pressure does not rise with age *(12)*. These communities are for the most part primitive societies with calorie and often salt intakes at subsistence level.

(b) SEX : Early in life there is little evidence of a difference in blood pressure between the sexes. However, at adolescence, men display a higher average level. This difference is most evident in young and middle aged adults. Late in life the difference narrows and the pattern may even be reversed *(1)*. Post-menopausal changes in women may be the contributory factor for this change. Studies are in progress to evaluate whether oestrogen supplementation protects against the late relative rise of blood pressure in women *(1)*.

(c) GENETIC FACTORS : There is considerable evidence that blood pressure levels are determined in part by genetic factors, and that the inheritance is polygenic. The evidence is based on twin and family studies. *Twin studies* have confirmed the importance of genetic factors in hypertension. The blood pressure values of monozygotic twins are usually more strongly correlated than those of zygotic twins. In contrast, no significant correlation has been noted between husbands and wives, and between adopted children and their adoptive parents *(5)*.

Family studies have shown that the children of two normotensive parents have 3 per cent possibility of developing hypertension, whereas this possibility is 45 per cent in children of two hypertensive parents *(13)*. Blood pressure levels among first degree adult relatives have also been noted to be statistically significant *(5)*.

Attempts to find genetic markers that are associated with hypertension have been largely unsuccessful. The detailed mechanism of heredity, i.e., how many genes and loci are involved and their mode of inheritance have not yet been conclusively elucidated.

(d) ETHNICITY : Population studies have consistently revealed higher blood pressure levels in black communities than other ethnic groups *(1)*. Average difference in blood pressure between the two groups vary from slightly less than 5 mm Hg during the second decade of life to nearly 20 mm Hg during the sixth. Black Americans of African origin have been demonstrated to have higher blood pressure levels than whites.

2. Modifiable risk factors

(a) OBESITY : Epidemiological observations have identified obesity as a risk factor for hypertension *(14)*. The greater the weight gain, the greater the risk of high blood pressure. Data also indicate that when people with high blood pressure lose weight, their blood pressure generally decreases. "Central obesity" indicated by an increased waist to hip ratio, has been positively correlated with high blood pressure in several populations.

(b) SALT INTAKE : There is an increasing body of evidence to the effect that a high salt intake (i.e., 7–8 g per day) increases blood pressure proportionately. Low sodium intake has been found to lower the blood pressure *(15)*. For instance, the higher incidence of hypertension is found in Japan where sodium intake is above 400 mmol/day while primitive societies ingesting less than 60 mmol/day have virtually no hypertension *(16)*. It has been postulated that essential hypertensives have a genetic abnormality of the kidney which makes salt excretion difficult except at raised levels of arterial pressure *(5)*.

Besides sodium, there are other mineral elements such as potassium which are determinants of blood pressure. Potassium antagonizes the biological effects of sodium, and thereby reduces blood pressure. Potassium supplements have been found to lower blood pressure of mild to moderate hypertensives. Other cations such as calcium, cadmium and magnesium have also been suggested as of importance in reducing blood pressure levels.

(c) SATURATED FAT : The evidences suggest that saturated fat raises blood pressure as well as serum cholesterol *(17)*. For further details refer to chapter 10.

(d) DIETARY FIBRE : Several studies indicate that the risk of CHD and hypertension is inversely related to the consumption of dietary fibre. Most fibres reduce plasma total and LDL cholesterol *(1)*.

(e) ALCOHOL : High alcohol intake is associated with an increased risk of high blood pressure. It appears that alcohol consumption raises systolic pressure more than the diastolic. But the finding that blood pressure returns to normal with abstinence suggests that alcohol–induced elevations may not be fixed, and do not necessarily lead to sustained blood pressure elevation *(3)*.

(f) HEART RATE : When groups of normotensive and untreated hypertensive subjects, matched for age and sex, are compared, the heart rate of the hypertensive group is invariably higher. This may reflect a resetting of sympathetic activity at a higher level. The role of heart variability in blood pressure needs further research to elucidate whether the relation is casual or prognostic *(1)*.

(g) PHYSICAL ACTIVITY : Physical activity by reducing body weight may have an indirect effect on blood pressure.

(h) ENVIRONMENTAL STRESS : The term hypertension itself implies a disorder initiated by tension or stress. Since stress is nowhere defined, the hypothesis is untestable *(3)*. However, it is an accepted fact that psychosocial factors operate through mental processes, consciously or unconsciously, to produce hypertension. Virtually all studies on blood pressure and catecholamine levels in young people revealed significantly higher noradrenaline levels in hypertensives than in normotensives. This supports the contention that over-activity of the sympathetic nervous system has an important part to play in the pathogenesis of hypertension *(11)*.

(i) SOCIO-ECONOMIC STATUS : In countries that are in post-transitional stage of economic and epidemiological change, consistently higher levels of blood pressure have been noted in lower socio-economic groups. This inverse relation has been noted with levels of education, income and occupation. However, in societies that are transitional or pre-transitional, a higher prevalence of hypertension have been noted in upper socio-economic groups. This probably represents the initial stage of the epidemic of CVD *(1)*.

(j) OTHER FACTORS : The commonest present cause of secondary hypertension is oral contraception, because of the oestrogen component in combined preparations. Other factors such as noise, vibration, temperature and humidity require further investigation *(5)*.

PREVENTION OF HYPERTENSION

The low prevalence of hypertension in some communities indicates that hypertension is potentially preventable *(18)*. The WHO has recommended the following approaches in the prevention of hypertension :

1. Primary prevention
   (a) Population strategy
   (b) High-risk strategy
2. Secondary prevention

1. PRIMARY PREVENTION

Although control of hypertension can be successfully achieved by medication (secondary prevention) the ultimate goal in general is primary prevention. Primary prevention has been defined as "all measures to reduce the incidence of disease in a population by reducing the risk of onset" *(19)*. The earlier the prevention starts the more likely it is to be effective.

In connection with primary prevention, terms such as "population strategy" and "high-risk strategy" have become established *(5, 20)*. The WHO has recommended these approaches in the prevention of hypertension. Both the approaches are complementary.

a. POPULATION STRATEGY

The population approach is directed at the whole population, irrespective of individual risk levels. The concept of population approach is based on the fact that even a small reduction in the average blood pressure of a population would produce a large reduction in the incidence of cardiovascular complications such as stroke and CHD *(18)*. The goal of the population approach is to shift

the community distribution of blood pressure towards lower levels or "biological normality" *(11)*. This involves a multifactorial approach, based on the following non-pharmacotherapeutic interventions :

(a) NUTRITION : Dietary changes are of paramount importance. These comprise : (i) reduction of salt intake to an average of not more than 5 g per day (ii) moderate fat intake (iii) the avoidance of a high alcohol intake, and (iv) restriction of energy intake appropriate to body needs. (b) WEIGHT REDUCTION : The prevention and correction of over weight/obesity (Body Mass Index greater than 25) is a prudent way of reducing the risk of hypertension and indirectly CHD; it goes with dietary changes. (c) EXERCISE PROMOTION : The evidence that regular physical activity leads to a fall in body weight, blood lipids and blood pressure goes to suggest that regular physical activity should be encouraged as part of the strategy for risk-factor control *(25)*. (d) BEHAVIOURAL CHANGES : Reduction of stress and smoking, modification of personal life-style, yoga and transcendental meditation could be profitable. (e) HEALTH EDUCATION : The general public require preventive advice on all risk factors and related health behaviour. The whole community must be mobilized and made aware of the possibility of primary prevention, and (f) SELF-CARE : An important element in community–based health programmes is patient participation. The patient is taught self-care, i.e., to take his own blood pressure and keep a log–book of his readings. By doing so, the burden on the official health services would be considerably reduced. Log–books can also be useful for statistical purposes and for the long-term follow-up of cases *(22)*.

Table 2 shows some of the lifestyle modifications to manage hypertension.

b. HIGH-RISK STRATEGY

This is also part of primary prevention. The aim of this approach is "to prevent the attainment of levels of blood pressure at which the institution of treatment would be considered" *(3)*. This approach is appropriate if the risk factors occur with very low prevalence in the community *(3)*.

Detection of high-risk subjects should be encouraged by the optimum use of clinical methods. Since hypertension tends to cluster in families, the family history of hypertension and "tracking" of blood pressure from childhood may be used to identify individuals at risk.

2. SECONDARY PREVENTION

The goal of secondary prevention is to detect and control high blood pressure in affected individuals. Modern anti-hypertensive drug therapy can effectively reduce high blood pressure and consequently, the excess risk of morbidity and mortality from coronary, cerebrovascular and kidney disease. The control measures comprise:

(i) EARLY CASE DETECTION : Early detection is a major problem. This is because high blood pressure rarely causes symptoms until organic damage has already occurred, and our aim should be to control it before this happens. The only effective method of diagnosis of hypertension is to screen the population. But screening, that is not linked to follow-up and sustained care, is a fruitless exercise. It is emphasized that screening should not be initiated if health resources for treatment and follow-up are not adequate.

In the developed countries, mass screening is not considered essential for the adequate control of blood pressure in the population. In Europe, the large majority of people have at least one contact in every 2 years with the health service. If blood pressure is measured at each such contact, the bulk of the problem of detecting those in need of intervention is solved.

(ii) TREATMENT : In essential hypertension, as in diabetes, we cannot treat the cause, because we do not know what it is. Instead, we try to scale down the high blood pressure to acceptable levels. The aim of treatment should be to obtain a blood pressure below 140/90, and ideally a blood pressure of 120/80. Control of hypertension has been shown to reduce the incidence of stroke and other complications. This is a major reason for identifying and treating asymptomatic hypertension. Care of hypertensives should also involve attention to other risk factors such as smoking and elevated blood cholesterol levels *(18)*.

TABLE 2
Lifestyle modifications to manage hypertension

Modification	Recommendation	Approximate Systolic BP Reduction, Range
Weight reduction	Maintain normal body weight (BMI, 18.5–24.9)	5–20 mm Hg/10 kg weight loss
Adopt DASH eating plan	Consume a diet rich in fruits, vegetables and low-fat dairy products with a reduced content of saturated fat and total fat	8–14 mm Hg
Dietary sodium reduction	Reduce dietary sodium intake to no more than 100 mEq/d (2.4 g sodium or 6 g sodium chloride)	2–8 mm Hg
Physical activity	Engage in regular aerobic physical activity such as brisk walking (at least 30 minutes per day, most days of the week)	4–9 mm Hg
Moderation of alcohol consumption	Limit consumption to no more than two drinks per day (1 oz or 30 ml ethanol eg, 24 oz beer, 10 oz wine, or 3 oz 80- proof whisky) in most men, and no more than one drink per day in women and lighter-weight persons	2–4 mm Hg

For overall cardiovascular risk reduction, stop smoking.
The effects of implementing these modifications are dose and time dependent and could be higher for some individuals.
BMI – body mass index calculated as weight in kilograms divided by the square of height in metres;
DASH – Dietary Approaches to Stop Hypertension.

Source : *(2)*

(iii) PATIENT COMPLIANCE : The treatment of high blood pressure must normally be life-long and this presents problems of patient compliance, which is defined as "the extent to which patient behaviour (in terms of taking medicines, following diets or executing other lifestyle changes) coincides with clinical prescription". The compliance rates can be improved through education directed to patients, families and the community.

Intensive research carried out during the past decade, aiming at control of hypertension at the community level, has already provided valuable results. The studies have shown that control of hypertension in a population is feasible, that it can be carried out through the existing system of health services in different countries, and that the control of blood pressure leads to a reduction of complications of high blood pressure – namely stroke, heart failure and renal failure. In some of the projects the incidence of myocardial infarction was also reduced. As a result of these findings some countries have launched nationwide control programmes in the field of hypertension *(23)*.

STROKE

The term "stroke" (syn : apoplexy) is applied to acute severe manifestations of cerebrovascular disease. It causes both physical and mental crippling. WHO defined stroke as "rapidly developed clinical signs of focal disturbance of cerebral function; lasting more than 24 hours or leading to death, with no apparent cause other than vascular origin" *(1)*. The 24 hours threshold in the definition excludes transcient ischaemic attacks (TIA) which is defined to last less than 24 hours, and patients with stroke symptoms caused by subdural haemorrhage, tumours, poisoning or trauma are excluded.

The disturbance of cerebral function is caused by three morphological abnormalities, i.e., stenosis, occlusion or rupture of the arteries. Dysfunction of the brain ("neurological deficit") manifests itself by various neurological signs and symptoms that are related to extent and site of the area involved and to the underlying causes. These include coma, hemiplegia, paraplegia, monoplegia, multiple paralysis, speech disturbances, nerve paresis, sensory impairment, etc. Of these hemiplegia constitutes the main somatoneurological disorder in about 90 per cent of patients *(2)*.

Stroke includes a number of syndromes with differing aetiologies, epidemiology, prognosis and treatment. These are listed below :

A. Ischaemic stroke
   a. Lacunar infarct
   b. Carotid circulation obstruction
   c. Vertebro-basilar obstruction

B. Haemorrhagic stroke
   a. Spontaneous intracerebral haemorrhage
   b. Subarachnoid haemorrhage
   c. Intracranial aneurysm
   d. Arteriovenous malformations.

Problem

Stroke is a worldwide health problem. It makes an important contribution to morbidity, mortality and disability in developed as well as developing countries. Although there are substantial differences in frequency from place to place, cerebral thrombosis is usually the most frequent form of stroke encountered in clinical studies, followed by haemorrhage. Subarachnoid haemorrhage and cerebral embolism come next as regards both mortality and morbidity *(2)*. However, stroke from cerebral haemorrhage is more common in Japan than elsewhere *(1)*.

MORBIDITY AND MORTALITY

Cerebrovascular disease remain a leading cause of death from NCDs. In 2008 it was estimated that cerebrovascular disease accounted for 6.1 million deaths worldwide, equivalent to 10.8 per cent of all deaths. Majority of these deaths occurred in people living in developing countries and 33.72 per cent of the subjects were aged less than 70 years *(3)*. Additionally, cerebrovascular disease is the leading cause of disability in adults and each year millions of stroke survivors have to adopt life with restriction in activities of daily living as a consequence of stroke. Many surviving stroke patients will often depend on other people's continuous support to live *(4)*.

In demographically developed countries, the average age at which stroke occurs is around 73 years reflecting the older age structure of these countries. The probability of a first stroke or first TIA is around 1.6 per 1000 and 0.42 per 1000 respectively. In less developed regions, the average age of stroke is less due to the different population age structure, resulting from higher mortality rates.

Stroke patients are at highest risk of death in the first weeks after the event, and between 20–50 per cent die within first month depending on type, severity, age, co-morbidity and effectiveness of treatment of complications. Patients who survive may be left with no disability or with mild, moderate or severe disability. Considerable spontaneous recovery occurs upto about 6 months. However, patients with history of stroke are at high risk of a subsequent event of around 10 per cent in the first year and 5 per cent year thereafter *(4)*.

The proportion of patients achieving independence in self-care by one year after a stroke range from around

60 to 83 per cent. This depends on whether the studies are community-based or hospital-based, which activity is considered in estimating independence, and the methods used to rate ability *(4)*.

There is evidence that mortality from stroke has been declining in many countries for several years. Some of the decline occurred before modern treatment methods became available, indicating that the decline in stroke was associated with social and economic changes.

INDIA

Although the prevalence of stroke appears to be comparatively less in India than in developed countries, it is likely to increase proportionally with the increase in life expectancy. The proportion of stroke in the young population is significantly more in India than in developed countries; some of the more important causes for this are likely to be rheumatic heart disease, ischaemic strokes in peripartum period and arteriopathies as a sequale of CNS infections like bacterial and tubercular meningitis etc. *(5)*.

The prevalence rate of stroke in India is about 1.54 per thousand and death rate about 0.6 per 1000. The DALYs lost is about 597.6 per lac *(5)*. The total number of stroke cases in India in the year 2004 were about 9.30 million with about 0.63 million deaths, and total DALYs lost in 2004 were about 6.36 million *(6)*.

1. RISK FACTORS

Epidemiological studies have indicated that stroke does not occur at random, and there are factors (risk factors) which precede stroke by several years. These are : *(a) Hypertension:* This is considered the main risk factor for cerebral thrombosis as well as cerebral haemorrhage; *(b) Other factors:* Additional factors contributing to risk are cardiac abnormalities (i.e., left ventricular hypertrophy, cardiac dilatation), diabetes, elevated blood lipids, obesity, smoking, glucose intolerance, blood clotting and viscosity, oral contraceptives, etc. The importance of these factors is not clearly defined. Although the risk factors for stroke are similar to those for CHD, their relative importance differs *(7)*.

2. TRANSCIENT ISCHAEMIC ATTACKS (TIA)

One phenomenon that has received increasing attention is the occurrence of TIA in a fair proportion of cases. These are episodes of focal, reversible, neurological deficit of sudden onset and of less than 24 hours duration. They show a tendency to recurrence. They are due to microemboli, and are a warning sign of stroke.

HOST FACTORS

(i) Age : Stroke can occur at any age. Usually incidence rates rise steeply with age. Globally about 47 per cent of all stroke deaths occur in persons over 70 years. In India, about one-fifth of all strokes occur below the age of 40 (called "strokes in the young"). This is attributed to our "young population", and shorter life expectancy.

(ii) Sex : The incidence rates are higher in males than females at all ages.

(iii) Personal history : The WHO Study showed that nearly three-quarters of all registered stroke patients had associated diseases, mostly in the cardiovascular system or of diabetes. This supports the view that in most cases stroke is merely an incident in the slowly progressive course of a generalized vascular disease.

Stroke control programme

The aim of a stroke control programme is to apply at community level effective measures for the prevention of stroke. The first priority goes to control of arterial hypertension which is a major cause of stroke. As transcient ischaemic attacks (TIA) may be one of the earliest manifestations of stroke, their early detection and treatment is important for the prevention of stroke *(2)*. Control of diabetes, elimination of smoking, and prevention and management of other risk factors at the population level are new approaches. Treatment for acute stroke is largely the control of complications. Facilities for the long-term follow-up of patients are essential. The education and training of health personnel and of the public form an integral part of the programme. For any such programme, reliable knowledge of the extent of the problem in the community concerned is essential *(2)*.

In summary, control of stroke that was once considered an inevitable accompaniment to ageing is now being approached through primary prevention. It has generated the hope that stroke can be tackled by community health action.

RHEUMATIC HEART DISEASE

Rheumatic fever (RF) and rheumatic heart disease (RHD) cannot be separated from an epidemiological point of view *(1)*. Rheumatic fever is a febrile disease affecting connective tissues particularly in the heart and joints initiated by infection of the throat by group A beta haemolytic streptococci. Although RF is not a communicable disease, it results from a communicable disease (streptococcal pharyngitis). Rheumatic fever often leads to RHD which is a crippling disease. The consequences of RHD include : continuing damage to the heart; increasing disabilities; repeated hospitalization, and premature death usually by the age of 35 years or even earlier. RHD is one of the most readily preventable chronic disease.

Problem

WORLD

The incidence of rheumatic fever and rheumatic heart disease has not decreased in developing countries. Retrospective studies reveal developing countries to have the highest figures for cardiac involvement and recurrence rates of rheumatic fever. Worldwide, there are over 15 million cases of RHD with 282,000 new cases. During 2008, 220,000 deaths from this disease occurred which is about 0.4 per cent of total deaths *(2)*.

RHD is a major cause of morbidity and a major cause of mitral insufficiency and stenosis in the world. Variables that correlate with the severity of valve disease include the number of previous attacks of RF, the length of time between the onset of disease and start of therapy, and sex (the disease

is more severe in females than in males). Insufficiency from acute rheumatic valve disease resolves in 60–80 per cent of patients who adhere to antibiotic prophylaxis *(3)*.

In a number of affluent countries (North America, Western Europe and in Japan) the incidence of RF and the prevalence of and mortality from RHD have fallen during the last two decades, where the disease is now generally uncommon. Some of this decline occurred before modern treatment methods became available, indicating that the fall in prevalence and incidence was associated with social and economic changes *(4)*.

As a result of the above decline, there has been a tendency to minimize the public health importance of RF – the assumption being that the disease may subside or even vanish spontaneously as living standards rise. However, even in the most affluent countries, there remain pockets of poverty where socio-economic conditions continue to favour the persistence of RF *(5)*.

INDIA

In India, RHD is prevalent in the range of 5–7 per thousand in 5–15 years age group and there are about 1 million RHD cases in India. RHD constitutes 20–30% of hospital admissions due to CVD in India *(6)*. Streptococcal infections are very common especially in children living in under-privileged conditions, and RF is reported to occur in 1–3 per cent of those infections *(7)*.

Jai Vigyan Mission Mode project on Community Control of RF/RHD in India is being carried out with four main components, viz. to study the epidemiology of streptococcal sore throats, establish registries for RF and RHD, vaccine development for streptococcal infection and conducting advanced studies on pathological aspects of RF and RHD *(7)*.

Epidemiological factors

1. AGENT FACTORS

(a) AGENT : The onset of RF is usually preceded by a streptococcal sore throat. Of the streptococci, it is the group A streptococcus that has been incriminated as the causative agent. It has been suggested that not all strains of group A streptococci lead to RF; it is believed that there might be some strains with "rheumatogenic potential". The serotype that has attracted special emphasis is M type 5 which is frequently associated with RF *(8)*. All group A streptococci are sensitive to penicillin. Unfortunately, the group consists of a great number of immunologically different types with little cross immunity, defying all attempts to produce an effective vaccine. Recently the virus (coxsackie B–4) has been suggested as a causative factor and streptococcus acting as a conditioning agent. There are many gaps in our knowledge about the causative agent and underlying pathogenic mechanisms. (b) CARRIERS : Carriers of group A streptococcus are frequent, e.g., convalescent, transcient and chronic carriers. In view of the high carrier rate, their eradication is not even theoretically possible *(9)*.

2. HOST AND ENVIRONMENTAL FACTORS

(a) AGE : RF is typically a disease of childhood and adolescence (5–15 years) although it also occured in adults (20 per cent cases). Mention has already been made about the high incidence of "juvenile mitral stenosis" in India *(9, 10)*. The initial attack of RF occurs at a young age, progresses to valvular lesions faster and is associated with pulmonary arterial hypertension. The cause of the "juvenile" disease in India is not known. (b) SEX : The disease affects both sexes equally but prognosis is worse for females than for males. (c) IMMUNITY : An immunological basis for RF and RHD has been proposed. The most prevalent concept is the toxic–immunological hypothesis. According to this theory, group A streptococcal products have certain toxic products, and components of the streptococcus and of host tissues have an antigenic cross-relationship, leading to immunological processes that result in an attack of RF *(11)*. (d) SOCIO-ECONOMIC STATUS : RF is a social disease linked to poverty, overcrowding, poor housing conditions, inadequate health services, inadequate expertise of health-care providers and a low level of awareness of the disease in the community. It declines sharply when the standard of living is improved, but even in the most affluent countries, there are areas where the disease still exists. (e) HIGH-RISK GROUPS : The school-age children between 5 and 15 years; slum dwellers; and those living in a closed community (e.g., barracks).

Table 1 summarizes the effects of environmental factors on RF and RHD.

TABLE 1

Direct and indirect results of enviromental and health-system determinants on rheumatic fever and rheumatic heart disease

Determinants	Effects	Impact on RF and RHD burden
Socio-economic and environmental factors : (poverty, undernutrition, overcrowding, poor housing).	Rapid spread of group A streptococcal strains. Difficulties in accessing health care.	Higher incidence of acute streptococcal-pharyngitis and suppurative complications. Higher incidence of acute RF. Higher rates of recurrent attacks.
Health-system related factors : – shortage of resources for health care;	Inadequate diagnosis and treatment of streptococcal pharyngitis.	Higher incidence of acute RF and its recurrence.
– inadequate expertise of health-care providers;	Misdiagnosis or late diagnosis of acute RF.	Patients unaware of the first RF episode. More severe evolution of disease.
– Low-level awareness of the disease in the community.	Inadequate secondary prophylaxis and/or non-compliance with secondary prophylaxis.	Untimely initiation or lack of secondary prophylaxis. Higher rates of recurrent attacks with more frequent and severe heart valve involvement, and higher rates of repeated hospital admissions and expensive surgical interventions.

Source : *(12)*

Clinical features

(a) FEVER : Fever is present at the onset of acute illness and may be accompanied by profuse sweating. It may last for about 12 weeks or longer and has a tendency to recur. (b) POLYARTHRITIS: This occurs in 90 per cent of cases. Large joints like ankles, knees, elbows and wrists are involved; uncommonly smaller joints of hands and feet may be involved. The pain and swelling come on quickly and also subside spontaneously within 5–7 days. There is no residual damage to the joint. (c) CARDITIS : Occurs in 60–70 per cent of cases. It starts early in the course of RF. Moreover RHD may not be preceded by a clinically apparent attack of RF. All layers of the heart– pericardium, myocardium and the heart valves – are involved. The involvement of heart is manifested by tachycardia, cardiac murmurs, cardiac enlargement, pericarditis and heart failure. The most common ECG finding is the first degree AV block. (d) NODULES : Nodules below the skin tend to appear 4 weeks after the onset of RF. They are small, painless and non-tender. They last for a variable period of time and then disappear leaving no residual damage. (e) BRAIN INVOLVEMENT: This manifests as abnormal jerky purposeless movements of the arms, legs and the body. It gradually disappears leaving no residual damage. (f) SKIN : Various types of skin rash are known to occur. It is thus obvious that except carditis all other manifestations of RF do not cause permanent damage.

Diagnosis

The 2002–2003 WHO criteria for the diagnosis of RF and RHD are based on revised Jones criteria (Table 2) and facilitate the diagnosis of :

a. a primary episode of RF
b. recurrent attacks of RF in patients without RHD
c. recurrent attacks of RF in patients with RHD
d. rheumatic chorea
e. insidious onset rheumatic carditis
f. chronic RHD.

For the diagnosis of a primary episode of RF, it is recommended that the major and minor clinical manifestations of RF, the laboratory manifestations, and evidence of a preceding streptococcal infection should all continue according to the 1988 WHO recommendations. In the context of a preceding streptococcal infection, two major manifestations, or a combination of one major and two minor manifestations, provide reasonable evidence for a diagnosis of RF. WHO has continued to maintain that a diagnosis of a recurrence of RF in a patient with established RHD should be permitted on the basis of minor manifestations plus evidence of a recent streptococcal infection.

Prevention

Two preventive approaches are possible :

a. PRIMARY PREVENTION

The aim of primary prevention is to prevent the first attack of RF, by identifying all patients with streptococcal throat infection and treating them with penicillin. While this approach is theoretically simple, in practice, it is difficult to achieve and may not be feasible in many developing countries *(4)*. In order to prevent a single case of RHD, several thousand cases of streptococcal throat infection must be identified and treated. Many infections are inapparent or if apparent are not brought to the attention of the health services; even if they are reported, quick and reliable laboratory services are needed to confirm the diagnosis.

A viable approach is to concentrate on "high-risk" groups such as school-age children. They should be kept under

TABLE 2

2002–2003 WHO criteria for the diagnosis of rheumatic fever and rheumatic heart disease (based on the revised Jones criteria)

Diagnostic categories	Criteria
Primary episode of RF.[a]	Two major *or one major and two minor** manifestations **plus** evidence of a preceding group A streptococcal infection***.
Recurrent attack of RF in a patient **without** established rheumatic heart disease.[b]	Two major or one major and two minor manifestations **plus** evidence of a preceding group A streptococcal infection.
Recurrent attack of RF in a patient **with** established rheumatic heart disease.	Two minor manifestations **plus** evidence of a preceding group A streptococcal infection.[c]
Rheumatic chorea. Insidious onset rheumatic carditis.[b]	Other major manifestations or evidence of group A streptococcal infection not required.
Chronic valve lesions of RHD (patients presenting for the first time with pure mitral stenosis or mixed mitral valve disease and/or aortic valve disease).[d]	Do not require any other criteria to be diagnosed as having rheumatic heart disease.
* Major manifestations	– carditis – polyarthritis – chorea – erythema marginatum – subcutaneous nodules
** Minor manifestations	– clinical; fever, polyarthralgia – laboratory; elevated acute phase reactants (erythrocyte sedimentation rate or leukocyte count)
*** Supporting evidence of a preceding streptococcal infection within the last 45 days	– electrocardiogram; prolonged P-R interval – elevated or rising antistreptolysin-O or other streptococcal antibody, or – a positive throat culture, or – rapid antigen test for group A streptococci, or – recent scarlet fever.

a Patients may present with polyarthritis (or with only polyarthralgia or monoarthritis) and with several (3 or more) other minor manifestations, together with evidence of recent group A streptococcal infection. Some of these cases may later turnout to be rheumatic fever. It is prudent to consider them as cases of "probable rheumatic fever" (once other diagnoses are excluded) and advise regular secondary prophylaxis. Such patients require close follow-up and regular examination of the heart. This cautious approach is particularly suitable for patients in vulnerable age groups in high incidence settings.

b Infective endocarditis should be excluded.

c Some patients with recurrent attacks may not fulfil these criteria.

d Congenital heart disease should be excluded.

Source : *(12)*

surveillance for streptococcal pharyngitis. Ideally a sore throat should be swabbed and cultured. If streptococci are present, the child should be put on penicillin. Since facilities for throat swab culture are not easily available, it is justified to treat a sore throat with penicillin even without having the culture. For this purpose, a single intramuscular injection of 1.2 million units of benzathine benzyl penicillin for adults and 600,000 units for children is adequate, or oral penicillin (Penicillin V or Penicillin G) should be given for 10 days. This is the least expensive method of giving penicillin for eradication of streptococci from the throat. For patients with allergy to penicillin, erythromycin is the drug of choice. The MCH and school health services should be utilized for this purpose.

In short, the impossible logistics of primary prevention coupled with enormous financial constraints force us to concentrate on secondary prevention *(10)*.

b. SECONDARY PREVENTION

Secondary prevention (i.e., the prevention of recurrences of RF) is a more practicable approach, especially in developing countries. It consists in identifying those who have had RF and giving them one intramuscular injection of benzathine benzyl penicillin (1.2 million units in adults and 600,000 units in children) at intervals of 3 weeks *(12)*. This must be continued for at least 5 years or until the child reaches 18 years whichever is later. For patients with carditis (mild mitral regurgitation or healed carditis) the treatment should continue for 10 years after the last attack, or at least until 25 years of age, which ever is longer. More severe valvular disease or post-valve surgery cases need life-long treatment *(12)*. This prevents streptococcal sore throat and therefore recurrence of RF and RHD.

However, the crucial problem is one of patient compliance as penicillin prophylaxis is a long-term affair. Studies have shown that secondary prevention is feasible, inexpensive and cost-effective, when implemented through primary health care systems *(13)*.

c. NON-MEDICAL MEASURES

Non-medical measures for the prevention/control of RF are related to improving living conditions, and breaking the poverty–disease–poverty cycle. Improvements in socio-economic conditions (particularly better housing) will in the long term reduce the incidence of RF.

Objective evaluation of available data indicates that penicillin alone will not lead to effective control. Predictions suggest that many of the countries which suffer severe economic constraints will not be likely to be able to raise their standards of living in the foreseeable future to significantly alter the incidence of this disease *(9)*.

d. EVALUATION

In the evaluation of the programme, the prevalence of RHD in school children from periodic surveys of random samples is probably the best indicator. It is suggested that surveys should be carried out on samples of schools (not individuals) in the 6–14 years age group at 5–year intervals. The recommended sample size is 20,000 to 30,000 children depending upon the expected prevalence *(13)*.

CANCER

Cancer may be regarded as a group of diseases characterized by an (i) abnormal growth of cells (ii) ability to invade adjacent tissues and even distant organs, and (iii) the eventual death of the affected patient if the tumour has progressed beyond that stage when it can be successfully removed. Cancer can occur at any site or tissue of the body and may involve any type of cells.

The major categories of cancer are : *(a) Carcinomas,* which arise from epithelial cells lining the internal surfaces of the various organs (e.g. mouth, oesophagus, intestines, uterus) and from the skin epithelium; *(b) Sarcomas*, which arise from mesodermal cells constituting the various connective tissues (e.g. fibrous tissue, fat and bone); and *(c) Lymphomas, myeloma* and *leukaemias* arising from the cells of bone marrow and immune systems.

The term "primary tumour" is used to denote cancer in the organ of origin, while "secondary tumour" denotes cancer that has spread to regional lymph nodes and distant organs. When cancer cells multiply and reach a critical size, the cancer is clinically evident as a lump or ulcer localized to the organ of origin in early stages. As the disease advances, symptoms and signs of invasion and distant metastases become clinically evident *(1)*.

Problem statement

WORLD

In 2012, the worldwide burden of cancer rose to an estimated 14 million new cases per year, a figure expected to rise to 22 million annually within the next two decades. Over the same period, cancer deaths are predicted to rise from an estimated 8.2 million annually to 13 million per year. Globally, during 2012, the most common cancers diagnosed were those of the lung (1.8 million), breast (1.7 million) and colorectal (1.4 million). The most common causes of cancer deaths were cancer of lung (1.6 million), liver (0.8 million) and stomach (0.7 million).

As a consequence of growing and ageing populations, developing countries are disproportionately affected by the increasing numbers of cancers. More than 60 per cent of the worlds total cases occur in Africa, Asia, and Central and South America, and these regions account for about 70 per cent of the world's cancer deaths. Situation is made worse by the lack of early detection and access to treatment *(2)*.

The "Westernization" trends : As low human-development index (HDI) countries become more developed through rapid societal and economic changes, they are likely to become "westernized". As such, the pattern of cancer

incidence is likely to follow that seen in high HDI settings, with likely decline in cancer incidence rate of cervix uteri and stomach, and increasing incidence rates of breast, prostate and colorectal cancers. This westernization effect is a result of reduction in infection-related cancers and increase in cancers associated with reproductive, dietary and hormonal risk factors *(3)*.

Large variations in both cancer frequency and case fatality are observed, even in relation to the major forms of cancer in different regions of the world for men and women. Table 1 and 2 show the age standardized incidence and mortality of most common cancers in men and women worldwide.

For any disease, the relationship of incidence to mortality is an indication of prognosis. Similar incidence and mortality rates being indicative of an essentially fatal condition. Thus, lung cancer accounts for most deaths from cancer in the world (1.6 million) annually, since it is most invariably

Proportion (per 100,000)	592.0	661.4	626.7

* Age-standardized rate (W): A rate is the number of new cases or deaths per 100 000 persons per year. An age-standardized rate is the rate that a population would have if it had a standard age structure. Standardization is necessary when comparing several populations that differ with respect to age because age has a powerful influence on the risk of cancer.

Risk of getting or dying from the disease before age 75 (%) : The probability or risk of individuals getting/dying from cancer. It is expressed as the number of new born children (out of 100) who would be expected to develop/die from cancer before the age of 75, if they had cancer.(in the absence of other causes of death).

Source : *(4)*

associated with poor prognosis. On the other hand, appropriate intervention is often effective in avoiding fatal outcome following diagnosis of breast cancer. Hence this particular cancer, which rank second in terms of incidence, is not among the top three causes of death from cancer, which are respectively cancers of the lung, stomach, and liver.

The most conspicuous feature of the distribution of cancers between the sexes is the male predominance of lung cancer. Prostate, colorectal, stomach and liver cancer are also much more common in males (Table 1). Cancer of breast, colorectum, cervix, uteri, lung and stomach are common in females *(4)*. For the most part, differences in distribution between the sexes are attributable to differences in exposure to causative agents rather than to variation in the susceptibility. For other tumour types, including cancers of pancreas and colorectum, there is little difference in the sex distribution. Generally speaking, the relationship of incidence to mortality is not affected by sex. Thus for example, the prognosis following diagnosis of liver or pancreatic cancer is dismal for both males and females. Many other tumour types are more responsive to therapy, so that cancers of breast, prostate and uterine cervix are the cause of death in only a minority of patients diagnosed *(5)*.

The burden of cancer is distributed unequally between developed and developing countries, with particular cancer types exhibiting different patterns of distribution.

INDIA

In India, the National Cancer Registry Programme of the ICMR provides data on incidence, mortality and distribution of cancer from 25 population-based registries and 5 hospital based registries.

It is estimated that during the year 2012, 10.15 lac new cancer cases occurred in the country, of these 4.77 lac were males and 5.37 lac females. It gives an incidence rate of 92.4 per lac population. Same year about 6.83 lac persons died of cancer, (3.57 lac males and 3.26 lac females), a mortality rate of 69.7 per lac population. Table 3 and 4 show the age standardized incidence and mortality due to cancer in India.

The five most frequent cancers in men were cancer lung, lip and oral cavity, stomach, colorectum and other pharynx, and in women, cancer breast, cervix uteri, colorectum, ovary, lip and oral cavity. Cancer in males were mostly tobacco related. In women, cervical cancer is closely associated with poor genital hygiene, early consummation of marriage, multiple pregnancies, and contact with multiple sexual partners. It is also reported that breast cancer is proportionately on the increase in a few metropolitan areas of India. This appears to be related to late marriage, birth of the first child at a late age, fewer children, and shorter periods of breast-feeding, which are increasingly common practice among the educated urban women *(7)*.

Facilities for screening and proper management of cancer patients are grossly limited in India. More than two-thirds of cancer patients are already in an advanced and incurable stage at the time of diagnosis. Appropriate strategies are being developed, including creating public awareness about cancer, tobacco control and application of self or assisted screening technique for oral, cervical, and breast cancers.

Time trends

Few decades ago, cancer was the sixth leading cause of death in industrialized countries; today, it is the second leading cause of death. There are a number of reasons for this increase, the three main ones being a longer life expectancy, more accurate diagnosis and the rise in cigarette smoking, especially among males. The overall rates do not reflect the different trends according to the type of cancer. For example, there has been a large increase in lung cancer incidence and the stomach cancer has shown a declining trend in most developed countries for reasons not understood.

Cancer patterns

There are wide variations in the distribution of cancer throughout the world. That cancer of the stomach is very common in Japan, and has a low incidence in United States. The cervical cancer is high in Columbia and has a low incidence in Japan. In the South-East Asia Region of WHO, the great majority are cancers of the oral cavity and uterine cervix. These and other international variations in the

pattern of cancer are attributed to multiple factors such as environmental factors, food habits, lifestyle, genetic factors or even inadequacy in detection and reporting of cases.

Hospital data clearly indicates that the two organ sites most commonly involved are: (i) the uterine cervix in women, and (ii) the oropharynx in both sexes. These two sites represent approximately 50 per cent of all cancer cases. Both these cancers are predominantly environment related and have a strong socio-cultural relationship. It is also important to note that these two kinds of cancer are easily accessible for physical examination and amenable to early diagnosis by knowledge already available. i.e., good clinical examination and exfoliative cytology. The cure rate for these neoplasma is also very high if they are treated surgically at stages I and II. But unfortunately, in most cases, the patients present themselves to a medical facility when the disease is far advanced and is not amenable to treatment. This is the crux of the problem.

Causes of cancer

As with other chronic diseases, cancer has a multifactorial aetiology.

1. ENVIRONMENTAL FACTORS

Environmental factors are generally held responsible for 80 to 90 per cent of all human cancers. The major environmental factors identified so far include : *(a) TOBACCO* : Tobacco in various forms of its usage (e.g., smoking, chewing) is the major environmental cause of cancers of the lung, larynx, mouth, pharynx, oesophagus, bladder, pancreas and probably kidney. It has been estimated that, in the world as a whole, cigarette smoking is now responsible for more than one million premature deaths each year *(8)*. *(b) ALCOHOL* : Excessive intake of alcoholic beverages is associated with oesophageal and liver cancer. Some recent studies have suggested that beer consumption may be associated with rectal cancer *(9)*. It is estimated that alcohol contributed to about 3 per cent of all cancer deaths *(10)*. *(c) DIETARY FACTORS* : Dietary factors are also related to cancer. Smoked fish is related to stomach cancer, dietary fibre to intestinal cancer, beef consumption to bowel cancer and a high fat diet to breast cancer. A variety of other dietary factors such as food additives and contaminants have fallen under suspicion as causative agents. (Refer to chapter 10 for further details.) *(d) OCCUPATIONAL EXPOSURES* : These include exposure to benzene, arsenic, cadmium, chromium, vinyl chloride, asbestos, polycyclic hydrocarbons, etc. Many others remain to be identified. The risk of occupational exposure is considerably increased if the individuals also smoke cigarettes. Occupational exposures are usually reported to account for 1 to 5 per cent of all human cancers *(11)*. *(e) VIRUSES* : An intensive search for a viral origin of human cancers revealed that hepatitis B and C virus is causally related to hepatocellular carcinoma. The relative risk of Kaposi's sarcoma occurring in patients with HIV infection is so high that it was the first manifestation of the AIDS epidemic to be recognized. Non–Hodgkin's lymphoma, a cancer of the lymph nodes and spleen is a late complication of AIDS. The Epstein-Barr virus (EBV) is associated with 2 human malignancies, viz. Burkitt's lymphoma and nasopharyngeal carcinoma. *Cytomegalovirus* (CMV) is a suspected oncogenic agent and classical Kaposi's sarcoma is associated with a higher prevalence of antibodies to CMV. *Human papilloma virus* (HPV) is a chief suspect in cancer cervix. Hodgkin's disease is also believed to be of viral origin. The human T–cell leukaemia virus is associated with adult T–cell leukaemia/lymphoma in the United States and southern parts of Japan *(5, 12)*. *(f) PARASITES* : Parasitic infections may also increase the risk of cancer, as for example, schistosomiasis in Middle East producing carcinoma of the bladder. *(g) CUSTOMS, HABITS AND LIFESTYLES* : To the above causes must be added customs, habits and lifestyles of people which may be associated with an increased risk for certain cancers. The familiar examples are the demonstrated association between smoking and lung cancer, tobacco and betel chewing and oral cancer, etc *(13)*. *(h) OTHERS* : There are numerous other environmental factors such as sunlight, radiation, air and water pollution, medications (e.g., oestrogen) and pesticides which are related to cancer.

2. GENETIC FACTORS

Genetic influences have long been suspected. For example, retinoblastoma occurs in children of the same parent. Mongols are more likely to develop cancer (leukaemia) than normal children. However, genetic factors are less conspicuous and more difficult to identify. There is probably a complex interrelationship between hereditary susceptibility and environmental carcinogenic stimuli in the causation of a number of cancers.

Cancer control

Cancer control consists of a series of measures based on present medical knowledge in the fields of prevention, detection, diagnosis, treatment, after care and rehabilitation, aimed at reducing significantly the number of new cases, increasing the number of cures and reducing the invalidism due to cancer.

The basic approach to the control of cancer is through primary and secondary prevention. It is estimated that at least one-third of all cancers are preventable *(14)*.

1. PRIMARY PREVENTION

Cancer prevention until recently was mainly concerned with the early diagnosis of the disease (secondary prevention), preferably at a precancerous stage. Advancing knowledge has increased our understanding of causative factors of some cancers and it is now possible to control these factors in the general population as well as in particular occupational groups. They include the following :

(a) CONTROL OF TOBACCO AND ALCOHOL CONSUMPTION : Primary prevention offers the greatest hope for reducing the number of tobacco–induced and alcohol related cancer deaths. It has been estimated that control of tobacco smoking alone would reduce the total burden of cancer by over a million cancers each year *(15)*. *(b) PERSONAL HYGIENE:* Improvements in personal hygiene may lead to declines in the incidence of certain types of cancer, e.g., cancer cervix. *(c) RADIATION:* Special efforts should be made to reduce the amount of radiation (including medical radiation) received by each individual to a minimum without reducing the benefits. *(d) OCCUPATIONAL EXPOSURES* : The occupational aspects of cancer are frequently neglected. Measures to protect workers from exposure to industrial carcinogens should be enforced in industries. *(e) IMMUNIZATION* : In the case of primary liver cancer, immunization against hepatitis B virus and for prevention of cancer cervix immunization against HPV presents an exciting prospect. *(f) FOODS, DRUGS AND COSMETICS:* These should be tested for carcinogens.

(g) AIR POLLUTION : Control of air pollution is another preventive measure. *(h) TREATMENT OF PRECANCEROUS LESIONS :* Early detection and prompt treatment of precancerous lesions such as cervical tears, intestinal polyposis, warts, chronic gastritis, chronic cervicitis, and adenomata is one of the cornerstones of cancer prevention. *(i) LEGISLATION :* Legislation has also a role in primary prevention. For example, legislation to control known environmental carcinogens (e.g., tobacco, alcohol, air pollution). *(j) CANCER EDUCATION :* An important area of primary prevention is cancer education. It should be directed at "high-risk" groups. The aim of cancer education is to motivate people to seek early diagnosis and early treatment. Cancer organizations in many countries remind the public of the early warning signs ("danger signals") of cancer. These are :

a. a lump or hard area in the breast
b. a change in a wart or mole
c. a persistent change in digestive and bowel habits
d. a persistent cough or hoarseness
e. excessive loss of blood at the monthly period or loss of blood outside the usual dates
f. blood loss from any natural orifice
g. a swelling or sore that does not get better
h. unexplained loss of weight.

There is no doubt that the possibilities for primary prevention are many. Since primary prevention is directed at large population groups (e.g., high risk groups, school children, occupational groups, youth clubs), the cost can be high and programmes difficult to conduct. Primary prevention, although a hopeful approach, is still in its early stages. Major risk factors have been identified for a small number of cancers only and far more research is needed in that direction.

2. SECONDARY PREVENTION

Secondary prevention comprises the following measures :

i) CANCER REGISTRATION

Cancer registration is a *sine qua non* for any cancer control programme. It provides a base for assessing the magnitude of the problem and for planning the necessary services. Cancer registries are basically of two types : hospital–based and population based. *(a) HOSPITAL-BASED REGISTRIES:* The hospital-based registry includes all patients treated by a particular institution, whether in-patients or out-patients. Registries should collect the uniform minimum set of data recommended in the "WHO Handbook for Standardized Cancer Registers" *(16).* If there is a long-term follow-up of patients, hospital-based registries can be of considerable value in the evaluation of diagnostic and treatment programmes. Since hospital population will always be a selected population, the use of these registries for epidemiological purposes is thus limited. *(b) POPULATION-BASED REGISTRIES :* A right step is to set up a "hospital–based cancer registry" and extend the same to a "population-based cancer registry". The aim is to cover the complete cancer situation in a given geographic area. The optimum size of base population for a population based cancer registry is in the range of 2–7 million *(17).* The data from such registries alone can provide the incidence rate of cancer and serve as a useful tool for initiating epidemiological enquiries into causes of cancer, surveillance of time trends, and planning and evaluation of operational activities in all main areas of cancer control.

ii) EARLY DETECTION OF CASES

Cancer screening is the main weapon for early detection of cancer at a pre-invasive *(in situ)* or pre-malignant stage. Effective screening programmes have been developed for cervical cancer, breast cancer and oral cancer. Like primary prevention, early diagnosis has to be conducted on a large scale; however, it may be possible to increase the efficiency of screening programmes by focussing on high-risk groups. Clearly, there is no point in detecting cancer at an early stage unless facilities for treatment and after-care are available. Early detection programmes will require mobilization of all available resources and development of a cancer infrastructure starting at the level of primary health care, ending with complex cancer centres or institutions at the state or national levels.

iii) TREATMENT

Treatment facilities should be available to all cancer patients. Certain forms of cancer are amenable to surgical removal, while some others respond favourably to radiation or chemotherapy or both. Since most of the known methods of treatment have complementary effect on the ultimate outcome of the patient, multi-modality approach to cancer control has become a standard practice in cancer centres all over the world. In the developed countries today, cancer treatment is geared to high technology. For those who are beyond the curable stage, the goal must be to provide pain relief. A largely neglected problem in cancer care is the management of pain. The WHO has developed guidelines on relief of cancer pain *(18).* "Freedom from cancer pain" is now considered a right of cancer patients.

CANCER SCREENING

In the light of present knowledge, early detection and prompt treatment of early cancer and precancerous conditions provide the best possible protection against cancer for the individual and the community. Now a good deal of attention is being paid to screening for early detection of cancer. This approach, that is, cancer screening may be defined as the "search for unrecognized malignancy by means of rapidly applied tests".

Cancer screening is possible because : (a) in many instances, malignant disease is preceded for a period of months or years by a premalignant lesion, removal of which prevents subsequent development of cancer; (b) most cancers begin as localized lesions and if found at this stage a high rate of cure is obtainable; and (c) as much as 75 per cent of all cancers occur in body sites that are accessible.

METHODS OF CANCER SCREENING

(a) Mass screening by comprehensive cancer detection examination: A rapid clinical examination, and examination of one or more body sites by the physician is one of the important approaches for screening for cancer. *(b) Mass screening at single sites :* This comprises examination of single sites such as uterine cervix, breast or lung. *(c) Selective screening :* This refers to examination of those people thought to be at special risk, for example, parous women of lower socio-economic strata upwards of 35 years of age for detection of cancer cervix, chronic smokers for lung cancer, etc.

1. Screening for cancer cervix

Screening for cervical cancer has become an accepted clinical practice. The prolonged early phase of cancer in situ can be detected by the Pap smear. Current policy suggests that all women should have a Pap test (cervical smear) at the beginning of sexual activity, and then every 3 years thereafter *(19)*. A periodic pelvic examination is also recommended. Organized population based screening programmes have reduced the incidence and mortality from cervical cancer in many developed countries.

However, screening for cancer cervix using Pap smear requires excessive resources in terms of laboratories, equipments and trained personnels. This has led to search for an alternative screening method that can be more cost-effective. Visual inspection based screening tests such as visual inspection with 5 per cent acetic acid (VIA), VIA with magnification (VIAM), and visual inspection post application of Lugol's iodine (VILI) are some of the alternative screening tests, which have been studied for their effectiveness in India. Sensitivity of VIA tends to be similar to cytology based screening. It is easy to carry out and easy to train appropriate health workers *(20)*.

The present strategy is to screen women using visual inspection after application of freshly prepared 5 per cent acetic acid solution (5 ml of glacial acetic acid mixed with 95 ml distilled water). Detection of well-defined opaque acetowhite lesions close to the squamo-columnar junction, well defined circum-orificial acetowhite lesion or dense acetowhitening of ulceroproliferative growth on the cervix constiute a positive VIA or VIAM. The test is followed by a single visit approach for further investigation and management at district hospital. The management at district hospital is planned in such a way that the treatment based on colposcopy is offered in the same visit. Pap smear and biopsy are the investigations that are done to ensure that there are cytological and histopathological back-up for the interventions *(20)*.

Intensive information, education and communication activities are required to sensitize the community about the significance of the disease and its early detection through screening.

2. Screening for breast cancer

There is evidence that screening for breast cancer has a favourable effect on mortality from breast cancer. The basic techniques for early detection of breast cancer are : (a) breast self-examination (BSE) by the patient (b) palpation by a physician (c) thermography, and (d) mammography.

All women should be encouraged to perform breast self-examination. Breast cancers are more frequently found by women themselves than by a physician during a routine examination. Although the effectiveness of BSE has not been adequately quantified, it is a useful adjuvant to early case detection. In many countries, BSE will probably be the only feasible approach to wide population coverage for a long time to come. *Palpation* is unreliable for large fatty breasts. *Thermography* has the advantage that the patient is not exposed to radiation. Unfortunately, it is not a sensitive tool. *Mammography* is most sensitive and specific in detecting small tumours that are sometimes missed on palpation. The use of mammography has three potential drawbacks: (i) exposure to radiation. This may amount to a dose of 500 milliroentgen compared to a 30–40 milliroentgen dose received in chest X-ray. Therefore, there has been concern about exposure to radiation from repeated mammographies and the risk of breast cancer developing as a result (ii) mammography requires technical equipment of a high standard and radiologists with very considerable experience – these two factors limit its more widespread use for mass screening purposes, and (iii) biopsy from a suspicious lesion may end up in a false-positive in as many as 5–10 cases for each case of cancer detected.

Although recent evidence points to the superiority of mammography over clinical examination in terms of sensitivity and specificity *(21)*, medical opinion is against routine mammography on the very young. Women under 35 years of age should not have X-rays unless they are symptomatic or a family history of early onset of breast cancer *(22)*.

3. Screening for lung cancer

At present there are only two techniques for screening for lung cancer, viz. chest radiograph and sputum cytology. Mass radiography has been suggested for early diagnosis at six monthly intervals, but the evidence in support of this is not convincing. So it is not recommended. It is doubtful whether the disease satisfies the criteria of suitability for screening (see chapter 4).

EPIDEMIOLOGY OF SELECTED CANCERS

1. Oral cancer

Oral cancer is one of the ten most common cancers in the world. Its high frequency in Central and South East Asian countries (e.g., India, Bangladesh, Sri Lanka, Thailand, Indonesia, Pakistan) has been well documented. It is estimated that during the year 2012, about 1.98 lac new cases and 98,000 deaths occurred worldwide, with a mortality rate of 2.1 per lac population *(4)*.

PROBLEM IN INDIA

For the year 2012, with estimated incidence of 10.1 cases per 100,000 population for males and 4.3 per 100,000 population in females, oral cancer is a major problem in India. The estimated mortality is about 6.7 per 100,000 in males and 3.0 per 100,000 in females. During the year, 77,003 new cases occurred in the country with 52,067 deaths due to oral cancer *(4)*.

EPIDEMIOLOGICAL FEATURES

(a) Tobacco : Approximately 90 per cent of oral cancers in South East Asia are linked to tobacco chewing and tobacco smoking. During 1966–1977, a large epidemiological survey was carried out in different parts of the country. In this 10–year follow-up study of 30,000 individuals in the three districts of Ernakulam (Kerala), Srikakulam (Andhra), and Bhavnagar (Gujarat), the results indicated that (i) oral cancer and precancerous lesions occurred almost solely among those who smoked or chewed tobacco, and (ii) oral cancer was almost always preceded by some type of precancerous lesion *(24, 25)*. The case about tobacco is further strengthened by the findings that the cancer almost always occurred on the side of the mouth where the tobacco quid was kept *(23)*, and the risk was 36 times higher than for non–chewers if the quid was kept in the mouth during sleep *(26)*.

(b) Alcohol : Data indicates that oral cancer can also be caused by high concentrations of alcohol, and that alcohol appears to have a synergistic effect in tobacco users *(23)*.

(c) Pre-cancerous stage : The natural history of oral cancer shows that often a precancerous stage precedes the development of cancer. The pre-cancerous lesions (leukoplakia, erythroplakia) can be detected for upto 15 years prior to their change to an invasive carcinoma *(23)*. Intervention at this stage may result in regression of the lesion.

(d) High-risk groups : These include tobacco chewers and smokers, bidi smokers, people using tobacco in other forms such as betel quid; people who sleep with the tobacco quid in the mouth *(27)*.

(e) Cultural patterns : In studying the tobacco habits in developing countries, indigenous forms of smoking, as well as chewing, which are characteristic of certain regions have to be taken into account *(8)*. Tobacco is smoked in the form of manufactured cigarettes. The indigenous forms of smoking are : *bidi, chutta* (cigar), *chilum, hookah* (hubble–bubble). Tobacco in powdered form is inhaled as snuff.

The most common form of tobacco chewing in India is the betel quid which usually consists of the betel leaf, arecanut, lime and tobacco. It is common for the poorer people to rub with the thumb flakes of sun-dried tobacco and slaked lime in the palm of their left hand until the desired mixture is obtained. The mixture *(khaini)* is then put into the mouth in small amounts and at frequent intervals during the day and slowly sucked and swallowed after dilution with saliva.

Cancer of the oral cavity is also very prevalent in Central Asian districts of USSR, where people chew "nass" or "nasswar" – a mixture of tobacco, ashes, lime and cotton-seed oil.

Another type of cancer common in the eastern coastal regions of Andhra Pradesh state in India is the epidermoid carcinoma of the hard palate. It is associated with the habit of reverse smoking of cigar *(chutta)*, i.e., smoking with the burning end inside the mouth *(28)*.

PREVENTION

a. PRIMARY PREVENTION

Oral cancer is amenable to primary prevention. If the tobacco habits are eliminated from the community, a great deal of reduction in the incidence of oral cancer can be achieved. This requires intensive public education and motivation for changing lifestyles supported by legislative measures like banning or restricting the sale of tobacco.

b. SECONDARY PREVENTION

Oral cancers are easily accessible for inspection allowing early detection. If detected early, possibly at the precancerous stage, they can be treated or cured. The precancerous lesions can be detected for up to 15 years, prior to their change to an invasive carcinoma. Leukoplakia can be cured by cessation of tobacco use. The main treatment modalities that offer hope are surgery and radiotherapy *(29)*. In developing countries over 50 per cent of oral cancers are detected only after they have reached an advanced stage *(14)*.

The primary health care workers (village health guides, and multi-purpose workers) are in a strategic position to detect oral cancers at an early stage during home visits. They can prove to be a vital link and a key instrument in the control of oral cancer in developing countries *(30)*.

2. Cancer of the cervix

This is the second most common cancer among women worldwide, with an estimated 527,624 new cases and 265,653 deaths with overall incidence: mortality ratio of 52 per cent *(4)*. Developing countries, where it is often the most common cancer among women, account for 88 per cent of cases. Wide variations in incidence and mortality from the disease exist between countries. Cases and deaths have declined markedly in the last 40 years in most industrialized countries, partly owing to a reduction in risk factors, but mainly as a result of extensive screening programmes. More limited improvements have been observed in developing countries, where persistently high rates tend to be the rule *(1)*.

In India, cancer of the cervix is the second most common number one killer cancer among women. It is estimated that during 2012, 122,644 new cases of cancer cervix occurred in the country (incidence rate of 22 per lac population) and about 67,477 women died of the disease (mortality rate of 12.4 per lac population). It comes to 20.7 per cent of all cancer deaths in women and about 9.9 per cent of total cancer deaths in the country *(6)*.

NATURAL HISTORY

(a) The disease: Cancer cervix seems to follow a progressive course from epithelial dysplasia to carcinoma *in situ* to invasive carcinoma (Fig. 1). There is good evidence that carcinoma *in situ* persists for a long time, more than 8 years on an average *(19)*. The proportion of cases progressing to invasive carcinoma from preinvasive stage is not known – it may average 15 to 20 years or longer *(31)*. The duration of the preinvasive stage is also not known. There is evidence that some *in situ* cases will spontaneously regress without treatment. Once the invasive stage is reached, the disease spreads by direct extension into the lymph nodes and pelvic organs.

Normal epithelium	↔	Dysplasia	↔	Cancer *in situ*	→	Invasive cancer

FIG. 1
Hypothetical model of the natural history of cancer cervix

(b) Causative agent : There is evidence pointing to Human papilloma virus (HPV) – sexually transmitted – as the cause of cervical cancer *(32)*. This virus was once supposed to produce only vegetant warts, but now acknowledged as responsible for a much wider clinical and subclinical lesions. The virus is found in more than 95% of the cancers. Current evidence suggests that the virus is a necessary but not sufficient cause of the disease and researchers are now trying to define other co-factors.

RISK FACTORS

(a) AGE : Cancer cervix affects relatively young women with incidence increasing rapidly from the age of 25 to 45, then levelling off, and finally falling again. *(b) GENITAL WARTS :* Past and/or present occurrence of clinical genital warts has been found to be an important risk factor *(32)*. *(c) MARITAL STATUS :* Cases are less likely to be single, more likely to be widowed, divorced or separated and having multiple sexual partners. The fact that cancer of the cervix is very common in prostitutes and practically unknown among virgins suggests that the disease could be linked with sexual intercourse. *(d) EARLY MARRIAGE:* Early marriage, early coitus, early childbearing and repeated

childbirth have been associated with increasing risk. *(e) ORAL CONTRACEPTIVE PILLS :* There is renewed concern about the possible relationship between pill use and the development of invasive cervical cancer *(33)*. A recent WHO study finds an increased risk with increased duration of pill use and with the use of oral contraceptives high in oestrogen *(34)*. *(f) SOCIO-ECONOMIC CLASS :* Cancer cervix is more common in the lower socio-economic groups reflecting probably poor genital hygiene.

PREVENTION AND CONTROL

(a) PRIMARY PREVENTION : Until the causative factors are more clearly understood, there is no prospect of primary prevention of the disease *(31)*. It may be that with improved personal hygiene and birth control, cancer of the cervix uteri will show the same decline in developing countries as already experienced in most of Europe and North America *(35)*.

(b) SECONDARY PREVENTION : This rests on early detection of cases through screening and treatment by radical surgery and radiotherapy. The 5–year survival rate is virtually 100 per cent for carcinoma *in situ*, 79 per cent for local invasive disease and 45 per cent for regional invasive disease *(19)*. Cancer cervix is difficult to cure once symptoms develop and is fatal if left untreated. Prognosis is strongly dependent upon the stage of disease at detection and treatment.

3. Breast cancer

Breast cancer is by far the most frequent cancer among women, with an estimated 1.67 million new cases diagnosed in 2012 (about 25 per cent of all cancers). It is now the most common cancer both in developed (794,000 cases) and developing regions (883,000 cases). Incidence rates vary from 27 per lac women in Eastern Africa to 98 per lac women in Western Europe. The range of mortality rate is similar, approximately 6–20 per lac, because of the more favourable survival of breast cancer cases in developed countries. As a result, breast cancer ranks as the fifth cause of death from cancer, but it is still the most frequent cause of cancer death in women in developing regions *(36)*.

It is estimated that during the year 2012, about 144,937 new cases of breast cancer in women occurred in India, which accounts for 27.0 per cent of all malignant cases (an incidence rate of 25.8 per lac population). About 70,218 women died of this cancer (mortality of 21.5 per cent of all cancer cases), mortality rate being 12.7 per lac population, ranking number one killer in women *(6)*.

RISK FACTORS

The established risk factors of breast cancer include the following:

(a) AGE : Breast cancer is uncommon below the age of 35, the incidence increasing rapidly between the ages of 35 and 50. A slight bimodal trend in the age distribution has been observed *(37)* with a dip in incidence at the time of menopause. A secondary rise in frequency often occurs after the age of 65. Women who developed their first breast cancer under the age of 40, had three times the risk of developing a second breast cancer than did those who developed their first cancer after the age of 40 *(38)*. Indeed the aetiologies of pre-menopausal and post-menopausal breast cancer appears to be different *(39)*.

Breast cancer is not only infrequent in Indian women, but also it occurs in them a decade earlier than in Western women – the mean age of occurrence is about 42 in India, as compared to 53 in the white women.

(b) FAMILY HISTORY : The risk is high in those with a positive family history of breast cancer, especially if a mother or sister developed breast cancer when premenopausal.

(c) PARITY : MacMahon, *et al (40)* in their international case–control study found that the risk of breast cancer is directly related to the age at which women bear the first child. An early first, full-term pregnancy seems to have a protective effect. Those whose first pregnancy is delayed to their late thirties are at a higher risk than multiparous women. Unmarried women tend to have more breast tumours than married single women, and nulliparous women had the same risk.

(d) AGE AT MENARCHE AND MENOPAUSE : Early menarche and late menopause are established risk factors *(41)*. The risk is reduced for those with a surgically induced menopause. Forty or more years of menstruation doubles the risk of breast cancer as compared with 30 years *(42)*.

(e) HORMONAL FACTORS : The association of breast cancer with early menarche and late menopause suggests that ovary appears to play a crucial role in the development of breast cancer. Evidence suggests that both elevated oestrogen as well as progesterone are important factors in increasing breast cancer risk *(43)*. In short, hormones appear to hold the key to the understanding of breast cancer.

(f) PRIOR BREAST BIOPSY : Prior breast biopsy for benign breast disease is associated with an increased risk of breast cancer.

(g) DIET : Current aetiological hypotheses suggest that cancer of the breast is linked with a high fat diet and obesity. It is not known how dietary fat influences breast cancer risk at a cellular level *(43)*.

(h) SOCIO-ECONOMIC STATUS : Breast cancer is common in higher socio-economic groups. This is explained by the risk factor of higher age at first birth.

(i) OTHERS : *(i) Radiation :* An increased incidence of breast cancer has been observed in women exposed to radiation. *(ii) Oral contraceptives :* Oral contraceptive appears to have little overall effect on breast cancer, although prolonged use of oral pills before the first pregnancy or before the age of 25 may increase the risk in younger women *(44)*.

PREVENTION

a. PRIMARY PREVENTION

Current knowledge of the aetiology of breast cancer *(35)* offers little prospect of primary prevention. However, the aim should be towards elimination of risk factors discussed above and promotion of cancer education. The average age at menarche can be increased through a reduction in childhood obesity, and an increase in strenuous physical activity; and the frequency of ovulation (after menarche) decreased by an increase in strenuous physical activity *(45)*. There is also good reason for reducing fat intake in the diet.

b. SECONDARY PREVENTION

Breast screening leads to early diagnosis of breast cancer,

which in turn influences treatment and, hopefully, mortality. An important component of secondary prevention is follow-up, i.e., to detect recurrence as early as possible; to detect cancer in the opposite breast at an early stage; and to generate research data that might be useful *(39)*.

No major improvement in survival rates has yet been shown by current treatment modalities. Some cases progress rapidly even if diagnosed at an apparently early stage, others surviving for 20 years even after metastatic spread. However, in general, the removal of the tumour early is more likely to be curative than removal at a later stage *(29)*.

4. Lung cancer

MAGNITUDE OF THE PROBLEM

Lung cancer has been known in industrial workers from the late 19th century. It came into prominence as a public health problem in the Western world in 1930s – at first in men, and later (in 1960s) among women *(46)*, and has followed the increasing adoption of cigarette smoking first by men and later by women. According to WHO reports, between 1960 and 1980, the death rate due to lung cancer increased by 76 per cent in men and by 135 per cent in women *(47, 27)*. In countries where cigarette smoking has only recently begun to be widely adopted, lung cancer deaths still remain low, but it may be expected that they will rise soon. In others, such as Poland, where the use of cigarettes began earlier, the rise is already occurring. The total burden of lung cancer in any country is directly related to the amount and duration of cigarette smoking.

Lung cancer has been the most common cancer in the world for several decades, and by 2012, there were an estimated 1.82 million new cases, representing 13.0% of all new cancers. It was also the most common cause of death from cancer, with 1.58 million deaths (19.4% of the total).

A majority of the cases now occur in the developing countries (55%). Lung cancer is still the most common cancer in men worldwide (16.5% of the total). In females, incidence rates are generally lower, but worldwide, lung cancer is now the fourth most frequent cancer of women (8.5% of all cancers) and the second most common cause of death from cancer (12.8% of the total). The highest incidence rate is observed in Northern America (where lung cancer is now the second most frequent cancer in women), and the lowest in Middle Africa (15th most frequent cancer).

Because of its high fatality (the ratio of mortality to incidence is 0.86) and the lack of variability in survival in developed and developing countries, the highest and lowest mortality rates are estimated in the same regions, both in men and women *(48)*.

The estimates for the year 2012 for India are about 70,276 new lung cancer cases of which 53,728 were men and 16,547 women (incidence rate of 6.9 per lac population). About 63,759 persons died of lung cancer during the same year, of which 48,697 were men and 15,062 women (a mortality rate of 6.3 per lac population). It accounts for 6.9 per cent of all malignancies and 9.3 per cent of all deaths due to cancer in the country *(6)*.

EPIDEMIOLOGICAL FEATURES

a. AGE AND SEX

About a third of all lung cancer deaths occur below the age of 65. In many industrialized countries, the incidence of lung cancer is at present increasing more in females than in males *(49)*.

b. RISK FACTORS

(i) Smoking : Tobacco smoking was first suggested as a cause of lung cancer in the 1920s. Subsequent studies proved the causal relationship between cigarette smoking and lung cancer. Two studies in India showed that the lung cancer risk for cigarette smokers is 8.6 times the risk for non-smokers *(50, 51)*. The risk is strongly related to the number of cigarettes smoked, the age of starting to smoke and smoking habits, such as inhalation and the number of puffs and the nicotine, the tar content and the length of cigarettes. Those who are highly exposed to "passive smoking" (somebody else's smoke) are at an increased risk of developing lung cancer. It has been calculated that in countries where smoking has been a widespread habit, it is responsible for 90 per cent of lung cancer deaths *(52)*. The strongest evidence that cigarette smoking is responsible for lung cancer is the incidence reduction that occurs after cessation of smoking. This has been convincingly demonstrated in a 20–year prospective study on male British doctors *(53)*.

The most noxious components of tobacco smoke are tar, carbon monoxide and nicotine. The carcinogenic role of tar is well established. Nicotine and carbon monoxide, particularly, contribute to increased risk of cardiovascular diseases through enhancement of blood coagulation in the vessels, interference with myocardial oxygen delivery, and reduction of the threshold for ventricular fibrillation *(8)*.

A study in India has shown that there is no difference between the tar and nicotine delivery of the filter and non-filter cigarettes smoked in India, so that a filter gives no protection to Indian smokers. The "king-size" filter cigarettes deliver more tar and nicotine than ordinary cigarettes. *Bidi* smoking appears to carry a higher lung cancer risk than cigarette smoking owing to the higher concentration of carcinogenic hydrocarbons in the smoke *(8)*.

(ii) Other factors : Besides cigarette smoking, there are other factors which are implicated in the aetiology of lung cancer. These include air pollution, radioactivity, and occupational exposure to asbestos, arsenic and its compounds, chromates, particles containing polycyclic aromatic hydrocarbons and certain nickel–bearing dusts. A number of studies have shown an interaction between smoking and asbestos exposure.

PREVENTION

1. PRIMARY PREVENTION

In lung cancer control, primary prevention is of greatest importance. The most promising approach is to control the "smoking epidemic", because 80 to 90 per cent of all cases of lung cancer in developed countries are due to smoking of cigarettes *(50)*. Methods of controlling the smoking epidemic have been described by the WHO expert committees in their reports *(49, 53)*. Broadly these methods include :

a. Public information and education
b. Legislative and restrictive measures
c. Smoking cessation activities
d. National and international coordination

a. Public information and education

The need of the hour is to create public awareness about the hazards of smoking through mass media. The target population should be the entire population with greater emphasis laid on young people and school children. Nothing less than a national anti-smoking campaign will be needed to change human behaviour or life styles associated with smoking. Curtailment of smoking must be an essential part of national health policy.

b. Legislative and restrictive measures

Legislation and restrictive measures have been suggested in the following areas : control of sales promotion; health warnings on cigarette packets and advertisements; product description showing yield of harmful substances; imposition of upper limits for harmful substances in smoking materials; taxation; sales restrictions; restriction on smoking in public places; restriction on smoking in places of work, etc. *(52)*.

The Government of India have provided legislative support to the anti-smoking campaign. "The Cigarettes (Regulation of production, supply and distribution) Act of 1975" which came into force from 1 April 1976, requires all manufacturers or persons trading in cigarettes to display prominently the statutory warning "Cigarette Smoking is Injurious to Health" on all cartons or packets of cigarettes that are put on sale. Most of the State Governments in India have promulgated laws prohibiting smoking in closed areas, e.g., cinemas, buses, educational institutions, and hospitals. Again in the year 2003, a comprehensive tobacco control legislation titled "The Cigarettes And Other Tobacco Products (Prohibition of Advertisement and Regulation of Trade and Commerce, Production, Supply and Distribution) Act 2003 was passed by the Govt of India. Refer to chapter 7 "National cancer control programme" for the details.

c. Smoking cessation activities

Research continues on different methods of smoking cessation. In all countries well over 90 per cent of those who give up smoking do so of their own volition, i.e., without use of any specific therapy. The basic role of most treatments for smoking cessation would be to relieve the smoker of "abstinence symptoms" (e.g., sleeplessness, craving for smoking, dizziness, constipation, etc). The report of the WHO expert committee *(52)* on smoking control contains information on specific smoking cessation methods such as smoking cessation clinics, nicotine substitutes, hypnosis, etc.

d. National and International coordination

Since smoking is a worldwide epidemic, it requires coordinated political and non-political approaches at local, national and international levels to contain the smoking epidemic.

2. SECONDARY PREVENTION

This rests on early detection of cases and their treatment. At present, there are only two procedures capable of detecting presymptomatic, early-stage lung cancer. These are the chest X-ray and sputum cytology. But screening for early–stage lung cancer is less attractive, more expensive and appears to have less potential for reducing mortality than primary prevention. Therefore, mass screening for lung cancer is not recommended as a routine public health policy *(49)*.

Efforts to find effective treatment for lung cancer have met with only limited success. For untreated patients, the median survival is 2 to 3 months, compared to 10–14 months for patients receiving combined chemotherapy. In view of these limitations, primary prevention merits greater attention. An important part of treatment is relief of pain so that each dying patient has the right to spend his last days as pain-free as possible.

5. Stomach cancer

About one million new cases of stomach cancer were estimated to have occurred in 2012 (6.8% of the total), making it currently the fifth most common malignancy in the world, behind cancers of the lung, breast, colorectum and prostate. More than 70% (677,000) of cases occur in developing countries (456,000 in men, 221,000 in women), and half the world total occurs in Eastern Asia (mainly in China).

Stomach cancer is the third leading cause of cancer death in both sexes worldwide (8.8% of the total). The highest mortality rates are estimated in Eastern Asia (24 per 100,000 in men, 9.8 per 100,000 in women), the lowest in Northern America (2.8 and 1.5 respectively) *(54)*.

About 63,097 new cases of stomach cancer were estimated to have occurred in India during 2012 (an incidence rate of 6.2 cases per lac population) of these 43,386 were in men and 19,711 in women. About 59,041 persons died of stomach cancer (mortality rate of 5.7 per lac population) of which 40,721 were men and 18,320 women *(6)*.

The constant decline of stomach cancer in industrialized countries is linked to improved food preservation practices; better nutrition more rich in vitamins from fresh vegetables and fruits; and less consumption of preserved, cured and salted foods. Infection with the bacterium *Helicobacter pylori* contributes to the risk, probably by interacting with the other factors.

Symptoms are non-specific, which explains why most of the cases are diagnosed when the disease is at an advanced stage. Patients may complain of weight loss, fatigue or gastric discomfort. Diagnosis is performed by barium X-rays and with biopsy.

This cancer is treated by surgical removal of the tumour, with or without adjuvant chemotherapy.

Stomach cancer cases have a generally poor survival prognosis, averaging no more than 20% survival after five years. If the tumour is localized to the stomach, 60% of patients survive five years or more. However, only 18% of all cases are diagnosed at this early stage. Screening by photofluoroscopy has been widespread in Japan since the late 1960s and mortality rates are declining. It is unclear whether this trend can be attributed to mass screening alone.

DIABETES MELLITUS

Once regarded as a single disease entity, diabetes is now seen as a heterogeneous group of diseases, characterized by a state of chronic hyperglycemia, resulting from a diversity of aetiologies, environmental and genetic, acting jointly *(1).* The underlying cause of diabetes is the defective production or action of insulin, a hormone that controls glucose, fat and amino acid metabolism. Characteristically, diabetes is a long-term disease with variable clinical manifestations and progression. Chronic hyperglycaemia, from whatever cause, leads to a number of complications – cardiovascular, renal, neurological, ocular and others such as intercurrent infections.

Classification

The classification adopted by WHO *(2)* is given in Table 1.

TABLE 1
Clinical classification of diabetes mellitus

1. Diabetes mellitus (DM)
i) Type 1 or Insulin-dependent diabetes mellitus
ii) Type 2 or Non–insulin dependent diabetes mellitus
iii) Malnutrition-related diabetes mellitus (MRDM)
iv) Other types (secondary to pancreatic, hormonal, drug-induced, genetic and other abnormalities)
2. Impaired glucose tolerance (IGT)
3. Gestational diabetes mellitus (GDM)

Source *(2)*

Type 1 diabetes (Insulin-dependent diabetes mellitus) is the most severe form of the disease. Its onset is typically abrupt and is usually seen in individuals less than 30 years of age. It is lethal unless promptly diagnosed and treated. This form of diabetes is immune-mediated in over 90 per cent of cases and idiopathic in less than 10 per cent cases. The rate of destruction of pancreatic β cell is quite variable. Rapid in some individuals and slow in others. Type 1 diabetes is usually associated with ketosis in its untreated state. It occurs mostly in children, the incidence is highest among 10–14 year old group, but occasionally occur in adults. It is catabolic disorder in which circulating insulin is virtually absent, plasma glucagon is elevated, and the pancreatic β cells fail to respond to all insulinogenic stimuli. Exogenous insulin is therefore required to reverse the catabolic state, prevent ketosis, reduce the hyperglucagonaemia, and reduce blood glucose *(3).*

Type 2 diabetes is much more common than type 1 diabetes. It is often discovered by chance. It is typically gradual in onset and occurs mainly in the middle-aged and elderly, frequently mild, slow to ketosis and is compatible with long survival if given adequate treatment. Its clinical picture is usually complicated by the presence of other disease processes.

Impaired glucose tolerance (IGT) describes a state intermediate– "at-risk" group – between diabetes mellitus and normality. It can only be defined by the oral glucose tolerance test (see Table 3).

Insulin resistance syndrome (Syndrome X)

In obese patients with type 2 diabetes, the association of hyperglycaemia, hyperinsulinaemia, dyslipidaemia and hypertension, which leads to coronary artery disease and stroke, may result from a genetic defect producing insulin resistance, with the latter being exaggerated by obesity. It has been proposed that insulin resistance predisposes to hyperglycaemia, which results in hyperinsulinaemia (which may or may not be of sufficient magnitude to correct the hyperglycaemia) and this excessive insulin level then

contributes to high levels of triglycerides and increased sodium retention by renal tubules, thus inducing hypertension. High levels of insulin can stimulate endothelial proliferation to initiate atherosclerosis *(3)*.

Problem statement

WORLD

Diabetes is an "iceberg" disease. Although increase in both the prevalence and incidence of type 2 diabetes have occurred gloablly, they have been especially dramatic in societies in economic transition, in newly industrialized countries and in developing countries. Currently the number of cases of diabetes worlwide is estimated to be around 347 million, of these more than 90 per cent are type 2 diabetes. In 2008, an estimated 1.2 million people died from consequences of high blood sugar *(4)*. More than 80 per cent diabetes deaths occur in low and middle income countries.

The apparent prevalence of hyperglycaemia depends on the diagnostic criteria used in epidemiological surveys. The global prevalence of diabetes in 2008 was estimated to be 10% in adults aged 25+ years. The prevalence of diabetes was highest in the Eastern Mediterranean Region and the Region of the Americas (11% for both sexes) and lowest in the WHO European and Western Pacific Regions (9% for both sexes). The magnitude of diabetes and other abnormalities of glucose tolerance are considerably higher than the above estimates if the categories of 'impaired fasting' and 'impaired glucose tolerance' are also included. The estimated prevalence of diabetes was relatively consistent across the income groupings of countries. Low-income countries showed the lowest prevalence (8% for both sexes), and the upper-middle-income countries showed the highest (10% for both sexes) *(5)*.

Unfavourable modification of lifestyle and dietary habits that are associated with urbanization are believed to be the most important factors for the development of diabetes. The prevalence of diabetes is approximately twice in urban areas than in rural population.

A bulk of evidence from studies on migrants indicates that the ethnic, presumably genetic, vulnerability of Asians manifests into diabetes when subjected to unfavourable life-styles. Population-based surveys completed recently in Bangladesh, India and Indonesia have shown considerable increase in the prevalence rate of the disease in both urban and rural dwellers when compared to results obtained earlier.

Diabetic patients, if undiagnosed or inadequately treated, develop multiple chronic complications leading to irreversible disability and death. Coronary heart disease and stroke are more common in diabetics than in the general population. Microvascular complications like diabetic renal disease and diabetic retinopathy and neuropathy are serious health problems resulting in deterioration of the quality of life and premature death. In fact, diabetes is listed among the five most important determinants of the cardiovascular disease epidemic in Asia. Lower limb amputation are at least 10 times more common in diabetic than in non-diabetic individuals in developed countries, more than half of all non-traumatic lower limb amputations are due to diabetes *(5)*. Metabolic disorders in pregnant diabetic women as well as those caused by gestational diabetes (diabetes diagnosed for the first time during pregnancy) pose a high health risk, to both the mother and foetus.

Unfortunately, there is still inadequate awareness about the real dimension of the problem among the general public. There is also a lack of awareness about the existing interventions for preventing diabetes and the management of complications. Inadequacies in primary health care systems, which are not designed to cope with the additional challenges posed by the chronic non-communicable diseases, result in poor detection of cases, suboptimal treatment and insufficient follow-up leading to unnecessary disabilities and severe complications, often resulting in early death.

The age-adjusted mortality rates among the people with diabetes are 1.5 to 2.5 times higher than in the general population *(6)*. In Caucassian population, much of the excess mortality is attributable to cardiovascular disease, especially coronary heart disease; amongst Asian and American Indian population, renal disease is a major contributor *(6)*; whereas in some developing societies, infections are an important cause of death. It is conceivable that the decline in mortality due to coronary heart disease which has occurred in many affluent countries may be halted or even reversed if rates of type 2 diabetes continue to rise. This may occur if the coronary risk factors associated with diabetes increase to the extent that the risk they mediate outweighs the benefit accrued from improvements in conventional cardiovascular risk factors, and the improved care of patients with established cardiovascular disease *(6)*.

In addition to non-insulin dependent diabetes, which is rather silent, chronic, often unidentified killer mostly among the adult population, the insulin dependent form of the disease (type 1) makes an even more dramatic appearance in affected children. They develop symptoms of ketoacidosis and often die, since the majority do not have access to adequate medical care, and since insulin is not available or too expensive. It is estimated that the prevalence of type 1 diabetes in Asia is relatively low, accounting for about 9.7 per cent of all diabetes mellitus cases in the Region. The insulin dependent diabetes registry at Chennai (India) reported an incidence of 10.5 per 100,000 children in the age group of 10–12 years *(7)*.

INDIA

The population in India has an increased susceptibility to diabetes mellitus. This propensity was demonstrated by multiple surveys of migrant Indians residing in Fiji, Singapore, South Africa, U.K. and USA. The rates of diabetes in migrants from the Indian subcontinent have consistently shown to exceed those of the local population.

The results of prevalence studies of diabetes mellitus in India were systematically reviewed with emphasis on those utilizing the standard WHO criteria for diabetes diagnosis. During the year 2004, there were an estimated 37.7 million cases of diabetes in the country, of these 21.4 million were in urban areas and 16.3 million in rural areas. The estimated total mortality due to diabetes was 1.09 lac; 62.5 thousand in urban areas and 46.6 thousand in rural areas. Same year 2.2 million DALYs were lost due to the disease *(8)*.

Natural history

Epidemiological determinants

1. AGENT

The underlying cause of diabetes is insulin deficiency which is absolute in type 1 diabetes and partial in type 2 diabetes. This may be due to a wide variety of mechanisms: (a) pancreatic disorders – inflammatory, neoplastic and

other disorders such as cystic fibrosis, (b) defects in the formation of insulin, e.g., synthesis of an abnormal, biologically less active insulin molecule; (c) destruction of beta cells, e.g., viral infections and chemical agents, (d) decreased insulin sensitivity, due to decreased numbers of adipocyte and monocyte insulin receptors. (e) genetic defects, e.g., mutation of insulin gene; and (f) auto–immunity. Evidence is accumulating that the insulin response to glucose is genetically controlled. The overall effect of these mechanisms is reduced utilization of glucose which leads to hyperglycaemia accompanied by glycosuria.

2. HOST FACTORS

(a) AGE : Although diabetes may occur at any age, surveys indicate that prevalence rises steeply with age. Type 2 diabetes usually comes to light in the middle years of life and thereafter begins to rise in frequency. Malnutrition related diabetes affects large number of young people. The prognosis is worse in younger diabetics who tend to develop complications earlier than older diabetics. *(b) SEX :* In some countries (e.g., UK) the overall male–female ratio is about equal *(9)*. In south-east Asia, an excess of male diabetics has been observed *(1)*, but this is open to question. *(c) GENETIC FACTORS:* The genetic nature of diabetes is undisputed. Twin studies showed that in identical twins who developed type 2 diabetes, concordance was approximately 90 per cent *(2)*, thus demonstrating a strong genetic component. In type 1 diabetes, the concordance was only about 50 per cent indicating that type 1 diabetes is not totally a genetic entity. *(d) GENETIC MARKERS :* Type 1 diabetes is associated with HLA–B8 and B15, and more powerfully with HLA–DR3 and DR4. The highest risk of type 1 diabetes is carried by individuals with both DR3 and DR4. On the other hand type 2 diabetes is not HLA–associated *(2)*. *(e) IMMUNE MECHANISMS :* There is some evidence of both cell–mediated and of humoral activity against islet cells. Some people appear to have defective immunological mechanisms, and under the influence of some environmental "trigger", attack their own insulin producing cells. *(f) OBESITY :* Obesity particularly central adiposity has long been accepted as a risk factor for type 2 diabetes and the risk is related to both the duration and degree of obesity. The association has been repeatedly demonstrated in longitudinal studies in different populations, with a striking gradient of risk apparent with increasing level of BMI, adult weight gain, waist circumference or waist to hip ratio. Indeed waist circumference or waist to hip ratio (reflecting abdominal or visceral adiposity) are more powerful determinants of subsequent risk of type 2 diabetes than BMI *(6)*. Central obesity is also an important determinant of insulin resistance, the underlying abnormality in most cases of type 2 diabetes. In some instances obesity reduces the number of insulin receptors on target cells. Voluntary weight loss improves insulin sensitivity and in several randomized controlled trials has shown to reduce the risk of progression from impaired glucose tolerence to type 2 diabetes *(10, 11)*. However, many obese subjects are not diabetic. Thus obesity by itself is inadequate to account for all, or even most, cases of type 2 diabetes; physical inactivity and/or deficiencies of specific nutrients may also be involved *(2)*. Obesity appears to play no role in type 1 diabetes pathogenesis *(12)*. *(g) MATERNAL DIABETES :* Offsprings of diabetic pregnancies including gestational diabetes are often large and heavy at birth, tend to develop obesity in childhood and are at high risk of developing type 2 diabetes at an early age. Those born to mothers after they have developed diabetes have a three-fold higher risk of developing diabetes than those born before. Maternal diabetes associated with intrauterine growth retardation and low birth weight, when associated with rapid growth catch-up later on, appears to increase the risk of subsequent diabetes in the child *(6)*.

3. ENVIRONMENTAL RISK FACTORS

Susceptibility to diabetes appears to be unmasked by a number of environmental factors acting on genetically susceptible individuals. They include : *(a) SEDENTARY LIFESTYLE* : Sedentary life style appears to be an important risk factor for the development of type 2 diabetes. Lack of exercise may alter the interaction between insulin and its receptors and subsequently lead to type 2 diabetes *(2)*. *(b) DIET* : A high saturated fat intake has been associated with a higher risk of impaired glucose tolerance, and higher fasting glucose and insulin levels *(6)*. Higher proportions of saturated fatty acids in serum lipid or muscle phospholipid have been associated with higher fasting insulin, lower insulin sensitivity and a higher risk of type 2 diabetes. Higher unsaturated fatty acids from vegetable sources and polyunsaturated fatty acids have been associated with reduced risk of type 2 diabetes and lower fasting and 2–hour glucose concentrations. Higher proportions of long-chain polyunsaturated fatty acids in skeletal muscle phospholipids have been associated with increased insulin sensitivity *(6)*. In human intervention studies, replacement of saturated by unsaturated fatty acids leads to improved glucose tolerence and enhanced insulin sensitivity. However, long chain polyunsaturated fatty acids do not appear to confer additional benefit over monounsaturated fatty acids. When total fat intake is high (greater than 37 per cent of total energy), altering the quality of dietary fat appears to have little effect *(13)*. *(c) DIETARY FIBRE :* In many controlled experimental studies, high intakes of dietary fibre have been shown to result in reduced blood glucose and insulin levels in people with type 2 diabetes and impaired glucose tolerance *(14)*. Moreover an increased intake of wholegrain cereals, vegetables and fruits (all rich in NSP) was a feature of diets in randomized controlled trials. Thus the evidence for a potential protective effect of dietary fibre appears strong. A minimum daily intake of 20 grams of dietary fibre is recommended *(6)*. Table 2 shows a summary of lifestyle and dietary factors associated with diabetes.*(d) MALNUTRITION :* Malnutrition (PEM) in early infancy and childhood may result in partial failure of β–cell function. Damage to beta cells may well explain the associated impaired carbohydrate tolerance in kwashiorkor *(2)*. *(e) ALCOHOL :* Excessive intake of alcohol can increase the risk of diabetes by damaging the pancreas and liver and by promoting obesity *(2)*. *(f) VIRAL INFECTIONS:* Among the viruses that have been implicated are rubella, mumps, and human coxsackie virus B4. Viral infections may trigger in immunogenetically susceptible people a sequence of events resulting in β–cell destruction. *(g) CHEMICAL AGENTS :* A number of chemical agents are known to be toxic to beta cells, e.g., alloxan, streptozotocin, the rodenticide VALCOR, etc *(15)*. A high intake of cyanide producing foods (e.g., cassava and certain beans) may also have toxic effects on β–cells. *(h) STRESS :* Surgery, trauma, and stress of situations, internal or external, may "bring out" the disease. *(i) OTHER FACTORS :* High and low rates of diabetes have been linked to a number of social factors such as occupation, marital status, religion, economic status, education, urbanization and changes in life style which are elements of what is broadly known as **social class.** One of the most important epidemiological features of diabetes is that it is now common in the lower social classes whereas

TABLE 2

Summary of strength of evidence on lifestyle factors and risk of developing type 2 diabetes

Evidence	Decreased risk	Increased risk
Convincing	Voluntary weight loss in overweight and obese people	Overweight and obesity Abdominal obesity
	Physical activity	Physical inactivity Maternal diabetes[a]
Probable	NSP[1]	Saturated fats Intrauterine growth retardation
Possible	η-3 fatty acids Low glycaemic index foods Exclusive breast-feeding[b]	Total fat intake Trans-fatty acids
Insufficient	Vitamin E Chromium Magnesium Moderate alcohol	Excess alcohol

1 NSP = non-starch polysaccharides.
a Includes gestational diabetes.
b As a global public health recommendation, infants should be exclusively breast-fed for the first six months of life to achieve optimal growth, development and health.

Source : *(6)*

50 years ago, the gradient was the reverse. One reason could be rapid changes in lifestyle in lower classes.

SCREENING FOR DIABETES

In the past, the commonest approach to diabetes screening was a preliminary, semi-quantitative test for glucose in a urine sample, followed by an oral glucose tolerance test for those found to have glycosuria. The underlying assumption is that early detection and effective control of hyperglycaemia in asymptomatic diabetics reduces morbidity.

1. Urine examination

Urine test for glucose, 2 hours after a meal, is commonly used in medical practice for detecting cases of diabetes. All those with glycosuria are considered diabetic unless otherwise proved by a standard oral glucose tolerance test. Most studies now confirm that although glucose is found in urine in the most severe cases of diabetes, it is often absent in milder forms of the disease, and such cases are likely to be missed by urine test. This is known as lack of "sensitivity". To be more precise, the sensitivity of the test (i.e., proportion of people with disease who have a positive test) varies between 10–50 per cent. The lack of sensitivity means that many diabetics would have been missed if this had been the only test. That is, the test yields too many "false-negatives". Further, glycosuria may be found in perfectly normal people; this gives rise to "false-positives". Since the specificity of the test is over 90 per cent, the yield of false-positives is not very high. For these reasons, urine testing is not considered an appropriate tool for case-finding or epidemiological surveys of the population *(2)*.

2. Blood sugar testing

Because of the inadequacies of urine examination, "standard oral glucose test" remains the cornerstone of diagnosis of diabetes. Mass screening programmes have used glucose measurements of fasting, postprandial or random blood sample. The measurement of glucose levels in random blood samples is considered unsatisfactory for epidemiological use; at the most, it can give only a crude estimate of the frequency of diabetes in a population *(2)*. The fasting value alone is considered less reliable since true fasting cannot be assured and spurious diagnosis of diabetes may more readily occur. Therefore, for epidemiological purposes, the 2–hour value after 75 g oral glucose may be used either alone or with the fasting value *(2)*. Automated biochemistry has now made it possible to screen thousands of samples for glucose estimation. The criteria for the diagnosis of diabetes, proposed by WHO, are given in Table 3.

TABLE 3

The WHO recommendations for the diagnostic criteria for diabetes and intermediate hyperglycaemia

Diabetes	
Fasting plasma glucose	≥ 7.0 mmol/l (126 mg/dl)
or	
2-h plasma glucose*	> 11.1 mmol/l (200 mg/dl)
Impaired Glucose Tolerance (IGT)	
Fasting plasma glucose	< 7.0 mmol/l (126 mg/dl)
and	
2-h plasma glucose*	≥ 7.8 and < 11.1 mmol/l (140 mg/dl to 200 mg/dl)
Impaired Fasting Glucose (IFG)	
Fasting plasma glucose	6.1 to 6.9 mmol/l (110 mg/dl to 125 mg/dl)
and (if measured)	
2-h plasma glucose*#	< 7.8 mmol/l (140 mg/dl)

* Venous plasma glucose 2-h after ingestion of 75g oral glucose load.
\# If 2-h plasma glucose is not measured, status is uncertain as diabetes or IGT cannot be excluded.

Source : *(16)*

Target population

Screening of the whole population for diabetes is not considered a rewarding exercise *(17, 18)*. However, screening of "high-risk" groups is considered more appropriate. These groups are: (i) those in the age group 40 and over (ii) those with a family history of diabetes (iii) the obese (iv) women who have had a baby weighing more than 4.5 kg (or 3.5 kg in constitutionally small populations) (v) women who show excess weight gain during pregnancy, and (vi) patients with premature atherosclerosis.

PREVENTION AND CARE

1. Primary prevention

Two strategies for primary prevention have been suggested: (a) population strategy, and (b) high-risk strategy *(2)*.

a. POPULATION STRATEGY

The scope for primary prevention of type 1 diabetes is limited on the basis of current knowledge and is probably not appropriate *(2)*. However, the development of prevention programmes for type 2 diabetes based on

elimination of environmental risk factors is possible. There is pressing need for **primordial prevention** – that is, prevention of the emergence of risk factors in countries in which they have not yet appeared. The preventive measures comprise maintenance of normal body weight through adoption of healthy nutritional habits and physical exercise. The nutritional habits include an adequate protein intake, a high intake of dietary fibre and avoidance of sweet foods. Elimination of other less well defined factors such as protein deficiency and food toxins may be considered in some populations. These measures should be fully integrated into other community–based programmes for the prevention of non-communicable diseases (e.g., coronary heart disease).

b. HIGH-RISK STRATEGY

There is no special high-risk strategy for type 1 diabetes. At present, there is no practical justification for genetic counselling as a method of prevention *(2)*.

Since NIDDM appears to be linked with sedentary life–style, over-nutrition and obesity, correction of these may reduce the risk of diabetes and its complications. Since alcohol can indirectly increase the risk of diabetes, it should be avoided. Subjects at risk should avoid diabetogenic drugs like oral contraceptives. It is wise to reduce factors that promote atherosclerosis, e.g., smoking, high blood pressure, elevated cholesterol and high triglyceride levels. These programmes may most effectively be directed at target population groups.

2. Secondary prevention

When diabetes is detected, it must be adequately treated. The aims of treatment are : (a) to maintain blood glucose levels as close within the normal limits as is practicable (see Table 3), and (b) to maintain ideal body weight. Treatment is based on (a) diet alone – small balanced meals more frequently, (b) diet and oral antidiabetic drugs, or (c) diet and insulin. Good control of blood glucose protects against the development of complications. Please see in chapter 10 "Nutrition and health" under title "Nutritional factors in selected diseases" for details.

Proper management of the diabetic is most important to prevent complications. Routine checking of blood sugar, of urine for proteins and ketones, of blood pressure, visual acuity and weight should be done periodically. The feet should be examined for any defective blood circulation (Doppler ultrasound probes are advised), loss of sensation and the health of the skin. Primary health care is of great importance to diabetic patients since most care is obtained at this level.

Glycosylated haemoglobin : There should be an estimation of glycated (glycosylated) haemoglobin at half–yearly intervals. This test provides a long-term index of glucose control. This test is based on the following rationale: glucose in the blood is complexed to a certain fraction of haemoglobin to an extent proportional to the blood glucose concentration. The percentage of such glycosylated haemoglobin reflects the mean blood glucose levels during the red cell life-time (i.e., about the previous 2–3 months) *(19)*.

Self-care : A crucial element in secondary prevention is self care. That is, the diabetic should take a major responsibility for his own care with medical guidance – e.g., adherence to diet and drug regimens, examination of his own urine and where possible blood glucose monitoring; self administration of insulin, abstinence from alcohol, maintenance of optimum weight, attending periodic check–ups, recognition of symptoms associated with glycosuria and hypoglycaemia, etc.

Table 4 shows some of the individual interventions in diabetes with evidence of efficacy.

TABLE 4

Individual interventions in diabetes with evidence of efficacy

Interventions with evidence of efficacy	Benefit
Lifestyle interventions for preventing type 2 diabetes in people of high risk	Reduction of 35–58% in incidence
Metformin for preventing type 2 diabetes for people at high risk	Reduction of 25–31% in incidence
Glycaemic control in people with HbA1c greater than 9%	Reduction of 30% in microvascular disease per 1 percent drop in HbA1c
Blood pressure control in people whose pressure is higher than 130/80 mmHg	Reduction of 35% in macrovascular and microvascular disease per 10 mmHg drop in blood pressure
Annual eye examinations	Reduction of 60 to 70% in serious vision loss
Foot care in people with high risk of ulcers	Reduction of 50 to 60% in serious foot disease
Angiotensin converting enzyme inhibitor use in all people with diabetes	Reduction of 42% in nephropathy; 22% drop in cardiovascular disease

Source : *(5)*

Home blood glucose monitoring : Assessment of control has been greatly aided by the recent facility of immediate, reasonably accurate, capillary blood glucose measurements either by one of the many meters now available or the direct reading Haemoglukotest strips *(20)*.

The patient should carry an identification card showing his name, address, telephone number (if any) and the details of treatment he is receiving. In short, he must have a working knowledge of diabetes. All these mean education of patients and their families to optimize the effectiveness of primary health care services.

3. Tertiary prevention

Diabetes is major cause of disability through its complications, e.g., blindness, kidney failure, coronary thrombosis, gangrene of the lower extremities, etc. The main objective at the tertiary level is to organize specialized clinics (Diabetic clinics) and units capable of providing diagnostic and management skills of a high order. There is a great need to establish such clinics in large towns and cities *(21)*. The tertiary level should also be involved in basic, clinical and epidemiological research. It has also been recommended that local and national registries for diabetics should be established *(2)*.

OBESITY

Obesity may be defined as an abnormal growth of the adipose tissue due to an enlargement of fat cell size (hypertrophic obesity) or an increase in fat cell number (hyperplastic obesity) or a combination of both *(1)*. Obesity is often expressed in terms of body mass index (BMI) (see Table 1). Overweight is usually due to obesity but can arise from other causes such as abnormal muscle development or fluid retention *(2)*.

However, obese individuals differ not only in the amount of excess fat that they store, but also in the regional distribution of the fat within the body. The distribution of fat induced by the weight gain affects the risk associated with obesity, and the kind of disease that results. It is useful therefore, to be able to distinguish between those at increased risk as a result of "abdominal fat distribution" or "android obesity" from those with the less serious "gynoid" fat distribution, in which fat is more evenly and peripherally distributed around the body.

Prevalence

Obesity is perhaps the most prevalent form of malnutrition. As a chronic disease, prevalent in both developed and developing countries, and affecting children as well as adults, it is now so common that it is replacing the more traditional public health concerns including undernutrition. It is one of the most significant contributors to ill health. For industrialized countries, it has been suggested that such increase in body weight have been caused primarily by reduced levels of physical activity, rather than by changes in food intake or by other factors. It is extremely difficult to assess the size of the problem and compare the prevalence rates in different countries as no exact figures are available and also because the definitions of obesity are not standardized.

TABLE 1

Adult weights and heights corresponding to recommended cut-off values for body mass index

	BMI							
	16.0	17.0	18.5	20.0	22.0	25.0	30.0	40.0
Height (cm)	Thinness					Overweight		
	Body weight (kg)

For easy reference and calculation of BMI values corresponding to recommended cut-offs, first find the height of the individual in the left hand column. The weights given in the row for that height correspond to various recommended cut-off values for adult BMI. Weight for two normal BMI values are also included.

Source : *(6)*

Overweight and obesity are the fifth leading risk of global deaths. Worldwide, obesity has more than doubled since 1980. In 2008, more than 1.4 billion adults, 20 years and older, were overweight. Of these over 200 million men and nearly 300 million women were obese *(3)*.

In 2012, more than 40 million children under 5 years of age were overweight. Once considered a high-income country problem, overweight and obesity are now rising in low-and middle-income countries, particularly in urban settings. Close to 30 million overweight children are living in developing and 10 million in developed countries *(3)*. Childhood obesity is associated with a higher chance of obesity, premature death and disability in adulthood. In addition, it is associated with future risk of increased breathing difficulties, increased risk of fractures, hypertension, early markers of cardiovascular disease, insulin resistance and psychological effects.

At least 3.4 million adults die each year as a result of being overweight or obese. In addition, 44 per cent of the diabetes burden, 23 per cent of ischaemic heart disease burden and between 7 to 41 per cent of certain cancer

burdens are attributable to overweight and obesity *(3)*. Overweight and obesity are linked to more deaths worldwide than underweight.

In India, the non-communicable risk factor survey phase 2 was carried out in the year 2007–2008, in the states of Andhra Pradesh, Kerala, Madhya Pradesh, Maharashtra, Tamil Nadu, Uttarakhand and Mizoram. The survey shows high prevalence of overweight in all age groups except in 15–24 years group. Overweight prevalence was higher among females than males and in urban areas than in rural areas. Low prevalence was recorded among lower level of education (ill-literate and primary level), and in people whose occupation was connected with agriculture or manual work *(4)*.

In India, 1.3 per cent males and 2.5 per cent females aged more than 20 years were obese in the year 2008 *(5)*.

As obesity is a key risk factor in natural history of other chronic and non-communicable diseases, the typical time sequence of emergence of chronic diseases following the increased prevalence of obesity is important in public health planning. The first adverse effects of obesity to emerge in population in transition are hypertension, hyperlipidaemia and glucose intolerence, while coronary heart disease and the long-term complications of diabetes, such as renal failure begin to emerge several years (or decades) later *(7)*. It is matter of time before same mortality rates for such diseases will be seen in developing countries as those prevailing 30 years ago in industrialized countries *(8)*.

Epidemiological determinants

The aetiology of obesity is complex, and is one of multiple causation:

(a) AGE : Obesity can occur at any age, and generally increases with age. Infants with excessive weight gain have an increased incidence of obesity in later life *(9)*. About one-third of obese adults have been so since childhood *(1)*. It has been well established that most adipose cells are formed early in life and the obese infant lays down more of these cells (hyperplastic obesity) than the normal infant. Hyperplastic obesity in adults is extremely difficult to treat with conventional methods.

(b) SEX : Women generally have higher rate of obesity than men, although men may have higher rates of overweight. In the Framingham, USA study, men were found to gain most weight between the ages of 29 and 35 years, while women gain most between 45 and 49 years of age *(10)*, i.e. at menopausal age. It has been claimed that woman's BMI increases with successive pregnancies. The recent evidence suggested that this increase is likely to be, on an average, about 1 kg per pregnancy. On the other hand in many developing countries, consecutive pregnancies at short intervals are often associated with weight loss rather than weight gain *(8)*.

(c) GENETIC FACTORS : There is a genetic component in the aetiology of obesity. Twin studies have shown a close correlation between the weights of identical twins even when they are reared in dissimilar environments *(11)*. The profile of fat distribution is also characterized by a significant heritability level of the order of about 50 per cent of the total human variation. Recent studies have shown that the amount of abdominal fat was influenced by a genetic component accounting for 50–60 per cent of the individual differences *(8)*.

(d) PHYSICAL INACTIVITY : There is convincing evidence that regular physical activity is protective against unhealthy weight gain. Where as sedentary lifestyle particularly sedentary occupation and inactive recreation such as watching television promote it, physical activity and physical fitness are important modifiers of mortality and morbildity related to overweight and obesity *(12)*. In some individuals a major reduction in activity without the compensatory decrease in habitual energy intake may be the major cause of increased obesity, e.g. in athletes when they retire and in young people who sustain injuries etc. Physical inactivity may cause obesity, which in turn restricts activity. This is a vicious circle. It is the reduced energy output that is probably more important in the aetiology of obesity than used to be thought *(11)*.

(e) SOCIO-ECONOMIC STATUS : The relationship of obesity to social class has been studied in some detail. There is a clear inverse relationship between socio-economic status and obesity. Within some affluent countries, however, obesity has been found to be more prevalent in the lower socio-economic groups.

(f) EATING HABITS : Eating habits (e.g., eating in between meals, preference to sweets, refined foods and fats) are established very early in life. The composition of the diet, the periodicity with which it is eaten and the amount of energy derived from it are all relevant to the aetiology of obesity. A diet containing more energy than needed may lead to prolonged post-prandial hyperlipidaemia and to deposition of triglycerides in the adipose tissue resulting in obesity *(13)*. Nowadays television and print media is playing an important role in producing obesity by heavy advertisement of fast food outlets of energy-dense, micronutrient poor food and beverages (usually classified under the "eat least" category in diet guidelines) of multinational corporations, which influence the daily eating habits. The consumer demand by itself may be influenced by advertising, marketing, culture, fashion and convenience *(8)*. It has been calculated that a child whose energy requirement is 2000 kcal/day and who consumes 100 kcal/day extra will gain about 5 kg a year *(10)*. The accumulation of one kilo of fat corresponds to 7,700 kcal of energy *(14)*.

(g) PSYCHOSOCIAL FACTORS : Psychosocial factors (e.g., emotional disturbances) are deeply involved in the aetiology of obesity. Overeating may be a symptom of depression, anxiety, frustration and loneliness in childhood as it is in adult life. Excessively obese individuals are usually withdrawn, self-conscious, lonely and secret eaters. An insight into the circumstances in which the obesity has developed is essential for planning the most suitable management.

(h) FAMILIAL TENDENCY : Obesity frequently runs in families (obese parents frequently having obese children), but this is not necessarily explained solely by the influence of genes.

(i) ENDOCRINE FACTORS : These may be involved in occasional cases, e.g., Cushing's syndrome, growth hormone deficiency.

(j) ALCOHOL : A recent review of studies concluded that the relationship between alcohol consumption and adiposity was generally positive for men and negative for women *(6)*.

(k) EDUCATION : In most affluent societies, there is an inverse relationship between educational level and prevalence of overweight *(6)*.

(l) SMOKING : Reports that the use of tobacco lowers

body weight began to appear more than 100 years ago, but detailed studies have been reported only during the past 10 years or so. In most populations, smokers weigh somewhat less than ex-smokers; individuals who have never smoked fall somewhat between the two.

(m) ETHNICITY : Ethnic groups in many industrialized countries appear to be especially susceptible to the development of obesity and its complications. Evidence suggests that this may be due to a genetic predisposition to obesity that only become apparent when such groups are exposed to a more affluent lifestyle *(8)*.

(n) DRUGS : Use of certain drugs, e.g., cortico-steroids, contraceptives, insulin, β-adrenergic blockers, etc. can promote weight gain *(8)*.

Use of BMI to classify obesity

Body mass index (BMI) is a simple index of weight-for-height that is commonly used to classify underweight, overweight and obesity in adults. It is defined as the weight in kilograms divided by the square of the height in metres (kg/m^2).

For example, an adult who weighs 70 kg and whose height is 1.75 m will have a BMI of 22.9:

$$BMI = 70 \text{ (kg)}/1.75^2 \text{ (m}^2\text{)} = 22.9$$

The classification of overweight and obesity, according to BMI, is shown in Table 2. Obesity is classified as a BMI ≥ 30.0. The classification shown is in agreement with that recommended by WHO *(12)*, but includes an additional subdivision at BMI 35.0–39.9 in recognition of the fact that management options for dealing with obesity differ above a BMI of 35. The WHO classification is based primarily on the association between BMI and mortality.

TABLE 2
Classification of adults according to BMI

Classification	BMI	Risk of comorbidities
Underweight	< 18.50	Low (but risk of other clinical problems increased)
Normal range	18.50-24.99	Average
Overweight :	≥ 25.00	
Pre-obese	25.00-29.99	Increased
Obese class I	30.00-34.99	Moderate
Obese class II	35.00-39.99	Severe
Obese class III	≥ 40.00	Very severe

Source : *(12)*

These BMI values are age-independent and the same for both sexes. The table shows a simplistic relationship between BMI and the risk of comorbidity, which can be affected by a range of factors, including the nature of the diet, ethnic group and activity level. The risks associated with increasing BMI are continuous and graded and begin at a BMI above 25.

Although it can generally be assumed that individuals with a BMI of 30 or above have an excess fat mass in their body, BMI does not distinguish between weight associated with muscle and weight associated with fat. As a result, the relationship between BMI and body fat content varies according to body build and proportion, and it has been shown repeatedly that a given BMI may not correspond to the same degree of fatness across populations. Polynesians, for example, tend to have a lower fat percentage than Caucasian Australians at an identical BMI. In addition, the percentage of body fat mass increases with age up to 60–65 years in both sexes, and is higher in women than in men of equivalent BMI. In cross-sectional comparisons, therefore, BMI values should be interpreted with caution if estimates of body fat are required.

INTRA-ABDOMINAL (CENTRAL) FAT ACCUMULATION AND INCREASED RISK

Compared with subcutaneous adipose tissue, intra-abdominal adipose tissue has more cells per unit mass, higher blood flow, more glucocorticoid (cortisol) receptors, probably more androgen (testosterone) receptors, and greater catecholamine-induced lipolysis. These differences make intra-abdominal adipose tissue more susceptible to both normal stimulation and changes in lipid accumulation and metabolism. Furthermore, intra-abdominal adipocytes are located upstream from liver in the portal circulation. This means that there is a marked increase in the flux of nonesterified fatty acid to the liver *via* the portal blood in patients with abdominal obesity.

There is good evidence that abdominal obesity is important in the development of insulin resistance, and in the metabolic syndrome (hyperinsulinaemia, dyslipidaemia, glucose intolerance, and hypertension) that link obesity with CHD *(8)*. Premenopausal women have quantitatively more lipoprotein lipase (LPL) and higher LPL activity in the gluteal and femoral subcutaneous regions, which contain fat cells larger than those in men, but these differences disappear after menopause *(8)*.

Assessment of obesity

Before we consider assessment of obesity, it will be useful to first look at body composition as under;

a. the active mass (muscle, liver, heart etc.)
b. the fatty mass (fat)
c. the extracellular fluid (blood, lymph, etc.)
d. the connective tissue (skin, bones, connective tissue)

Structurally speaking, the state of obesity is characterized by an increase in the fatty mass at the expense of the other parts of the body. The water content of the body is never increased in case of obesity.

Although obesity can easily be identified at first sight, a precise assessment requires measurements and reference standards. The most widely used criteria are :

1. BODY WEIGHT

Body weight, though not an accurate measure of excess fat, is a widely used index. In epidemiological studies it is conventional to accept + 2 SD (standard deviations) from the median weight for height as a cut-off point for obesity.

For adults, some people calculate various other indicators such as *(10)* :

(1) *Body mass index* (Quetelet's index)

$$= \frac{\text{Weight (kg)}}{\text{Height}^2\text{(m)}}$$

(2) *Ponderal index*

$$= \frac{\text{Height (cm)}}{\text{Cube root of body weight (kg)}}$$

(3) *Brocca index*

= Height (cm) *minus* 100

For example, if a person's height is 160 cm, his ideal weight is (160–100) = 60 kg

(4) *Lorentz's formula*

$$= \text{Ht (cm)} - 100 - \frac{\text{Ht (cm)} - 150}{\text{2 (women) or 4 (men)}}$$

(5) *Corpulence index*

$$= \frac{\text{Actual weight}}{\text{Desirable weight}}$$

This should not exceed 1.2

The body mass index (BMI) and the Brocca index are widely used. A FAO//WHO/UNU Report gives the much needed reference tables for body mass index (see Table 1) which can be used internationally as reference standards for assessing the prevalence of obesity in a community.

2. SKINFOLD THICKNESS

A large proportion of total body fat is located just under the skin. Since it is most accessible, the method most used is the measurement of skinfold thickness. It is a rapid and "non–invasive" method for assessing body fat. Several varieties of callipers (e.g., Harpenden skin callipers) are available for the purpose. The measurement may be taken at all the four sites – mid-triceps, biceps, subscapular and suprailiac regions. The sum of the measurements should be less than 40 mm in boys and 50 mm in girls *(15)*. Unfortunately standards for subcutaneous fat do not exist for comparison. Further, in extreme obesity, measurements may be impossible. The main drawback of skinfold measurements is their poor repeatability.

3. WAIST CIRCUMFERENCE AND WAIST : HIP RATIO (WHR)

Waist circumference is measured at the mid point between the lower border of the rib cage and the iliac crest. It is a convenient and simple measurement that is unrelated to height, correlates closely with BMI and WHR and is an approximate index of intra-abdominal fat mass and total body fat. Changes in waist circumference reflect changes in risk factors for cardiovascular disease and other forms of chronic diseases. There is an increased risk of metabolic complications for men with a waist circumference ≥ 102 cm, and women with a waist circumference ≥ 88 cm *(12)*.

Over the past 10 years or so, it has become accepted that a high WHR (> 1.0 in men and > 0.85 in women) indicates abdominal fat accumulation.

4. OTHERS

In addition to the above, three well-established and more accurate measurements are used for the estimation of body fat. They are measurement of total body water, of total body potassium and of body density. The techniques involved are relatively complex and cannot be used for routine clinical purposes or for epidemiological studies *(8)*. The introduction of measuring fat cells has opened up a new field in obesity research.

Hazards of obesity

Obesity is a health hazard and a detriment to well-being which is reflected in the increased morbidity and mortality: (a) INCREASED MORBIDITY : Obesity is a positive risk factor in the development of hypertension, diabetes, gall bladder disease and coronary heart disease and certain types of cancers, especially the hormonally related and large bowel cancers. There are in addition, several associated diseases, which, although not usually fatal, cause a great deal of morbidity in the community, e.g., varicose veins, abdominal hernia, osteoarthritis of the knees, hips and lumbar spine, flat feet and psychological stresses particularly during adolescence. Obese persons are exposed to increased risk from surgery. Obesity may lead to lowered fertility. Table 3 shows the relative risk of health problems associated with obesity. (b) INCREASED MORTALITY : The Framingham Heart Study in United States showed a dramatic increase in sudden death among men more than 20 per cent overweight as compared with those with normal weight. The increased mortality is brought about mainly by the increased incidence of hypertension and coronary heart disease. There is also an excess number of deaths from renal diseases. Obesity lowers life expectancy. More information is needed about the relationship between different degrees of obesity and morbidity and mortality. Please see in chapter 10 under heading "Nutritional factors in selected diseases" for dietary factors of obesity.

TABLE 3

Relative risk of health problems associated with obesity[a]

Greatly increased	Moderately increased	Slightly increased
Type 2 diabetes	CHD	Cancer (breast cancer in postmenopausal women, endometrial cancer, colon cancer)
Gall bladder disease	Hypertension	Reproductive hormone abnormalities
Dyslipidaemia	Osteoarthritis (knees)	Polycystic ovary syndrome
Insulin resistance	Hyperuricaemia and gout	Impaired fertility
Breathlessness		Low back pain due to obesity
Sleep apnea		Increased risk of anaesthesia complications
		Fetal defects associated with maternal obesity

[a] All relative risk values are approximate.

Source : *(8)*

Prevention and control

Weight control is widely defined as approaches to maintaining weight within the 'healthy' (i.e. 'normal' or 'acceptable') range of body mass index of 18.5 to 24.9 kg/m² throughout adulthood (WHO Expert Committee, 1995). It should also include prevention of weight gain of more than 5 kg in all people. In those who are already over-weight, a reduction of 5–10 per cent of body weight is recommended as an initial goal *(7)*.

Prevention of obesity should begin in early childhood. Obesity is harder to treat in adults than it is in children. The control of obesity centres around weight reduction. This can be achieved by dietary changes, increased physical activity and a combination of both. (a) DIETARY CHANGES: The following dietary principles apply both to prevention and treatment : the proportion of energy-dense foods such as simple carbohydrates and fats should be reduced; the fibre

content in the diet should be increased through the consumption of common un-refined foods; adequate levels of essential nutrients in the low energy diets (most conventional diets for weight reduction are based on 1000 kcal daily model for an adult) should be ensured, and reducing diets should be as close as possible to existing nutritional patterns *(16)*. The most basic consideration is that the food energy intake should not be greater than what is necessary for energy expenditure. It requires modification of the patient's behaviour and strong motivation to lose weight and maintain ideal weight. Unfortunately, most attempts to reduce weight in obese persons by dietary advice remain unsuccessful. (b) INCREASED PHYSICAL ACTIVITY: This is an important part of weight reducing programme. Regular physical exercise is the key to an increased energy expenditure. (c) OTHERS: Appetite suppressing drugs have been tried in the control of obesity. They are generally inadequate to produce massive weight loss in severely obese patients. Surgical treatment (e.g., gastric bypass, gastroplasty, jaw-wiring, to eliminate the eating of solid food have all been tried with limited success *(17)*. In short, one should not expect quick or even tangible results in all cases from obesity prevention programmes. Health education has an important role to play in teaching the people how to reduce overweight and prevent obesity. A fruitful approach will be to identify those children who are at risk of becoming obese and find way of preventing it.

VISUAL IMPAIRMENT AND BLINDNESS

A compilation published by WHO in 1966 *(1)* lists 65 definitions of blindness. As might be expected the definitions differed widely. Terms such as total blindness, economic blindness, and social blindness were in vogue. The 25th World Health Assembly in 1972 noted the complexity of the problem and considered the need for a generally accepted definition of blindness and visual impairment for national and international comparability. Taking into consideration existing definitions, the WHO proposed a uniform criterion and defined blindness as "visual acuity of less than 3/60 (Snellen) or its equivalent" *(2)*. The current WHO International Classification of Diseases (ICD–10) describes the levels of visual impairment as shown in Table 1.

The term "low vision" included in the previous revision has been replaced by the categories 1 and 2 to avoid confusion with those requiring low vision care.

TABLE 1

Revision of categories of visual impairment

Category	Presenting distance visual acuity	
	Worse than:	Equal to or better than:
Mild or no visual impairment 0		6/18
Moderate visual impairment 1	6/18	6/60
Severe visual impairment 2	6/60	3/60
Blindness 3	3/60	1/60*
Blindness 4	1/60*	Light perception
Blindness 5	No light perception	
9	Undetermined or unspecified	

* Or counts fingers at 1 metre.

The problem

WORLD

In 2010, an estimated 285 million people worldwide were visually disabled, of whom nearly 39 million were blind and 246 million were with low vision, about 90 per cent of them living in developing countries. About 80 per cent of blindness is avoidable (treatable or potentially preventable). However, a large proportion of those affected remain blind for want of access to affordable eye care. Blindness leads not only to reduced economic and social status but may also result in premature death. The major causes of blindness and their estimated prevalence are cataract (33 per cent); glaucoma (2 per cent); and uncorrected refractive errors (myopia, hyperopia or astigmatism (43 per cent) *(3)*. The number of people visually impaired from infectious disesases has greatly reduced in the last 20 years.

About 82 per cent of all people who are visually impaired are aged 50 years and older, while this age group comprises about 20 per cent of the world's population. With an increasing elderly population in many countries, more people will be at risk of age-related visual impairment. An estimated 19 million children are visually impaired. Of these, 12 million children are visually impaired due to refractory errors, a condition that could be easily diagnosed and corrected. 1.4 million are irreversibly blind for the rest of their lives *(3)*.

Overall, visual imairment worldwide has decreased since the early 1990s. This decrease is principally the result of a reduction of visual impairment from infectious diseases through public health action.

INDIA

The estimated prevalence of blindness in India for the year 2004 was about 11.2 per 1000 population, of this 0.1 per 1000 population was in age group 0–14 years, 0.6 in age group 15–49 years, and 77.3 in 50+ years age group. In men the prevalence was 10.2 per 1000 population and in women 12.2 per 1000 population *(4)*. According to rapid national survey on blindness 2006–07, the prevalence rate reduced from 1.1 per cent to 1.0 per cent and estimated national prevalence of childhood blindness/low vision was 0.8 per 1000 *(5)*.

Causes of blindness

WORLD

The most frequent causes of blindness in developed countries are accidents, glaucoma, diabetes, vascular diseases (hypertension), cataract and degeneration of ocular tissues especially of the retina, and hereditary conditions.

In South–East Asia Region, cataract is the single most common cause of blindness being responsible for 50–80 per cent of all blindness. Uncorrected refractive errors are being increasingly recognized as a cause of blindness and low vision. Vitamin A deficiency, which has been responsible for most childhood blindness in the Region is gradually declining. The emerging causes of blindness include glaucoma, age-related macular degeneration, diabetic retinopathy, corneal ulcer and ocular trauma *(6)*.

Among the leading causes of childhood blindness in the region are xerophthalmia, congenital cataract, congenital glaucoma and optic atrophy due to meningitis, retinopathy of prematurity, and uncorrected refractive errors. Xerophthalmia is largely under control with vitamin A distribution in immunization programmes.

There are an estimated 3–4 million persons blind, due to corneal opacity. With declining incidence of trachoma and xerophthalmia, the consequences of ocular trauma and corneal ulceration are emerging as important causes. According to an estimate, 6.5 million people are affected with, and 1.3 million eyes become blind due to corneal ulcer every year in the Region *(6)*. Trachoma remains an important cause in pockets in some countries although its importance as a cause of blindness has declined over the years *(7)*.

INDIA

The National Survey on Blindness 2006–07 conducted in the country recognized the main causes responsible for visual impairment and blindness. As shown in Table 3, the principal cause of blindness in India today is cataract, responsible for about 62.6 per cent of all cases. Cataract occurs more frequently with advancing age. Senile cataract occurs a decade earlier in India relative to Europe and America. Uncorrected refractive error are responsible for about 19.7 per cent of blindness; overall prevalence of glaucoma was about 5.8 per cent; posterior segment pathology accounts for about 4.7 per cent cases *(5)*. In a camp based study, glaucoma prevalence was found to be about 3.07 per cent with a slight female preponderance (males 2.9 per cent and females 3.19 per cent). Primary open angle glaucoma was more common (about 1.7 per cent) than primary angle closure glaucoma (0.73 per cent) *(8)*. In the others group, injuries as a cause of blindness accounts for 1.2 per cent *(9)*. There is evidence that injuries are on the increase due to increase in cottage industry (e.g. carpentry, black smithy, stone crushing, chiselling and hammering and chopping wood), and rapid industrialization in the country. The other causes in this group includes congenital disorder, uveitis, retina detachment, tumours, diabetes, hypertension, diseases of the nervous system, leprosy, etc.

Retinopathy of prematurity (ROP) is emerging as an important cause of childhood blindness. With the advent of hyperbaric oxygen and opening of large number of private and governmnet NICUs, the survival of the premature babies (born before 30 weeks of gestation and 1500 grams of weight at birth) has improved considerably. These babies are at risk of developing ROP and there is dire necessity to create awareness not only in public but also amongst opthalmologists and paediatricians to detect and treat ROP in time.

TABLE 3
Causes of blindness in India
(2006–07 National survey on blindness)

Cataract	62.6 per cent
Refractive error	19.7 per cent
Glaucoma	5.8 per cent
Posterior segment pathology	4.7 per cent
Corneal opacity	0.9 per cent
Surgical complications	1.2 per cent
Posterior capsular opification	0.9 per cent
Other causes	4.19 per cent

Source : *(5)*

Epidemiological determinants

(a) AGE : About 30 per cent of the blind in India are said to lose their eyesight before they reach the age of 20 years, and many under the age of 5 years. Refractive error, trachoma, conjunctivitis and malnutrition (vitamin A deficiency) are important causes of blindness among children and the younger age groups; cataract, refractive error, glaucoma and diabetes are causes of blindness in middle age; accidents and injuries can occur in all age groups, but more importantly in the age group 20 to 40 years. (b) SEX : A higher prevalence of blindness is reported in females than in males in India. This has been attributed to a higher prevalence of trachoma, conjunctivitis and cataract among females than in males *(10)*. (c) MALNUTRITION : Malnutrition as a cause of blindness was hardly recognized a few years ago. It is closely related not only with low vitamin A intake, but also with infectious diseases of childhood especially measles and diarrhoea (which precipitate malnutrition). In many cases protein energy malnutrition (PEM) is also associated with blindness. Severe blinding corneal destruction due to vitamin A deficiency (e.g., keratomalacia) is largely limited to the first 4–6 years of life and is especially frequent among those 6 months to 3 years of life. (d) OCCUPATION : It has long been recognized that people working in factories, workshops and cottage industries are prone to eye injuries because of exposure to dust, airborne particles, flying objects, gases, fumes, radiation (usually welding flash), electrical flash, etc. Many workers including doctors are known to have developed premature cataracts while exposed to X-rays, ultraviolet rays or heat waves. (e) SOCIAL CLASS : There is a close relationship between the incidence of blindness and socio-economic status. Surveys indicate that blindness is twice more prevalent in the poorer classes than in the

well-to-do *(10)*. (f) SOCIAL FACTORS: Many people lose their eyesight because of meddlesome ophthalmology by quacks. The basic social factors are ignorance, poverty, low standard of personal and community hygiene, and inadequate health care services.

Changing concepts in eye health care

Recent years have witnessed a change from acute intervention (cure) typical of clinical ophthalmology to comprehensive eye-health care which includes the following concepts :

1. Primary eye care

One of the most significant developments in the field of eye health care over the last few years has been the concept of *primary eye care,* that is, the inclusion of an eye-care component in primary health care system. The idea of primary eye care, as one of the main ingredients of a primary health care approach to blindness, has rapidly gained acceptance the world over. It is today recognized as a model for eye care at the community level. The promotion and protection of eye health, together with on-the-spot treatment for the commonest eye diseases, are its cornerstones. The final objective of primary eye care is to increase the coverage and quality of eye health care through primary health care approach and thereby improve the utilization of existing resources.

2. Epidemiological approach

The epidemiological approach which involves studies at the population level has been recognized. It focuses, among other things, on the measurement of the incidence, prevalence of diseases and their risk factors. The local epidemiological situation will determine the action needed.

3. Team concept

In many developing countries, there is only one eye specialist for more than a million people. Increasingly, therefore, health care leans on the use of auxiliary health personnel to fill many gaps. In India this gap is filled by village health guides, ophthalmic assistants, multi-purpose workers, and voluntary agencies.

4. Establishment of national programmes

Another important development in connection with the prevention of blindness has been the establishment of national programmes. Many of these programmes were first started by voluntary agencies concerned with blindness prevention (e.g., eye camps) and some of them focused on a single disease, such as trachoma. The increasing recognition of the primary health care approach to blindness resulted in comprehensive national programmes for the prevention of blindness *(11)* from all causes.

Prevention of blindness

The concept of **avoidable blindness** (i.e., preventable or curable blindness) has gained increasing recognition during recent years. A great many of the causes of blindness lend themselves to prevention and/or control – whether by improving nutrition, by treating cases of infectious diseases, or by controlling the organisms which cause infection, or by improving safety conditions – particularly on the roads, at work or in the home *(12)*.

The components for action in national programmes for the prevention of blindness comprise the following :

1. INITIAL ASSESSMENT

The first step is to assess the magnitude, geographic distribution and causes of blindness within the country or region by prevalence surveys. This knowledge is essential for setting priorities and development of appropriate intervention programmes.

2. METHODS OF INTERVENTION *(15)*

(a) Primary eye care

A wide range of eye conditions (e.g., acute conjunctivitis, ophthalmia neonatorum, trachoma, superficial foreign bodies, xerophthalmia) can be treated/prevented at the grass-root level by locally trained primary health workers (e.g., village health guides, multi-purpose workers) who are the first to make contact with the community. For this purpose, they are provided with essential drugs such as topical tetracycline, vitamin A capsules, eye bandages, shields, etc. They are also trained to refer difficult cases (e.g., corneal ulcer, penetrating foreign bodies, painful eye conditions and infections which do not respond to treatment) to the nearest PHC or district hospital. Their activities also involve promotion of personal hygiene, sanitation, good dietary habits and safety in general. Currently, there is one village health guide for 1000 population and 2 multipurpose workers for 5000 population in India.

In short, primary eye care is based firmly in primary health care which is ".....essential health care.....made universally accessible to individuals and families in the community through their full participation and at a cost that the community and country can afford ...." (Article VI of the Declaration of Alma Ata, 1978).

(b) Secondary care

Secondary care involves definitive management of common blinding conditions such as cataract, trichiasis, entropion, ocular trauma, glaucoma, etc. This care is provided in PHCs and district hospitals where eye departments or eye clinics are established. The secondary care may involve the use of mobile eye clinics. For instance, cataract accounts for over 62 per cent of blindness in India. The eye camp approach to make cataract surgery available has been highly successful, and has received wide popular support. Apart from cataract operations, these camps undertake general health surveys for the early detection of visual defects as well as education of the masses. For mobile services to be effective, there must be good community participation in the programme. Adequate follow-up and evaluation must also be provided. The "mobile units", though valuable, lack permanence and are being utilized as part of a comprehensive strategy for eye care. The great advantage of this strategy is, it is problem-specific and makes the best use of local resources and provides inexpensive eye care to the population at the peripheral level *(13)*.

(c) Tertiary care

These services are usually established in the national or regional capitals and are often associated with Medical Colleges and Institutes of Medicine. They provide sophisticated eye care such as retinal detachment surgery, corneal grafting and other complex forms of management not available in secondary centres. The majority of States in India has passed the Corneal Grafting Acts which have helped the establishment of Eye Banks. Other measures of rehabilitation comprise education of the blind in special

schools and utilization of their services in gainful employment. The central government has established National Institute for the Blind in Dehradun (U.P.) to work out new approaches and strategies for solving the problems of the blind.

(d) Specific programmes

(i) *Trachoma control :* Endemic trachoma and associated infections are a major cause of preventable blindness in many developing countries. Early diagnosis and treatment will cure trachoma. National programmes have been mounted against trachoma in many countries. Mass campaigns with topical tetracycline and the improvement of socio-economic conditions have markedly reduced the severity of trachoma and associated bacterial conjunctival infections. The Trachoma Control Programme launched in India in 1963 was merged with the National Programme for the Control of Blindness in 1976.

(ii) *School eye health services :* This is another useful approach to the eye health problems in the community. School children who form a sizable segment of the community can be screened and treated for defects such as refraction errors, squint, amblyopia, trachoma, etc. Health education is an important component of school health service. Students should be taught to practise the principles of good posture, proper lighting, avoidance of glare, proper distance and angle between the books and the eyes. Use of suitably readable type style in textbooks should be encouraged.

(iii) *Vitamin A prophylaxis :* Under the vitamin A distribution scheme in India, 200,000 IU of vitamin A are given orally at 6–monthly intervals between the ages 1–6 years. To be able to control xerophthalmia, the whole family should be kept under surveillance for one year and children for 5 years *(14)*.

(iv) *Occupational eye health services:* This is to prevent/ treat eye hazards in industries. Education on the prevention of occupational eye hazards and the use of protective devices in some occupations (like welding) is essential. The key to the prevention of accidents in factories is to improve the safety features of machines, to have proper illumination of the working area, to select workers with the requisite alertness and good vision, and to encourage the use of protective devices *(15)*.

3. LONG-TERM MEASURES

Long-term measures also have a part to play in controlling eye infections. Broadly these measures are aimed at improving the quality of life and modifying or attacking the factors responsible for the persistence of eye health problems, e.g., poor sanitation, lack of adequate safe water supplies, little intake of foods rich in vitamin A, lack of personal hygiene, etc. Health education is an important long-term measure in order to create community awareness of the problem; to motivate the community, to accept total eye health care programmes, and to secure community participation.

4. EVALUATION

Evaluation should be an integral part of intervention programmes to measure the extent to which ocular diseases and blindness have been alleviated, assess the manner and degree to which programme activities have been carried out, and determine the nature of other changes that may have been produced *(16)*.

National and International agencies

The National Association for the Blind (NAB), a voluntary organization which came into existence in 1952 has been active in the field of providing welfare services to the blind throughout India. The Royal Commonwealth Society for the Blind has been working in the field since 1950. In 1974, by invitation of WHO, the organizations concerned with blindness and with its prevention came together to build a new agency, the "International Agency for Prevention of Blindness". The Agency's primary task is to prevent blindness. There is a growing movement for direct technical cooperation among the developing countries. Neighbouring countries may provide training, exchange workers, share plans, and, in a variety of ways enrich and stimulate their programmes *(16)*.

National Programme for the Control of Blindness

See chapter 7 for details.

Vision 2020 : The Right to Sight

Vision 2020 : The Right to Sight, a global initiative to eliminate avoidable blindness was launched by WHO on 18th Feb. 1999. One significant way in which this initiative differs from previous ones is that the concept centres around Rights issues. Recognition of sight as a fundamental human right by all countries can be an important catalyst of initiatives for the prevention and control of blindness. The objective of Vision 2020 is to assist member countries in developing sustainable systems which will enable them to eliminate avoidable blindness from major causes, i.e. cataract, xerophthalmia and other causes of childhood blindness, refractive error and low vision, trachoma and other causes of corneal blindness by the year 2020 *(5, 6)*.

ACCIDENTS AND INJURIES

An accident has been defined as : "an unexpected, unplanned occurrence which may involve injury" *(1)*. A WHO Advisory Group in 1956 defined accident as an

"unpremeditated event resulting in recognizable damage" *(2)*. According to another definition, an accident is that "occurrence in a sequence of events which usually produces unintended injury, death or property damage".

Accidents represent a major epidemic of non–communicable disease in the present century. They are no longer considered accidental. They are part of the price we pay for technological progress.

Accidents have their own natural history and follow the same epidemiological pattern as any other disease – that is, the agent, the host and the environment interacting together to produce injury or damage. They occur more frequently in certain age–groups, at certain times of day and week and at certain localities. Some people are more prone to accidents than others and susceptibility is increased by the effect of alcohol and other drugs as well as physiological state such as fatigue. Lastly, a majority of accidents are preventable.

Measurement of the problem

a. MORTALITY

The following epidemiological indices will be useful in assessing the magnitude of the problem : (i) Proportional mortality rate : That is, the number of deaths due to accidents per 100 (or 1000) total deaths. (ii) Number of deaths per million population : The term "killed" (in a road traffic accident) is defined as any person who was killed outright or who died within 30 days as a result of the accident *(3)*. (iii) Death rate per 1000 (or 100,000) registered vehicles per year. (iv) Number of accidents or fatalities as a ratio of the number of vehicles per kilometre or passengers per kilometre. (v) Deaths of vehicle occupants per 1000 vehicles per year, etc.

b. MORBIDITY

Morbidity is measured in terms of "serious injuries" and "slight injuries" *(4)*. The seriousness of the injury is assessed by a scale known as "Abbreviated Injury Scale" *(3)*. Morbidity rates are generally less reliable because of under-reporting and mis-reporting.

c. DISABILITY

An important outcome of the accident process is disability, which may be temporary or permanent, partial or total. Measurement of disability in terms of its duration is a limited concept; it does not take into consideration the psychological or social aspects of an accident or injury *(5)*. The International classification of impairments, disabilities and handicaps'' is an attempt by WHO *(6)* to estimate the disability of individuals at a given moment.

The problem

WORLD

Injuries constitute a variable epidemic. During 2008 road traffic injuries ranked fourth among the leading causes of deaths in the world. Injuries are responsible for approximately 9 per cent (about (5.12 million) of all causes of deaths in the world and about 16 per cent of the disabilities are reported due to injuries. They are also the major cause of death among persons aged 10–24 years. In the developed regions, 57 per cent of male deaths and 43 per cent of female deaths in this age group are due to injuries, mainly traffic accidents. The main causes of injuries worldwide and their percentages are shown in Table 1. About 3.6 million people die of unintentional injuries and about 1.5 million die of intentional injuries. Road traffic accidents claim 1.2 million lives, self inflicted injuries and violence are becoming important causes of loss of lives.

TABLE 1

Global estimates of injuries related deaths by cause and sex (2008)

Cause	Total No. of deaths (000)	% of all causes of deaths	% of all causes of deaths due to injury	
			Male	Female
Unintentional	3619	6.4	46.50	24.05
Road traffic accidents	1209	2.1	17.98	5.58
Poisoning	252	0.4	3.35	1.56
Falls	510	0.9	5.60	4.34

INDIA

Accidents are definitely on an increase in India. Increasing mechanization in agriculture and industry, induction of semi-skilled and unskilled workers in various operations and rapid increase in vehicular traffic have resulted in an increase in morbidity and mortality due to accidents. Overcrowding, lack of awareness and poor implementation of essential safety precautions result in an increasing number of accidents. Consumption of poisonous substances accidentally or intentionally is also on the rise. Deaths, disabilities and hospitalization due to injuries continue to have impact of socio-economic loss to individuals, families, society and infrastructure. The traditional view of injury as an accident, has resulted in the neglect of this aspect of public health. Today injuries are low in priority for policy makers, and only few plans are drawn for injury prevention.

Table 2 shows the reported number of accidental deaths by main causes in India.

TYPES OF ACCIDENTS

1. Road traffic accidents

In many countries, motor vehicle accidents rank first among all fatal accidents. Every year almost 1.24 million people die from road accidents in the world. In addition, for every death, there are as many as 20–50 non-fatal injuries and 10–20 serious injuries requiring long periods of expensive care, nursing and treatment. Road traffic fatalities rate is higher in younger age groups. Children and young people under the age of 25 years account for over 30 per cent of those killed and injured in road accidents.

From a young age, males are more likely to be involved in road traffic crashes than females. Among young drivers, males under the age of 25 years are almost 3 times as likely to be killed in a car crash as young females *(9)*.

Nearly half (46 per cent) of those dying on roads are vulnerable road users like pedestrians, cyclists and

TABLE 2

Reported number of accidental deaths in India by main cause (2007–2011)

Cause	No. of Deaths				
	2007	2008	2009	2010	2011
1. Natural calamity	25153	23993	22255	25066	22415

Source : *(8)*

motorcyclists. Compared to cars the two-wheelers are unstable and provide little protection for their riders in accidents. In developed countries, four wheelers are more frequently involved in accidents.

More than 90 per cent deaths that result from road traffic accidents occur in low and middle-income countries. Even within high-income countries, people from lower socio-economic backgrounds are more likely to be involved in road traffic accidents *(9)*.

INDIA

During the year 2011, a total of 4.43 lac road traffic accidents were reported in the country. The rate of death per 1000 vehicles has decreased from 1.6 in 2007 to 1.2 in 2011. The rate of accidental deaths per 1000 vehicles was highest in Bihar and Sikkim at 1.6, followed by West Bengal at 1.5 *(10)*.

24.9 per cent of victims of road traffic accidents were occupants of two wheelers. Maximum number (73,001) of accidents occurred between 6 PM and 9 PM time period *(10)*. Maximum number of road accidents were reported in the month of May (43,064) followed by January (39,185).

Risk factors *(9)*

Speed

An increase in average speed is directly related both to the likelihood of a crash occurring and to the severity of the consequences of the crash. Some other facts are as below.

- Pedestrians have a 90% chance of surviving a car crash at 30 km/h or below, but less than a 50% chance of surviving an impact of 45 km/h or above.
- 30 km/h speed zones can reduce the risk of a crash and are recommended in areas where vulnerable road users are common (e.g. residential areas, around schools).
- Apart from reducing road traffic injuries, lower average traffic speeds can have other positive effects on health outcomes (e.g. by reducing respiratory problems associated with car emissions).

Drink-driving

Drinking and driving increases both the risk of a crash and the likelihood that death or serious injury will result.

- The risk of being involved in a crash increases significantly above a blood alcohol concentration (BAC) of 0.04 g/dl.
- Laws that establish BACs of 0.05 g/dl or below are effective at reducing the number of alcohol-related crashes.
- Enforcing sobriety check-points and random breath testing can lead to reductions in alcohol-related crashes by about 20%, and have shown to be very cost-effective.

Motorcycle helmets

- Wearing a motorcycle helmet correctly can reduce the risk of death by almost 40% and the risk of severe injury by over 70%.
- When motorcycle helmet laws are enforced effectively, helmet wearing rates can increase to over 90%.
- Requiring helmets to meet a recognized safety standard is important to ensure that helmets can effectively reduce the impact of a collision to the head in the event of a crash.

Seat-belts and child restraints

- Wearing car seat-belt reduces the risk of fatality among

front-seat passengers by 40–50% and of rear-seat passengers by between 25–75%.

- Mandatory seat-belt laws and their enforcement have been shown to be very effective at increasing seat-belt wearing rates.
- If correctly installed and used, child restraints reduce deaths among infants by approximately 70%, and deaths among small children by between 54% and 80%.

Distracted driving

There are many types of distractions that can lead to impaired driving, but recently there has been a marked increase around the world in the use of mobile phones by drivers that is becoming a growing concern for road safety. The distraction caused by mobile phones can impair driving performance in a number of ways, e.g. longer reaction times (notably braking reaction time, but also reaction to traffic signals), impaired ability to keep in the correct lane, and shorter following distances.

- Text messaging also results in considerably reduced driving performance, with young drivers at particular risk of the effects of distraction resulting from this use.
- Drivers using a mobile phone are approximately four times more likely to be involved in a crash than when a driver does not use a phone. Hands-free phones are not much safer than hand-held phone sets.
- While there is little concrete evidence yet on how to reduce mobile phone use while driving, governments need to be proactive. Actions that can be taken include adopting legislative measures, launching public awareness campaigns, and regularly collecting data on distracted driving to better understand the nature of this problem.

Developing countries are very different from the industrialized countries with regard to the environment and the mix of vehicles in the traffic stream. The following are the more important differences *(11)*:

1. Large numbers of pedestrians and animals share the roadway with fast-moving and slow-moving (e.g., bullock carts) vehicles. There is almost no segregation of pedestrians from wheeled traffic
2. Large numbers of old, poorly maintained vehicles
3. Large numbers of motor cycles, scooters, and mopeds
4. Low driving standards
5. Large numbers of buses, often overloaded
6. Widespread disregard of traffic rules
7. Defective roads, poor street lighting, defective lay-out of cross roads and speed breakers
8. Unusual behaviour of men and animals.

In South-East Asia Region countries, semi-urban and rural areas contribute 60–80 per cent of road accident injuries, although all media attention is focussed on urban road accidents.

Road traffic injuries cause the considerable economic loss to victims, their families, and to the nation as a whole. These losses arise from the cost of treatment (including rehabilitation and incident investigation) as well as reduced/ lost productivity (e.g. in wages) for those killed or disabled by their injuries, and for family members who need to take time off work (or school) to care for the injured *(9)*.

Multiple causation

Accidents are a complex phenomena of multiple causation (Fig. 1). The aetiological factors may be classified into two broad categories – human and environmental. Upto 90 per cent of the factors responsible for accidents are attributed to human failure. Many of the psychological circumstances in which accidents occur are still poorly known *(5)*.

PREVENTION

Accidents don't just happen; they are caused. The causes in a given situation must be identified by epidemiological methods. Since accidents are multifactorial, they call for an intersectoral approach to both prevention and care of the injured. The various measures comprise the following :

1. Data collection

There should be a basic reporting system of all accidents. The national data should be supplemented by special surveys and in-depth studies. These studies will bring out the risk factors, the circumstances and chain of events leading upto the accident. These details are rarely provided by the basic reporting system. Detailed environmental data relating to the road, vehicle, weather, etc must also be collected. The police have a statutory duty in many countries to investigate accidents, for legal as well as preventive purposes; the data collecting systems should recognize this and take police records as their starting point *(3)*. Without adequate data collection, analysis and interpretation there could be no effective counter–measures, evaluations and strategies for prevention.

2. Safety education

There is a widespread belief that accidents are inevitable; this fatalistic attitude must be curbed. Safety education must begin with school children. The drivers need to be trained in proper maintenance of vehicles and safe driving. Young people need to be educated regarding risk factors, traffic rules and safety precautions. They should also be trained in first aid. It has been aptly said that "if accident is a disease, education is its vaccine".

3. Promotion of safety measures

(a) Seat belts: The use of seat belts reduces the number of fatalities and non-fatal injuries by approximately 50 per cent each. They should be made compulsory for cars, light trucks and similar vehicles *(3)*. *(b) Safety helmets:* They reduce the risk of head injury by 30 per cent on an average and that of fatalities by 40 per cent *(5)*. They prevent laceration of the scalp to a great extent. Recently, the full-face integral helmet has become very popular. *(c) Children:* Another safety measure is to ensure that children remain seated when they are in a vehicle. They should be prohibited to take the front seats of cars *(5)*. A few countries have introduced laws which require that children of under 12–15 years in cars to be in the rear seats only. *(d) Others:* These comprise use of door locks, proper vehicle design, use of laminated high-penetration resistance windscreen glass, etc.

4. Alcohol and other drugs

Alcohol impairs driving ability and increases the risk of an accident as well as the severity of its consequences. Conclusions of surveys carried out in several countries have shown that alcohol is the direct cause of 30 to 50 per cent of severe road accidents.

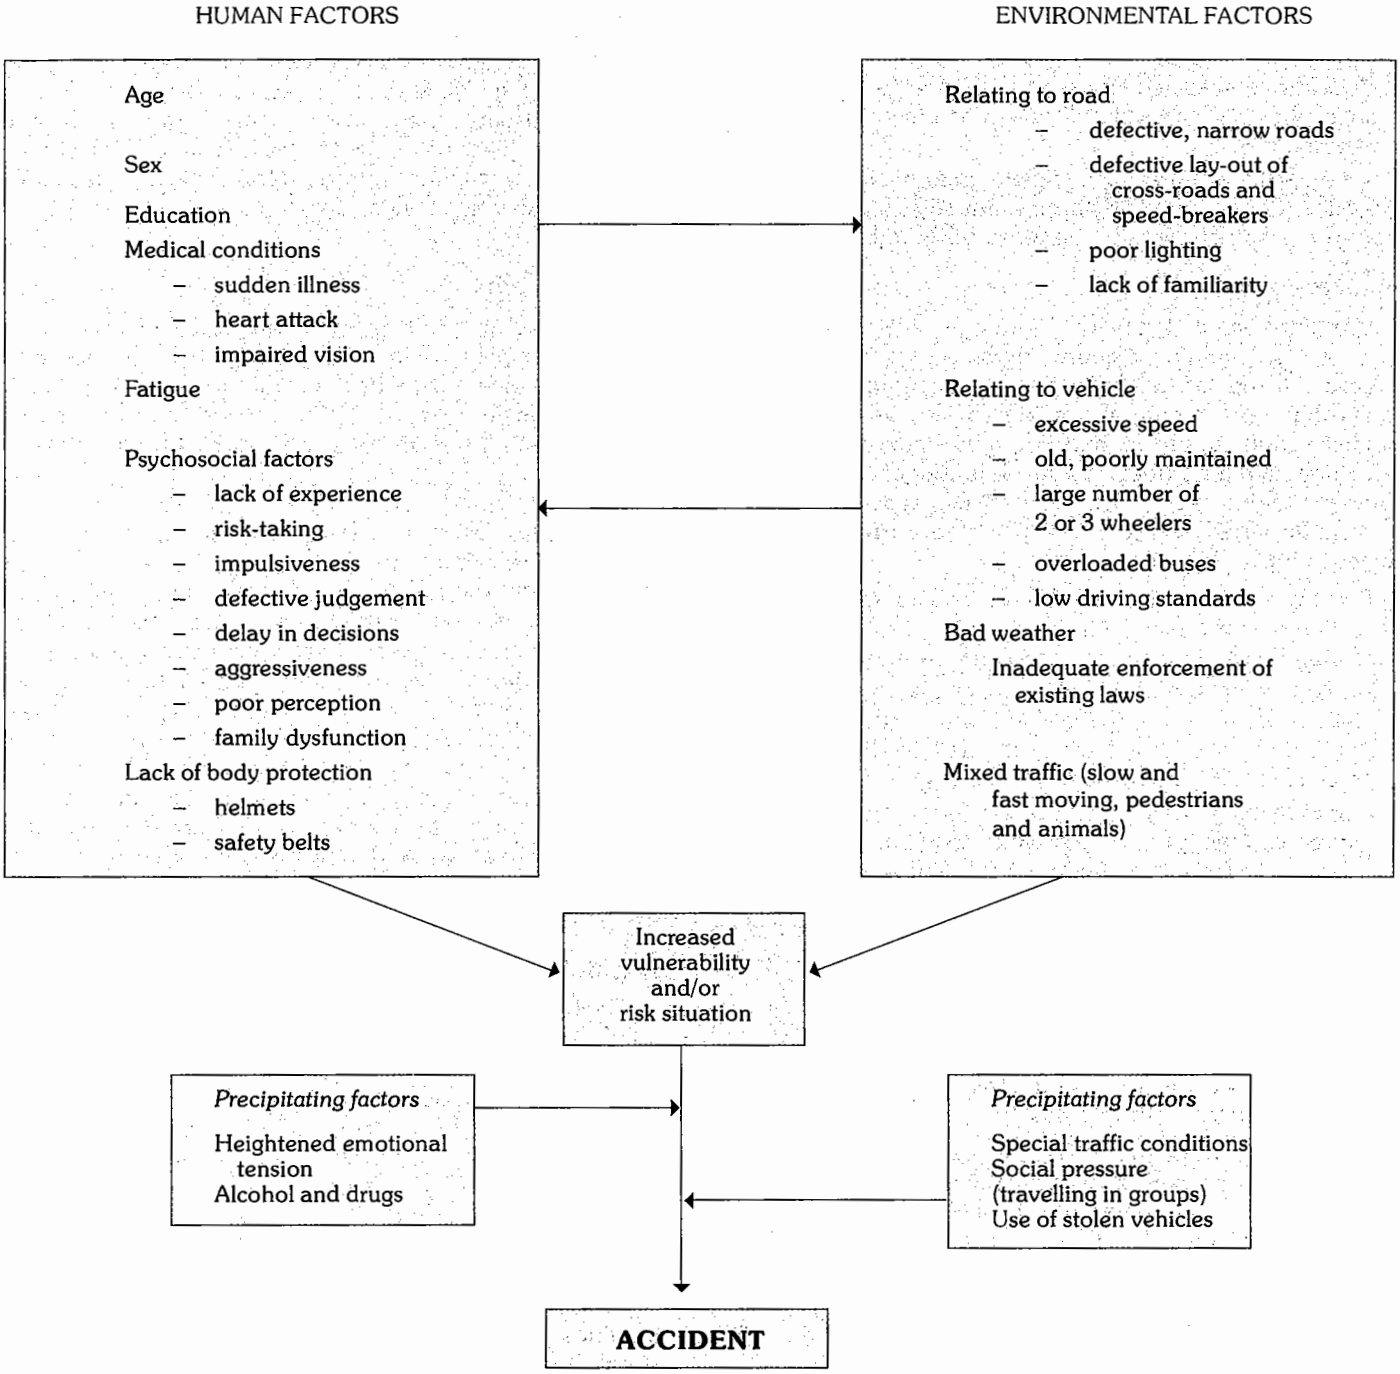

FIG. 1
Primary factors in accidents

Drugs such as barbiturates, amphetamines, and cannabis impair one's ability to drive safely. They should be avoided totally.

5. Primary care

Planning, organization and management of trauma treatment, and emergency care services should be a fundamental element of health service managerial process. Emergency care should begin at the accident site, continued during transportation, and conclude in the hospital emergency room. At any of these stages a life may be saved or lost, depending upon the skill of the health care worker and the availability of needed emergency equipment. To achieve these ends, there should be an Accident Services Organization and one fully equipped specialized trauma care hospital in all major cities.

6. Elimination of causative factors

The factors which tend to cause accidents must be sought out and eliminated, e.g., improvement of roads, imposition of speed limits and marking of danger points.

7. Enforcement of laws

Legislation embodies codified set of rules. These are enforced by the State to prevent accidents. These include driving tests, medical fitness to drive, enforcement of speed limits, compulsory wearing of seat-belts and crash-helmets, checking of blood alcohol concentration, road-side breath testing for alcohol, regular inspection of vehicles, periodic re-examination of drivers over the age of 55, etc.

8. Rehabilitation services

Rehabilitation consists of a number of elements which each injured person should benefit from. These are medical rehabilitation, social rehabilitation, occupational rehabilitation, etc. The aim of rehabilitation is to prevent, reduce or compensate disability and thereby handicap.

9. Accident research

The future of accident prevention is in research. Such research will be concerned with gathering precise information about the extent, type and other characteristics of accidents, correlating accident experience with personal attributes and the environments in which accidents occur, investigating new and better methods of altering human behaviour; seeking ways to make environments safer; and evaluating more precisely the efficiency of control measures. This area is now termed **accidentology**.

2. Domestic accidents

By "domestic accident" is meant an accident which takes place in the home or in its immediate surroundings, and, more generally, all accidents not connected with traffic, vehicles or sport *(16)*. The most frequent causes of domestic accidents are :

1. drowning
2. burns (by a flame, hot liquid, electricity, crackers or fire works, chemicals)
3. falls
4. poisoning (e.g., drugs, insecticides, rat poisons, kerosene)
5. injuries from sharp or pointed instruments
6. bites and other injuries from animals.

Drowning *(12)*

Drowning is the process of experiencing respiratory impairment from submersion/immersion in liquid.

Victims of drowning have a very slim chance of survival after immersion. The victim loses consciousness after approximately 2 minutes of immersion, and irreversible brain damage can take place after 4–6 minutes. Therefore, prevention strategies are very important.

In 2011, an estimated 359,000 people died from drowning, making drowning a major public health problem worldwide. Injuries account for nearly 10% of total global mortality. Drowning is the 3rd leading cause of unintentional injury/ death. It accounts for 7% of all injury-related deaths. It is a common method of suicide.

The global burden and death from drowning is found in all economies and regions, however; low and middle-income countries account for 95% of unintentional drowning deaths; over 50% of the world's drowning occurs in the WHO Western Pacific Region and WHO South-East Asia Region; China and India have particularly high drowning mortality rates and together contribute 43% of the world's drowning deaths and 41% of the total global DALYs (disability-adjusted life years) lost related to drowning.

There is a wide range of uncertainty around the estimate of global drowning deaths. It is important to point out that the global problem is much greater than the above figures reveal; due to the way data are classified, global numbers exclude drowning due to floods (cataclysms), boating and water transport mishaps. Non-fatal drowning statistics in many countries are not readily available or are unreliable.

Risk factors *(12)*

1. *Age :* Age is one of the major risk factor for drowning. This relationship is often associated with a lapse in supervision. In general, children under 5 years of age have the highest drowning mortality rates worldwide. Canada and New Zealand are the only exceptions, where adult males drown at higher rates.

2. *Gender :* Males are especially at risk of drowning with twice the overall mortality rate of females. They are more likely to be hospitalized than females for non-fatal drowning. Studies suggest that the higher drowning rates among males are due to increased exposure to water and riskier behaviour such as swimming alone, drinking alcohol before swimming alone, and boating.

3. *Access to water :* Increased access to water is another risk factor for drowning. Individuals with occupations such as commercial fishing or fishing for subsistence, using small boats in low-income countries, are more prone to drowning. Children who live near open water sources, such as ditches, ponds, irrigation channels, or pools are especially at risk.

4. *Other risk factors :* There are other factors that are associated with an increased risk of drowning, such as :

a. infants left unsupervised or alone, or with another child in a bathtub;
b. unsafe or overcrowded transportation vessels lacking flotation devices;
c. alcohol use, near or in the water;
d. medical conditions, such as epilepsy;
e. tourists unfamiliar with local water risks and features; and
f. floods and other cataclysmic events like tsunamis.

Prevention *(12)*

Drowning prevention strategies should be comprehensive and include: engineering methods which help to remove the hazard, legislation to enforce prevention and assure decreased exposure, education for individuals and communities to build awareness of risk and to aid in response if a drowning occurs.

Engineering methods to eliminate exposure to water hazards are the most effective strategy for drowning prevention. Examples include :

- development and implementation of safe water systems, such as drainage systems, piped water systems, flood control embankments in flood prone areas;
- building four-sided pool fences or barriers preventing access to standing water;
- creating and maintaining safe water zones for recreation;
- covering of wells or open cisterns;
- emptying buckets and baths, and storing them upside-down.

Laws or regulations which target risk factors for drowning include laws requiring regular safety checks of transportation vessels, and laws on alcohol use while boating or swimming.

Individual and community education on drowning awareness, learning water survival skills and ensuring the presence of lifeguards at swimming areas are promising strategy to prevent drowning.

Burns *(13)*

A burn is an injury to the skin or other organic tissue primarily caused by heat or due to radiation, radioactivity,

electricity, friction or contact with chemicals. Thermal (heat) burns occur when some or all of the cells in the skin or other tissues are destroyed by :

- hot liquids (scalds)
- hot solids (contact burns), or
- flames (flame burns).

The problem

Burns are a global public health problem, accounting for an estimated 265,000 deaths annually. About 11 million people worldwide require medical attention due to severe burns. The majority of these occur in low and middle-income countries and almost half occur in the South-East Asia Region.

In many high-income countries, burn death rates have been decreasing, and the rate of child deaths from burns is currently over seven times higher in low and middle-income countries than in high-income countries.

Non-fatal burns are a leading cause of morbidity, including prolonged hospitalization, disfigurement and disability, often with resulting stigma and rejection.

It is estimated that over one million people are moderately or severely burnt every year in India. In Bangladesh 1.73 lac children get moderate or severe burns every year with about 17 per cent getting temporary disability and 18 per cent permanent disability. Burns are the second most common injury in rural Nepal accounting for 5 per cent disabilities.

Risk factors *(13)*

Gender : Females suffer burns more frequently than males. Women in the South-East Asia Region have the highest rate of burns, accounting for 27% of global burn deaths and nearly 70% of burn deaths in the region. The high risk for females is associated with open fire cooking, or inherently unsafe cookstoves, which can ignite loose clothing. Open flames used for heating and lighting also pose risks, and self-directed or interpersonal violence are also important factors (although understudied).

Age : Along with adult women, children are particularly vulnerable to burns. Burns are the 11th leading cause of death of children aged 1–9 years and are also the fifth most common cause of non-fatal childhood injuries. While a major risk is improper adult supervision, a considerable number of burn injuries in children result from child maltreatment.

Socio-economic factors

People living in low and middle-income countries are at higher risk for burns than people living in high-income countries. Within the countries also, burn risk correlates with socio-economic status.

Other risk factors

There are a number of other risk factors for burns, including :

- occupations that increase exposure to fire;
- poverty, overcrowding and lack of proper safety measures;
- placement of young girls in household roles such as cooking and care of small children;
- underlying medical conditions, including epilepsy, peripheral neuropathy, and physical and cognitive disabilities;
- alcohol abuse and smoking;
- easy access to chemicals used for assault (such as in acid violence attacks);
- use of kerosene (paraffin) as a fuel source for non-electric domestic appliances;
- inadequate safety measures for liquefied petroleum gas and electricity.

Burns occur mainly in the home and workplace. Community surveys in Bangladesh and Ethiopia showed that 80–90% of burns occur at home. Children and women usually get burns in domestic kitchens, from upset receptacles containing hot liquids, or flames, or from cookstove explosions. Men are more likely to get burns in the workplace due to fire, scalds, chemicals and electricity.

Prevention *(13)*

Burns are preventable. High-income countries have made considerable progress in lowering rates of burn deaths, through a combination of prevention strategies and improvemetns in the care of people affected by burns. Most of these advances in prevention and care have been incompletely applied in low and middle-income countries. Increased efforts to do so would likely lead to significant reduction in rates of burn-related death and disability.

Prevention strategies should address the hazards for specific burn injuries, education for vulnerable populations and training of communities in first-aid. An effective burn prevention plan should be multisectoral. There are a number of specific recommendations for individuals, communities and public health officials to reduce burn risk.

FIRST-AID *(13)*

Do's

1. Stop the burning process by removing clothing and irrigating the burns.
2. Use cool running water to reduce the temperature of the burn.
3. Extinguish flames by allowing the person to roll on the ground, or by applying a blanket, or by using water or other fire-extinguishing liquids.
4. In chemical burns, remove or dilute the chemical agent by irrigating with large volumes of water.
5. Wrap the patient in a clean cloth or sheet and transport to the nearest appropriate facility for medical care.

Don'ts

1. Do not start first-aid before ensuring your own safety (switch off electrical current, wear gloves for chemicals etc.)
2. Do not apply paste, oil, haldi (turmeric) or raw cotton to the burn.
3. Do not apply ice because it deepens the injury.
4. Avoid prolonged cooling with water because it may lead to hypothermia.
5. Do not open blisters until topical antimicrobials can be applied, by a health-care provider.
6. Do not apply any material directly to the wound as it might become infected.
7. Avoid application of topical medication until the patient has been placed under appropriate medical care.

Falls

Globally, falls are a major public health problem. An estimated 424,000 fatal falls occur each year, making it the second leading cause of unintentional injury death, after road traffic injuries. Though not fatal 37.3 million falls are severe enough to require medical attention. Such falls are responsible for 17 million DALYs lost. Over 80% of fall-related fatalities occur in low and middle-income countries, with regions of the Western Pacific and South East Asia accounting for more than two-thirds of these deaths. In all regions of the world, death rates are highest among adults over the age of 60 years *(14)*.

Falls are responsible for the largest number of hospital visits for non-fatal injuries, especially for children and young adults. Falls from rooftops, balconies, windows and stair cases are common. Factors specific to SEAR countries are falls from trees of workers picking fruits or coconuts, tapping toddy, children falling from rooftops while flying kites, high incidence of falls among construction and forestry workers. As life expetancy increases in these countries, the incidence of hip and other fractures due to fall among the elderly are also assuming greater proportions *(15)*.

Some of the risk factors include *(14)* :

- occupations at elevated heights or other hazardous working conditions;
- alcohol or substance use;
- socio-economic factors including poverty, overcrowded housing, young maternal age;
- underlying medical conditions, such as neurological, cardiac or other disabling conditions;
- side-effects of medication, physical inactivity and loss of balance, particularly among older people;
- unsafe environments, particularly for those with poor balance and limited vision.

Prevention *(14)*

For children, effective interventions include multifaceted community programmes; engineering modifications of nursery furniture, playground equipment, and other products; and legislation for the use of window guard.

For older individuals, fall prevention programmes can include a number of components to identify and modify risk, such as :

- screening within living environments for risks for falls;
- clinical interventions to identify risk factors, such as medication review and modification, treatment of low blood pressure, Vitamin D and calcium supplementation, treatment of correctable visual impairment;
- home assessment and environmental modification for those with known risk factors or a history of falling;
- prescription of appropriate assistive devices to address physical and sensory impairments;
- muscle strengthening and balance retraining prescribed by a trained health professional;

Poisoning

Poisoning was responsible for an estimated 252,000 deaths during the year 2008 worldwide. In India about 28,012 poisoning deaths were reported during the year 2010 *(7)*. The most common agents responsible for poisoning are pesticides, kerosene, prescription drugs, and household chemicals. Pesticides are widely used in many countries where agriculture is an important part of the economy. Reports from India, Indonesia, Sri Lanka, and Thailand indicate that common availability and use of toxic pesticides is responsible for intentional and unintentional morbidity and mortality.

In Sri Lanka, pesticides are one of the main agents used in attempted suicide in rural areas. The use of organophosphorous insecticides in suicide events has been reported to be as high as 20–30 per cent. Paraquat intoxication is known to cause irreversible damage in patients. Many countries also report accidental ingestion of kerosene as a leading cause of poisoning, especially among children *(15)*. A study from Thailand revealed that 54 per cent of cases of poisoning among pre-school children involved therapeutic drugs.

Snake bite

Snake bite is a neglected public health issue in many tropical and subtropical countries. About 5 million snake bites occur each year, resulting in upto 2.4 million envenomings (poisoning from snake bites) at least 94,000–125,000 deaths and around 400,000 amputations and other permanent disabilities. Most of these occur in Africa, Asia and Latin America. In Africa alone there are an estimated 1 million snake bites annually with about half needing treatment. This type of injury is often found among women, children and farmers in poor rural communities in low and middle-income countries *(18)*.

The outcome of snake bite depends on numerous factors, including the species of snake, the area of the body bitten, the amount of venom injected, and the health condition of the victim. Feelings of terror and panic are common after a snake bite and can produce a characteristic set of symptoms mediated by the autonomic nervous system, such as a tachycardia and nausea. Bites from non-venomous snakes can also cause injury, often due to lacerations caused by the snake's teeth, or from a resulting infection. A bite may also trigger an anaphylactic reaction, which is potentially fatal. First-aid recommendations for bite depends on the snakes inhabiting the region, as effective treatment for bite inflicted by some species can be ineffective for others.

The venom of poisonous snakes may be predominantly neurotoxic or predominantly cytolytic. Neurotoxins cause respiratory paralysis and cytolytic venoms cause tissue destruction by digestion and haemorrhage due to haemolysis and destruction of the endothelial lining of the blood vessels. The manifestations of rattlesnake envenomation are mostly local pain, redness, swelling and extravasation of blood. Perioral tingling, metallic taste, nausea, and vomiting, hypotension and coagulopathy may also occur. Neurotoxic envenomation may cause ptosis, dysphagia, diplopia, and respiratory failure. Venom emitted from some types of cobras, almost all vipers cause necrosis of muscle tissue. Muscle tissues begin to die throughout the body and it results in accumulation of myoglobin in the renal tubules which leads to acute renal failure.

Early clues that a patient has severe envenoming *(19)* :

- Snake identified as a very dangerous one.
- Rapid early extension of local swelling from the site of the bite.
- Early tender enlargement of local lymph nodes, indicating spread of venom in the lymphatic system.

- Early systemic symptoms: collapse (hypotension, shock), nausea, vomiting, diarrhoea, severe headache, "heaviness" of the eyelids, inappropriate (pathological) drowsiness or early ptosis/ophthalmoplegia.
- Early spontaneous systemic bleeding.
- Passage of dark brown/black urine.

FIRST-AID

The Government of India developed a national snake-bite protocol in 2007 which includes following advice :

1. Reassure the patient. 70% of all snake bites are from non-venomous species. Only 50% of bites by venomous species actually envenomate the patient.
2. Immobilize in the same way as a fractured limb. Use bandages or cloth to hold the splints, not to block the blood supply or apply pressure. Do not apply any compression in the form of tight ligatures, they don't work and can be dangerous.
3. Do not give alcoholic beverages or stimulants. They are known vasodilators and they speed up the absorption of venom.
4. Remove any items or clothings which may constrict the bitten limb if it swells (rings, bracelets, watches, footwear, etc.).
5. Do not incise or manipulate the bitten site. Do not apply ice.
6. Transport the patient to a medical faculty for definitive treatment.

ANTIVENOM *(19)*

Until the advent of antivenom, bites from some species of snake were almost universally fatal. Despite huge advances in emergency therapy, antivenom is often still the only effective treatment for envenomation. The first antivenom was developed in 1895 by French physician Albert Calmette for the treatment of Indian cobra bites. Antivenom is made by injecting a small amount of venom into an animal (usually a horse or sheep) to initiate an immune system response. The resulting antibodies are then harvested from the animal's blood.

Antivenom is injected into the person intravenously, and works by binding to, and neutralizing venom enzymes. It cannot undo damage already caused by venom, so antivenom treatment should be sought as soon as possible. Modern antivenoms are usually polyvalent, making them effective against the venom of numerous snake species.

Pharmaceutical companies which produce antivenom target their products against the species native to a particular area. Although some people may develop serious adverse reactions to antivenom, such as anaphylaxis, in emergency situations this is usually treatable and hence the benefit outweighs the potential consequences of not using antivenom.

3. Industrial accidents

There are approximately 580 million workers in the South–East Asia Region. Approximately 60–80 per cent of these workers are employed in agriculture, fisheries, home industries, and small-scale units. Injuries due to these occupations result in an estimated 120 million injuries and 200,000 deaths per year *(15)*.

Though reliable estimates for work related injuries and deaths in the Region are not available, partly because a majority of the workers are employed in unorganized sectors, few studies indicate that nearly one per cent of deaths and 10 per cent of permanent impairment result from agricultural injuries. Agriculture workers are exposed to wide variety of physical, chemical (pesticide and fertilizers), biological (animal bites and animal related injuries) and mechanical injuries. The estimates from agriculture injury vary from 22–29 per 1000 workers. The incidence rate of injury among agriculture workers in India is estimated to be 116 per 100,000 workers. In a study population of 23,000 in rural Haryana, nearly 31 per cent of the injuries were related to agricultural activity *(17)*. Of these, serious injuries were caused by mechanized equipment and tractors *(15)*.

Rapid industrialization has also resulted in mortality and morbidity of many workers in hazardous industries.

The unique features common to the workplace in this region are that the manual labour content is high and the man–machine interaction is unsafe. In addition, there is greater emphasis on attempts to change the worker's behaviour, but designs that provide automatic protection are ignored. Children and people who are challenged physically as well as mentally are at a greater risk of encountering occupational injuries *(15)*.

4. Railway accidents

With the increase in number of trains and passengers, the increase in the number of accidents and casualties resulting therefrom is not unexpected. During 2010, about 30,576 people died of railway accidents in India *(8)*. The main factor involved in railway accidents is human failure.

5. Violence

An estimated 1,510,000 persons died in 2008 due to violence or intentional injuries (homicide, suicide and war) worldwide, of which 420,000 were in SEAR countries *(7)*. The accurate statistics are not available, as not all those injured go to the hospital or state that the injury is because of violence. Violence behind closed doors are grossly unreported.

Violence is reported to be increasing rapidly. It also follow the same epidemiological pattern as any other disease (host, agent and environment), i.e. a motivated person who injures; a suitable target; and a suitable environment or the absence of a guardian, all coinciding in time and space. Often, it may only be possible to initiate steps for prevention after an episode of violence has already taken place.

Some of the risk factors for violent behaviour are *(15)* :

- Exposure to violence and societal acceptability of violence as a means to solve problems. The image of violence as an acceptable and effective tool for solving problems, whether across international borders, on the street, or around the home, may spill over into real behaviour;
- Availability of lethal weapons like fire-arms significantly increases the possibility of both fatal and non-fatal injuries;
- Consumption of alcohol and other drugs is linked to almost 2/3 of cases of violence according to several studies.

Violence due to war and political unrest is fairly common in several countries. Organized and unorganized, ethnic and communal violence are well known in some places.

Suicides have been increasing at an alarming rate in SEAR countries. Incidence rates of 11 per lac population in Bangladesh, 36 per lac population in India, 8 per lac in Sri Lanka, and 22 per lac in Thailand; per year have been reported. Nearly 70 per cent of suicides in all countries have been reported in the age group of 15–34 years with male-female ratio of 1:1.2 to 1:3 from different countries. Poisoning, hanging, self-immolation and drowning are the most commonly reported methods of suicide *(17)*.

In India, an average of 369 suicides take place every day, out of these 248 are committed by males and 121 by females (62 are house wives). Family problems (89) and illness (72) are the main cause of suicides. Majority cases are below 29 years of age (136) followed by 30–44 years of age group (125) *(10)*.

7 Health Programmes in India

"Those who would benefit most from a service are least likely to obtain it"

Since India became independent, several measures have been undertaken by the National Government to improve the health of the people. Prominent among these measures are the NATIONAL HEALTH PROGRAMMES, which have been launched by the Central Government for the control/ eradication of the communicable diseases, improvement of environmental sanitation, raising the standard of nutrition, control of population and improving rural health. Various international agencies like WHO, UNICEF, UNFPA, World Bank, as also a number of foreign agencies like SIDA, DANIDA, NORAD and USAID have been providing technical and material assistance in the implementation of these programmes. A brief account of these programmes which are currently in operation is given below :

NATIONAL VECTOR BORNE DISEASE CONTROL PROGRAMME

The National Vector Borne Disease Control Programme (NVBDCP) is implemented in the State/UT's for prevention and control of vector borne diseases namely Malaria, Filariasis, Kala-azar, Japanese Encephalitis (JE), Dengue and Chikungunya. The Directorate of NVBDCP is the nodal agency for planning, policy making and technical guidance and monitoring and evaluation of programme implementation in respect of prevention and control of these vector borne diseases under the overall umbrella of NRHM. The States are responsible for planning, implementation and supervision of the programme. The vector borne diseases are major public health problems in India. Chikungunya fever which has re-emerged as epidemic outbreaks after more than three decades has added to the problem. The prevention and control of vector borne diseases is complex; as their transmission depends on interaction of numerous ecological, biological, social and economic factors including migration *(1)*.

Out of the six vector borne diseases, malaria, filariasis, japanese encephalitis, dengue and chikungunya are transmitted by different kind of vector mosquitoes, while kala-azar is transmitted by sand flies. The transmission of vector borne diseases in any area is dependent on frequency of man-vector contact, which is further, influenced by various factors including vector density, biting time, etc. Mosquito density is directly related with water collection, clean or polluted, in which the mosquitoes breed.

Under NVBDCP, the three pronged strategy for prevention and control of VBDs is as follows : (i) Disease management including early case detection and complete treatment, strengthening of referral services, epidemic preparedness and rapid response (ii) Integrated vector management (IVM) for transmission risk reduction including indoor residual spraying in selected high-risk areas, use of insecticide treated bed-nets, use of larvivorous fish, anti-larval measures in urban areas, source reduction and minor environmental engineering (iii) Supportive interventions including behaviour change communication (BCC), public private partnership and inter-sectoral convergence, human resource development through capacity building, operational research including studies on drug resistance and insecticide susceptibility, monitoring and evaluation through periodic reviews/field visits, web based management information system, vaccination against JE and annual mass drug administration against lymphatic filariasis *(1)*.

(A) MALARIA

The programme began originally as National Malaria Control Programme in 1953, during the First Five Year Plan. Because of the spectacular success achieved in the control of malaria, the control programme, was converted in 1958 into an eradication programme, with the objective of eradicating malaria once and for all from the country. Since then the programme has undergone many changes and the milestones of malaria control activities in India are as shown below *(2)* :

Milestones of malaria control activities in India

Year	Milestone
Prior to 1953	Estimated malaria cases in India – 75 million; Deaths due to malaria – 0.8 million
1953	Launching of National Malaria Control Programme (NMCP)
1958	NMCP was changed to National Malaria Eradication Programme
1965	Cases reduced to 0.1 million
Early 1970's	Resurgence of malaria
1976	Malaria cases – 6.46 million
1977	Modified Plan of Operations implemented
1997	World Bank assisted Enhanced Malaria Control Project (EMCP) launched
1999	Renaming of programme to National Anti Malaria Programme (NAMP)
2002	Renaming of NAMP to National Vector Borne Disease Control Programme
2005	Global Fund assisted Intensified Malaria Control Project (IMCP) launched
2005	Introduction of RDT in the programme
2006	ACT introduced in areas showing chloroquine resistance in falciparum malaria

2008	ACT extended to high *Pf* predominant districts covering about 95% *Pf* cases
2008	World Bank supported National Malaria Control Project launched
2009	Introduction of LLINs
2010	New drug policy 2010
2012	Introduction of bivalent RDT
2013	New drug policy 2013.

The main activities of the programme are :

1. Formulating policies and guidelines.
2. Technical guidance.
3. Planning.
4. Logistics.
5. Monitoring and evaluation.
6. Coordination of activities through the States/Union Territories and in consultation with national organizations such as National Centre for Disease Control (NCDC), National Institute of Malaria Research (NIMR).
7. Collaboration with international organizations like the WHO, World Bank, GFATM and other donor agencies.
8. Training.
9. Facilitating research through NCDC, NIMR, Regional Medical Research Centres etc.
10. Coordinating control activities in the inter-state and inter-country border areas.

Organization *(2)*

There are 19 Regional Offices for Health and Family Welfare under Directorate General of Health Services, Ministry of Health and Family Welfare, located in 19 states, which play a crucial role in monitoring the activities under NVBDCP. These offices are equipped with malaria trained staff.

The state governments are required to plan and implement the malaria control operations in their respective states. Every state has a Vector Borne Disease Control Division under its Department of Health and Family Welfare. It is headed by the State Programme Officer (SPO) who is responsible for supervision, guidance and effective implementation of the programme and for coordination of the activities with the neighbouring States/UTs. States are responsible for the procurement of certain insecticides for indoor residual spray (IRS), spray equipment and certain anti-malarials, the central government supplies DDT and larvicides.

Each state has established a State Vector Borne Disease Control Society, which includes civil society and sometimes private sector representation. These are now merged with similar entities for other centrally sponsored schemes into a single state-level Health and Family Welfare Society. The main role of these societies is to channelize funds from GOI to the states and onwards to districts for financing of the programmes. They also play a role in district level planning and in monitoring of programme activities within districts.

At the divisional level, zonal officers have technical and administrative responsibilities of the programme in their areas under the overall supervision of Senior Divisional Officers (SDOs).

At the district level, the Chief Medical Officer (CMO)/ District Health Officer (DHO) has the overall responsibility of the programme. At the district level, district malaria offices have been established in many places headed by the DVBDC officer to assist the CMO/DHO. This office is the key unit for the planning and monitoring of the programme. Spray operations are the direct responsibility of DMO/DVBDC officer in the entire district under overall supervision of CMO and collaborative supervision/monitoring by PHC's Medical Officer. There is one Assistant Malaria Officer (AMO) and Malaria Inspectors (MIs) to assist him *(2)*.

In many districts, District Vector Borne Disease Control Societies (now merged with District Health Societies under NRHM) have been established to assist the management of funds and planning, and monitoring of programme activities.

The laboratories have been decentralized and positioned at the PHCs. The medical officer – PHC has the overall responsibility for surveillance and laboratory services, and also supervises the spray. Case detection management and community outreach services are carried out by MPWs as well as ASHAs and other community health volunteers.

DRUG DISTRIBUTION CENTRES AND FEVER TREATMENT DEPOTS

With the increasing number of malaria cases, the demand for antimalarial drugs has increased tremendously. It became clear that drug supply only through the surveillance workers and medical institutions was not enough. This led to the establishment of a wide network of Drug Distribution Centres and Fever Treatment Depots and malaria clinics at some sub-centres. Drug Distribution Centres are only to dispense the anti-malarial tablets as per NMEP schedules. Fever Treatment Depots collect the blood slides in addition to the distribution of antimalarial tablets. These centres are manned by voluntary workers from the community.

URBAN MALARIA SCHEME

The urban malaria scheme was launched in 1971 to reduce or interrupt malaria transmission in towns and cities. The methodology comprises vector control by intensive antilarval measures and drug treatment.

About 7.4 per cent of the total cases of malaria and 10.9 per cent of deaths due to malaria are reported from urban areas. Maximum cases are reported from Chennai, Vadodara, Vishakhapatnam, Ahmedabad, Kolkata, New Mumbai, Vijaywada etc. *(3)*. The vector of malaria in the urban areas breeds largely in man-made containers including overhead tanks and underground water storage tanks, water coolers, cisterns, roof gutters, flower vases, bottles and ornamental ponds, old tyres etc., which can collect water. Large construction activities provide suitable breeding sites for the mosqitoes. Influx of migrant labour, from malarious zones contribute to increase in incidence. Control of urban malaria lies primarily in the implementation of civil bye-laws to prevent mosquito breeding in the domestic and peridomestic areas. Use of larvivorous fish in the water bodies such as slow moving streams, ornamental ponds etc. is recommended. Larvicides are used for water bodies which are unsuitable for fish use *(2)*. The urban malaria scheme under national vector disease control programme is presently protecting 116 million population from malaria and other mosquito borne diseases in 131 towns in 19 states and Union Territories. The civic bye-laws have been enacted and implemented in Delhi, Mumbai, Kolkata, Chandigarh, Bangalore, Chennai, Ahmedabad and Goa etc *(3)*.

The Expert Committee on Malaria had recommended the inclusion of all urban areas with more than 50,000 population and reporting slide positivity rate of 5 per cent and above, under Urban Malaria Scheme and introduction of active surveillance under this scheme.

Strategic action plan for malaria control in India (2012–2017)

The vision of strategic action plan is a substantial and sustained reduction in the burden of malaria in the near and mid-term, and the elimination of malaria in the long-term, when new tools, in combination with strengthening of health systems, will make national elimination possible.

Malaria control is now incorporated into the health service delivery programmes under the umbrella of NRHM. This provides opportunities for strengthening malaria prevention and treatment services close to the community. All available methods and means are being used to deliver these interventions, at entry-level facilities (e.g. CHCs, PHCs, and sub-centres), community outreach services using community health workers and volunteers (ASHAs) at village level, NGOs, private-sector providers and district and regional health facilities and hospitals.

Objective

To achieve API < 1 per 1000 population by the end of 2017.

Goals

The national goals for strategic plan are *(2)* :

1. Screening all fever cases suspected for malaria (60% through quality microscopy and 40% by rapid diagnostic test.
2. Treating all *P. falciparum* cases with full course of effective ACT and primaquine, and all *P. vivax* cases with 3 days chloroquine and 14 days primaquine.
3. Equipping all health institutions (PHC level and above), especially in high-risk areas, with microscopy facility and RDT for emergency use and injectable artemisinin derivatives.
4. Strengthening all district and sub-district hospitals in malaria endemic areas as per IPHS with facilities for management of severe malaria cases.

Outcome Indicators

The outcome indicators of strategic plan are :

1. At least 80% of those suffering from malaria get correct, affordable, appropriate and complete treatment within 24 hours of reporting to the health system, by the year 2017.
2. At least 80% of those at high risk of malaria get protected by effective preventive measures such as ITN/LLIN or IRS by 2017.
3. At least 10% of the population in high-risk areas is surveyed annually (annual blood examination rate > 10%).

Impact Indicators

The impact indicators of strategic plan are :

1. To bring down annual incidence of malaria to less than 1 per 1000 population at national level by 2017.
2. At least 50% reduction in mortality due to malaria by the year 2017, taking 2010 level as baseline.

Strategies

India's national malaria strategic plan (2012–17) is in line with the following broad strategies of the regional malaria strategy of WHO/SEARO.

- Reform approaches to programme planning and management.
- Improve and enhance surveillance and strengthen monitoring and evaluation.
- Scale up coverage and proper use of insecticide treated bed nets.
- Target interventions to risk groups.
- Scale up control of *P. vivax*.

Reforms are an ongoing process and during the current five year strategic plan, continued use of ACT, and RDTs at village level and IVM along with LLIN use is envisaged. These strategies are congruent with the WHO global recommendations, and offer the possibility of dramatically improved outcomes for malaria. Reforms are also in place, or underway, to address governance issues to strengthen accountability.

Categorized strategic interventions for achieving pre-elimination status

During the 11th Five-Year Plan period (2007–12), the malaria strategy adopted was for malaria control. At present, malaria incidence in many states in India is very low. In view of the feasibility of shrinking the map of malaria and progress towards malaria elimination (defined as no indigenous transmission, i.e., API less than one) it is proposed to change the strategies according to malaria endemicity at state and district level. This approach is expected to lead to reduction in malaria incidence in high endemic areas and sustain reduced incidence in low endemic areas to pave the way for the country to enter into the "pre-elimination stage". This requires adequate inputs in terms of technical, logistic and financial support.

The Technical Advisory Committee (TAC) for the programme has approved the following category specific broad strategies *(2)* :

Category	Definition	Strategies
Category 1	States with API less than one and all the districts in the state are with API less than one	– Active, passive and sentinel surveillance with focus on quality surveillance. – Screening of migrants. – IVM with involvement of Village Health and Sanitation Committeees (VHSCs), other PRIs and MNREGA schemes. – Supportive interventions including BCC activities.
Category 2	States having API less than one and one or more districts reporting API more than one	– Epidemiological surveillance and disease management (3 Ts–Test, Treat and Track). – Screening of migrants. – IVM by source reduction through minor engineering, environmental management and focal spray. – Supportive interventions including BCC activities with involvement of private health care providers, community involvement and NGOs.
Category 3	States with API more than one	– Epidemiological surveillance and disease management: by early diagnosis and complete treatment (EDCT). – Management of severe malaria cases by strengthening of district and sub-district hospitals and quality referral services. – IVM by IRS and LLIN distribution so as to saturate the entire high risk population. – Supportive interventions.

The API wise distribution of the states/UTs in 2011 is given in the Table 1 :

TABLE 1

API wise distribution of States/UTs in 2011

API	No. of States/ UTs	Name of States/UTs
>10	2	Dadra and Nagar Haveli and Arunachal Pradesh
5–10	4	Mizoram, Meghalaya, Orissa and Chhattisgarh
2–5	3	Jharkhand, Tripura and Andaman & Nicobar islands
1–2	6	Assam, Gujarat, Haryana, Madhya Pradesh, Nagaland and Daman and Diu
<1	15	Andhra Pradesh, Jammu & Kashmir, Karnataka, Maharashtra, Goa, Manipur, Rajasthan, Sikkim, Tamil Nadu, Uttarakhand, Uttar Pradesh, West Bengal, Chandigarh, Lakshadweep and Puducherry
<0.1	5	Bihar, Himachal Pradesh, Kerala, Punjab and Delhi

Source : *(2)*

Major activities according to API *(2)*

For areas having API less than 1

1. Vector control by minor engineering measures like desilting, deweeding and cleaning of canals and irrigation channels, biological control by use of larvicides and environmental management.
2. Involving PRIs by sensitizing them in rural areas and municipal bodies in urban areas.
3. Cooperation from VHSCs and nodal officers from MNREGA.

For areas having API between 1–2

1. Vector control by source reduction and biological control.
2. Active surveillance by ASHA/ANM and positioning of MPW in SCs where there is provision for 2nd ANM.

For areas having API between 2–5

1. Vector control by distribution of LLIN if acceptability of IRS is low @ 2 LLIN per household of 5 members.
2. For areas which can be supervised and accessible, quality IRS for selective vector control based on epidemiological impact of earlier vector control measures, if needed; these areas can also be provided with LLINs.

For areas having API above 5

a. For areas having perennial transmission (more than 5 months in a year)
   1. 2 rounds of IRS with DDT and 3 rounds with malathion.
   2. Priority distribution of LLINs as per the guidelines.
   3. Vector bionomics studies for future change of strategy.

b. For areas having seasonal transmission (less than 5 months in a year)
   1. 1 round of IRS with DDT before start of transmission.
   2. Focal spray whenever and wherever needed.
   3. Priority distribution of LLINs as per the guidelines.

For surveillance, the states which are reporting an API of <1 for three consecutive years shall initiate action for declaring malaria as a notifiable disease in the state *(2)*.

Malaria control strategies

The strategies for prevention and control of malaria and its transmission are :

1. Surveillance and case management
   - Case detection (passive and active)
   - Early diagnosis and complete treatment
   - Sentinel surveillance.
2. Integrated vector management (IVM)
   - Indoor residual spray (IRS).
   - Insecticide treated bed nets (ITNs)/Long Lasting Insecticidal Nets (LLINs).
   - Antilarval measures including source reduction.
3. Epidemic preparedness and early response
4. Supportive interventions
   - Capacity building
   - Behaviour change communication (BCC)
   - Intersectoral collaboration
   - Monitoring and evaluation
   - Operational research and applied field research.

Surveillance and case management

Surveillance (2)

The primary purpose of case management is to shorten the duration of illness, prevent the development of severe disease and death, especially in *falciparum* malaria. Therefore, case management for malaria is based on early diagnosis followed immediately by effective treatment. Early effective treatment is also important for limiting transmission of the disease.

The malaria surveillance system in India was initially set up in the early 1960s to detect remaining foci at that time, when the country was aiming to eliminate the disease and, not to measure the burden of the disease. The system has since been adapted to the needs of control and now monitors malaria incidence trends and geographic distribution. The aim is to target control interventions in high transmission areas and assessing their impact. Surveillance also plays a key role in the early detection of outbreaks.

Active case detection (ACD) is carried out in rural areas with blood smears collected by MPWs during fortnightly house visits. Passive case detection (PCD) is done in fever cases reporting to peripheral health volunteers/ASHAs and at sub-centres, malaria clinic, CHC, and other secondary and tertiary level health institutions that patients visit for treatment. ASHA and other volunteer workers provide diagnostic services by RDTs, and at PHCs by examination of blood smears. In villages where no ASHA or other volunteer has been trained and deployed for providing early diagnosis and effective treatment, ACD and case management is done by the MPWs.

The surveillance data of NVBDCP reflects malaria trends reasonably well because the ABER in the country as a whole has remained relatively constant at about 10%, and the surveillance system has not undergone any major changes. The ABER is, however, low in a few states, while in most of the high endemic areas it is much above 10%. Microscopy remains the best method of diagnosis on account of its high

sensitivity and specificity. It is also more economical in facilities where large number of slides are examined daily.

There are about 100 million blood slides collected from fever cases in India annually from which about 1.5 million malaria cases are detected. The new norms for case management emphasize quality care for patients. The implementation of use of Rapid Diagnostic Tests (RDTs) and Artesunate combination therapy (ACT) and the improvements in service delivery is expected to attract greater number of fever cases to the programme in the coming years. The programme also plans to supply RDT kits to private providers in return for data. The current level of screening of 100 million fever cases will not be reduced as it is aimed to screen 10% of the population, even though the disease transmission is expected to reduce.

During 2003, the NVBDCP introduced the use of RDT in 8 states under the World Bank assisted EMCP for early diagnosis of malaria. In the year 2012, bivalent RDT were introduced in the programme to detect *P. vivax* and *P. falciparum*. Since then, the programme has procured and distributed RDTs to community level workers/volunteers who have been trained to use them to enable timely diagnosis in these areas. In remote and inaccessible rural and tribal areas, RDTs are now the established method of choice for malaria diagnosis.

Parameters of malaria surveillance

By definition, surveillance also implies the continuing scrutiny of all aspects of occurrence and spread of a disease, that are pertinent to effective control. Included in these are the systematic collection and evaluation of field investigations, etc. The following parameters are widely used in the epidemiological surveillance of malaria : a. Annual parasite incidence (API); b. Annual blood examination rate (ABER); c. Annual *falciparum* incidence (AFI); d. Slide positivity rate (SPR); e. Slide *falciparum* rate (SFR).

Case management

According to the revised drug policy, there is no scope of presumptive treatment in malaria control. The new drug policy of 2013 is being followed in the country. For further details please refer to page 262, chapter 5.

Sentinel surveillance

One of the weakness of the existing malaria surveillance system is the lack of articulation with hospitals, which means that severe malaria cases are not reported separately and that only a small fraction of malaria deaths are recorded. Therefore, sentinel surveillance is being established in high endemic districts, by selecting in each district, depending on its size, 1–3 sentinel sites in large hospitals for recording of all out-patient and in-patient cases of malaria, and malaria related deaths.

Integrated vector management (IVM)

The NVBDCP aims to achieve effective vector control by the appropriate biological, chemical and environmental interventions of proven efficacy, separately or in combination as appropriate to the area through the optimal use of resources. Efforts are made for collaboration with various public and private agencies and community participation for vector control. Integration of IVM is done by using identical vector control methods to control malaria and leishmaniasis in rural areas, and malaria and dengue in urban areas, to achieve cost-effectiveness and synergy. The IVM includes safe use of insecticides and monitoring of insecticide resistance. The measures of vector control and protection include :

- Measures to control adult mosquitoes : Indoor Residual Spray (IRS)
- Antilarval measures : chemical, biological and environmental
- Personal protection : use of bed-nets, including insecticide treated nets.

The national malaria control program is currently using IRS as the primary method of vector control in rural settings, and anti-larval measures in the urban areas. Insecticide treated bed-nets have been introduced in the programme and the programme envisages a scale up in their use as vector control option for full population coverage, which will replace IRS in areas, where operational factors indicate that this method alone will give sufficient impact.

High-risk areas and populations *(2)*

Micro-stratification has been applied in malaria control for decades, and will now be applied more rigorously, as resources are increasing, making it possible to protect maximum number of populations living in high risk areas. Using local surveillance data and vector control experience, including the knowledge, habits and attitudes of the local community, district VBDC staff will be responsible for identification and mapping of high risk areas and risk populations as a basis for planning vector control. The stratification will be flexible, but firm enough to provide the corner-stone for planning, monitoring and evaluation.

IRS was carried out at the beginning of the NMEP in 1958 in all rural areas. However, under the MPO in 1977, it was decided to cover only high risk rural areas, i.e., those areas with API ≥ 2. The Technical Advisory Committee on Malaria (2002) further prioritized the criteria for undertaking IRS, which was at that time the only vector control method recognized for broad application. These criteria are as follows :

(1) To spray on priority basis with suitable insecticide all areas with ≥ 5 API where ABER is 10 per cent or more, taking the sub-centre as a unit.

(2) To spray on priority basis with suitable insecticide all areas reporting ≥ 5 per cent SPR (based on passive collection of blood slides), if the ABER is below 10 per cent.

(3) Due priority be accorded for spray if *Pf* proportion is more than 50 per cent.

(4) To accord priority for IRS in areas with less than API 5 or SPR<5 per cent in case of drug resistant foci, project areas with population migration and aggregation or other vulnerable factors including peri-cantonment areas.

(5) To make provision for insecticidal spraying in epidemic situation.

(6) Other parameters including entomological, ecological etc. may also be considered while prioritizing areas for spraying.

As much as possible, the village is to be the unit of intervention, but in some districts, data available with knowledge of ecological conditions may make it more rational to classify whole sub-centre areas as high-risk areas. High risk areas and populations will be re-defined at least annually. Such villages shall be protected by indoor residual spray and insecticide treated nets and the coverage will be more than 80 per cent, whatever may be the intervention.

The population living in areas with API ≥ 5 (69.1 million) is planned to be covered by LLINs and population living in endemic areas registering API≥2 is covered with conventional net treated with insecticides and IRS. Conventional nets treated with insecticides will continue to be used in areas registering API 2 to 5. IRS is still the preferred method of vector control in areas with very hot summers and where ITNs are not acceptable to population.

A population of about 80 million is at present being covered by IRS in the country. DDT is the insecticide of choice; in areas where the vector has shown resistance to DDT, the alternatives are malathion and synthetic pyrethroids. Two rounds of spraying are done for DDT and synthetic pyrethroids to provide protection during the entire transmission season, and in the case of malathion, three rounds of spraying are required. About 60 per cent of the high risk areas targeted under IRS are under coverage with DDT. The real coverage by IRS is, however, limited by the low community acceptance due to the white marks left on plastered surface, acrid smell associated with malathion, re-plastering of walls after completion of IRS etc.

Malaria paradigms/ecotypes *(2)*

The association between malaria and various ecological situations have been studied in India since the early part of the 20th century. There is considerable heterogenicity in malaria transmission characteristics between and within the states of the country, and many ecotypes/paradigms of malaria have been recognized. They are discussed in detail on page 256 chapter 5. The vector control recommendations according to the classification, when ITNs have emerged as a vector control option are as shown in Table 2.

Presently, malaria burden in the country is highly concentrated in a few forest-tribal states and areas. In most of these states, vector control interventions are limited to villages with API ≥ 5 or other high risk criteria, due to resource constraints. The North-East has specific difficulties in implementation and monitoring due to various reasons, including difficulty of terrain and exophily of vector *An. dirus*. It is also possible that reductions in malaria burden in high burden areas will translate to a reduction of malaria risk in low burden areas in the country inspite of continued population movements.

Behaviour change communication (BCC)

BCC is a systematic process that motivates individuals, families and communities to change their inappropriate or unhealthy behaviour, or to continue a healthy behaviour. BCC is a key supportive strategy for malaria prevention and treatment under NVBDCP.

BCC is directed at : (a) early recognition of signs and symptoms of malaria; (b) early treatment seeking from appropriate provider; (c) adherence to treatment regimens; (d) ensuring protection of children and pregnant women; (e) use of ITNs/LLINs; (f) acceptance of IRS, etc.

Anti-malaria month campaign

Anti-malaria month is observed every year in the month of June throughout the country, prior to the onset of monsoon and transmission season, to enhance the level of awareness and encourage community participation through mass media campaign and inter-personal communication and consolidate inter-sectoral collaborative efforts with other government departments, corporate and voluntary agencies at national, state and district levels.

Interaction of malaria control with other health programmes

The other main public health programmes related to malaria control are :

(1) Integrated Disease Surveillance Project (IDSP) : The project, with weekly fever alerts is increasingly providing the early warning signals on malaria outbreaks.

(2) Other vector borne diseases : Dengue and malaria control activities overlap in many urban areas, malaria and kala-azar in a few districts of Jharkhand, and malaria and filariasis in some areas including a few districts of Odisha.

(3) Reproductive and child health : Antenatal care services are utilized in distribtuion of LLINs to pregnant women

TABLE 2

Malaria ecotypes/paradigms in India and recommended vector control measures

Ecotype/paradigm	Main recommended measures
Tribal areas with malaria associated with forest environment (all 7 NE states, Orissa, Jharkhand, Chhattisgarh, foci in other states)	
Undulating Hills/Foothills with perennial rain in NE, hilly rainforest with *An. dirus*	IRS/ITNs/LLINs
Hilly partially deforested cultivated forest fringe (*An. dirus, minimus*)	Limited role for larval control
Undulating, sometimes deforested with rice cultivation (*An. fluviatilis, minimus*)	
Peninsular deep forest or forest fringe (*An. fluviatilis, culicifacies*)	
Malaria in organized sector/army/road construction/tea gardens	Same as above and in some situations personal protection, chemoprophylaxis
Epidemic prone areas (Punjab, Haryana, Western UP and Rajasthan)	Antilarval measures, including fish in some areas
Plain tubewell irrigated areas	One round of IRS in selected villages
Plains with sandy soil and no waterlogging	Space spray and IRS in case of outbreaks
Deserts (especially Rajasthan)	
Economic development project areas	Mass screening of incoming labourers, antilarval measures, IRS/ITNs/LLINs
Urban malaria	Chemical and biological larviciding, environmental measures, ITNs/LLINs, house screening, other personal protection measures and focal IRS in areas where this is possible (mainly single-storey buildings).

Source : *(2)*

in some areas of the country. Janani Suraksha Yojana also makes provision of bed-nets distribution to pregnant women. Changes in the malaria case management norms have been included in the Integrated Management of Neonatal and Childhood Illness.

The major externally supported projects *(1)*

Additional support for combating malaria is provided through external assistance in high malaria risk areas. There are two such externally funded projects which are currently being implemented for malaria control :

(i) Global Fund supported Intensified Malaria Control Project (IMCP II).

(ii) World Bank supported project on Malaria Control & Kala-azar Elimination.

The areas covered under these projects are as under :

(i) The Global Fund supported Intensified Malaria Control Project II (IMCP II) : Global Fund Round 9 supported IMCP II is being implemented since October 2010 for a period of five years in 7 North East states. The project area covers a population of 46 million in 86 districts. The strategy of the project are early diagnosis and complete treatment, integrated vector control including promotion of ITN (LLINs).

Additional support provided in project area is as follows :

a. Human resource such as consultants and support staff for project monitoring units at state and district level and malaria technical supervisor and laboratory technicians at sub-district level;

b. Capacity building of Medical Officer/Lab. Technicians/Fever Treatment Depots/volunteers etc.;

c. Commodities such as long-lasting insecticidal nets (LLINs), rapid diagnostic tests for quick diagnosis of malaria, alternate drugs (Artesunsate Combination Therapy, inj. Arteether) for treating severe malaria cases; and

d. Planning and administration including mobility support, monitoring, evaluation and operational research (studies on drug resistance and entomological aspects).

(ii) The World Bank supported project on malaria control and kala-azar elimination : This project was approved for 5 years effective from March 2009 to December 2013. The total financial outlay for this project is Rs. 1000 crores. This project was initiated in 93 malarious districts of eight states, namely Andhra Pradesh, Chhattisgarh, Gujarat, Jharkhand, Madhya Pradesh, Maharashtra, Orissa & Karnataka and 46 kala-azar districts in three states namely Bihar, Jharkhand and West Bengal. The project is being implemented in two phases. Phase-I covered 50 most malaria endemic districts in five states, namely Andhra Pradesh, Chhattisgarh, Madhya Pradesh, Orissa and Jharkhand, and 46 kala-azar districts in Bihar, Jharkhand & West Bengal. From 3rd year, Phase-II is being implemented in remaining (43) malaria districts. Additional 31 high endemic districts from three states namely Jharkhand, Orissa and West Bengal have been included in Phase-II for malaria control making a total of 124 districts to be supported for malaria control and kala-azar elimination under the World Bank project.

Additional supports provided in this project are :

a. Provision of human resource like consultants and support staff at national, state, district and sub-district level for surveillance and monitoring;

b. Promotion and use of long lasting insecticide nets (LLINs) in high malaria endemic areas;

c. Strong BCC/IEC activities at sub-district level; and

d. Supply of rapid kits for malaria diagnosis and drug Artesunate Combination Therapy for treatment of *P. falciparum* cases.

- At least 80 per cent of those suffering from malaria get correct, affordable and appropriate treatment within 24 hours of reporting to the health system, by the year 2012.
- At least 80 per cent of those at high risk of malaria get protected by effective preventive measures such as ITNs/ LLINs or IRS by 2012.

An overview of actions with tentative targets for burden reduction of malaria in different areas of the country for the period upto 2017 are as shown in Table 3.

TABLE 3

Overview of National Malaria Control Strategy 2012–2017

	7 states of North-East	Odisha, Chhattisgarh Jharkhand, W. Bengal Madhya Pradesh	Urban malaria scheme	Rural malaria (not forest related)	National level
12th Five Year Plan period (2012-2017)					
ITN coverage IRS coverage RDT+ACT	Upto 90% (mainly LLINs) Down to 20% Upto 80% Innovative vector control and case management delivery	Upto 90% (mainly LLINs) Down to 20% Upto 90% Defined high-risk areas, Annual/biannual mass vaccination with RTS-S	Strong inter-sectoral collaboration for greater, more effective coverage. Operations gradually transferred to municipality responsibility	Differentiated vector control coverage towards 90%. Down-classification of 50% of populations to low risk, not needing vector control	
R & D	Vector bionomics, resistance	Vector bionomics, resistance	Impact & coverage assessments operational research to enhance efficiency	Continued operational research with increasing focus on larval control	New treatments against *P.v.* liver stage
2017 cases as percentage of cases in 2002	<30%	<25%	<20%	<30%	<30%

Source : *(2)*

(B) ELIMINATION OF LYMPHATIC FILARIASIS

The disease is endemic in 250 districts in 20 states and UTs. According to recent estimates about 600 million people are exposed to the risk of infection *(1)*.

The National Filaria Control Programme has been in operation since 1955. In June 1978, the operational component of the NFCP was merged with the urban malaria scheme for maximum utilization of available resources. The training and research components, however, continue to be with the Director, National Institute of Communicable Diseases, Delhi.

Training in filariology is being given at three Regional Filaria Training and Research Centres situated at Calicut (Kerala), Rajahamundry (A.P.) and Varanasi (U.P.) under the National Institute of Communicable Diseases, Delhi. Besides, 12 headquarters bureaux are functioning at the state level.

Filaria control strategy includes vector control through anti larval operations, source reduction, detection and treatment of microfilaria carriers, morbidity management and IEC. National Filaria Control Programme is being implemented through 206 filaria control units, 199 filaria clinics and 27 survey units, primarily in endemic urban towns. In rural areas anti filaria medicines and morbidity management services are provided through primary health care system.

In India, the National Health Policy (2002), envisages elimination of lymphatic filariasis (ELF) by 2015. The elimination is defined as "lymphatic filariasis ceases to be public health problem, when the number of microfilaria carriers is less than 1 per cent and the children born after initiation of ELF are free from circulating antigenaemia (presence of adult filaria worm in human body).

The strategy of lymphatic filariasis elimination is through :

(a) Annual Mass Drug Administration (MDA) of single dose of antifilarial drug for 5 years or more to the eligible population (except pregnant women, children below 2 years of age and seriously ill persons) to interrupt transmission of the disease.

(b) Home based management of lymphoedema cases and up-scaling of hydrocele operations in identified CHCs/ district hospitals/medical colleges.

To achieve elimination of lymphatic filariasis, during 2004 the Govt. of India launched annual MDA with single dose of DEC tablets in addition to scaling-up home based foot care and hydrocele operation. The co-administration of DEC + Albendazole has been upscaled since 2007. The programme covered 202 districts in 2004 whereas by the year 2007, all the 250 LF endemic districts were covered. The mass drug administration starts in the month of November and the coverage has improved from 72.4 per cent in the year 2004 to 87.5 per cent in 2012.

During the year 2012, two districts of Goa, Puducherry, Daman & Diu and 16 districts of Tamil Nadu stopped MDA as validation process was initiated through Transmission Assessment Survey *(1)*.

The line listing of lymphoedema and hydrocele cases were initiated since 2004 by door-to-door survey in filaria endemic districts. The updated figure till December 2012 reveals about 12 lac cases with clinical manifestation of lymphoedema (8 lacs) and hydrocele (4 lacs). Initiation has also been taken to demonstrate the simple washing of foot to maintain hygiene for prevention of secondary bacterial and fungal infection in chronic lymphoedema cases, so that the patients get relief from frequent acute attacks.

The microfilaria survey in all the implementation units is being done through night blood survey before MDA. The survey is done in 4 sentinel and 4 random sites collecting total 4000 slides (500 from each site). There is definite evidence of microfilaria reduction in the MDA districts. However, the coverage of population with MDA should be above 80 per cent persistently for 5–6 years, which would reduce microfilaria load in the community, and thereby, interrupt the transmission *(3)*.

(C) KALA-AZAR

Kala-azar is now endemic in 31 districts of Bihar, 4 districts of Jharkhand, 11 districts of West Bengal and 6 districts of Uttar Pradesh, besides sporadic cases in few other districts of Uttar Pradesh. A centrally sponsored programme was launched in 1990–91. This has brought down the incidence of the disease from 77,102 cases in 1992 to 13,869 cases in 2013 *(1)*.

The strategies for Kala-azar elmination are : (a) Enhanced case detection and complete treatment including introduction of PK39 rapid diagnostic kits and oral drug Miltefosine for treatment of Kala-azar cases; (b) Interruption of transmission through vector control. It has been decided to replace DDT with synthetic pyrethroid for the purpose of fogging to eliminate sandfly, as the insect is becoming resistant to DDT; (c) Communication for behavioural impact and intersectoral convergence; (d) Capacity building; (e) Monitoring, supervision and evaluation; (f) Research guidelines on prevention and control of Kala-azar have been developed and circulated to the states.

ACTIVE CASE SEARCH : The frequency of case searches has been increased from a single annual case search to quarterly case searches. The active case searches are carried out during a fortnight designated as the "Kala-azar Fortnight", during which the peripheral health workers and volunteers are engaged to make door-to-door search and refer the cases conforming to the case definition of kala-azar and PKDL to the treatment centres for definitive diagnosis and treatment *(3)*.

An incentive amount of Rs. 300 is provided to ASHA for identifying each case of kala-azar and Rs. 100 for ensuring community support during insecticide spraying. Even the patient being treated in the hospital will be given Rs. 500 as compensation of daily wage for the time he spends in the hospital during the treatment. This revised strategy of total eradication of kala-azar was launched on 2nd September 2014.

The new strategy also includes introduction of Rapid Diagnostic Kit developed by ICMR into the programme and single dose treatment with Liposomal Amphoterecin B, which is given intravenously in 10 mg dose. It is to reduce the human reservoir of infection. WHO will supply the drug free of cost *(4)*.

(D) JAPANESE ENCEPHALITIS

Japanese encephalitis is a disease with high mortality rate and those who survive do so with various degrees of neurological complications. During the last few years it has become a major public health problem. States of Andhra Pradesh, West Bengal, Assam, Tamil Nadu, Karnataka,

Bihar, Maharashtra, Manipur, Haryana, Kerala and Uttar Pradesh are reporting maximum number of cases.

The strategies for prevention and control of Japanese encephalitis include strengthening of the surveillance activities through sentinel sites in tertiary health care institutions, early diagnosis and proper case management, integrated vector control, particularly personal protection and use of larvivorous fishes, capacity building and behaviour change communication. As the JE vectors are outdoor resters, indoor residual spray is not effective. The government of India provides need–based assistance to the states, including support for training programmes and social mobilization.

As there is no specific cure for this disease, early case management is very important to minimize the risk of complications and death. JE vaccination is recommended for children between 1 to 15 years of age. In addition, health education through different media and interpersonal communication for the community is crucial. Emphasis should be given on keeping pigs away from human dwellings, or in pigsties, particularly during dusk to dawn, which is the biting time of vector mosquitoes. Use of clothes which cover the body fully to avoid mosquito bites are advocated. Use of bed-nets is also very important precaution. Since early reporting of case is important to avoid complications, the community should be given full information about the signs and symptoms of the disease, and the health facilities available at health centres/hospitals. The states are advised to use malathion for outdoor fogging as outbreak control measure in the affected areas *(5)*. Epidemiological monitoring of the disease for effective implementation of preventive and control measure and technical support is provided on request by the state health authorities.

(E) DENGUE FEVER/ DENGUE HAEMORRHAGIC FEVER

During 1996, an outbreak of dengue was reported in Delhi. Since then dengue has been reported from other states also. In view of this major outbreak of the disease a "Guideline of Preparation of Contingency Plan in case of outbreak/epidemic of Dengue/Dengue haemorrhagic fever" was prepared and sent to all the states. It includes all the important aspects of control measures like identification of outbreak, demarcation of affected area, containment of outbreak, case management, vector control, IEC activities about Do's and Don't's for prevention of dengue, monitoring and reporting etc.

Since early reporting of cases is crucial to avoid any complication and mortality, the community is given full information about the signs and symptoms as well as availability of health services at health centres/hospitals. Alerting the hospitals for making adequate arrangements for management of dengue/dengue haemorrhagic fever cases has also been advised.

Government of India in consultation with states has identified 311 sentinel surveillance hospitals with laboratory support for augmentation of diagnostic facilities in the endemic states. Further, for advanced diagnosis and back-up support 14 Apex Referral Laboratories have been identified and linked with sentinel surveillance hospitals. To make these functional IgM capture ELISA test kits are provided through National Institute of Virology, Pune free of cost. Contingency grant is also provided to meet the operational costs.

For early diagnosis ELISA based NSI kits have been introduced under the programme which can detect the cases from 1st day of infection. IgM capture ELISA tests can detect the cases after 5th day of infection.

The GOI has taken the following steps for prevention and control of dengue *(6)* :

- Monitoring the situation through reports received from state health authorities.
- A mid-term plan for prevention and control of dengue has been developed in 2011 and circulated to the states for implementation. The main components of mid term plan for prevention and control of dengue are as follows :
  - (a) *Surveillance* : Disease and entomological surveillance
  - (b) *Case mangement* : Laboratory diagnosis and clinical management
  - (c) *Vector management* : Environmental management for source reduction, chemical control, personal protection and legislation
  - (d) *Outbreak response* : Epidemic preparedness and media management
  - (e) *Capacity building* : Training, strengthening human resource and operational research
  - (f) *Behavioural change communication* : Social mobilization, and information, education and communication (IEC)
  - (g) *Inter-sectoral coordination* : with ministries of urban development, rural development, panchayati raj, surface transport and education sector
  - (h) *Monitoring and supervision* : Analysis of reports, review, field visit and feed-back

(F) CHIKUNGUNYA FEVER

Chikungunya fever is a debilitating non-fatal viral illness, re-emerging in the country after a gap of three decades. Govt. of India is continuously monitoring the situation. Guidelines for prevention and control of the disease have been prepared. Since same vector is involved in the transmission of dengue and chikungunya, strategies for transmission risk reduction by vector control are also the same. Support in the form of logistics and funds are provided to the states.

For carrying out proactive surveillance and enhancing diagnostic facilities for chikungunya, the 137 sentinel surveillance hospitals involved in dengue in the affected states also carry out chikungunya tests. The diagnostic kits are provided through National Institute of Virology, Pune, by the central government.

NATIONAL LEPROSY "ERADICATION" PROGRAMME

The National Leprosy Control Programme (NLCP) has been in operation since 1955, as a centrally aided programme to achieve control of leprosy through early detection of cases and DDS (dapsone) monotherapy on an ambulatory basis. The NLCP moved ahead initially at a slow pace, presumably for want of clear-cut policies or operational objectives for nearly two decades *(7)*. The programme gained momentum during the Fourth Five Year Plan after it was made a centrally-sponsored programme. In 1980 the Government of India declared its resolve to

"eradicate" leprosy by the year 2000 and constituted a Working Group to advise accordingly. The Working Group submitted its report in 1982 and recommended a revised strategy based on multi-drug chemotherapy aimed at leprosy "eradication" through reduction in the quantum of infection in the population, reduction in the sources of infection, and breaking the chain of transmission of disease. In 1983 the control programme was redesignated National Leprosy "Eradication" Programme with the goal of eradicating the disease by the turn of the century. The aim was to reduce case load to 1 or less than 1 per 10,000 population.

To strengthen the process of elimination of leprosy in the country, the first World Bank supported project was introduced in 1993. On completion of this project, the 2nd phase of project with World Bank support was started in 2001–02 which ended in December 2004. Since then, the programme is being continued with Government of India funds with technical support from WHO and International Federation of Anti-Leprosy Association (ILEP) organizations. The programme has been integrated with general health care system in 2002–03, since then leprosy diagnosis and treatment services are available at all PHCs and government hospitals.

The components of the programme are as follows :

(1) Decentralized integrated leprosy services through general health care system;
(2) Capacity building of all general health services functionaries;
(3) Intensified information, education and communication;
(4) Prevention of disability and medical rehabilitation; and
(5) Intensified monitoring and supervision.

After introduction of MDT, the recorded case load of leprosy came down from 57.6 cases per 10,000 population in 1981 to less than one at the national level in December 2005, and the country could achieve the goal of leprosy elimination at national level as set by the National Health Policy (2002). 33 states/UTs achieved the status of leprosy elimination. Only 2 States/UTs viz. Chattisgarh and Dadra & Nagar Haveli are yet to achieve elimination *(1)*.

A total of 209 high endemic districts were identified for special action during 2012–13. 1792 blocks and 150 urban areas were identified for special activities, i.e., house to house survey along with IEC and capacity building of the workers and volunteers *(1)*.

Major initiatives

Major initiatives taken are as follows :

(1) More focus has now been given to new case detection than prevalence which only gives the number of cases on record at a point in time. The new case detection rate is the main indicator for programme monitoring.
(2) Treatment completion rate has been taken as an important indicator, to be calculated by states at yearly basis.
(3) More emphasis is being given on providing disability prevention and medical rehabilitation (DPMR) services to leprosy affected persons. The aid provided is as follows :
   (a) Dressing materials, supportive medicines and ulcer kits are provided to leprosy affected persons with ulcers and wounds. These services are also provided to leprosy affected persons residing in self settled colonies.
   (b) Micro-cellular rubber footwear is provided for protection of insensitive feet. 41 NGOs in the country and 42 Government Medical Colleges have been strengthened for providing reconstructive surgery services to leprosy affected persons for correction of their disability, thus totalling to 83 centres for conducting reconstructive surgeries in the country.
   (c) An amount of Rs. 5000/- is provided as incentive to each leprosy affected person from BPL family undergoing reconstructive surgery in these identified institutions to compensate for loss of wages.
   (d) Support is also provided to government institutions/ PMR centres in the form of Rs 5000/- per reconstructive surgery conducted.
(4) ASHAs have been involved in bringing out suspected leprosy cases from their villages for diagnosis and treatment at PHC and follow-up of confirmed cases for their treatment completion. To facilitate the involvement of ASHA in the programme, they are being paid incentive money as below :
   (a) On confirmed diagnosis of case brought by them – Rs. 100/-
   (b) On completion of full course of treatment of the case within specified time – PB leprosy case – Rs 200/-, and MB leprosy case – Rs 400/-.
(5) There are 612 self settled colonies in the country where more than 50,000 leprosy affected persons reside. Free medical facilities like care of ulcers, self care training, counselling and MCR footwear are provided to leprosy affected persons residing in these colonies through para-medical workers/NGOs on weekly/fortnightly basis.
(6) Intensive IEC campaign with a theme "Towards Leprosy Free India" has been carried out towards further reduction of leprosy burden in the community, early reporting of cases and their treatment completion, provision of quality leprosy services and reduction of stigma and discrimination against leprosy affected persons. Awareness generation activities are carried out through mass media and local media.

Urban leprosy control programme

The urban leprosy control programme was initiated in 2005 to address the complex problem of larger population size, migration, poor health infrastructure and increasing leprosy cases in urban areas.

Under this component, assistance is provided to urban areas having population size of more than 1 lakh. For the purpose of providing graded assistance, the urban areas are grouped in four categories i.e. Township I, Medium Cities I, Medium Cities II, and Mega Cities *(3)*.

Disability prevention and medical rehabilitation (DPMR)

The main activities carried out under DPMR are as follows *(8)* :

(1) Implementation of DPMR activities as per guidelines and reporting its outcome eg. treatment of leprosy reaction, ulcers, physiotherapy, reconstructive surgery and providing MCR footwear.
(2) Integrating DPMR services – There are provision of services to persons with disability by various departments under different ministries. Convergence of NLEP services into NRHM facilitates this integration.

(3) To develop a referral system to provide prevention of disability services to all leprosy disabled persons in an integrated set-up.

The DPMR activities are planned to be carried out in a three tier system i.e. the primary level care (First level), secondary level care (Second level) and the tertiary level care (Third level). The primary level care institutions are all PHCs, CHCs, Sub-divisional hospitals and urban leprosy centres/dispensaries. The secondary level care institutions are all District Head Quarter Hospitals and District Nucleus Units. The tertiary level care institutions are :

1. Central Government Institutes (CLTRI Chingalpettu and RLTRI at Aska/Gauripur/Raipur)
2. ICMR Institute JALMA, Agra.
3. ILEP supported Leprosy Hospitals.
4. All PMR Institutes and departments of medical colleges.

The other support units are :

(1) Orthopaedics and plastic surgery departments of medical colleges.
(2) Identified NGO institutions.
(3) All National Institutes under Ministry of Social Justice and Empowerment.
(4) Contractual surgeons skilled in RCS and Rehabilitation Programmes.

The referral system in NLEP is as shown in Fig. 1.

Decentralization and institutional development : Integration of leprosy services into the general health care system has been completed. Services are available from all PHCs, and other health centres where a medical officer is available. District nucleus has been formed to supervise and monitor the programme. State leprosy societies formed will merge with the state health society under the National Rural Health Mission.

Programme Implementation Plan for 12th Plan Period (2012–13 to 2016–17)

As the disease is still prevalent with moderate endemicity in about 15 per cent of the country, the plan objectives are set as follows *(9)*.

a. Elimination of leprosy i.e. prevalence of less than 1 case per 10,000 population in all districts of the country.

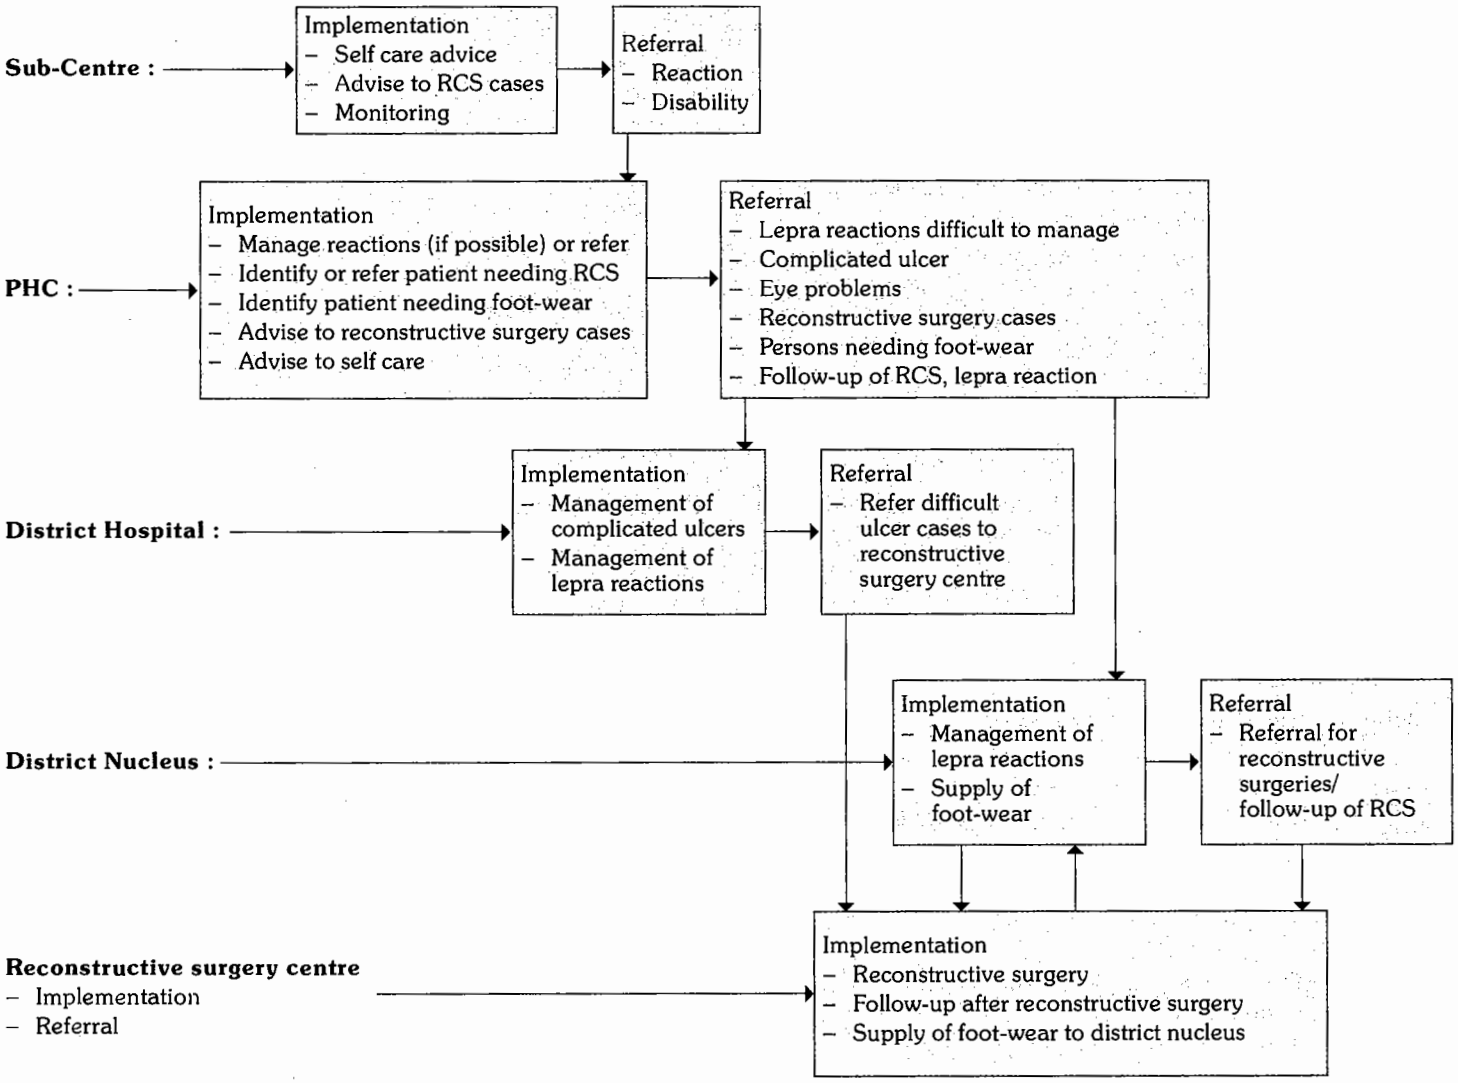

FIG. 1

Referral system in NLEP

Source : *(8)*

b. Strengthen disability prevention and medical rehabilitation of persons affected by leprosy.

c. Reduction in the level of stigma associated with leprosy.

Targets *(9)*

The plan targets are as shown in Table 4.

TABLE 4

Targets for the plan period 2012–13 to 2016–17

Indicator	Baseline (2011–12)	Targets (by March 2017)
Prevalence Rate (PR) < 1/10,000	543 districts (84.6%)	642 districts (100%)
Annual New Case Detection Rate (ANCDR) <10/100,000 population	445 districts (69.3%)	642 districts (100%)
Cure rate multi bacillary leprosy cases (MB)	90.56%	>95%
Cure rate pauci bacillary leprosy cases (PB)	95.28%	>97%
Gr.II disability rate in percentage of new cases	3.04% *	35% reduction 1.98%
Stigma reduction	Percentage reported (NSS 2010–11)**	50% reduction over the percentage reported by NSS

* Gr-II disability rate among new cases per million population to be reduced by 35% i.e. from 3 (2011–12) to 2 per million population by end of the 12th Plan.

** Based on the National Sample Survey (NSS) report, 2010–11.

Programme strategy *(9)*

To achieve the objectives of the plan, the main strategies to be followed are :

- Integrated leprosy services through general health care system.
- Early detection and complete treatment of new leprosy cases.
- Carrying out house-hold contact survey for early detection of cases.
- Involvement of Accredited Social Health Activist (ASHA) in the detection and completion of treatment of leprosy cases on time.
- Strengthening of disability prevention and medical rehabilitation (DPMR) services.
- Information, Education & Communication (IEC) activities in the community to improve self-reporting to Primary Health Centre (PHC) and reduction of stigma.
- Intensive monitoring and supervision at block primary health centre/community health centre.

Case detection and management *(9)*

It is expected that the new cases will continue to occur regularly but the people are still hesitant to come forward to get themselves diagnosed and treated due to the stigma associated with the disease. Detection of the new cases at the early stage is the only solution to cut down the transmission potential in the community, and also to provide relief to the leprosy affected persons by preventing disabilities. It is therefore suggested that the states will draw up innovative plans :

(i) To improve access to services.

(ii) To involve women including leprosy affected persons in case detection.

(iii) To organize skin camps for detecting leprosy patients while providing services for other skin conditions.

(iv) To undertake contact survey to identify the source in the neighbourhood of each child or multibacillary case.

(v) To increase awareness through the ANM, AWW, ASHA and other health workers visiting the villages and people affected by leprosy, to motivate leprosy affected persons for early reporting to the medical officer.

Integrated leprosy services through all the primary health care facilities will continue to be provided in the rural areas. However, for providing technical support to the primary health care system, to stengthen the quality of services being provided, a team of dedicated workers including medical officer and para-medical workers are placed at district level. This will be known as "District Leprosy Cell".

Services in the urban areas *(9)*

The health services in the urban areas differ from the rural areas because of non-availability of infrastructure like PHC and manpower for providing services upto domicilliary level. The services in urban areas are provided mainly through institutional level. Multiple organizations provide health services in urban localities without much of coordination amongst them.

More number of cases are detected in urban localities due to migration of people, availability of good quality institutions with easy accessibility, but treatment completion rate is less as compared to rural areas.

For the implementation of special action under the plan, about 524 urban localities have been identified out of 4,388 urban areas (census 2011). These localities are having population more than 100,000. Remaining areas will be covered by PHC services as in rural areas *(9)*. These urban areas are divided into 4 categories : (a) Town and city (population 1 lac to 5 lacs) – 432 areas; (b) Medium city (population >5 lac to 1 million) – 53 areas; (c) Mega city (population >1 million to 4.5 million) – 34 areas; and (d) Areas with >4.5 million population – 5 areas.

Additional activities in urban areas : Component wise activities under NLEP will be carried out in the urban areas as in the case of rural areas. Thus training, IEC, procurement and supply of MDT and other required medicines, MCR footwear, aids and appliances, payments of incentive for RCS etc. will be covered under regular provision. However, it is necessary to carry out following additional activities, which are specific to the needs of the urban population :

1. Identify human resources available with Government, civil societies, NGOs and private medical practitioners for leprosy services like suspect and referral. Population groups may be allocated to each human resource, and for follow-up of the cases.
2. Build capacity of the identified human resources at the time of induction and periodically.
3. Examination of all household contacts of all new cases at least once before the completion of treatment of index case.
4. Identify one referral centre in each urban location for diagnosis and to manage leprosy with or without complications.

5. Supervision and monitoring of the programme is the responsibility of the district leprosy officer, and medical officer of the referral centre.
6. Mobile health clinics of general health services include leprosy services on their visit to slums, peri-urban villages and migrant agglomerations.
7. Develop a system of record keeping and reporting by each participating centre.
8. Develop a system of regular MDT supply to each health centre.
9. Procure additional requirement of drugs, dressing material, aids and appliances for inhabitants of leprosy colony requiring regular care for their disabilities.
10. Organize sensitization meetings for IEC and advocacy, participate in exhibitions, quiz competition for awareness to reduce stigma.

Out of these 524 urban areas, 150 areas reported ANCDR of > 10 per lac population during the year 2011–12. As in case of rural blocks, these urban areas will also be provided with one para-medical worker on contractual basis for monitoring the leprosy services in the area.

ASHA involvement *(9)*

Accredited Social Health Activists (ASHA) will be involved to bring out suspected cases from their villages for diagnosis at PHC and after confirmation of diagnosis, will follow up the patients for completion of treatment. Her duties will be monitored by the concerned PHC medical officer. She will be entitled to receive incentive as below :

(i) At confirmation of diagnosis – Rs. 250/-

(ii) On completion of full course of treatment in time – PB–additional Rs.400/- MB–additional Rs.600/-

Activities to be performed by ASHA are as follows :

1. Search for suspected cases of leprosy i.e. before any sign of disability appears. Such early detection will help in prevention of disability and also cut down transmission potential.
2. Follow-up all cases for completion of treatment in scheduled time. During follow up visit, also look for symptoms of any reaction due to leprosy and refer them to the Health Workers/PHC for treatment. This will again reduce chances of disability occurring in cases under treatment.
3. Advise and motivate self-care practices by disabled cases for proper care of their hands and feet during the follow-up period. This will improve quality of life of the affected persons and prevent deterioration of disabilities.
4. Spreading awareness.

SET scheme

Under the SET scheme, the NGOs are presently involved in disability prevention and ulcer care, IEC, referral of suspected cases, referral for reconstruction surgery (RCS), research and rehabilitation. NGO support is mainly required for follow-up of under treatment cases in urban locations and difficult to reach areas.

Disability prevention and medical rehabilitation (DPMR)

The services under DPMR will cover reaction mangagement, self-care practices, provision of MCR footwear, aids and appliances, referral services at district hospital and medical college/central leprosy institutions/ NGO institutions, and reconstructive surgery.

Incentive to patient *(9)*

An incentive of Rs. 8000/- will be paid to all patients affected by leprosy undergoing major reconstructive surgery irrespective of their financial status. The payment will be made by the district leprosy officer. As on January 2013, there were 94 recognized RCS centres in the country.

Information, education and communication (IEC/BCC)

The IEC strategy during the 12th plan period will focus on communication for behavioural changes in general public against the stigma and discrimination against the leprosy affected persons. Making the public aware about the availability of MDT, correction of deformity through surgery and that the leprosy affected person can live a normal life with the family *(9)*.

Research into the basic problems of leprosy is also part of the activities of the NLEP. This is mainly carried out in the Government sector, viz. the Central JALMA Institute of Leprosy at Agra and the Central Leprosy Teaching and Training Institute at Chingelput, Chennai supported by Regional Training and Referral Institutes at Aska (Orissa), Raipur (Chhattisgarh) and Gouripur (West Bengal).

ILEP Agencies

The International Federation of Anti-Leprosy Associations is actively involved as partner in NLEP. In India, ILEP is constituted by 10 agencies viz. The Leprosy Mission, Damien Foundation of India Trust, Netherland Leprosy Relief, German Leprosy Relief Association, Lepra India, ALES, AIFO, Fontilles–India, AERF–India and American Leprosy Mission. ILEP is providing support in the form of planning, monitoring and supervision of the programme, capacity building of general health care staff, IEC, providing re-constructive surgery services and socio-economic rehabilitation of persons affected with leprosy. 36 NGOs conducting re-constructive surgeries for disability correction in leprosy affected persons are also supported by ILEP *(1)*.

Non Government Organizations have been involved in the programme for many decades and have provided valuable contribution in reducing the burden of leprosy. Presently, 43 NGOs are getting grant-in-aid from Government of India under SET scheme. NGOs serve in remote, inaccessible areas, urban slums, industrial/labour population and other marginalized population groups. IEC, prevention of disability, case detection and referral, and follow-up for treatment completion are some important activities taken up by NGOs *(1)*.

The leprosy scene in India is passing through an important phase of transition – from a high burden country of leprosy to a relatively low burden country, from a partially vertical programme to a more integrated one, from a programme aimed at increase in coverage for leprosy services to one of sustaining quality services, and from centralization to decentralization *(10)*.

Recently WHO has announced "enhanced global strategy" for further reducing the disease burden due to leprosy (2011–2015). Please refer to page 315 for details.

REVISED NATIONAL TUBERCULOSIS CONTROL PROGRAMME

National Tuberculosis Programme (NTP) has been in operation since 1962. However, the treatment success rates were unacceptably low and the death and default rates remained high. Spread of multidrug resistant TB was threatening to further worsen the situation. In view of this, in 1992 Government of India along with WHO and SIDA reviewed the TB situation in the country and came up with following conclusions :

- NTP, though technically sound, suffered from managerial weaknesses
- Inadequate funding,
- Over-reliance on X-ray for diagnosis
- Frequent interrupted supplies of drugs
- Low rates of treatment completion

In 1993, in order to overcome these lacunae, the Government of India decided to give a new thrust to TB control activities by revitalizing the NTP, with the assistance from international agencies. The Revised National TB Control Programme (RNTCP) thus formulated, adopted the internationally recommended Directly Observed Treatment Short-course (DOTS) strategy, as the most systematic and cost-effective approach to revitalize the TB control programme in India. Political and administrative commitment, to ensure the provision of organized and comprehensive TB control services was obtained. Adoption of smear microscopy for reliable and early diagnosis was introduced in a decentralized manner in the general health services. DOTS was adopted as a strategy for provision of treatment to increase the treatment completion rates. Supply of drugs was also strengthened to provide assured supply of drugs to meet the requirements of the system *(11)*.

The objectives of the RNTCP are :

1. Achievement of at least 85 per cent cure rate of infectious cases of tuberculosis; through DOTS involving peripheral health functionaries; and
2. Augmentation of case finding activities through quality sputum microscopy to detect at least 70 per cent of estimated cases.

The revised strategy was introduced in the country in a phased manner as Pilot Phase I, Pilot Phase II and Pilot Phase III. By the end of 1998, only 2 per cent of the total population of India was covered by RNTCP. Large-scale implementation began in late 1998. The RNTCP has expanded rapidly over the years and since March 2006, it covers the whole country. The RNTCP has now entered into it's second phase in which the programme aims to consolidate the gains made to date, to widen services in terms of activities and access and to sustain the achievements. The new initiatives and the wider collaboration with other sectors aim to provide standardized treatment and diagnostic facilities to all TB patients irrespective of the health care facility from which they seek treatment. The RNTCP also envisages improved access to marginalized groups such as urban slum dwellers and tribal groups etc.

RNTCP is built upon infrastructure already established by the previous national tuberculosis programme, while incorporating the elements of the internationally recommended DOTS.

DOTS strategy adopted by Revised National TB Control Programme initially had the following five main components:

1. Political will and administrative commitment.
2. Diagnosis by quality assured sputum smear microscopy.
3. Adequate supply of quality assured short course chemotherapy drugs.
4. Directly observed treatment.
5. Systematic monitoring and accountability.

In 2006, STOP TB strategy was announced by WHO and adopted by RNTCP. The components are as follows :

- Pursuing quality DOTS – expansion and enhancement.
- Addressing TB/HIV and MDR-TB.
- Contributing to health system strengthening.
- Engaging all care providers.
- Empowering patients and communities.
- Enabling and promoting research (diagnosis, treatment, vaccine).

Many of the initiatives like developing and piloting the feasibility of National Airborne Infection Control Guidelines, developing and piloting strategy for 'Practical Approach to Lung Health' are the examples of initiatives taken by RNTCP under the comprehensive strategy of STOP TB *(11)*.

ORGANIZATION

The profile of RNTCP in a state is as follows :

– State Tuberculosis Office	– State Tuberculosis Officer
– State Tuberculosis Training and Demonstration Centre	– Director
– District Tuberculosis Centre	– District Tuberculosis Officer
– Tuberculosis Unit	– Medical Officer – TB Control
	– Senior Treatment Supervisor
	– Senior TB Laboratory Supervisor

- Microscopy Centres, Treatment Centres
- DOTS Providers

LABORATORY NETWORK

Quality Assured Laboratory services : RNTCP has established a nationwide laboratory network, encompassing over 13,309 designated sputum microscopy centres (DMCs), which are being supervised by inter-mediate reference laboratories (IRL) at state level, and national reference laboratories (NRL) and central TB division at the National level. RNTCP aims to consolidate the laboratory network into a well-organized one, with a defined hierarchy for carrying out sputum microscopy with external quality assessment (EQA). The structure of laboratory network at different levels is as shown in Fig. 2.

National Reference Laboratories (NRL) : The six NRLs under the programme are National Institute for Research in Tuberculosis (NIRT) Chennai, National Tuberculosis Institute (NTI), Bangalore, Lala Ram Swarup Institute of Tuberculosis and Respiratory diseases (LRS), Delhi and JALMA Institute, Agra; Regional Medical Research Centre, Bhubaneswar; and Bhopal Memorial Hospital and Research Centre, Bhopal *(12)*. The NRLs work closely with the IRLs, monitor and

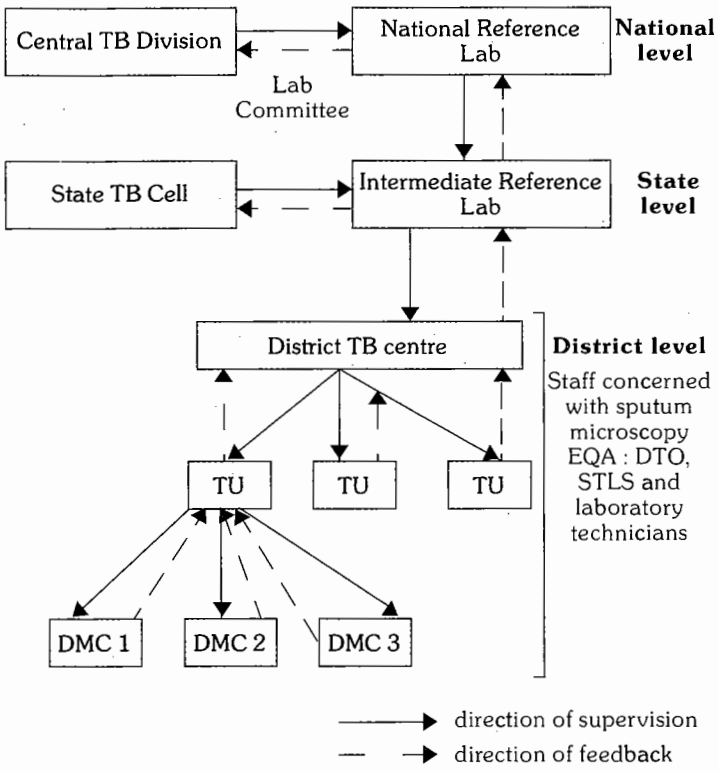

FIG. 2

Structure of RNTCP laboratory network
(The different levels of laboratories under RNTCP)

Source : *(13)*

supervise the IRL's activities and also undertake periodic training for the IRL staff in EQA, Culture & DST activities.

Three microbiologists and four laboratory technicians have been provided by the RNTCP on contractual basis to each NRL for supervision and monitoring of laboratory activities. The NRL microbiologist and laboratory supervisor/technician visits each assigned state at least once a year for 2 to 3 days as a part of on-site evaluation under the RNTCP EQA protocol.

Intermediate reference laboratory (IRL) : One IRL has been designated in the state tuberculosis training and demonstration centres (STDC)/public health laboratory/ medical college of the respective state. The functions of IRL are supervision and monitoring of EQA activities, mycobacterial culture and DST, and also drug resistance surveillance (DRS) in selected states. The IRL ensures the proficiency of staff in performing smear microscopy activities by providing technical training to district and sub-district laboratoy technicians and senior TB laboratory supervisors (STLSs). The IRLs undertake on-site evaluation and panel testing to each district in the state, as least once a year.

Designated microscopy centre (DMC) : The most peripheral laboratory under the RNTCP network is the DMC which serves a population of around 100,000 (50,000 in tribal and hilly areas). Currently all the districts in the country are implementing EQA. For quality improvement purposes, the NRL on-site evaluation (OSE) recommendations to IRLs and districts are discussed in the RNTCP laboratory committee meetings, quarterly at CTD. Quality improvement workshops for the state level TB officers and laboratory managers are conducted at NRLs based on the observations of the NRL-OSEs. These workshops focus on issues such as human resources, trainings, AMC for binocular microscopes, quality specifications for ZN stains, RBRC blinding and coding issues, bio-medical waste disposal, infection control measures etc.

The Quality Assurance activities include :

- On-site evaluation,
- Panel testing and
- Random blinded rechecking.

Culture and DST laboratories (C & DST) *(12)*

In addtion to IRLs, the RNTCP also involves the microbiology department of medical colleges for providing diagnostic services for the drug resistant TB, extra-pulmonary TB and research. There are 51 RNTCP certified C & DST laboratories in the country which includes laboratories from public sector (IRLs and medical colleges, private sector and operated by NGOs).

Solid culture certification : The RNTCP has certified 37 laboratories for solid C & DST. These include 4 NRLs, 18 IRLs, 6 medical colleges, 3 NGOs, 4 ICMR institutes and 2 private laboratories.

Liquid culture certification : The RNTCP has certified 12 laboratories for liquid culture, which include 4 NRLs, 4 IRLs, one NGO laboratory and 2 private laboratories.

Line Probe Assay (LPA) : The LPA is a molecular diagnostic test, which can provide the DST results within one day. The RNTCP has adopted the policy for rapid diagnosis of MDR-TB by LPA. As on December 2013, about 41 laboratories have been certified by RNTCP, these include 4 NRLs, 24 IRLs, 8 medical colleges, 4 NGO laboratories and one private medical college.

The molecular laboratories are equipped with clean room facility and GT BLOT machines to perform upto 90 tests per day for the diagnosis of MDR-TB.

Second line DST (SLD) : As on December 2013, five laboratories which includes 3 NRLs, one IRL and one NGO laboratory are performing second line DST in solid and liquid culture.

RNTCP endorsed TB diagnostics *(1)*

1. Smear microscopy for acid fast bacilli.
   a. Sputum smear stained with Zeihl-Neelsen staining; or
   b. Fluoresence stains and examined under direct or indirect microscopy with or without LED.
2. Culture
   a. Solid (Lowenstein Jansen) media; or
   b. Liquid media (Middle Brook) using manual semi-automatic or automatic machines, e.g., Bactec, MGIT etc.
3. Rapid diagnostic molecular test
   a. Conventional PCR based Line Probe Assay for MTB complex; or
   b. Real-time PCR based Nucleic Acid Amplification Test NAAT for MTB complex, e.g. GeneXpert.

New Initiatives

1. The RNTCP has completed the feasibility study of introducing GeneXpert in RNTCP in 18 Tuberculosis Units in 12 states. RNTCP is currently using CB NAAT for the

diagnosis of tuberculosis and MDT-TB in high risk population like HIV positive and paediatric groups (12).

2. *Nikshay : TB surveillance using case based web based IT system (12)*

Central TB Division in collaboration with National Informatics Centre has undertaken the initiative to develop a case based web based application named Nikshay.

This software was launched in May 2012 and has following functional components.

- Master management
- User details
- TB Patient registration and details of diagnosis, DOT provider, HIV status, follow-up, contact tracing, outcomes.
- Details of solid and liquid culture and DST, LPA, CBNAAT details.
- DR-TB patient registration with details.
- Referral and transfer of patients.
- Private health facility registration and TB notification.
- Mobile application for TB notification.
- SMS alerts to patients on registration.
- SMS alerts to programme officers.
- Automated periodic reports
  a. Case finding
  b. Sputum conversion
  c. Treatment outcome.

3. *TB Notification*

In order to ensure proper diagnosis and management of TB cases, and to reduce TB transmission and the emergence and spread of MDR-TB, it is essential to have complete information of all TB cases. According to the Government of India notification dated 7th May 2012, it is now mandatory for all healthcare providers to notify every TB case to local authorities i.e. District Health Officer/Chief Medical Officer of a district and Municipal health officer, every month in a given format *(14)*.

At present, 57,000 health facilities have been registered and 35,000 patients have been notified *(1)*.

4. *Ban on TB Serology*

The serological tests are based on antibody response, which is highly variable in TB and may reflect remote infection rather than active disease. Currently available serological tests are having poor specificity and should not be used for the diagnosis of pulmonary or extra-pulmonary TB. Their import, manufacturing, sale, distribution and use is banned by the Government of India *(12)*.

Initiation of treatment

Under the RNTCP active case finding is not pursued. Case finding is passive. Patients presenting themselves with symptoms suspicious of tuberculosis are screened through 2 sputum smear examinations. Sputum microscopic examination is done in designated RNTCP microscopy centres. They are located either in the CHC, PHC, Taluka Hospitals or in the TB dispensary. Each centre has a skilled technician to ensure quality control, a senior TB laboratory supervisor is appointed for every 5 microscopy centres. The senior TB laboratory supervisor rechecks all the positive slides and 10 per cent of the negative slides of these five microscopy centres. Thus the error in diagnosing a patient is minimized. It is essential to examine 2 sputum specimens of each patient before a conclusive diagnosis can be made. One sputum sample is not sufficient for diagnosis as the chance of detecting smear positive case is only 80 per cent. Sputum microscopy not only confirms the diagnosis, but also indicates the degree of infectivity and response to treatment. Fig. 3 shows the criteria of diagnosis and initiation of treatment.

All patients are provided short-course chemotherapy free of charge. During the intensive phase of chemotherapy all the drugs are administered under direct supervision called Direct Observed Therapy Short–term (DOTS). DOTS is a community based tuberculosis treatment and care strategy which combines the benefits of supervised treatment, and the benefits of community based care and support. It ensures high cure rates through its three components: appropriate medical treatment, supervision and motivation by a health or non-health worker, and monitoring of disease status by the health services. DOTS is given by peripheral health staff such as MPWs, or through voluntary workers such as teachers, anganwadi workers, dais, ex-patients, social workers etc. They are known as DOT 'Agent' and paid incentive/honorarium of Rs 150 per patient completing the treatment.

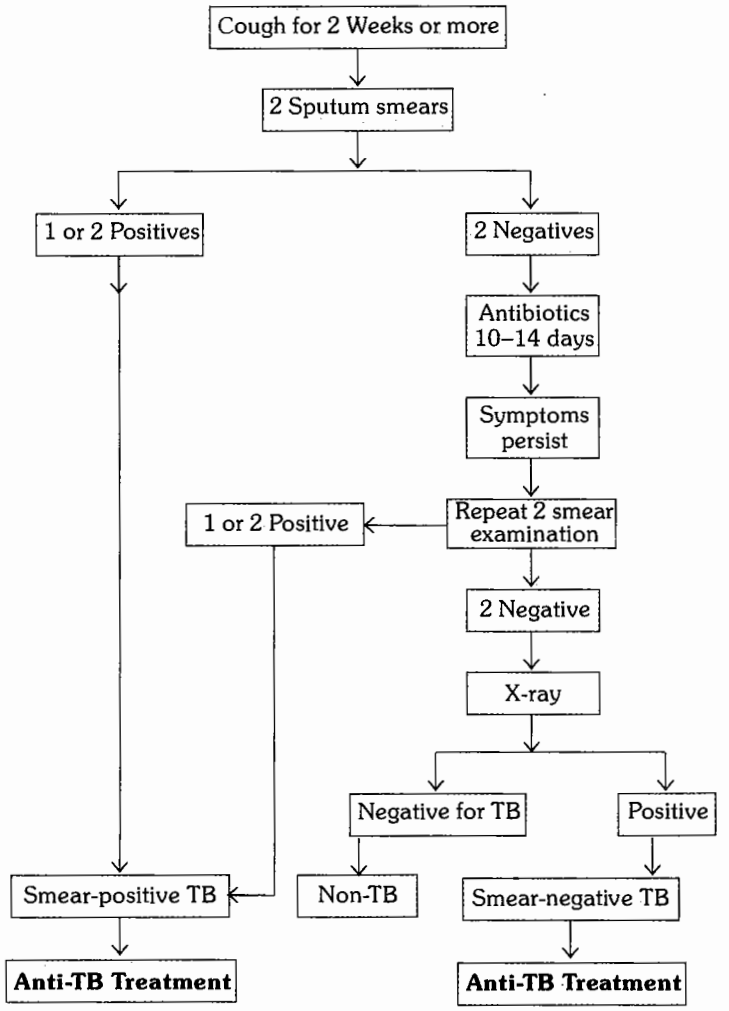

FIG. 3
Diagnosis of tuberculosis in RNTCP

The drugs are supplied in patient-wise boxes containing the full course of treatment, and packaged in blister packs. For the intensive phase, each blister pack contains one day's medication. For the continuation phase, each blister pack contains one weeks supply of medication. The combipack drugs for extension of intensive phase are supplied separately. The boxes are coloured according to the category of the regimen, red for category I patients, blue for category II patients.

Paediatric tuberculosis *(12)*

Please refer to page 193 for details.

Drug resistance surveillance (DRS) under RNTCP *(11)*

The prevalence of drug resistance to TB can be taken as an indicator of the effectiveness of the TB control activities over a period of time and, therefore, RNTCP has taken steps to measure this important indicator.

The aim of DRS is to determine the prevalence of antimycobacterial drug resistance among new sputum smear positive pulmonary tuberculosis (PTB) patients, and also amongst previously treated sputum smear positive PTB patients. Drug–resistant TB has frequently been encountered in India, and its presence has been known virtually from the time anti-TB drugs were introduced for the treatment of TB.

To obtain a more precise estimate of Multi-Drug Resistant TB (MDR-TB) burden in the country, RNTCP carried out drug resistance surveillance (DRS) surveys in accordance with global guidelines in selected states. The results of these surveys indicate prevalence of MDR-TB to be about 2.2 (1.9–2.6) per cent in new cases and 15 (11–19) per cent in retreatment cases *(16)*.

PROGRAMMATIC MANAGEMENT OF DRUG RESISTANT TB (PMDT)

DOTS–Plus

The PMDT services for quality diagnosis and treatment of drug resistant TB cases were initiated in 2007 in Gujarat and Maharashtra. These services since then have been scaled up and currently these services are available across the country from March 2013. As of 2013, about 20,000 (17,000–24,000) among new pulmonary TB cases and 41,000 retreatment cases of MDR-TB have been reported in India, and of these 32,622 confirmed cases were put on standard regimen for MDR-TB under RNTCP *(16)*.

For full details about the DOTS-Plus programme and patient regimens please refer to page 190 and 199.

TB-HIV coordination *(15)*

Since the advent of the collaborative efforts in 2001, TB-HIV activities have evolved to cover most of the recommendations as per the latest WHO policy statement issued in 2012. In 2007, the first national framework for joint TB-HIV collaborative activities was developed which endorsed a differential strategy reflective of the heterogeneity of TB-HIV epidemic. Coordinated TB-HIV interventions were implemented including establishment of a coordinating body at national and state level, dedicated human resources, integration of surveillance, joint monitoring and evaluation, capacity building and operational research.

The implementation of collaborative TB/HIV activities are as follows :

1. Intensified TB case finding has been implemented nationwide at all HIV testing centres (known as integrated counselling and testing centres, or ICTCs), and has now been extended to all ART centres.
2. HIV testing of TB patients is now routine through provider initiated testing and counselling (PITC), implemented in all states with the intensified TB-HIV package.
3. Persons found to be HIV-positive are eligible for free HIV care at a network of antiretrovial treatment (ART) centres. ART centres are located in medical colleges, mainly staffed and operated by the state AIDS control societies, and a few are situated within the facilities of private or NGO partners. As of December 2012, there were 410 ART centres operating in the country, 811 link-ART centres and 158 link-ART plus centres. Ten Regional Centres of Excellence provide second-line ART services for PLHIV, and 24 centres provide second line ART (ART-plus centres). HIV-infected TB patients who are on protease inhibitor based second line ART are getting rifabutin-based TB treatment in place of Rifampicin.
4. Policy decision has been taken by National Technical Working Group on TB/HIV collaborative activities (NTWG on TB/HIV) to expand coverage of whole blood finger prick HIV screening test at all DMC without a stand-alone or F-ICTC.
5. Provider initiated HIV testing and counselling (PITC) among presumptive TB cases (TB suspects) is now a policy –
   a. In high HIV prevalent states/settings – The implementation will be done in a phased manner, starting with high prevalent states and then in A and B category districts in rest of the country.
   b. In low HIV prevalent states/settings – HIV testing among presumptive TB cases should be routinely implemented in the age-group of 25–54 years in low HIV prevalent districts (C & D) at places where there are co-located TB and HIV testing facilities.
6. Intensified case finding activities to be specifically monitored among HIV infected pregnant women and children living with HIV.
7. The National AIDS Control Programme (NACP) and RNTCP have taken the policy decision to adopt isoniazid prophylaxis therapy (IPT) as a strategy for prevention of TB among PLHIV. The implementation will be in a phased manner.
8. The RNTCP has prioritized presumptive TB cases among people living with HIV for diagnosis of TB and Rifampicin resistance with rapid diagnostic tools having high sensitivity e.g. Xpert MTB/RIF.

The treatment guidelines are discussed in detail on page 201.

Tuberculosis in pregnancy

Please refer to page 196 for details.

National Strategic Plan (2012–2017)

With progress in achieving objectives in the 11th Five Year Plan and defining newer targets of universal access to TB care, newer strategies have been developed as a comprehensive National Strategic Plan under the 12th Five

Year Plan. The following thrust areas were identified *(15)* :

- Strengthening and improving the quality of basic DOTS services.
- Further strengthen and align with health system under NRHM.
- Deploying improved rapid diagnosis at the field level.
- Expand efforts to engage all care providers.
- Strengthen urban TB control.
- Expand diagnosis and treatment of drug resistant TB.
- Improve communication and outreach.
- Promote research for development and implementation of improved tools and strategies.

Strategic vision to move towards universal access

The vision of the Government of India is for a "TB-free India" with reduction of the burden of the disease until it is no longer a major public health problem. To achieve this vision, the programme has adopted the new objective of Universal Access for quality diagnosis and treatment for all TB patients in the community. This entails sustaining the achievements of the programme to date, and extending the reach and quality of services to all persons diagnosed with TB.

The objectives of the programme proposed in the plan are *(15)* :

- Early detection and treatment of at least 90% of estimated all type of TB cases in the community, including drug resistant and HIV associated TB.
- Successful treatment of at least 90% of new TB patients, and at least 85% of previously-treated TB patients.
- Reduction in default rate of new TB cases to less than 5% and re-treatment TB cases to less than 10%.
- Initial screening of all re-treatment smear-positive till 2015, and all smear positive TB patients by year 2017 for drug-resistant TB and provision of treatment services for MDR-TB patients;
- Offer of HIV counselling and testing for all TB patients and linking HIV-infected TB patients to HIV care and support;
- Extend RNTCP services to patients diagnosed and treated in the private sector.

Targets

The targets proposed are :

1. Detection and treatment of about 87 lakh tuberculosis patients during the 12th Five Year Plan.
2. Detection and treatment of at least 2 lakh MDR-TB patients during the 12th Five Year Plan.
3. Reduction in delay in diagnosis and treatment of all types of TB cases.
4. Increase in access to services to marginalized and hard to reach populations, and high risk and vulnerable groups.

Achievements of RNTCP

The RNTCP covers the whole country since March 2006. Phase II of the RNTCP has been launched in the country from 1st October 2006. The treatment success rate has more than trebled from 25 per cent in 1998 to 88 per cent in 2013. Death rate has been brought down seven folds from 29 per cent to 4 per cent. 662 DTCs, 2,698 TB Units and 13,209 DMCs are functional in the country. The programme involves more than 2,708 NGOs, more than 13,311 private practitioners, over 319 medical colleges and more than 150 corporate health facilities. More than 13,309 peripheral laboratories/Designated Microscopy Centres have been established. More than 6 lacs public health care providers have been trained under the programme. Master trainers on TB/HIV have been trained on TB/HIV related issues in 12 states. More than 16 million patients have been initiated in treatment, saving almost 2.8 million lives. Four urban DOTS projects have also been launched to solve the problems of inaccessibility of TB care faced by urban poor utilizing GFATM (Global Fund to fight AIDS, TB & Malaria) support in Mumbai, Hyderabad, Varanasi and Chennai.

The laboratory services provided are as follows *(16)*

Laboratories 2013	
Smear (per 100,000 population)	1.0
Culture (per 5 million population)	0.2
Drug susceptibility testing (per 5 million population)	0.2
Sites performing Xpert MTB/RIF	54
Is second-line drug susceptibility testing available ?	Yes, in country

For the incidence rate, prevalence rate and treatment outcome details, please refer to page 177.

Financial resources

The programme is being assisted by the World Bank and the Department for International Development (DFID) *via* WHO. In addition, the RNTCP is supported by the Global TB Drug Facility (GDF), Global Fund to Fight AIDS, Tuberculosis and Malaria (GFATM), the United States Agency for International Development (USAID) and DANIDA. Government of India provides 100 per cent grant-in-aid to the implementing agencies i.e., states/UTs, besides free drugs. The states are expected to use the existing infrastructure and also to provide some manpower resources.

NATIONAL AIDS CONTROL PROGRAMME

National AIDS Control Programme was launched in India in the year 1987. The Ministry of Health and Family Welfare has set up National AIDS Control Organization (NACO) as a separate wing to implement and closely monitor the various components of the programme. The aim of the programme is to prevent further transmission of HIV, to decrease morbidity and mortality associated with HIV infection and to minimize the socio-eonomic impact resulting from HIV infection.

The milestones of the programme are summarized as follows *(17)* :

1986 – First case of HIV detected.
- AIDS Task Force set up by the ICMR.
- National AIDS Committee established under the Ministry of Health.

1990 – Medium Term Plan launched for four states and the four metros.

1992 – NACP–I launched to slow down the spread of HIV infection.
- National AIDS Control Board constituted.
- NACO set-up.

1999 – NACP–II begins, focussing on behaviour change, increased decentralization and NGO involvement.
- State AIDS Control Societies established.

2002 – National AIDS Control Policy adopted.
– National Blood Policy adopted.

2004 – Anti-retroviral treatment initiated.

2006 – National Council on AIDS constituted under chairmanship of the Prime Minister.
– National Policy on Paediatric ART formulated.

2007 – NACP–III launched for 5 years (2007–2012).

2014 – NACP–IV launched for 5 years (2012–2017).

The national strategy has the following components : establishment of surveillance centres to cover the whole country; identification of high-risk group and their screening; issuing specific guidelines for management of detected cases and their follow-up; formulating guidelines for blood bank, blood product manufacturers, blood donors and dialysis units; information, education, and communication activities by involving mass media and research for reduction of personal and social impact of the disease; control of sexually transmitted diseases; and condom programme.

The Government of India initiated programmes of prevention and raising awareness under the Medium Term Plan (1990–92), NACP–I (1992–99), NACP–II (1999–2006) and NACP–III (2007–2012). Based on the lessons learnt and achievements made in Phase I, II and III. India developed the Fourth National Programme Implementation Plan (NACP–IV, 2012–2017). The primary goal of NACP–IV is to halt and reverse the epidemic in India over the next 5 years by integrating programmes for prevention, care, support and treatment.

The package of services under NACP-IV are as follows *(18)* :

1. *Prevention services*

- Targeted interventions for high-risk groups (female sex workers, men who have sex with men, transgenders/ hijras, injecting drug users) and bridge population (truckers and migrants)
- Needle-syringe exchange programme and opioid substitution therapy for IDUs
- Prevention interventions for migrant population at source, transit and destination
- Link worker scheme for HRGs and vulnerable population in rural areas
- Prevention and control of sexually transmitted infections/reproductive tract infections
- Blood safety
- HIV counselling and testing services
- Prevention of parent to child transmission
- Condom promotion
- Information, education and communication and behaviour change communication (BCC)
- Social mobilization, youth interventions and adolescence education programme
- Mainstreaming HIV/AIDS response
- Work place interventions.

2. *Care, support and treatment services*

- Laboratory services for CD4 testing and other investigations
- Free first-line and second-line Anti-Retroviral Therapy (ART) through ART centres and Link ART Centres (LACs), Centres of Excellence (CoE) and ART plus centres
- Paediatric ART for children
- Early infant diagnosis for HIV exposed infants and children below 18 months
- Nutritional and psycho-social support through Care and Support Centres (CSC)
- HIV/TB coordination (cross-referral, detection and treatment of co-infections)
- Treatment of opportunistic infections
- Drop-in centres for PLHIV networks.

Country scenario

Based on sentinel surveillance data, the HIV prevalence in adult population can be broadly classified into three groups of States/UTs in the country.

Group I High Prevalence States : includes states of Maharashtra, Tamil Nadu, Karnataka, Andhra Pradesh, Manipur and Nagaland where the HIV infection has crossed 5 per cent mark in high-risk group and 1% or more in antenatal women.

Group II Moderate Prevalence States : includes states of Gujarat, Goa and Puducherry where HIV infection has crossed 5% or more among high risk groups but the infection is below 1% in antenatal women.

Group III Low Prevalence States : includes remaining states where the HIV infection in any of the high risk groups is still less than 5% and is less than 1% among antenatal women.

Categories of Districts

In the country, the districts have been classified according to the epidemiological and vulnerability–criteria using the sentinel surveillance data for the last 3 years (Table 5). Accordingly, 156 districts have been classified as category A. 39 districts as category B, 296 as category C and 118 as category D districts. The planning for HIV related services has also been graded as per categorization of districts. This approach has been implemented since March 2007.

TABLE 5

Categories of districts

Category of districts	
More than 1% ANC/PTCT prevalence in district at any time in any of the sites in the last 3 years	A
Less than 1% ANC/PTCT prevalence in all the sites during last 3 years associated with more than 5% prevalence in any HRG group (STD/CSW/MSM/IDU)	B
Less than 1% in ANC prevalence in all sites during last 3 years with less than 5% in all STD clinic attendees or any HRG with known hot spots (Migrants, truckers, large aggregation of factory workers, tourist etc.)	C
Less than 1% in ANC prevalence in all sites during last 3 years with less than 5% in all STD clinic attendees or any HRG OR, poor HIV data with no known hot spots.	D
ANC – Antenatal clinic PTCT – Parent to child transmission

HIV surveillance

Different types of surveillance activities are being carried out in the country to detect the spread of the disease and to make appropriate strategy for prevention and control viz., area specific targeted intervention and best practice approach. The types of surveillance are : (a) HIV Sentinel Surveillance, (b) HIV Sero–Surveillance, (c) AIDS Case Surveillance, (d) STD Surveillance, (e) Behavioural Surveillance, and (f) Integration with surveillance of other diseases like tuberculosis etc.

HIV SENTINEL SURVEILLANCE : After the establishment of the fact that HIV infection is present in wide geographic areas, the aim of surveillance was redefined to monitor the trends of HIV infection. The objectives of the surveillance are as follows *(20)* :

1. To determine the level of HIV infection among general population as well as high-risk groups in different states;
2. To understand the trends of HIV epidemic among general population as well as high-risk groups in different states;
3. To understand the geographical spread of HIV infection and to identify emerging pockets;
4. To provide information for prioritization of programme resources and evaluation of programme impact; and
5. To estimate HIV prevalence and HIV burden in the country.

The objective of the surveillance is best achieved by annual cross-sectional survey of the risk group, in the same place over few years by unlinked anonymous serological testing procedures by two ERS (i.e., when HIV testing is carried out without indentification of name of samples collected for other purposes e.g., VDRL in STD clinics. The objective of surveillance may be fulfilled in this example whereas the positive person is not identified). The number of samples to be screened must represent the risk group under study and the sample size is determined accordingly. Clinical based approach for such collection has many advantages including the procedure for collection of samples which should be carried out on the above lines to avoid "selection bias" and "participation bias"

To start with, the HIV sentinel surveillance for HIV was taken up from 1994 in 55 sentinel sites attached to the existing surveillance centres and were increased to 180 in 1998. While the number of the high risk groups of HIV sentinel sites were increased every year, with change of sites, these 180 sites have remained consistent. Inclusion of data from high-risk population through targeted intervention sites and the additional sub–set of rural samples through ante-natal clinics are the key features of HIV sentinel surveillance. Pregnant women attending antenatal clinics are taken as proxy for general population. The number of HIV sentinel surveillance sites for different population groups during 2008–09 and 2010–11 are as shown in Table 6.

TABLE 6

Number of HIV sentinel surveillance sites (2008–09 and 2010–2011)

Site type	2008–09	2010–11
STD	217	184
ANC	498	506
ANC (rural)	162	182
ANC (youth)	8	8
IDU	61	79
MSM	67	96
FSW	194	262
Migrant	8	20
TG	1	3
Truckers	7	20
TB	–	–
Fisher-folk/seamen	–	–
Total	1,223	1,359

Source : *(21)*

The strategy adopted for collection and testing of samples during HIV Sentinel Surveillance Round 2010–11 was as follows (Table 7).

TABLE 7

HIV sentinel surveillence round 2010–2011

	High risk groups: IDU/MSM/FSW/TG	Bridge population: STD patients/SMM/LDT	General population: Pregnant women attending ANC clinics
Sentinel site	Targeted interventions (TI) projects	STD clinic, TI projects	Antenatal clinic
Sample size	250	250	400
Duration	3 months	3 months	3 months
Frequency	Once in 2 years	Once in 2 years	Once in 2 years
Sampling method	Consecutive/random	Consecutive	Consecutive
Age group	15–49 years	15–49 years	15–49 years
Testing strategy	Unlinked anonymous with informed consent	Unlinked anonymous at STD, with informed consent at TI sites	Unlinked anonymous
Blood specimen	Dried blood spot	Serum at STD, DBS at TI sites	Serum
Testing protocol	Two test protocol	Two test protocol	Two test protocol

Counselling and HIV testing services

The Basic Service Division of the department of AIDS control provides HIV counselling and testing services for HIV infection. The national programme is offering these services since 1997 with the goal to identify as many people living with HIV, as early as possible (after acquiring the HIV infection), and linking them appropriately and in a timely manner to prevention, care and treatment services. The introduction of ART services for people living with HIV/AIDS in 2004, gave a major boost to counselling and testing services in India. The HIV counselling and testing services include the following components:

1. Integrated Counselling and Testing Centres (ICTC)
2. Prevention of parent-to-child transmission of HIV (PPTCT)
3. HIV/tuberculosis collaborative activities.

INTEGRATED COUNSELLING AND TESTING CENTRES

Diverse models of HIV counselling and testing services are available to increase access to HIV diagnosis, these include testing services in health care facilities, standalone sites and community-based approaches at various levels of public health systems in India from state, district, sub-district and village/community levels as depicted in Fig. 4.

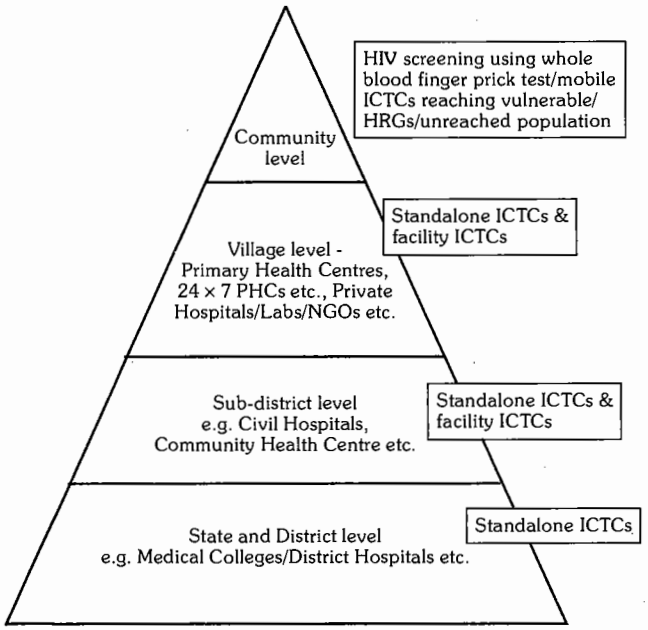

FIG. 4

Level of HIV counselling and testing services in India

Source : *(22)*

Types of facilities for HIV counselling and testing services

Integrated Counselling and Testing Centres (ICTC): A person is counselled and tested for HIV at ICTC, either of his own free will (client initiated) or as advised by a medical provider (provider initiated). Functions of ICTC include early detection of HIV, provision of basic information on modes of transmission and prevention of HIV/AIDS for promoting behavioural change and reducing vulnerability, and linking PLHIV with other HIV prevention, care and treatment services. The ICTC have been classified into two types: Fixed facility ICTC and Mobile ICTC.

1. Fixed facility ICTCs are located within an existing healthcare facility/hospital/health centre, and are of two types – Standalone ICTC and Facility-integrated counselling and testing centres.
   a. *Standalone ICTC (SA-ICTC):* The client load is high in these centres, with full-time counsellor and laboratory technician who provide HIV counselling and testing services. SA-ICTC are located in medical colleges, district hospitals, sub-district hospitals, CHCs etc.
   b. *Facility-integrated counselling and testing centres (F-ICTCs):* Considering the need for rapid scale-up and sustainability of HIV counselling and testing services, the F-ICTCs have been set up below the block levels at 24 × 7 PHC, etc. Staff of the existing health facilities are trained in counselling and testing services of HIV. The HIV service delivery is ensured with logistic support from DAC. Similar to F-ICTC at 24 × 7 PHC, the Public Private Partnership (PPP)-ICTCs were established in private facilities (for profit/ not-for-profit hospitals, laboratories, non-governmental organizations etc.), and have been supported by DAC/SACs in supply of rapid HIV testing kits, training of existing staff, quality assurance, supply of protective kits and prophylactic drugs for post-exposure prophylaxis for staff, supply of IEC materials such as flip charts, posters etc. required for ICTC.
2. Mobile ICTC: Mobile counselling and testing centre is a van with a room to conduct general examination, counselling and space for collection and processing blood samples by a team of paramedical healthcare providers (a health educator/ANM, counsellor and laboratory technician). Mobile ICTC are set up as temporary clinics in hard-to-reach areas with flexible working hours and provide a wide range of services like counselling and testing services for HIV, syndromic management of STI/ RTI and other minor ailments, along with regular health check-ups, antenatal, immunization services etc.

Community based HIV screening: In order to offer HIV testing to every pregnant woman in the country, so as to detect all HIV positive pregnant women and eliminate transmission of HIV from parent to child, the community-based HIV screening is conducted by frontline health workers (Auxiliary Nurse Midwives) at the sub-centre level.

PREVENTION OF PARENT-TO-CHILD TRANSMISSION OF HIV

The prevention of parent-to-child transmission of HIV/ AIDS (PPTCT) programme was started in the country in the year 2002. Currently there are more than 15,000 ICTCs in the country which offer PPTCT services to pregnant women. The aim of the PPTCT programme is to offer HIV testing to every pregnant woman (universal coverage) in the country, so as to cover all estimated HIV positive pregnant women and eliminate transmission of HIV from mother-to-child.

In India, PPTCT interventions under NACP was started in 2002, using SD-NVP prophylaxis for HIV positive pregnant women during labour and also for her new born child immediately after birth. With the department of AIDS control adopting "Option B" of the World Health Organization recommendations (2010), India has also transitioned from the single dose Nevirapine strategy to that of multi-drug ARV prophylaxis from September 2012. This strategy was executed in the three southern high HIV

prevalence states of Andhra Pradesh, Karnataka and Tamil Nadu. The national strategic plan for PPTCT services using multi-drug ARVs in India was developed in May-June 2013 for nationwide implementation in a phased manner. Based on the new WHO guidelines (June 2013) and on the suggestions from the technical resource groups during December 2013, department of AIDS control has decided to initiate lifelong ART (using the triple drug regimen) for all pregnant and breast-feeding women living with HIV, regardless of CD4 count or WHO clinical stage, both for their own health and to prevent vertical HIV transmission, and for additional HIV prevention benefits.

The PPTCT services provide access to all pregnant women for HIV diagnostic, prevention, care and treatment services. As such, the key goal is to ensure the integrated PPTCT service delivery with the existing Reproductive and Child Health (RCH) programme.

The essential package of PPTCT services in India are as follows *(22)* :

1. Routine offer of HIV counselling and testing to all pregnant women enrolled into antenatal care, with an 'opt out' option.
2. Ensuring involvement of spouse and other family members, and move from an "ANC-Centric" to a "Family-Centric" approach.
3. Provision of life-long ART (TDF+3TC+EFV) to all pregnant and breast-feeding HIV infected women, regardless of CD4 count and clinical stage of HIV progression.
4. Promotion of institutional deliveries of all HIV infected pregnant women.
5. Provision of care for associated conditions (STI/RTI, TB and other opportunistic infections).
6. Provision of nutrition, counselling and psychosocial support for HIV infected pregnant women.
7. Provision of counselling and support for initiation of exclusive breast-feeds within an hour of delivery as the preferred option and continued for 6 months.
8. Provision of ARV prophylaxis to infants from birth upto a minimum of 6 months.
9. Integrating follow-up of HIV-exposed infants into routine healthcare services including immunization.
10. Ensuring initiation of Co-trimoxazole Prophylactic Therapy (CPT) and Early Infant Diagnosis (EID) using HIV-DNA PCR at 6 weeks of age onwards, as per the EID guidelines.
11. Strengthening community follow-up and outreach through local community networks to support HIV-positive pregnant women and their families.

HIV TESTING OF TB PATIENTS

Detection of HIV by offering HIV tests to diagnosed TB patients is being implemented by NACP and RNTCP jointly since 2007–08. States with high HIV prevalence cover about 90% TB patients for HIV testing, but case fatality rate among HIV infected TB cases remains 13–14%, as compared to less than 4% in HIV negative TB cases, indicating delayed detection of HIV/TB inspite of good coverage. Therefore, NACP and RNTCP have jointly decided to offer HIV testing upstream during evaluation of patients for TB when they present with TB symptoms. This activity is expected to expedite detection of HIV within 2–4 weeks of TB positivity, leading to early linkage to HIV treatment and hence reduction in mortality. HIV testing in presumptive TB cases was rolled-out in India in October 2012 in Karnataka, followed by Maharashtra, Andhra Pradesh and Tamil Nadu. It is planned to extend this strategy to high HIV prevalence districts i.e. A and B category districts. Further the NTWG has recommended implementation of this strategy among 25–54 years age group in the rest of the country.

The four pronged strategy for HIV–TB coordination activity to reduce mortality are summarized in Fig. 5.

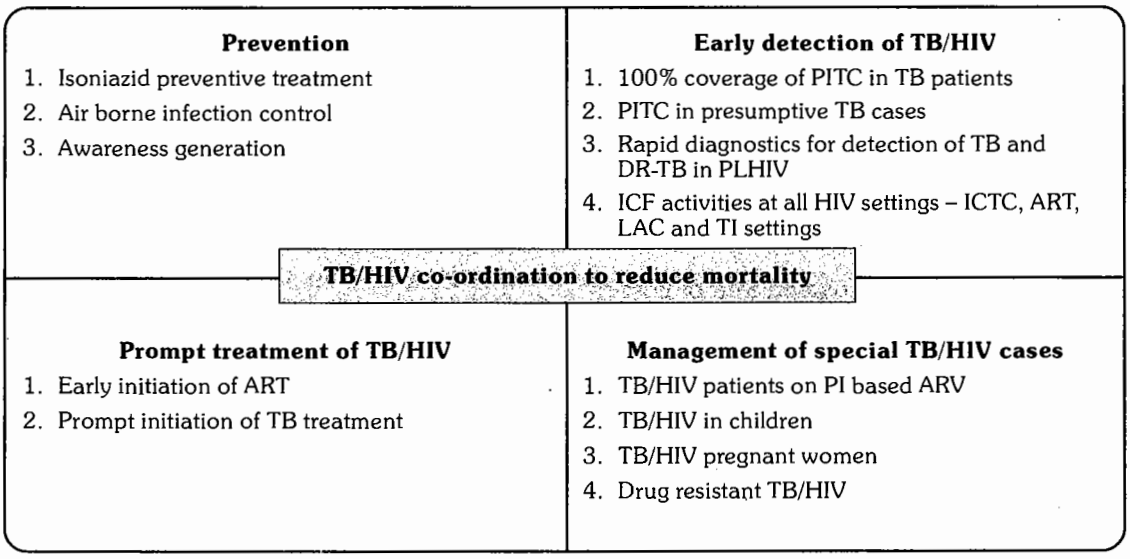

FIG. 5

Activities to reduce HIV–TB mortality

PITC – provider initiated HIV testing and counselling; ICF – intensified case finding; LAC – link ART centres; TI – Targeted interventions

Source : *(23)*

Care, support and treatment

The care, support and treatment (CST) component of NACP aims to provide comprehensive services to people living with HIV (PLHIV) with respect to free Anti-Retroviral Therapy (ART), psychosocial support, prevention and treatment of opportunistic infections (OI) including tuberculosis, and facilitating home-based care and impact mitigation.

CST services are provided through ART centres established by DAC in health facilities across the country. These are linked to Centres of Excellence (CoE) and ART-Plus centres at selected institutions, while some of the services have been decentralized through Link ART Centres (LAC). ART centres are also linked to ICTCs, STI clinics, PPTCT services and other clinical departments in the institutions of their location, as well as with the Revised National Tuberculosis Programme (RNTCP), in order to ensure proper management of TB–HIV co-infected patients. Fig. 6 gives a graphic view of this service delivery model.

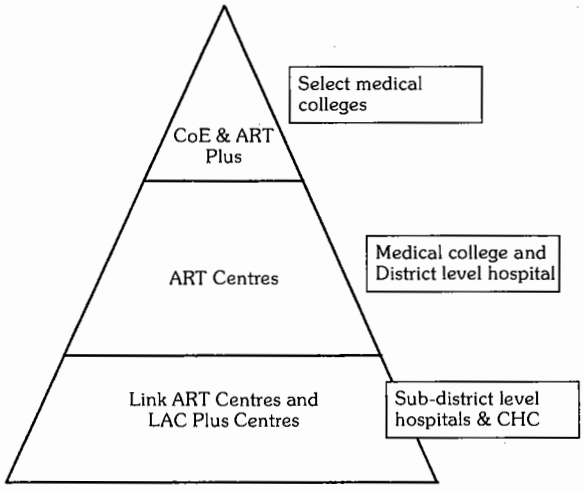

FIG. 6

Model of HIV treatment services

Source : *(22)*

As of March 2014, about 425 ART centres, 870 link ART centres, 10 centres of excellence, 7 paediatric centres of excellence, 37 ART Plus centres and 224 care and support centres are functioning in the country *(22)*.

Services provided

1. *First-line ART:* First-line ART is provided free of cost to all eligible PLHIV through ART centres. Positive cases referred by ICTCs are registered in ART centres for pre-ART and ART services. The assessment for eligibility for ART is done through clinical examination and CD4 count. Patients are also provided counselling on treatment adherence, nutrition, positive prevention and positive living. Follow-up of patients on ART is done by assessing drug adherence, regularity of visits, periodic examination and CD4 count (every six months). Treatment for opportunistic infections is also provided through ART centres. Till March 2014, 7.68 lakh PLHIV were on first-line ART.
2. *Alternative first-line ART:* It has been observed that a small number of patients initiated on first-line ART experience acute/chronic toxicity/intolerance to first-line ARV drugs, thus necessitating change of ARV drugs to alternative first-line drugs. Presently, the provision of alternative first-line ART is done through the Centres of Excellence and ART-Plus centres across the country.
3. *Second-line ART:* The second-line ART began in January 2008 at two sites – GHTM, Tambaram, Chennai and JJ Hospital, Mumbai on a pilot basis, and was then further expanded to the other CoEs in January 2009. Further decentralization of second-line ART was done through capacitating and upgrading some well-functioning ART centres as 'ART-Plus Centres'. Till March 2014, 8,897 patients were receiving second-line drugs at CoEs and ART-Plus centres. All ART centres are linked to CoE/ART-Plus centres. For the evaluation of patients for initiation on second-line and alternate first-line ART, a State AIDS Clinical Expert Panel (SACEP) has been constituted by DAC at all CoEs and ART-Plus centres. This panel meets once in a week for taking decisions on patients referred to them with treatment failure/major side effects.

National paediatric HIV/AIDS initiative: The national paediatric HIV/AIDS initiative was launched on 30 November 2006. Till March 2014, nearly 1,06,824 children living with HIV/AIDS (CLHIV) were registered in HIV care at ART centres, of whom 42,015 were receiving free ART. Paediatric formulations of ARV drugs are available at all ART centres.

Paediatric second-line ART: While the first-line therapy is efficacious, certain proportion of children do show evidence of failure. There is not much data available on the failure rate of Nevirapine-based ART in children. However, WHO estimates that the average switch rate from first to second-line ART is 2–3% per year for adults. It is likely that similar rates are applicable for children as well. Currently, second-line ART for children has been made available at all CoE and ART-Plus centres.

Early infant diagnosis: In order to promote confirmatory diagnosis for HIV exposed children, a programme on Early Infant Diagnosis (EID) was launched by DAC. All children with HIV infection confirmed through EID have been linked to ART services.

TARGETED INTERVENTIONS FOR HIGH RISK GROUPS: The main objective of targeted interventions (TI) is to improve health-seeking behaviour of high risk groups (HRG) and reduce their risk of acquiring sexually transmitted infections (STI) and HIV infections. High risk groups under TI include female sex workers (FSW), men who have sex with men (MSM), transgenders (TG)/hijras and injecting drug users (IDU), and bridge populations include high risk behaviour migrants and long distance truckers. Targeted interventions provide the information, means and skills needed to prevent HIV transmission and improve their access to care, support and treatment services. These programmes also focus on improving sexual and reproductive health and general health of high-risk population.

The services offered through targeted interventions include:

- Detection and treatment for sexually transmitted infections
- Condom distribution (except in TIs for bridge population)
- Condom promotion through social marketing (for HRG and bridge population)

- Behaviour change communication
- Creating an enabling environment with community involvement and participation
- Linkages to integrated counselling and testing centres
- Linkages with care and support services for HIV positive HRGs
- Community organization and ownership building
- Specific interventions for IDUs
  - Distribution of clean needles and syringes
  - Abscess prevention and management
  - Opioid substitution therapy
  - Linkage with detoxification/rehabilitation services
- Specific interventions for MSM/TGs
  - Provision of lubricants
  - Specific interventions for TG/hijra populations
  - Provision of project-based STI clinics

Link worker scheme: The Link worker scheme is a community-based outreach strategy to address HIV prevention and care needs of HRG and vulnerable population in rural areas. The specific objectives of the scheme include reaching out to these groups with information and knowledge on prevention and risk reduction of HIV and STI, condom promotion and distribution, providing referral and follow-up linkages for various services. It includes counselling, testing and treatment of STI and opportunistic infections through link workers, creating an enabling environment for PLHIV and their families, and reducing stigma and discrimination against them. In partnership with various development partners, the link worker scheme has been expanded and is being implemented in 17 states covering 163 highly vulnerable districts.

Blood transfusion services: The division of blood safety has been renamed as the division of blood transfusion services. The change in nomenclature is to broaden the horizon of blood safety to include transfusion transmitted infections, immuno-hematology, quality management systems, logistics and other processes involved to improve confidence in the "safe blood".

Blood transfusion services have been considered as an integral part of the health care system. Blood Transfusion Councils have been set-up at national and state levels. Professional blood donation has been prohibited in the country since 1st January 1998. Only licensed blood banks are permitted to operate in the country and voluntary blood donation is encouraged. The strategy is to ensure safe collection, processing, storage and distribution of blood and blood products. Zonal blood testing centres have been established to provide linkage with other blood banks affiliated to public, private and voluntary sectors. As per national blood safety policy, testing of every unit of blood is mandatory for detecting infections like HIV, hepatitis B, hepatitis C, malaria and syphilis.

Access to safe blood for the needy is the primary responsibility of NACO. It is supported by a network of 1,137 blood banks, including 258 Blood Component Separation Units (BCSU) and 34 Model Blood Banks. NACO supported the installation of BCSU and has given funds for modernization of all major blood banks at state and district levels. Besides enhancing awareness about the need to procure safe blood and blood products, NACO has supported the procurement of equipment, test kits and reagents, and is helping in the recurring expenditure of government blood banks and those run by voluntary/ charitable organizations, that were modernized.

In order to ease the situation of shortage of availability of blood in the rural areas, where it is not feasible to operate a blood bank, Govt. has decided to establish blood storage centres at First Referral Units (FRUs), at sub-district levels, for wider availability of safe blood, particularly for emergency obstetric care and trauma care services.

Condom promotion: Condom promotion strategies will be strengthened through free distribution and social marketing channels, non-traditional outlets, female condoms, etc. aided by an effective communication strategy. The programme will continue to link prevention with care, support and treatment. This will promote positive prevention.

On the basis of HIV prevalence and family planning needs, the districts have been mapped and classified into four categories: (a) High prevalence of HIV and high fertility (HPHF); (b) High prevalence of HIV and low fertility (HPLF); (c) Low prevalence of HIV and low fertility (LPLF); and (d) Low prevalence of HIV and high fertility (LPHF). During 2013–14 the coverage of condom social marketing programme implementation was spread across 222 districts, i.e. 42 HPHF, 45 HPLF and 135 LPHF districts in 11 states *(22)*.

STD CONTROL PROGRAMME : STD control is linked to HIV/AIDS control as behaviour resulting in the transmission of STD and HIV are same. HIV is transmitted more easily in the presence of another STD. Hence, early diagnosis and treatment of STD is now recognized as one of the major strategies to control spread of HIV infection. The following approach is adopted for the STD control *(24)* :

a. Management of STDs through syndromic approach (management of sexually transmitted diseases based on specific symptoms and signs and not dependent on laboratory investigations).

b. STDs among women, though highly prevalent, are suppressed because of the social stigma attached to the disease. It has, therefore, been decided to integrate services for treatment of reproductive tract infections (RTIs) and sexually transmitted diseases (STDs) at all levels of health care. Department of Family Welfare and NACO will coordinate their activities for an effective implementation of such integration. STDs Clinics at district / block/ First Referral Unit (FRU) level would function as referral centres for treatment of STDs referred from peripheries. STDs clinics in all district hospitals, medical colleges and other centres would be strengthened by providing technical support, equipment, reagents and drugs. A massive orientation-training programme would be undertaken to train all the medical and paramedical workers engaged in providing STDs/RTIs services through a syndromic approach. All STDs clinics would also provide counselling services and good quality condoms to the STD patients. Services of NGOs would be utilised for providing such counselling services at the STDs clinics.

NACO has branded the STI/RTI services as **"Suraksha Clinic"**, and has developed a communication strategy for generating demand for these services *(3)*.

PRE-PACKED STI/RTI COLOUR CODED KITS : Pre-packed colour coded STI/RTI kits have been provided for free supply to all designated STI/RTI clinics. These kits are

being procured centrally and supplied to all State AIDS Control Societies.

The colour code is as follows *(25)* :

Kit 1 – grey, for urethral discharge, ano-rectal discharge and cervicitis.
Kit 2 – green, for vaginitis.
Kit 3 – white, for genital ulcers.
Kit 4 – blue, for genital ulcers.
Kit 5 – red, for genital ulcers.
Kit 6 – yellow, for lower abdominal pain.
Kit 7 – black, for scrotal swelling.

Information, education and communication

Communication is the key to generating awareness on prevention as well as motivating access to testing, treatment, care and support. With the launch of NACP-IV, the impetus is on standardizing the lessons learned during the third phase. Communication in NACP-IV is directed at:

a. To increase knowledge among general population (especially youth and women) on safe sexual behaviour;
b. To sustain behaviour change in high risk groups and bridge populations;
c. To generate demand for care, support and treatment services; and
d. To make appropriate changes in societal norms that reinforce positive attitude, beliefs and practices to reduce stigma and discrimination.

Adolescence Education Programme: This programme runs in secondary and senior secondary schools to built up life skills of adolescents to cope with the physical and psychological changes associated with growing up. Under the programme, 16 hour sessions are scheduled during the academic terms of class IX and XI. State AIDS control society have further adapted the modules after state level consultations with NGOs, academicians, psychologists and parent-teacher bodies. This programme is being implemented in 23 states and by March 2014, 49,000 schools have been covered.

Red Ribbon Clubs: The purpose of Red Ribbon Club formation in colleges is to encourage peer-to-peer messaging on HIV prevention and to provide a safe space for young people to seek clarifications of their doubts and myths surrounding HIV/AIDS. The RRCs also promote voluntary blood donation among youth.

Year-wise targets of NACP-IV are as shown in Table 8.

TABLE 8
Year-wise targets under NACP-IV

Programme component	2012–13	2013–14	2014–15	2015–16	2016–17
Prevention					
A. *Targeted interventions among high risk groups and bridge populations*					
No. of FSW covered	774,000	834,300	882,000	900,000	900,000
No. of MSM covered	276,000	360,800	411,400	418,000	440,000
No. of IDU covered	150,000	155,000	158,000	160,000	162,000
No. of truckers covered	940,000	1,120,000	1,120,000	1,600,000	1,600,000
No. of high risk migrants covered	2,880,000	4,480,000	5,152,000	5,600,000	5,600,000
No. of targeted interventions	1,867	2,256	2,459	2,605	2,703
B. *Link worker scheme*					
No. of HRGs covered	140,000	160,000	180,000	200,000	220,000
C. *Integrated counselling and testing*					
No. of vulnerable population accessing ICTC services/annum (in lakh)	168	224	236.6	264.6	280
No. of pregnant mothers tested under PPTCT/annum (in lakh)	84	112	118.3	132.3	140
No. of PPTCT/ICTC centres	11,369	12,019	12,889	14,029	14,769
No. of HIV +ve mother and child pairs receiving anti-retroviral prophylaxis	18,060	24,080	25,435	28,445	30,100
D. *Sexually transmitted infections*					
No. of adults with STI symptoms accessing syndromic management/annum (in lakh)	56	67.5	76.5	85.5	90
No. of designated STI/RTI clinics	1,150	1,200	1,250	1,250	1,250
E. *Blood tranfusion services*					
No. of blood banks supported under NACP	1,170	1,170	1,235	1,235	1,300
No. of units of blood collected in DAC supported blood banks/annum (in lakh)	56	67.5	76.5	85.5	90
Percentage of voluntary blood donation in DAC supported blood banks	80%	80%	85%	90%	95%
F. *Condom promotion*					
No. of condoms distributed (in crore pieces)	109.2	116.1	123.3	129.7	136.4
G. *Comprehensive care, support and treatment*					
No. of ART centres	400	450	500	550	600
No. of PLHIV provided free ART (includes first-line, second-line and children)	6,42,400	7,51,400	8,40,200	9,40,000	10,05,000

NATIONAL PROGRAMME FOR CONTROL OF BLINDNESS

The National Programme for Control of Blindness was launched in the year 1976 as a 100 per cent centrally sponsored programme and incorporates the earlier trachoma control programme started in the year 1968. The programme was launched with the goal to reduce the prevalence of blindness from 1.4 to 0.3 per cent. As per 2006–07 survey the prevalence of blindness was 1.0 per cent *(1)*.

Main objectives of the programme in the 12th Five Year Plan period are:

1. To reduce the backlog of avoidable blindness through identification and treatment of curable blind at primary, secondary and tertiary levels, based on assessment of the overall burden of visual impairment in the country;
2. Develop and strengthen the strategy of NPCB for "Eye Health for All" and prevention of visual impairment, through provision of comprehensive universal eye-care services and quality service delivery;
3. Strengthening and upgradation of Regional Institutes of Ophthalmology (RIOs) to become centre of excellence in various sub-specialities of ophthalmology and also other partners like Medical Colleges, District Hospitals, Sub-district Hospitals, Vision Centres, NGO Eye Hospitals;
4. Strengthening the existing infrastructure facilities and developing additional human resources for providing high quality comprehensive eye care in all districts of the country;
5. To enhance community awareness on eye care and lay stress on preventive measures;
6. Increase and expand research for prevention of blindness and visual impairment, and
7. To secure participation of voluntary organizations/ private practitioners in delivering eye care.

Salient features/strategies adopted to achieve the objectives are:

1. Continued emphasis on free cataract surgery through the health care delivery system as well as by the involvement of NGO sector and private practitioners.
2. Emphasis on the comprehensive eye care programmes by covering diseases other than cataract, like diabetic retinopathy, glaucoma, corneal transplantation, vitreo-retinal surgery, treatment of childhood blindness etc. These emerging diseases need immediate attention to eliminate avoidable blindness from the country.
3. Reduction in the backlog of blind persons by active screening of population above 50 years age, organizing screening eye camps and transporting operable cases to fixed eye care facilities.
4. Refractive error comprises a major part of avoidable blindness. Screening of children for identification and treatment of refractive errors and provision of free glasses to those affected and belonging to poor socio-economic strata.
5. Coverage of underserved area for eye care services through public-private partnership.
6. Capacity building of health personnel for improving their knowledge and skill in delivery of high quality eye services.
7. Information Education Communication (IEC) activities for creating awareness on eye-care within the community.
8. Regional Institutes of Ophthalmology and Medical Colleges of the states to be strengthened in a phased manner with latest equipments and training of manpower so that they can be upgraded as Centres of Excellence in the regions.
9. The district hospitals to be strengthened by upgrading infrastructure, equipment and providing adequate manpower like ophthalmologists and PMOAs on contractual basis and provide earmarked funds for basic medicines and drugs.
10. Continuing emphasis on primary healthcare (eye care) by establishing vision centres in all PHCs with a PMOA in position.
11. Multipurpose District Mobile Ophthalmic Units for better coverage.

To avoid duplicity of work, State Ophthalmic Cell has been merged with State Blindness Control Society, and after the launch of NRHM, State Blindness Control Societies have been further merged with State Health Society. Likewise, District Blindness Control Societies have also been merged with District Health Societies. Facilities for intra-ocular lense implantation have been expanded to taluka level.

The problem of blindness is acute in rural areas, and hence the programme has tried to expand the accessibility of eye services in these areas. At present there are 80 central mobile units attached to medical colleges and 341 district mobile units to provide eye care in mobile eye camps. These units have a vehicle, ophthalmic surgeon and other paramedical staff. Most of the cataract surgeries in rural population are conducted through these mobile camps. Primary health centres are the basic units in the rural areas.

The findings of the survey conducted during 2001–2002, in randomly selected districts of the states covered by World Bank Project shows that dependence on eye camps has reduced, except in remote and tribal areas; involvement of PHC/CHC doctor in the programme has increased; higher percentage of cataract operated persons consult the doctor at an early stage; there is an increase in demand for modern techniques like intra-ocular lenses and suture-less surgeries; and about 84 per cent of cataract operated persons receive free spectacles from the health facilities.

The organizational structure for the national programme for control of blindenss is as shown in Fig. 7.

SCHOOL EYE SCREENING PROGRAMME : 6–7 per cent of children aged 10–14 years have problem with their eye sight affecting their learning at school. Children are being first screened by trained teachers. Children suspected to have refractive error are seen by ophthalmic assistants and corrective spectacles are prescribed or given free for persons below poverty line.

COLLECTION AND UTILIZATION OF DONATED EYES : During 2013–14 nearly 34,492 donated eyes were collected for corneal implantation *(1)*. Hospital retrieval programme is the major strategy for collection of donated eyes, which envisage motivation of relatives of terminally ill patients, accident victims and others with grave diseases to donate eyes. Eye donation fortnight is organized from 25th August to 8th September every year to promote eye donation/eye banking. Gujarat, Tamil Nadu, Maharashtra and Andhra Pradesh are leading states in this activity *(1)*.

The voluntary organizations such as Lions International and its branches, Rotary International and its branches, NSPB India etc. are encouraged to organize eye camps in

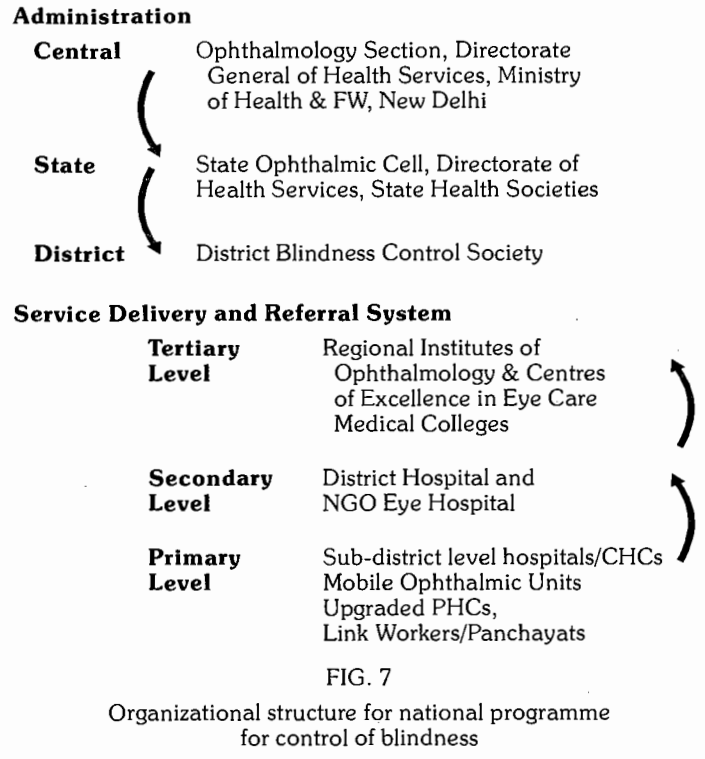

FIG. 7

Organizational structure for national programme for control of blindness

Source : *(26)*

remote rural and urban areas as per guidelines, with the permission from the state authorities. They have been active in providing eye health education, preventive, rehabilitative and surgical services for control of blindness.

Community health education is a built-in component at all levels of implementation of National Blindness Control Programme. The programme also includes regular eye check-up and provision of vitamin A prophylaxis and service facilities in rural areas.

WHO assistance for prevention of blindness : This includes intra-country fellowships in corneal transplantation, vitreo-retinal surgery, lasers in ophthalmology and paediatric ophthalmology; pilot survey on childhood blindness in Delhi; training in district programme management; study on situational analysis of eye care infrastructure and human resources in India; high quality workshops in eye care for faculty of medical colleges; and developement of plan of action for "Vision 2020 : The Right to Sight" initiative.

Vision 2020 : The Right to Sight

It is a global initiative to reduce avoidable (preventable and curable) blindness by the year 2020. India is also committed to this initiative. The plan of action for the country has been developed with following main features :

1. Target diseases are cataract, refractive errors, childhood blindness, corneal blindness, glaucoma, diabetic retinopathy.
2. Human resource development as well as infrastructure and technology development at various levels of health system. The proposed four tier structure includes Centres of Excellence (20), Training Centres (200), Service Centres (2000), and Vision Centres (20,000).

Fig. 8 shows the proposed structure for primary, secondary and tertiary eye care.

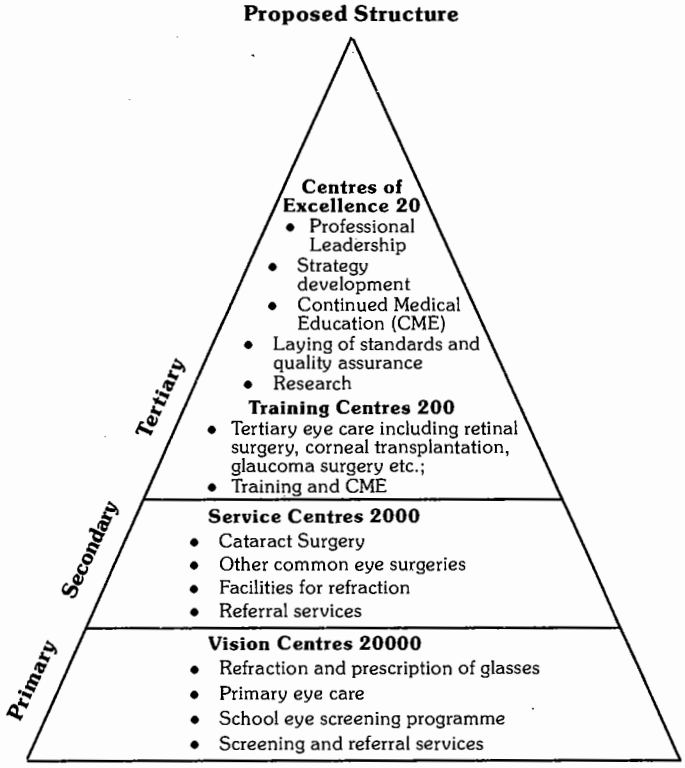

FIG. 8

Proposed structure for Vision 2020 : The Right to Sight

Source : *(26)*

Universal eye health : a global action plan 2014–2019 *(26A)*

WHO estimates that in 2010 there were 285 million people visually impaired, of which 39 million were blind. If just the two major causes of visual impairment were considered priorities and control measures were implemented consistently by providing refractive services and offering cataract surgery to the people in need, two-thirds of the visually impaired people could recover good eye sight.

Provision of effective and accessible eye care services is the key to control measures. The preference should be given to strengthening eye care services through their integration into the primary health care and health system development, as almost all causes of visual impairment are avoidable, e.g., diabetes mellitus, smoking, premature birth, rubella, vitamin A deficiency etc., and visual impairment is frequent among older age groups. Improvements in the areas of maternal, child and reproductive health and the provision of safe drinking water and basic sanitation are important. Eye health should be included in the broader non-communicable and communicable disease frameworks, as well as those addressing ageing populations. There are three indicators to measure progress at the national level. They are:

1. The prevalence and causes of visual impairment. As a global target, reduction in prevalence of avoidable visual impairment by 25 per cent by 2019 from the baseline of 2010 has been selected for this action plan;
2. The number of eye care personnel; and
3. Cataract surgical service delivery. The cataract surgical rate (number of surgeries performed per year, per million population) and cataract surgical coverage (number of individuals with bilateral cataract causing visual impairment, who have received cataract surgery on one or both eyes).

IODINE DEFICIENCY DISORDERS (IDD) PROGRAMME

India commenced a goitre control programme in 1962, based on iodized salt. At the end of three decades, the prevalence of the disease still remained high.

As a result, a major national programme – "The IDD Control Programme" was initiated in which nation-wide, rather than area-specific use of iodized salt is being promoted. It was decided as a national policy to fortify all edible salt in a phased manner by end of 8th Plan. The essential components of a national IDD programme are use of iodized salt in place of common salt, monitoring and surveillance, manpower training and mass communication.

The objectives of the programme are *(1)* :

1. Surveys to assess the magnitude of the Iodine Deficiency Disorders in districts.
2. Supply of iodized salt in place of common salt.
3. Resurveys to assess iodine deficiency disorders and the impact of iodized salt after every 5 years in districts.
4. Laboratory monitoring of iodized salt and urinary iodine excretion.
5. Health education and publicity.

Significant achievements

Consequent upon liberalization of iodized salt production, Salt Commissioner has issued licenses to 824 salt manufacturers out of which 532 units have commenced production. These units have an annual production capacity of 120 lakh metric tonnes of iodized salt.

The production/supply of iodized salt from April 2013 to March 2014 was 58.64 lakh tonnes and 55.08 lakh tonnes.

Notification banning the sale of non-iodized salt for different human consumption in the entire country is already issued under "Food Safety & Standards Act 2006 and Regulations 2011".

For effective implementation of National Iodine Deficiency Disorders Control Programme 33 States/UTs have established Iodine Deficiency Disorders Control Cells in their State Health Directorate.

UNIVERSAL IMMUNIZATION PROGRAMME

Experience with smallpox eradication programme showed the world that immunization was the most powerful and cost-effective weapon against vaccine preventable diseases. In 1974, the WHO launched its "Expanded Programme on Immunization" (EPI) against six, most common, preventable childhood diseases, viz. diphtheria, pertussis (whooping cough), tetanus, polio, tuberculosis and measles. From the beginning of the programme UNICEF has been providing significant support to EPI.

"Expanded" in the WHO definition meant adding more disease controlling antigens of vaccination schedules, extending coverage to all corners of a country and spreading services to reach the less privileged sectors of the society *(27)*.

The primary health care concept as enunciated in the 1978 Alma-Ata Declaration included immunization as one of the strategies for reaching the goal of "Health For All" by the year 2000. While the WHO's programme is called EPI, the UNICEF in 1985 renamed it as "Universal Child Immunization" (UCI). There was absolutely no difference between these two. The goal was the same, i.e., to achieve universal immunization by 1990. EPI is regarded as the instrument of UCI *(28)*.

The Government of India launched its EPI in 1978 with the objective of reducing the mortality and morbidity resulting from vaccine-preventable diseases of childhood, and to achieve self-sufficiency in the production of vaccines. Universal Immunization Programme was started in India in 1985. It has two vital components: immunization of pregnant women against tetanus, and immunization of children in their first year of life against the six EPI target diseases. The aim was to achieve 100 per cent coverage of pregnant women with 2 doses of tetanus toxoid (or a booster dose), and at least 85 per cent coverage of infants with 3 doses each of DPT, OPV, one dose of BCG and one dose of measles vaccine by 1990. Universal immunization was first taken up in 30 selected districts and catchment areas of 50 Medical Colleges in November 1985. The programme has now been extended to all the districts and practice areas of all the 242 Medical colleges, thus creating a base for wider coverage *(29)*. A "Technology Mission on Vaccination and Immunization of Vulnerable Population, specially Children" was set up to cover all aspects of the immunization activity from research and development to actual delivery of services to the target population *(30)*.

The immunization services are being provided through the existing health care delivery system (i.e., MCH centres, primary health centres and subcentres, hospitals, dispensaries and ICD units). There is no separate cadre of staff for EPI. The recommended immunization schedule is on page 123.

Although the target was "universal" immunization by 1990, in practice, no country, even in the industrialized world, has ever achieved 100 per cent immunization in children. 'Universal' immunization is, therefore, best interpreted as implying the ideal that no child should be denied immunization against tuberculosis, diphtheria, whooping cough, tetanus, polio and measles. It is, however, generally agreed that when immunization coverage reaches a figure of 80 per cent or more, then disease transmission patterns are so severely disrupted as to provide a degree of protection even for the remaining children who have not been immunized, because of "herd immunity" *(31)*. It is also important that children are immunized during the first year of life and that levels of immunization are sustained so that each new generation is protected.

Significant achievements have been made in India. At the beginning of the programme in 1985–86, vaccine coverage ranged between 29 per cent for BCG and 41 per cent for DPT. By the end of 2012, coverage levels had gone up significantly to about 87 per cent for tetanus toxoid for pregnant women, about 87 per cent for BCG, 72 per cent for DPT 3 doses, 74 per cent for measles, 70 per cent for OPV 3 doses and 70 per cent for $HepB_3$. Since then, there is a significant decline in the reported incidence of the vaccine preventable diseases as compared to their incidence in 1987, as shown in Table 9.

TABLE 9

Decline in reported vaccine preventable diseases from year 1987 to 2013

Disease	1987	2013
Poliomyelitis	28,257	0
Diphtheria	12,952	4,090
Pertussis	163,786	36,661
NNT	11,849	528
Measles	247,519	15,768

To strengthen routine immunization, Government of India has planned the State Programme Implementation Plan (PIP) part C. It consists of : (a) Support for alternate vaccine delivery from PHC to sub-centre and outreach sessions; (b) Deploying retired manpower to carry out immunization activities in urban slums and underserved areas, where services are deficient; (c) Mobility support to district immunization officer as per state plan for monitoring and supportive supervision; (d) Review meeting at the state level with the districts at 6 monthly intervals; (e) Training of ANM, cold chain handlers, mid-level managers, refrigerator mechanics etc.; (f) Support for mobilization of children to immunization session sites by ASHA, women self-help groups etc.; (g) Printing of immunization cards, monitoring sheet, cold chain chart vaccine inventory charts etc.

In addition, central government is supporting in supplies of auto-disposable syringes, downsizing the BCG vial from 20 doses to 10 doses to ensure that BCG vaccine is available in all immunization session sites, strengthening and maintenance of the cold chain system in the states, and supply of vaccines and vaccine van.

PULSE POLIO IMMUNIZATION PROGRAMME

Pulse Polio Immunization Programme was launched in the country in the year 1995. Under this programme children under five years of age are given additional oral polio drops in December and January every year on fixed days. From 1999–2000, house to house vaccination of missed children was also introduced. The NIDs rounds cover approximately 172 million children and SNIDs rounds cover 40–80 million children. In addition, large scale multi-district mop-ups have been conducted *(6)*. As a result only one case of polio was reported in 2011 in the month of January. As on 25th Feb 2012, India was removed from the list of polio endemic countries, and on 27th March 2014, India was certified as polio-free country. Please see page 209 for more details.

INTRODUCTION OF HEPATITIS-B VACCINE

In 2010–2011, Government of India universalized hepatitis B vaccination to all States/UTs in the country. Monovalent hepatitis B vaccine is given as intramuscular injection to the infant at 6th, 10th and 14th week alongwith primary series of DPT and polio vaccines. In addition one dose of hepatitis B is given at birth for institutional deliveries within 24 hours of birth.

INTRODUCTION OF JAPANESE ENCEPHALITIS VACCINE

The programme was introduced in 2006 to cover 104 endemic districts in phased manner, using SA 14-14-2 vaccine, imported from China. Single dose of JE vaccine was given to all children between 1 to 15 years of age through campaigns *(3)*. The JE vaccine is being integrated into routine immunization in the districts where campaign had already been conducted to immunize the new cohort of children by vaccinating with two doses at 9–12 months and 16–24 months *(1)*.

INTRODUCTION OF MEASLES VACCINE SECOND OPPORTUNITY

In order to accelerate the reduction of measles related morbidity and mortality, second opportunity for measles vaccination is being implemented. The National Technical Advisory Group on immunization recommended introduction of 2nd dose of measles vaccine to children between 9 months and 10 years of age through supplementary immunization activity (SIA) for states where evaluated coverage of first dose of measles vaccination is less than 80 per cent. In states, with coverage of measles vaccination more than 80 per cent, the second dose of vaccine will be given through routine immunization at 16–24 months *(1)*.

INTRODUCTION OF PENTAVALENT VACCINE (DPT + Hep-B + Hib)

India introduced pentavalent vaccine containing DPT, hepatitis B and Hib vaccines in two states viz. Kerala and Tamil Nadu under routine immunization programme from December 2011. DPT and hepatitis B vaccination require 6 injections to deliver primary doses. With the introduction of pentavalent vaccine, a new antigen, i.e., Hib has been added which protects against haemophilus influenzae type B (associated with pneumonia and meningitis) and the number of injections are reduced to 3. The vaccine has been expanded to 6 more states, i.e., Haryana, Jammu and Kashmir, Gujarat, Karnataka, Goa and Puducherry in 2012–13. Further expansion is planned to 11 states in October 2014 and rest of 16 states from April 2015 *(1)*.

MISSION INDRADHANUSH

The Government of India launched Mission Indradhanush on 25th December 2014, to cover children who are either unvaccinated or partially vaccinated against seven vaccine preventable diseases, i.e., diphtheria, whooping cough, tetanus, polio, tuberculosis, measles and hepatitis B. The goal is to vaccinate all under-fives by the year 2020. Under the programme, four special vaccination campaigns will be conducted between January and June 2015. Intensive planning and monitoring experience of pulse polio immunization programme will be used. 201 high focus districts will be covered in the first phase. Of these 82 districts are from Uttar Pradesh, Bihar, Madhya Pradesh and Rajasthan. These 201 districts have nearly 50 per cent of all unvaccinated children of the country. The drive will be through a "catch-up" campaign mode. The mission will be technically supported by WHO, UNICEF, Rotary International and other donor partners.

Very frequently queries come up about the vaccines and the vaccination schedule. It is important to have the exact answer to these questions.

Questions about all vaccines *(32)*

Q. If the mother/caregiver permits administration of only one injection during an infant's first visit at 9 months of age, which vaccine should be given ?

A. At 9 months of age, the priority is to give measles vaccine with OPV and Vitamin-A.

Q. Which vaccines can be given to a child between 1–5 years of age, who has never been vaccinated ?

A. The child should be given DPT1, OPV-1, measles and 2 ml of vitamin A solution. It should then be given the second and third doses of DPT and OPV at one month intervals. Measles second dose is also to be given as per the schedule. The booster dose of OPV/DPT can be given at a minimum of 6 months after administering OPV3/DPT3.

Q. Which vaccines can be given to a child between 5–7 years of age, who has never been vaccinated ?

A. The child should be given first, second and third doses of DPT at one month intervals. The booster dose of DPT can be given at a minimum of 6 months after administering DPT3 upto 7 years of age.

Q. Should one re-start with the first dose of a vaccine if a child is brought late for a dose ?

A. Do not start the schedule all over again even if the child is brought late for a dose. Pick up where the schedule

was left off. For example: If a child who has received BCG, HepB-1, DPT-1 and OPV-1 at 5 months of age, returns at 11 months of age, vaccinate the child with DPT-2, HepB-2, OPV-2 and measles and do not start from DPT-1, HepB-1 again.

Q. Why is it not advisable to clean the injection site with a spirit swab before vaccination ?

A. This is because some of the live components of the vaccine are killed if they come in contact with spirit.

DPT vaccine

Q. If a child could not receive DPT1, 2, 3 and OPV 1, 2, 3 according to the schedule, upto what age can the vaccine be given ?

A. The DPT vaccine can be given upto 7 years of age and OPV can be given upto 5 years of age. If a child has received previous doses but not completed the schedule, do not restart the schedule and instead administer the remaining doses needed to complete the series.

Q. Why should there be a minimum gap of 4 weeks between two doses of DPT ?

A. This is because decreasing the interval between two doses may not obtain optimal antibody production for protection.

Q. Why give the DPT vaccine in the antero-lateral mid thigh and not the gluteal region ?

A. DPT is given in the antero-lateral mid-thigh and not the gluteal region to prevent damage to the sciatic nerve. Moreover, the vaccine deposited in the fat of gluteal region does not invoke the appropriate immune response.

Q. What should one do if the child is found allergic to DPT or develops encephalopathy after DPT ?

A. A child who is allergic to DPT or develops encephalopathy after DPT should be given the DTaP/DT vaccine instead of DPT for the remaining doses, as it is usually the P (whole cell Pertussis) component of the vaccine which causes the allergy/encephalopathy. It may be purchased with locally available resources.

Q. Why DT is replaced by DPT vaccine for children above 2 years of age ?

A. As pertussis cases were reported in higher age group children and the risk of AEFIs were not found to be more after DPT vaccine as compared to DT vaccine.

Measles vaccine

Q. Why give the measles vaccine only on the right upper arm ?

A. The measles vaccine is given on the right upper arm to maintain uniformity and to help surveyors in verifying the receipt of the vaccine.

Q. If a child has received the measles vaccine before 9 months of age, is it necessary to repeat the vaccine later ?

A. Yes, the measles vaccine needs to be administered, according to the National Immunization Schedule i.e. after the completion of 9 months until 12 months of age and at 16–24 months. If not administered in the ideal age for measles vaccine, it can be administered upto 5 years of age.

Q. What is measles catch-up campaign ?

A. A measles catch-up campaign is a special campaign to vaccinate all children in a wide age group in a state or a district with one dose of measles vaccine. The catch-up campaign dose is given to all children, both immunized and un-immunized, who belong to the target age group of 9 months to 10 years. The goal of a catch-up campaign is to quickly make the population immune from measles and reduce deaths from measles. A catch-up campaign must immunize nearly 100% of target age group children.

Q. Why 2nd dose of measles vaccine is introduced in the National Immunization Programme ?

A. Measles is highly infectious disease causing illness and death due to complications such as diarrhoea, penumonia or brain infection. One dose of measles vaccine at 9 months of age protects 85% of infants. With 2nd dose the aim is to protect all the children who remain unprotected after first dose.

Q. If a child comes late for the first dose, then can it get the second dose ?

A. All efforts should be made to immunize the children at the right age i.e. first dose at completed 9 months to 12 months and second dose at 16–24 months. However if a child comes late then give two doses of measles vaccine at one month interval until 5 years of age.

Q. If a child received one dose of measles vaccine during an SIA campaign, should it receive the routine dose of measles vaccine ?

A. Yes, the child should receive routine doses of measles vaccine according to the Immunization Schedule irrespective of the measles SIA dose.

BCG vaccine

Q. Why give BCG vaccine only on the left upper arm ?

A. BCG is given on the left upper arm to maintain uniformity and for helping surveyors in verifying the receipt of the vaccine.

Q. Why do we give 0.05 ml dose of BCG to newborns (below 1 month of age) ?

A. This is because the skin of newborns is thin and an intra-dermal injection of 0.1 ml may break the skin or penetrate into the deeper tissue and cause local abscess and enlarged axillary lymph nodes. Dose of 0.05 ml is sufficient to elicit adequate protection.

Q. Why is BCG given only upto one year of age ?

A. Most children acquire natural clinical/sub-clinical tuberculosis infection by the age of one year. This too protects against severe forms of childhood tuberculosis e.g. TB meningitis and miliary disease.

Q. If no scar appears after administering BCG, should one re-vaccinate the child ?

A. There is no need to re-vaccinate the child, even if there is no scar.

OPV

Q. Till what age can a child be given OPV ?

A. OPV can be given to children till 5 years of age.

Q. Can OPV and vitamin A be given together with DPT-booster dose ?

A. Yes.

Q. Can an infant be breast-fed immediately after OPV ?

A. Yes.

TT vaccine

Q. If a girl has received all doses of DPT and TT as per the NIS till 16 years of age and she gets pregnant at 20 years, should she get one dose of TT during pregnancy ?

A. Give 2 doses of TT during the pregnancy as per the schedule.

Q. Is TT at 10 years and 16 years meant only for girls ?

A. No, it is to be given to both boys and girls.

Q. Can TT be given in the first trimester of pregnancy ?

A. Yes, it should be given as soon as pregnancy is diagnosed.

Hepatitis B vaccine

Q. Up to what age can hepatitis B vaccine be given ?

A. According to the National Immunization Schedule, Hepatitis B vaccine should be given with the first, second and third doses of DPT till one year of age.

Q. Why give the birth dose of hepatitis B vaccine only within 24 hours of birth ?

A. The birth dose of Hepatitis B vaccine is effective in preventing perinatal transmission of Hepatitis B if given within the first 24 hours.

JE vaccine

Q. If a child 16–24 months of age has been immunized with JE vaccine during an SIA, can it receive the JE vaccine again, as part of routine immunization ?

A. No, currently this is a single dose vaccine and should not be repeated.

Q. If a child above 2 years (24 months) of age has not received the JE vaccine through either RI or an SIA, should she/he be given the JE vaccine ?

A. Yes, the child is eligible to receive a dose of the JE vaccine, through RI, till the age of 15 years.

Following are some Do's and Don'ts during immunization sessions *(32)* :

Do's and Don'ts during immunization sessions

Do's	Don'ts
Vaccination schedule	
– It is safe and effective to give BCG, DPT, OPV and Measles vaccines at the same time to a child who has completed 9 months and never been vaccinated. – Give BCG to infants less than 1 year of age (never give BCG to children above 1 year of age). – If a child is brought late for a dose, pick up where the schedule was left off. For example, if a child left with DPT-2 and comes after 3 months give DPT-3.	– Withhold the vaccine in case of illness such as cold, cough, diarrhoea or fever.
Cold chain	
– Check expiry date and VVM label of vaccine vial before immunizing every child. – Keep the vaccines and diluents in a plastic bag/zipper bag in the centre of vaccine carrier with 4 conditioned ice-packs. Make sure that the diluents are also at +2 to +8 centigrade before reconstitution. – Take one ice pack from vaccine carrier and keep reconstituted BCG & Measles vaccines only on the top of the ice pack.	– Leave vaccine carrier in sunlight; this spoils vaccines that are sensitive to heat and light. – Leave the lid open, this can allow heat and light into the carrier, which can spoil vaccine. – Drop or sit on the vaccine carrier: this can damage the carrier. – Carry vaccines in handbag as this can spoil vaccines that are sensitive to heat. – Keep the DPT, DT, TT and Hep. B vaccines on the ice pack during the session.
Vaccine handling and administration	
– Welcome beneficiaries. – Wash hands before conducting the session. – Verify beneficiary's record and age of the child. – Screen for contraindications. – Check label of the vial and expiry date. – Lightly shake the vial of T-Series Vaccine before drawing the dose. – Use a new AD syringe for each injection and new disposable syringe for each reconstitution. – Use correct diluent for reconstitution of vaccine. – Give appropriate vaccine. – Inject vaccine using the correct site and route for the vaccine e.g. Intradermal in left arm for BCG; subcutaneous in right arm for Measles; intramuscular in anterolateral aspect of mid thigh for DPT and Hepatitis B. – Allow dose to self-disperse instead of massaging. – Explain potential adverse events following immunization and what to do. – Discuss with beneficiaries/parents about next visit.	– Use un-sterile syringe or needle for immunization. – Draw air into AD syringes. – Touch any part of the needle. – Recap the needle. – Leave the needle inside the vial. – Ever inject in the buttock, never do that. – Massage the vaccination site after vaccination. – Use reconstituted measles and BCG vaccine after 4hrs and JE after 2 hrs. – Use vaccine with VVM in unusable stage or with expiry date.
Recording and reporting	
– Fully document each immunization in the immunization card, tally sheet and immunization register. Ask parents/guardians to bring the card on next visit. – Retain the counterfoil.	– Turn away beneficiaries for not bringing the card. – Leave any cell blank in immunization card.
Adverse events following immunization (AEFI)	
– In case of serious AEFI refer the patient to appropriate health facility, inform your supervisor immediately – document the type of vaccine(s), batch number, expiry date, and full address of the child. – Report all serious AEFIs to the MOI/C.	– Report minor reaction following vaccination (mild fever of less than three days, redness and pain).
Social mobilization	
– Use vaccination card to remind parents when to return with their child. – Enlist community team like AWW, ASHA, NGOs and other community-based workers to remind parents of the importance of full immunization.	– Leave any community meeting without communicating about immunization session days.

NATIONAL HEALTH MISSION

The Ministry of Health and Family Welfare is implementing various schemes and programmes and national initiatives to provide universal access to quality health care. The approach is to increase access to the decentralized health system by establishing new infrastructure in defecient areas and by upgrading the infrastructure in existing institutions. As part of the plan process, many different programmes have been brought together under the overarching umbrella of National Health Mission (NHM), with National Rural Health Mission (NRHM) and National Urban Health Mission (NUHM) as its two sub–Missions. The National Health Mission was approved in May 2013. The main programmatic components include health system strengthening in rural and urban areas; Reproductive – Maternal – Newborn – Child and Adolescent Health (RMNCH+A); and control of communicable and non-communicable diseases. An important achievement of NHM has been considerable reduction in out of pocket expenses from 72 per cent to 60 per cent *(1)*.

The Government of India has introduced a series of programmes over the past two decades to address maternal and newborn health. The major milestones so far include *(33)*

a. 1992 – Child Survival and Safe Motherhood Programme (CSSM)
b. 1997 – RCH I
c. 1997 – RCH II
d. 2005 – National Rural Health Mission
e. 2013 – RMNCH+A Strategy
f. 2013 – National Health Mission
g. 2014 – India Newborn Action Plan (INAP)

The RMNCH+A strategy is based on a continuum of care approach and defines integrated packages of services for different stages of life. This approach brings focus on adolescents as a critical life stage and linkages between child survival, maternal health and family planning efforts. It aims to strengthen the referral linkages between community and facility based health services and between the various levels of health system itself. These packages provide a framework for delivering services at the state and district level. For details please refer to page 461.

Recently, new initiatives have been launched under NHM. Rashtriya Bal Swasthya Karyakram (RBSK) was launched to provide comprehensive healthcare and improve the quality of life of children through early detection of birth defects, diseases, deficiencies, and development delays including disability. Another initiative, viz. Rashtriya Kishor Swasthya Karyakram (RKSK) was launched to comprehensively address the health needs of the 253 million adolescents, who account for over 21% of the country's population, by bringing in several new dimensions like mental health, nutrition, substance misuse, injuries and violence, and non-communicable diseases.

In addition to these initiatives, the Weekly Iron Folic Acid Supplementation Programme (WIFS) was launched to address adolescent anaemia. In this programme supervised Iron-Folic Acid (IFA) tablets are given to adolescent population between 10–19 years of age in both rural and urban areas throughout the country. NHM is a step towards realizing the objective of universal health coverage in the country *(1)*.

NATIONAL URBAN HEALTH MISSION

NUHM seeks to improve the health status of the urban population particularly slum dwellers and other vulnerable section by facilitating their access to quality health care. NUHM would cover all state capitals, district headquarters and about 779 other cities/towns with a population of 50,000 and above (as per census 2011) in a phased manner. Cities and towns below 50,000 population will be covered by NRHM. The NUHM will focus on *(27)* :

1. Urban poor population living in listed and unlisted slums;
2. All other vulnerable population such as homeless, rag-pickers, street children, rickshaw pullers, construction and brick and lime-kiln workers, sex workers and other temporary migrants;
3. Public health thrust on sanitation, clean drinking water, vector control etc.; and
4. Strengthening public health capacity of urban local bodies.

The treatment of seven mteropolitan cities, viz., Mumbai, New Delhi, Chennai, Kolkata, Hyderabad, Bengaluru and Ahmedabad will be different. These cities are expected to manage NUHM through their Municipal Corporation directly.

The NUHM will provide flexibility to the states to choose which model suits the needs and capacities of the states to best address the healthcare needs of the urban poor. Models will be decided through community led action. All the services delivered under the urban health delivery system through the urban PHCs and urban CHCs will be universal in nature, whereas the outreach services will be targetted to the target group (slum dwellers and other vulnerable groups). Outreach services will be provided through the Female Health Workers (FHWs), essentially ANMs with an induction training of three to six months, who will be placed at the Urban PHCs. These ANMs will report at the U-PHC and then move to their respective areas for outreach services on designated days. On other days, they will conduct immunization and ANC clinics etc. at the U-PHC itself.

The NUHM would encourage the effective participation of the community in planning and management of health care services. It would promote a community health volunteer – Accredited Social Health Activist (ASHA) or Link Worker (LW) in urban poor settlement (one ASHA for 1000–2500 urban poor population covering about 200 to 500 households); ensure the participation by creation of community based institutions like Mahila Arogya Samiti (MAS) (50–100 households) and Rogi Kalyan Samitis. However, the states will have the flexibility to either engage ASHA or entrust her responsibilities to MAS. In that case, the incentives accruing to ASHA would accrue to MAS *(34)*. The NUHM would provide annual grant of Rs. 5000/- to MAS every year.

Essential services to be rendered by the ASHA may be as follows *(34)*:

(i) Active promoter of good health practices and enjoying community support.

(ii) Facilitate awareness on essential RCH services, sexuality, gender equality, age at marriage/pregnancy; motivation on contraception adoption, medical termination of pregnancy, sterilization, spacing methods. Early registration of pregnancies, pregnancy care, clean and safe delivery, nutritional care during

pregnancy, identification of danger signs during pregnancy; counselling on immunization, ANC, PNC etc., act as a depot holder for essential provisions like oral re-hydration therapy (ORS), Iron Folic Acid Tablet (IFA), chloroquine, oral pills and condoms, etc.; identification of target beneficiaries and support the ANM in conducting regular monthly outreach sessions and tracking service coverage.

(iii) Facilitate access to health related services available at the Anganwadi/Primary Urban Health Centres/Urban Local Body (ULBs) and other services being provided by the ULB/State/Central Government.

(iv) Formation and promotion of Mahila Arogya Samitis in her community.

(v) Arrange escort/accompany pregnant women and children requiring treatment to the nearest Urban Primary Health Centre, secondary/tertiary level health care facility.

(vi) Reinforcement of community action for immunization, prevention of water borne and other communicable diseases like TB (DOTS), Malaria, Chikungunya and Japanese Encephalitis.

(vii) Carrying out preventive and promotive health activities with AWW/Mahila Arogya Samiti.

(viii) Maintenance of necessary information and records about births and deaths, immunization, antenatal services in her assigned locality as also about any unusual health problem or disease outbreak in the slum, and share it with the ANM in charge of the area.

In return for the services rendered, she would receive a performance based incentive. For this purpose a revolving fund would be kept with the ANM at the U-PHC (in the PHC account), which would be replenished from time to time.

The urban health care facilities are as shown in Fig. 9.

Urban Primary Health Centre

Functional for a population of around approximately 50,000–60,000, the U-PHC may be located preferably within a slum or near a slum within half a kilometer radius, catering to a slum population of approximately 25,000–30,000, with provision for OPD. The cities, based upon the local situation may establish a U-PHC for 75,000 for areas with very high density and can also establish one for around 5,000–10,000, slum population for isolated slum clusters.

At the U-PHC level services provided will include OPD (consultation), basic laboratory diagnosis, drug/ contraceptive dispensing, apart from distribution of health education material and counselling for all communicable and non-communicable diseases. In order to ensure access to the urban slum population at convenient timings, the U-PHC may provide services from 12 noon to 8 pm. It will not include in-patient care. The staff pattern will be as shown in Fig. 9.

Referral unit

Urban Community Health Centre (U-CHC) may be set up as a satellite hospital for every 4–5 U-PHCs. The U-CHC would cater to a population of 2,50,000. It would provide in-patient services and would be a 30–50 bedded facility. U-CHCs would be set up in cities with a population of above 5 lakhs, wherever required. These facilities would be in addition to the existing facilities (SDH/DH) to cater to the urban population in the locality.

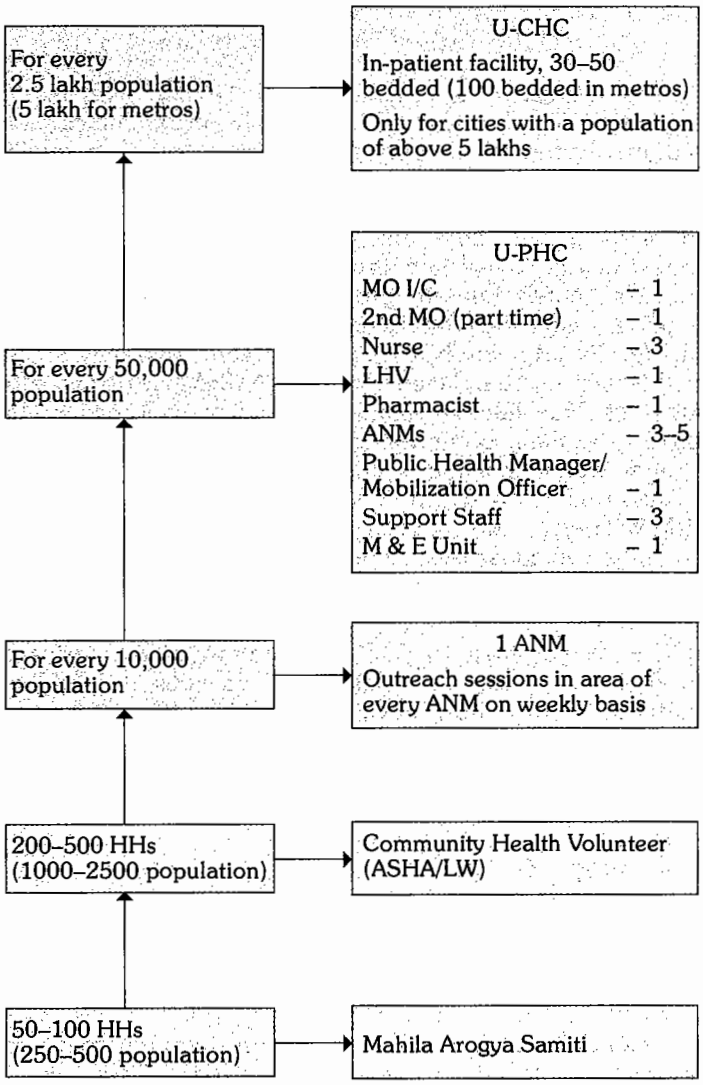

FIG. 9
Urban Health Care Facilities

Source : *(35)*

For the metro cities, the U-CHCs may be established for every 5 lakh population with 100 beds.

For setting up the U-CHCs the Central Government would provide only a one time capital cost, and the recurrent costs including the salary of the staff would be borne by the respective state governments.

The U-CHC would provide medical care, minor surgical facilities and facilities for institutional delivery.

Referral linkages

Existing hospitals, including ULB maternity homes, state government hospitals and medical colleges, apart from private hospitals will be empanelled/accredited to act as referral points for different types of healthcare services like maternal health, child health, diabetes, trauma care, orthopaedic complications, dental surgeries, mental health, critical illness, deafness control, cancer management, tobacco counselling/cessation, critical illness, surgical cases etc.

The services provided at different levels are as shown in Table 10 *(35)*.

TABLE 10

Service norm by level of care facility

Services	Levels of service delivery		
	Community (Outreach)	First point of service delivery (U-PHC)	Referral Centre - U-CHC (specialist services)
A. Essential Health Services			
A1. Maternal health	Registration, ANC, identification of danger signs, referral for institutional delivery, follow-up counselling and behavior promotion	ANC, PNC, initial management of complicated delivery cases and referral, management of regular maternal health conditions, referral of complicated cases	Delivery (normal and complicated), management of complicated gynae/maternal health condition, hospitalization and surgical interventions, including blood transfusion
A2. Family welfare	Counselling, distribution of OCP/CC, referral for sterilization, follow-up of contraceptive related complications	Distribution of OCP/CC, IUD insertion, referral for sterilization, management of contraceptive related complications	Sterilization operations, fertility treatment
A3. Child health and nutrition	Immunization, identification of danger signs, referral, follow-up, distribution of ORS, paediatric cotrimoxazole, post-natal visits/counselling for newborn care	Diagnosis and treatment of childhood illnesses, referral of acute cases/chronic illness, identification and referral of neonatal sickness	Management of complicated paediatric/neo-natal cases, hospitalization, surgical interventions, blood transfusion
A4. RTI/STI (including HIV/AIDS)	referral, community level follow-up for ensuring adherence to treatment regime of cases undergoing treatment	Symptomatic diagnosis and primary treatment and referral of complicated cases	Management of complicated cases, hospitalization (if needed)
A5. Nutrition deficiency disorders	Height/weight measurement, Hb testing, distribution of IFA tablets promotion of iodized salt, nutrition supplements to children and pregnant/lactating women, promotion of breast feeding.	Diagnosis and treatment of seriously deficient patients, referral of acute deficiency cases	Management of acute deficiency cases, hospitalization, treatment and rehabilitation of severe under-nutrition
A6. Vector-borne diseases	Slide collection, testing using RDKs, DDT, counselling for practices for vector control and protection	Diagnosis and treatment, referral of terminally ill cases	Management of terminaly ill cases, hospitalization
A7. Mental health	–	Initial screening and referral	Psychiatric, neurological services
A7.1 Oral health	–	Diagnosis and referral	Management of complicated cases
A7.2 Hearing Impairment/ deafness	–	–	Management of complicated cases
A8. Chest infections (TB/asthma)	Symptomatic search and referral, ensuring adherence to DOTS, other treatment	Diagnosis and treatment, referral of complicated cases	Management of complicated cases
A9. Cardiovascular diseases	BP measurement, symptomatic search and referral, follow-up of under-treatment patients	Diagnosis and treatment and referral during specialist visits	Management of emergency cases, hospitalization and surgical interventions (if needed)
A10. Diabetes	Blood/urine sugar test (using disposable kit), symptomatic search and referral	Diagnosis and treatment, referral of complicated cases	Management of complicated cases, hospitalization (if needed)
A11. Cancer	Symptomatic search and referral, follow-up of under-treatment patients	Identification and referral, follow-up of under-treatment patients	Diagnosis treatment, hospitalization (if and when needed)
A12. Trauma care (burns and injuries)	First aid and referral	First-aid/emergency resucitation, documentation for medicolegal case (if applicable) and referral	Case management and hospitalization, physiotherapy and rehabilitation
A13. Other surgical interventions	Not applicable	Identification and referral	Hospitalization and surgical intervention
B. Other support services like IEC, BCC, counselling and personal and social hygiene.			

City level indicators

The city level indicators are as shown in Table 11.

TABLE 11

Process and input indicators in NUHM

Indicator	Baseline (as applicable)	Number Proposed (2013–14)	Number Achieved (2013–14)
Community Processes			
1. Number of Mahila Arogya Samiti (MAS) formed *	0		
2. Number of MAS members trained *	0		
3. Number of Accredited Social Health Activists (ASHAs) selected and trained	0		
Health Systems			
4. Number of ANMs recruited *	0		
5. No. of Special Outreach health camps organized in the slum/HFAs *	0		
6. No. of UHNDs organized in the slums and vulnerable areas *	0		
7. Number of UPHCs made operational *	0		
8. Number of UCHCs made operational *	0		
9. No. of RKS created at UPHC and UCHC *	0		
10. OPD attendance in the UPHCs			
11. No. of deliveries conducted in public health facilities			
RCH Services			
12. ANC early registration in first trimester			
13. Number of women who had ANC check-up in their first trimester of pregnancy			
14. TT (2nd dose) coverage among pregnant women			
15. No. of children fully immunized (through public health facilities)			
16. No. of Severely Acute Malnourished (SAM) children identified and referred for treatment			
Communicable Diseases			
17. No. of malaria cases detected through blood examination			
18. No. of TB cases identified through chest symptomatic			
19. No. of suspected TB cases referred for sputum examination			
20. No. of MDR-TB cases put under DOTS-plus			
Non-communicable Diseases			
21. No. of diabetes cases screened in the city			
22. No. of cancer cases screened in the city			
23. No. of hypertension cases screened in the city			

* Year 2013–14 being the baseline year, the indicators for these NUHM components would be zero. For other indicators, the figure for 2012–13 will be the base line.

Source : *(34)*

Impact level targets of NUHM are as follows :

1. Reduce IMR by 40% (in urban areas) – National Urban IMR down to 20 per 1000 live births by 2017
   - 40% reduction in U5MR and IMR
   - Achieve universal immunization in all urban areas.
2. Reduce MMR by 50%
   - 50% reduction in MMR (among urban population of the state/ country)
   - 100% ANC coverage (in urban areas)
3. Achieve universal access to reproductive health including 100% institutional delivery
4. Achieve replacement level fertility (TFR 2.1)
5. Achieve all targets of disease control programmes.

Source : *(35)*

NATIONAL RURAL HEALTH MISSION

Recognizing the importance of health in the process of economic and social development and to improve the quality of life of its citizens, the government of India launched "National Rural Health Mission" (NRHM) on 5th April, 2005 for a period of 7 years (2005–2012) and recently extended upto year 2017. The mission seeks to improve rural health care delivery system. It is operational in the whole country with special focus on 18 states viz. 8 Empowered Action Group states (Bihar, Jharkhand, Madhya Pradesh, Chattisgarh, Uttar Pradesh, Uttaranchal, Orissa and Rajasthan), 8 North East states (Assam, Arunachal Pradesh, Manipur, Meghalaya, Mizoram, Nagaland, Sikkim and Tripura), Himachal Pradesh and Jammu and Kashmir. By making necessary changes in the basic health care delivery

system the mission adopts a synergic approach by relating health to determinants of good health viz. of nutrition, sanitation, hygiene and safe drinking water. It also brings the Indian system of medicine (AYUSH) to the mainstream of health care *(5)*.

The main aim of NRHM is to provide accessible, affordable, accountable, effective and reliable primary health care, and bridging the gap in rural health care through creation of a cadre of Accredited Social Health Activist (ASHA). The mission is an instrument to integrate multiple vertical programmes alongwith their funds at the district level. The programmes integrated into NRHM are existing programmes of health and family welfare including RCH II; national vector borne disease control programmes against malaria, filaria, kala-azar, dengue fever/DHF and Japanese encephalitis; national leprosy eradication programme; revised national tuberculosis control programme; national programme for control of blindness; iodine deficiency disorder control programme, and integrated disease surveillance project *(5)*.

PLAN OF ACTION TO STRENGTHEN INFRASTRUCTURE

1. Creation of a cadre of Accredited Social Health Activist (ASHA).
2. Strengthening sub-centres by : (a) Supply of essential drugs both allopathic and AYUSH to the sub-centre; (b) In case of additional outlay, provision of multipurpose worker (male)/additional ANMs wherever needed, sanction of new sub-centres and upgrading existing sub-centres; and (c) Strengthening sub-centres with untied funds of Rs. 10,000 per annum in all 18 states.
3. Strengthening Primary Health Centres : Mission aims at strengthening PHCs for quality preventive, promotive, curative, supervisory and outreach services through (a) Adequate and regular supply of essential drugs and equipment to PHCs (including supply of auto-disabled syringes for immunization); (b) Provision of 24 hours service in at least 50 per cent PHCs by including an AYUSH practitioner; (c) Following standard treatment guidelines; (d) Upgradation of all the PHCs for 24 hours referral service and provision of second doctor at PHC level (one male and one female) on the basis of felt need; strengthening the ongoing communicable disease control programmes and new programmes for control of non-communicable diseases.
4. Strengthening Community Health Centres for First Referral care by (a) Operating all existing CHCs (30–50 beds) as 24 hours first referral units, including posting of an anaesthetist; (b) Codification of new "Indian Public Health Standards" (Refer to chapter 20 for more details) by setting up norms for infrastructure, staff, equipment, management etc. for CHCs; (c) Promotion of *"Rogi Kalyan Samiti"* for hospital management; (d) Developing standards of services and costs in hospital care.

The NRHM infrastructure is as shown in Fig. 10.

District is the core unit of planning, budgeting and implementation of the programme. All vertical health and family welfare programmes at district level have merged into one common "District Health Mission" and at state level into "State Health Mission". There is provision of a *"mobile medical unit"* at district level for improved outreach services.

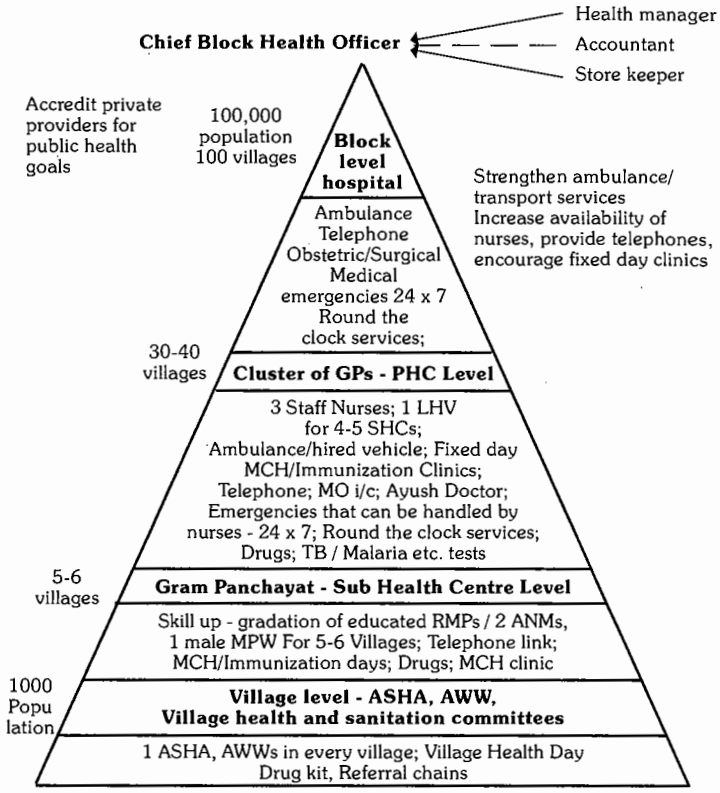

Fig. 10
The NRHM infrastructure

Since almost 75 per cent of health services are being currently provided by the private sector, it is contemplated that involving the private sector as part of the RCH initiatives will provide more effective health care delivery system. Thus setting up of *"Public Private Partnership"* (PPP)" is to help to make the RCH II programme better, and ensure availability of preventive and curative reproductive and child health services to the community.

Major initiatives under NRHM

1. *Selection of ASHA:* ASHA must be the resident of the village – a woman (married / widow / divorced) preferably in the age group of 25 to 45 years with formal education up to eighth class, having communication skills and leadership qualities. Adequate representation from the disadvantaged population group will ensure to serve such groups better.

The general norm of selection is *one* ASHA *for 1000 population*. In tribal, hilly and desert areas the norm could be relaxed to one ASHA per habitation.

Role and responsibilities of ASHA

ASHA will be a health activist in the community who will create awareness on health. Her responsibilities will be as follows *(36)* :

1. ASHA will take steps to create awareness and provide information to the community on determinants of health such as nutrition, basic sanitation and hygienic practices, healthy living and working conditions, information on existing health services, and the need for timely utilization of health and family welfare services.
2. She will counsel women on birth preparedness, importance of safe delivery, breast-feeding and complementary feeding, immunization, contraception

and prevention of common infections including reproductive tract infection/sexually transmitted infection and care of the young child.

3. ASHA will mobilize the community and facilitate them in accessing health and health related services available at the anganwadi/subcentre/primary health centres, such as immunization, antenatal check-up, postnatal check-up, supplementary nutrition, sanitation and other services being provided by the government.
4. She will work with the village health and sanitation committee of the gram panchayat to develop a comprehensive village health plan.
5. She will arrange escort/accompany pregnant women and children requiring treatment/admission to the nearest pre-identified health facility i.e. primary health centre/community health centre/First Referral Unit.
6. ASHA will provide primary medical care for minor ailments such as diarrhoea, fevers, and first-aid for minor injuries. She will be a provider of directly observed treatment short-course (DOTS) under revised national tuberculosis control programme.
7. She will also act as a depot holder for essential provisions being made available to every habitation like oral rehydration therapy, iron folic acid tablet, chloroquine, disposable delivery kits, oral pills and condoms etc. A drug kit will be provided to each ASHA. Contents of the kit will be based on the recommendations of the expert/technical advisory group set up by the government of India, and include both AYUSH and allopathic formulations.
8. Her role as a provider can be enhanced subsequently. States can explore the possibility of graded training to her for providing newborn care and management of a range of common ailments, particularly childhood illnesses.
9. She will inform about the births and deaths in her village and any unusual health problems/disease outbreaks in the community to the sub-centre/primary health centre.
10. She will promote construction of household toilets under total sanitation campaign.

Role and integration with Anganwadi *(36)*

Anganwadi worker will guide ASHA in performing following activities : (a) Organizing Health Day once/twice a month. On health day, the women, adolescent girls and children from the village will be mobilized for orientation on health related issues such as importance of nutritious food, personal hygiene, care during pregnancy, importance of antenatal check-up and institutional delivery, home remedies for minor ailment and importance of immunization etc. AWWs will inform ANM to participate and guide organizing the Health Days at anganwadi centre; (b) AWWs and ANMs will act as resource persons for the training of ASHA; (c) IEC activity through display of posters, folk dances etc. on these days can be undertaken to sensitize the beneficiaries on health related issues; (d) Anganwadi worker will be depot holder for drug kits and will be issuing it to ASHA. The replacement of the consumed drugs can also be done through AWW; (e) AWW will update the list of eligible couples and also the children less than one year of age in the village with the help of ASHA; and (f) ASHA will support the AWW in mobilizing pregnant and lactating women and infants for nutrition supplement. She would also take initiative for bringing the beneficiaries from the village on specific days of immunization, health check-ups/health days etc. to anganwadi centres.

Role and integration with ANM *(36)*

Auxiliary Nurse Midwife (ANM) will guide ASHA in performing following activities : (a) She will hold weekly/ fortnightly meeting with ASHA and discuss the activities undertaken during the week/fortnight. She will guide her in case ASHA had encountered any problem during the performance of her activity; (b) AWWs and ANMs will act as resource persons for the training of ASHA; (c) ANMs will inform ASHA regarding date and time of the outreach session and will also guide her for bringing the beneficiary to the outreach session; (d) ANM will participate and guide in organizing the Health Days at anganwadi centre; (e) She will take help of ASHA in updating eligible couple register of the village concerned; (f) She will utilize ASHA in motivating the pregnant women for coming to sub-centre for initial check-ups. She will also help ANMs in bringing married couples to sub-centres for adopting family planning; (g) ANM will guide ASHA in motivating pregnant women for taking full course of iron and folic acid tablets and tetanus toxoid injections etc.; (h) ANMs will orient ASHA on the dose schedule and side effects of oral pills; (i) ANMs will educate ASHA on danger signs of pregnancy and labour so that she can timely identify and help beneficiary in getting further treatment; and (j) ANMs will inform ASHA on date, time and place for initial and periodic training schedule. She will also ensure that during the training ASHA gets the compensation for performance and also TA/DA for attending the training.

2. *Rogi Kalyan Samiti (Patient Welfare Committee/ Hospital Management Society:* It is a simple yet effective management structure. This committee is a registered society whose members act as trustees to manage the affairs of the hospital and is responsible for upkeep of the facilities and ensure provision of better facilities to the patients in the hospital. Financial assistance is provided to these Committees through untied fund to undertake activities for patient welfare. 31,109 Rogi Kalyan Samitis (RKS) have been set up involving the community members in almost all District Hospitals (DHs), Sub-District Hospitals (SDHs), Community Health Centres (CHCs) and Primary Health Centres (PHCs) till March 2014.

3. *The untied grants to sub-centres (SCs):* The SCs are far better equipped now with blood pressure measuring equipment, haemoglobin (Hb) measuring equipment, stethoscope, weighing machine etc. This has facilitated provision of quality antenatal care and other health care services.

4. *The Village Health Sanitation and Nutrition Committee (VHSNC):* It is an important tool of community empowerment and participation at the grassroots level. The VHSNC reflects the aspirations of the local community, especially the poor households and children. Upto 31st March 2014, 5.12 lakh VHSNCs have been set up across the country.

5. *Janani Suraksha Yojana (JSY):* aims to reduce maternal mortality among pregnant women by encouraging them to deliver in government health facilities. Under the scheme, cash assistance is provided to eligible pregnant women for giving birth in a government health facility. Since the inception of NRHM, 7.04 crore women have benefited under this scheme. For details please refer to page 455.

6. *Janani Shishu Suraksha Karyakarm (JSSK):* Launched on 1st June, 2011, JSSK entitles all pregnant women delivering in public health institutions to absolutely free and no expense delivery, including caesarean section. This marks a shift to an entitlement based approach. Please refer to page 456 for details.

7. *National Mobile Medical Units (NMMUs):* Support has been provided in 418 out of 640 districts for 2127 MMUs under NRHM in the country. To increase visibility, awareness and accountability, all Mobile Medical Units have been repositioned as "National Mobile Medical Unit Service" with universal colour and design.

8. *National Ambulance Services:* NRHM has supported free ambulance services to provide patients transport in every nook and corner of the country connected with a toll free number. Over 16,000 basic and emergency patient transport vehicles have been provided under NRHM. Besides these, over 4,769 vehicles have been empanelled to transport patients, particularly pregnant women and sick infants from home to public health facilities and back. 28 states have set up a call centre for effective patient transport system.

9. *Web enabled Mother and Child Tracking System (MCTS):* The name-based tracking of pregnant women and children has been initiated under NRHM with an intention to track every pregnant woman, infant and child upto the age of three years by name, for ensuring delivery of services like timely antenatal care, institutional delivery and postnatal care for the mother, and immunization and other related services for the child. The MCTs is to be fully updated for regular and effective monitoring of service delivery, including tracking and monitoring of severely anaemic women, low birth weight babies and sick neonates. In the long run, it could be used for tracking the health status of the girl child and school health services. A more recent initiative is to link MCTS with AADHAR in order to track subsidies to eligible women (37).

New initiatives *(6)*

The following are the major decisions of Mission Steering Group; taken since 2011 :

1. Home delivery of contraceptives (condoms, oral contraceptive pills, emergency contraceptive pills) by ASHA;
2. Conducting District Level Household Survey (DLHS) – 4 in 26 States/UTs where the Annual Health Survey (AHS) is not being done;
3. Modifications in the scheme for promotion of menstrual hygiene covering 152 districts and nearly 1.5 crores of adolescent girls in 20 states;
4. Differential financial approach for comprehensive health care by which allocation of Untied Funds and Rogi Kalyan Samiti grants will be made based on the case load and services provided by the health facility;
5. Involving ASHA in Home Based Newborn Care;
6. Revision in the criterion of allocation of funds to the states under NRHM based on the performance of the states against the monitorable targets and implementation of specific reform agenda in the health sector;
7. Expansion of Village Health and Sanitation Committees to include nutrition in its mandate and renaming it as Village Health, Sanitation and Nutrition Committee (VHSNC); and
8. Partial modification of the centrally sponsored scheme for development of AYUSH hospitals and dispensaries for mainstreaming of AYUSH under NRHM.
9. Rashtriya Bal Swasthya Karyakram (RBSK): This initiative was launched in February 2013 and provides for Child Health Screening and Early Intervention Services through early detection and management of 4 Ds i.e., Defects at birth, Diseases, Deficiencies, Development delays including disability. For details please refer to page 460.
10. Rashtriya Kishor Swasthya Karyakram (RKSK): This is a new initiative, launched in January 2014 to reach out to 253 million adolescents in the country in their own spaces and introduces peer-led interventions at the community level, supported by augmentation of facility based services. This initiative broadens the focus of the adolescent health programme beyond reproductive and sexual health and brings in focus on life skills, nutrition, injuries and violence (including gender based violence), non-communicable diseases, mental health and substance misuse *(1)*.
11. Mother and Child Health Wings (MCH Wings): 100/50/30 bedded Maternal and Child Health (MCH) Wings have been sanctioned in public health facilities with high bed occupancy to cater to the increased demand for services. More than 28,000 additional beds have been sanctioned across 470 health facilities across 18 states.
12. Free drugs and free diagnostic service.
13. National Iron+ Initiative is another new initiative launched in 2013, to prevent and control iron deficiency anaemia, a grave public health challenge in India. Besides pregnant women and lactating mothers, it aims to provide IFA supplementation for children, adolescents and women in reproductive age group. Weekly Iron and Folic Acid Supplementation (WIFS) for adolescents is an important strategy under this initiative. WIFS (for 10–19 years age) has already been rolled out in 32 states and UTs under the National Iron Plus Initiative. WIFS covered around 3 crore beneficiaries in December 2013 *(1)*.
14. Reproductive, Maternal, Newborn, Child and Adolescent Health Services (RMNCH+A): A continuum of care approach has now been adopted under NRHM with the articulation of strategic approach to Reproductive Maternal, Newborn, Child and Adolescent Health (RMNCH+A) in India. This approach brings focus on adolescents as a critical life stage and linkages between child survival, maternal health and family planning efforts. It aims to strengthen the referral linkages between community and facility based health services and between the various levels of health system itself. Please refer to page 461 for details.
15. Delivery Points (DPs): Health facilities that have a high demand for services and performance above a certain benchmark have been identified as "Delivery Points" with the objective of providing comprehensive reproductive, maternal, newborn, child and adolescent health services (RMNCH+A) at these facilities. Funds have been allocated to strengthen these DPs in terms of infrastructure, human resource, drugs, equipments etc. Around 17,000 health facilities have been identified as "Delivery Points" for focussed support under NRHM.
16. Universal Health Coverage (UHC): Moving towards Universal Health Coverage (UHC) is a key goal of the 12th Five Year Plan. The National Health Mission is the primary vehicle to move towards this goal.

Achievements : The achievements of NRHM as on 30th June 2013 are as follows *(1)* :

(1) 8.89 lakh ASHAs have been selected in the entire country of which 8.06 lakh ASHAs have been trained and provided with drug kits.
(2) 1.47 lakh sub-centres in the country are provided with untied funds of Rs 10,000 each. 40,426 sub-centres are functional with second ANM.
(3) 31,109 Rogi Kalyan Samitis have been registered at different level of facilities.
(4) 8,129 doctors and specialists, 70,608 ANMs, 34,605 staff nurses, 13,725 paramedics have been appointed on contract to fill-in critical gaps in services.
(5) 1,691 professionals (CA/MBA/MCA) have been appointed to support NRHM.
(6) 2,127 Mobile Medical Units are operational under NRHM in states.
(7) Emergency transport system operational in 12 states.
(8) Accelerated immunization programme taken up for North-East states and EAG (Empowered Action Group) states. Progress made in pulse polio immunization (India declared polio free country); neonatal tetanus declared eliminated in 7 states in the country; JE vaccination completed in 11 districts in 4 states.
(9) Janani Suraksha Yojana is operational in all the states. 106.57 lakh women were benefitted in the year 2012–13.
(10) Integrated Management of Neonatal and Childhood Illness (IMNCI) started in 310 districts.
(11) Monthly Health and Nutrition Days being organized at the village level in various states.
(12) The states have constituted 5.12 lakh Village Health Sanitation and Nutrition Committees.
(13) School health programme have been initiated in over 26 states.

Monitoring and evaluation under NRHM

A baseline survey is to be taken up at the district level incorporating facility survey (including private facilities) as well as survey of the households. The baseline survey is to help the mission in fixing decentralized monitorable goals and indicators. There would be community monitoring at the village level. The panchayat raj institutions, rogi kalyan samitis, quality assurance committees at the state level and district level, state and district health missions, mission steering group at the central level. Planning commission is to be the eventual monitor of the outcomes. External evaluation is also to be taken up at frequent intervals.

REPRODUCTIVE AND CHILD HEALTH PROGRAMME

Reproductive and child health approach has been defined as "people have the ability to reproduce and regulate their fertility, women are able to go through pregnancy and child birth safely, the outcome of pregnancies is successful in terms of maternal and infant survival and well being, and couples are able to have sexual relations, free of fear of pregnancy and of contracting disease" *(38)*.

The concept is in keeping with the evolution of an integrated approach to the programme aimed at improving the health status of young women and young children which has been going on in the country namely family welfare programme, universal immunization programme, oral rehydration therapy, child survival and safe motherhood programme and acute respiratory infection control etc. It is obviously sensible that integrated RCH programme would help in reducing the cost inputs to some extent because overlapping of expenditure would not be necessary and integrated implementation would optimise outcomes at field level.

The RCH phase–I programme incorporated the components relating child survival and safe motherhood and included two additional components, one relating to sexually transmitted disease (STD) and other relating to reproductive tract infection (RTI).

The RCH programme was based on a differential approach. Inputs in all the districts were not kept uniform. While the care components was same for all districts, the weaker districts got more support and sophisticated facilities were proposed for relatively advanced districts. On the basis of crude birth rate and female literacy rate, all the districts were divided into three categories. Category A having 58 districts, category B having 184 districts and category C having 265 districts. All the districts were covered in a phased manner over a period of three years. The programme was formally launched on 15th October 1997.

RCH phase–I interventions at district level were as follows :

Interventions in all districts

- Child Survival interventions i.e. immunization, Vitamin A (to prevent blindness), oral rehydration therapy and prevention of deaths due to pneumonia.
- Safe Motherhood interventions e.g. antenatal check up, immunization for tetanus, safe delivery, anaemia control programme.
- Implementation of Target Free Approach.
- High quality training at all levels.
- IEC activities.
- Specially designed RCH package for urban slums and tribal areas.
- District sub-projects under Local Capacity Enhancement.
- RTI/STD Clinics at District Hospitals (where not available)
- Facility for safe abortions at PHCs by providing equipment, contractual doctors etc.
- Enhanced community participation through Panchayats, Women's Groups and NGOs.
- Adolescent health and reproductive hygiene.

Interventions in selected States/Distts.

- Screening and treatment of RTI/STD at sub-divisional level.
- Emergency obstetric care at selected FRUs by providing drugs.
- Essential obstetric care by providing drugs and PHN/ Staff Nurse at PHCs.
- Additional ANM at sub-centres in the weak districts for ensuring MCH care.
- Improved delivery services and emergency care by providing equipment kits, IUD insertions and ANM kits at sub-centres.
- Facility of referral transport for pregnant women during emergency to the nearest referral centre through Panchayat in weak districts.

The major interventions under RCH – Phase I

Essential obstetric care (39)

Essential obstetric care intends to provide the basic maternity services to all pregnant women through (1) early registration of pregnancy (within 12–16 weeks). (2) provision of minimum three antenatal check ups by ANM or medical officer to monitor progress of the pregnancy and to detect any risk/complication so that appropriate care including referral could be taken in time. (3) provision of safe delivery at home or in an institution, and (4) provision of three postnatal check ups to monitor the postnatal recovery and to detect complications.

Emergency obstetric care

Complications associated with pregnancy are not always predictable, hence, emergency obstetric care is an important intervention to prevent maternal morbidity and mortality. Under the CSSM programme 1748 Referral Units were identified and supported with equipment kit E to kit P. However, these FRUs were not fully operational because of lack of manpower and adequate infrastructure. Under the RCH programme the FRUs were strengthened through supply of emergency obstetric kit, equipment kit and provision of skilled manpower on contract basis etc. Traditional Birth Attendant still plays an important role during deliveries in our society.

24-Hour delivery services at PHCs/CHCs

To promote institutional deliveries, provision has been made to give additional honorarium to the staff to encourage round the clock delivery facilities at health centres.

Medical Termination of Pregnancy

MTP is a reproductive health measure that enables a woman to opt out of an unwanted or unintended pregnancy in certain specified circumstances without endangering her life, through MTP Act 1971. The aim is to reduce maternal morbidity and mortality from unsafe abortions. The assistance from the Central Government is in the form of training of manpower, supply of MTP equipment and provision for engaging doctors trained in MTP to visit PHCs on fixed dates to perform MTP.

Control of reproductive tract infections (RTI) and sexually transmitted diseases (STD)

Under the RCH programme, the component of RTI/STD control is linked to HIV and AIDS control. It has been planned and implemented in close collaboration with National AIDS Control Organization (NACO). NACO provides assistance for setting up RTI/STD clinics upto the district level. The assistance from the Central Government is in the form of training of the manpower and drug kits including disposable equipment. Each district is assisted by two laboratory technicians on contract basis for testing blood, urine and RTI/STD tests.

Immunization

The Universal Immunization Programme (UIP) became a part of CSSM programme in 1992 and RCH programme in 1997. It will continue to provide vaccines for polio, tetanus, DPT, DT, measles and tuberculosis. The cold chain established so far will be maintained and additional items will be provided to new health facilities.

Essential newborn care

The primary goal of essential newborn care is to reduce perinatal and neonatal mortality. The main components are resuscitation of newborn with asphyxia, prevention of hypothermia, prevention of infection, exclusive breast feeding and referral of sick newborn. The strategies are to train medical and other health personnel in essential newborn care, provide basic facilities for care of low birth weight and sick new borns in FRU and district hospitals etc.

Diarrhoeal disease control

In the districts not implementing Integrated Management of Neonatal and Childhood Illness, the vertical programme for control of diarrhoeal disease will continue. India is the first country in the world to introduce the low osmolarity Oral Rehydration Solution. Zinc is to be used as an adjunct to ORS for the management of diarrhoea. Addition of Zinc would result in reduction of the number and severity of episodes and the duration of diarrhoea. De-worming guidelines have been formulated. The incidence of diarrhoea is reduced by provision of safe drinking water.

Acute respiratory disease control

The standard case management of ARI and prevention of deaths due to pneumonia is now an integral part of RCH programme. Peripheral health workers are being trained to recognize and treat pneumonia. Cotrimoxazole is being supplied to the health workers through the drug kit.

Prevention and control of vitamin A deficiency in children

It is estimated that large number of children suffer from sub-clinical deficiency of vitamin A. Under the programme, doses of vitamin A are given to all children under 5 years of age. The first dose (1 lakh units) is given at nine months of age along with measles vaccination. The second dose (2 lakh units) is given after 9 months. Subsequent doses (2 lakh units each) are given at six months intervals upto 5 years of age *(3)*. All cases of severe malnutrition to be given one additional dose of vitamin A.

Prevention and control of anaemia in children

Iron deficiency anaemia is widely prevalent in young children. To manage anaemia, the policy has been revised. Infants from the age of 6 months onwards upto the age of 5 years are to receive iron supplements in liquid formulation in doses of 20 mg elemental iron and 100 mcg folic acid per day for 100 days in a year. Children 6 to 10 years of age will receive iron in the dose of 30 mg elemental iron and 250 mcg folic acid for 100 days in a year. Children above this age group would receive iron supplement in the adult dose *(3)*.

Introduction of Hepatitis B Vaccination

Introduction of Hepatitis B in the National Immunization Programme has been approved by the Government. Under this project hepatitis B vaccine will be administered to infants alongwith the primary doses of DPT vaccine.

Training of dais

A scheme for training of dais was initiated during 2001–02. The scheme is being implemented in 156 districts in 18 states/UTs of the country. The districts have been selected on the basis of the safe delivery rates being less

than 30 per cent. The scheme was extended to all the districts of EAG states. The aim was to train at least one Dai in every village, with the objective of making deliveries safe.

Empowered Action Group (EAG)

An Empowered Action Group has been constituted in the Ministry of Health and Family Welfare, with Union Minister for Health and Family Welfare as chairman on 20th March 2001. As 55 per cent of the increase in the population of India is anticipated in the states of Uttar Pradesh, Bihar, Madhya Pradesh, Rajasthan, Odisha, Chhattisgarh, Jharkhand and Uttaranchal, these states are perceived to be most deficient in critical socio–demographic indices. Through EAG, these states will get focussed attention for different health and family welfare programmes.

District Surveys

There is no regular source of data to indicate the reproductive health status of women. The RCH programme conducts district based rapid household survey to assess the reproductive health status of women. The key indicators are :

a. Percentage of pregnant women with full ANC;
b. Percentage of institutional deliveries and home deliveries;
c. Percentage of home deliveries by trained birth attendant;
d. Current contraceptive prevalence rate;
e. Percentage of children fully immunized;
f. Percentage of unmet need for family planning; and
g. Percentage of household reported visits by health worker in previous 3 months.

RCH – PHASE II

RCH–phase II began from 1st April, 2005. The focus of the programme is to reduce maternal and child morbidity and mortality with emphasis on rural health care.

The major strategies under the second phase of RCH are *(40)* :

- *Essential obstetric care*
  a. Institutional delivery
  b. Skilled attendance at delivery
- *Emergency obstetric care*
  a. Operationalizing First Referral Units
  b. Operationalizing PHCs and CHCs for round the clock delivery services
- *Strengthening referral system*

The Government of India has given some broad guidelines and strategies for achieving the reduction in maternal mortality rate and infant mortality rate. The initiatives which have been planned are :

Essential obstetric care

a. Institutional delivery – To promote institutional delivery in RCH Phase II, it was envisaged that fifty percent of the PHCs and all the CHCs would be made operational as 24–hour delivery centres, in a phased manner, by the year 2010. These centres would be responsible for providing basic emergency obstetric care and essential newborn care and basic newborn resuscitation services round the clock. The experience of RCH phase-I indicates that giving incentive to health workers for providing round the clock services did not function well in most of the states. On the contrary there is the experience from government of Andhra Pradesh and Tamil Nadu, where round the clock delivery and new born care services could be ensured by providing 3 to 4 staff nurses/ANM at the PHCs.
b. Skilled attendance at delivery – It is now recognized globally that the countries which have been successful in bringing down maternal mortality are the ones where the provision of skilled attendance at every birth and its linkage with appropriate referral services for complicated cases have been ensured. The WHO has also emphasized that skilled attendance at every birth is essential to reduce the maternal mortality in any country. Guidelines for normal delivery and management of obstetric complications at PHC/CHC for medical officers and for ANC and skilled attendance at birth for ANM/LHVs have been formulated and disseminated to the states.
c. The policy decisions : ANMs / LHVs / SNs have now been permitted to use drugs in specific emergency situations to reduce maternal mortality. They have also been permitted to carry out certain emergency interventions when the life of the mother is at stake.

Emergency obstetric care

Operationalization of FRUs and skilled attendance at birth are the two activities which go hand in hand. In view of this, simultaneous steps have been taken to ensure tackling obstetric emergencies. It has been decided that all the First Referral Units be made operational for providing emergency and essential obstetric care during the second phase of RCH.The minimum services to be provided by a fully functional FRU are *(41)* :

1. 24 hour delivery services including normal and assisted deliveries;
2. Emergency obstetric care including surgical interventions like caesarean sections;
3. New-born care;
4. Emergency care of sick children;
5. Full range of family planning services including laproscopic services;
6. Safe abortion services;
7. Treatment of STI/RTI;
8. Blood storage facility;
9. Essential laboratory services; and
10. Referral (transport) services.

There are three critical determinants of a facility being 'declared' as a FRU. They are : availability of surgical interventions, new-born care and blood storage facility on a 24 hours basis.

To be able to perform the full range of FRU function, a health facility must have the following facilities : (a) A minimum bed strength of 20–30. However, in difficult areas, as the North–East states and the underserved areas of EAG states, this could initially be relaxed to 10–12 beds (b) A fully functional operation theatre (c) A fully functional labour room (d) An area earmarked and equipped for new-born care in the labour room, and in the ward (e) A functional laboratory (f) Blood storage facility (g) 24 hour water supply and electricity supply (h) Arrangements for waste disposal, and (i) Ambulance facility.

Strengthening referral system

During RCH phase–I, funds were given to the Panchayat for providing assitance to poor people in the case of obstetric emergencies. Feedback from the states indicate that there was no active involvement of Panchayats in running the scheme. Based on these experiences different states have proposed different modes of referral linkage in RCH Phase II. Some of them have indicated to involve local self help groups, NGOs and women groups, whereas few others have indicated to outsource it.

New initiatives

1. Training of MBBS doctors in life saving anaesthetic skills for emergency obstetric care : Provision of adequate and timely emergency obstetric care (EmOC) has been recognized as the most important intervention for saving lives of pregnant women who may develop complications during pregnancy or childbirth. The operationalisation of First Referral Unit at sub-district/CHC level for providing EmOC to pregnant women is a crucial strategy of RCH-II, which needs focussed attention. The training of MBBS doctors will be undertaken for only such numbers who are required for the functioning of FRUs and CHCs, and shall be limited to the requirement of tackling emergency obstetric situations only. It is **not** the replacement of the specialist anaesthetist. Government of India is also introducing training of MBBS doctors in obstetric management skills. Federation of Obstetric and Gynaecology Society of India has prepared a training plan for 16 weeks in all obstetric management skills, including caesarean section operation.
2. Setting up of blood storage centres at FRUs according to government of India guidelines.

JANANI SURAKSHA YOJANA

The National Maternity Benefit scheme has been modified into a new scheme called *Janani Suraksha Yojana* (JSY). It was launched on 12th April, 2005. The objectives of the scheme are – reducing maternal mortality and infant mortality through encouraging delivery at health institutions, and focusing at institutional care among women in below poverty line families.

The salient features of *Janani Suraksha Yojana* are as follows *(5)* :

a. It is a 100 per cent centrally sponsored scheme;
b. Under National Rural Health Mission, it integrates the benefit of cash assistance with institutional care during antenatal, delivery and immediate post-partum care; This benefit will be given to all women, both rural and urban, belonging to below poverty line household and aged 19 years or above, up to first two live births. However, with a view to give special focus in 10 low performing states (states having low institutional delivery rate), namely Uttar Pradesh, Uttaranchal, Madhya Pradesh, Jharkhand, Bihar, Rajasthan, Chattisgarh, Odisha, Assam and Jammu & Kashmir, the benefit will be extended upto the third child if the mother, of her own accord, chooses to undergo sterilization in the health facility where she delivered, immediately after delivery. The other states are called high performing states. The Accredited Social Health Activist (ASHA) would work as a link health worker between the poor pregnant women and public sector health insitution in the low performing states. ASHA would be responsible for making available institutional antenatal as well as postnatal care. She would also be responsible for escorting the pregnant women to the health centre. The scale of assistance under the scheme from 2012–13 would be as follows :

Category	Rural Area			Urban Area		
	Mother's package	ASHA's package*	Total Rs.	Mother's package	ASHA's package**	Total Rs.
LPS	1400	600	2000	1000	400	1400
HPS	700	600	1300	600	400	1000

LPS : Low performing states, HPS : High performing states
* ASHA incentive of Rs. 600/- in rural areas includes Rs. 300/- for ANC component and Rs. 300/- for accompanying pregnant woman for institutional delivery.
** ASHA incentive of Rs. 400/- in urban area includes Rs. 200/- for ANC component and Rs. 200/- for accompanying pregnant woman for institutional delivery.

Source : *(1)*

The eligibility of cash assistance is as follows *(1)* :

1. *In low performing states (LPS) :* All women, including those from SC and ST families, delivering in government health centres like sub-centre, primary health centre, community health centre, first referral unit, general wards of district and state hospitals or accredited private institutions.
2. *In high performing states (HPS) :* Below poverty line women, aged 19 years and above and the SC and ST pregnant women.

The limitation of cash assistance for institutional delivery is as follows :

1. In low performing states : All births, delivered in health centre, government or accredited private health institutions will get the benefit.
2. In high performing states the benefit is only upto 2 live births.

ASHA package is available in all low performing states, North-East states and in tribal districts of all states and UTs.In rural areas it includes the following components : (a) Cash assistance for referral transport for pregnant women to go to the nearest health centre for delivery (should not be less than Rs. 250/-); (b) Cash incentive : This should not be less than Rs. 200/- per delivery. ASHA should get her money after her post-natal visit to the beneficiary, and when the child has been immunized for BCG; and (c) Balance amount to be paid to ASHA in lieu of her services rendered by her. The payment should be made at the hospital/health institution itself.

The Yojana subsidizes the cost of caesarean section and for management of obstetric complications, upto Rs. 1500 per delivery to the government institutions, where government specialists are not in position.

In low performing and high performing states, all below poverty line pregnant women preferring to deliver at home, are entitled to cash assistance of Rs. 500 per delivery, regardless of age and number of children *(1)*.

The year 2006–07 was declared as the year for institutional deliveries. During the year scope of the scheme was extended to the urban areas of high performing states and restriction of age and birth order were removed in the low performing states. The benefits of the scheme was also extended to all women belonging to SC/ST families for institutional deliveries.

During the year 2012–13, about 1.06 crore pregnant women were benefitted from the scheme *(1)*.

Vandemataram scheme

This is a voluntary scheme wherein any obstetric and gynaec specialist, maternity home, nursing home, lady doctor/MBBS doctor can volunteer themselves for providing safe motherhood services. The enrolled doctors will display 'Vandemataram logo' at their clinic. Iron and Folic Acid tablets, oral pills, TT injections etc. will be provided by the respective District Medical Officers to the 'Vandemataram doctors/ clinics' for free distribution to beneficiaries. The cases needing special care and treatment can be referred to the government hospitals, who have been advised to take due care of the patients coming with Vandemataram cards.

Safe abortion services

In India, abortion is a major cause of maternal mortality and morbidity and accounts for nearly 8.9 per cent maternal deaths. Majority of abortions take place outside authorized health services and/or by unauthorized and unskilled persons. Whether spontaneous or induced, abortion is a matter of concern as it may lead to complications. Under RCH phase II following facilities are provided :

a. *Medical method of abortion :* Termination of early pregnancy with two drugs – Mifepristone (RU 486) followed by Misoprostol. They are considered safe under supervision, with appropriate counselling. Currently its use in India is recommended upto 7 weeks (49 days) of amenorrhoea in a facility with provision for safe abortion services and blood transfusion. Termination of pregnancy with RU 486 and Misoprostol is offered to women under the preview of the MTP Act, 1971.

b. *Manual Vacuum Aspiration (MVA) :* The department of family welfare has introduced Manual Vacuum Aspiration (MVA) technique in the family welfare programme. Manual Vacuum Aspiration is a safe and simple technique for termination of early pregnancy, makes it feasible to be used in primary health centres or comparable facilities, thereby increasing access to safe abortion services. The project of introducing the MVA technique has been piloted in coordination with FOGSI, WHO and respective state governments before being accepted for implementation by the ministry of health and family welfare.

Village Health and Nutrition Day

Organizing Village Health and Nutrition Day once a month at anganwadi centre to provide antenatal/post-partum care for pregnant women, promote institutional delivery, health education, immunization, family planning and nutrition services etc.

Maternal death review

Maternal death review as a strategy has been spelt out clearly in the RCH-II. Maternal death audit, both facility and community based, is an important strategy to improve the quality of obstetric care and reduce maternal mortality and morbidity. Guidelines and tools for initiating maternal death review have been formulated *(3)*.

Pregnancy tracking

The link between pregnancy-related care and maternal mortality is well established. RCH-II stresses the need for universal screening of pregnant women and providing essential and emergency obstetric care. Focussed antenatal care, birth preparedness and complication readiness, skilled attendance at birth, care within the first seven days etc. are the factors that can reduce the maternal mortality *(3)*.

JANANI-SHISHU SURAKSHA KARYAKRAM (JSSK)

Government of India launched the Janani-Shishu Suraksha Karyakram (JSSK) on 1st June 2011, a new national initiative, to make available better health facitlies for women and child. The new initiatives provide the following facilities to the pregnant women *(42)* :

- All pregnant women delivering in public health institutions to have absolutely free and no expense delivery, including caesarean section. The entitlements include free drugs and consumables, free diet upto 3 days during normal delivery and upto 7 days for C-section, free diagnostics, and free blood wherever required. This initiative would also provide for free transport from home to institution, between facilities in case of a referral and drop back home. Similar entitlements have been put in place for all sick newborns accessing public health institutions for treatment till 30 days after birth. The scheme has now been extended to cover the complications during ANC, PNC and also sick infants.
- The scheme is estimated to benefit more than 12 million pregnant women who access government health facilities for their delivery. Moreover, it will motivate those who still choose to deliver at their homes to opt for institutional deliveries.

Child health components

The strategy for child health care, aims to reduce under-five child mortality through interventions at every level of service delivery and through improved child care practices and child nutrition.

Nutritional rehabilitation centres (NRCs)

Severe acute malnutrition is an important contributing factor for most deaths among children suffering from common childhood illness such as diarrhoea and pneumonia. Deaths among these malnourished children are preventable, provided timely and appropriate actions are taken. NRCs are facility based units providing medical and nutritional care to severe acute malnutrition (SAM) children under 5 years of age who have medical complications. In addition special focus is on improving the skill of mothers on child care and feeding practices so that the child continues to get adequate care at home. The services provided at the NRCs include *(1)*:

a. 24 hours care and monitoring of the child;
b. Treatment of medical complication;
c. Therapeutic feeding;
d. Sensory stimulation and emotional care;
e. Counselling on appropriate feed, care and hygiene; and
f. Demonstration and practice-by-doing on the preparation of energy dense food using locally available, culturally acceptable and affordable food items.

Presently 872 NRCs are functional across 17 states/UTs with 9377 dedicated beds *(1)*.

Integrated Management of Neonatal and Childhood Illness (IMNCI)

IMNCI strategy is one of the main intervention under the RCH II/ NRHM. The strategy encompasses a range of interventions to prevent and manage the commonest major childhood diseases.

Pre-service IMNCI

Pre-service IMNCI has been accepted as an important strategy to scale up IMNCI by Govt. of India and is being included in the curriculum of medical colleges of the country. This will help in providing the much needed trained IMNCI manpower in the public and private sector.

Facility based IMNCI (F–IMNCI)

F–IMNCI is the integration of the facility based care package with the IMNCI package, to empower the health personnel with the skill to manage new born and childhood illness at the community level as well as the health facility. It focusses on providing appropriate inpatient management of the major causes of neonatal and childhood mortality such as asphyxia, sepsis, low birth weight, pneumonia, diarrhoea, malaria, meningitis and severe malnutrition in children. The master trainers at state and district level are paediatricians from tertiary hospitals and medical colleges *(3)*.

Facility based newborn care (43)

As more sick children are screened at the peripheries through IMNCI and referred to the health facilities, care of the sick newborn and child at CHCs, FRUs, district hospitals and medical college hospitals assumes priority. Equipping the facilities to provide the requisite level of care and simultaneously enhancing the capacity of the medical officers at these facilities to handle such cases thus becomes important. The setting up of SNCUs at district hospitals, stabilization units at CHCs, and newborn care corners at all facilities offering delivery facilities, is thus a key activity *(3)*.

In the overall planning of facility based care it is important to understand the level of care that is provided at the various facility levels. The newborn care facilities at different levels are as follows :

Health facility	All newborns at birth	Sick newborns
Primary health centre (PHC)/Sub-centre (SC) identified as MCH level I	Newborn care corner in labor rooms	Prompt referral
Community health centre (CHC)/First referral unit (FRU) identified as MCH Level II	Newborn care corner in labor rooms and in operation theatre	Newborn stabilization unit (SNBU)
District hospital identified as MCH Level III	Newborn care corner in labor room and in operation theatre	Special newborn care unit (SNCU)

Newborn Care Corner (NBCC)

NBCC is a space within the delivery room in any health facility where immediate care is provided to all newborns at birth. This area is MANDATORY for all health facilities where deliveries are conducted. As of March 2014, about 13,653 NBCCs are operational in the country *(1)*.

Newborn Stabilization Unit (NBSU)

NBSU is a facility within or in close proximity of the maternity ward where sick and low birth weight newborns can be cared for during short periods. All FRUs/CHCs need to have a neonatal stabilization unit, in addition to the newborn care corner. It requires space for 4 bedded unit and two beds in post-natal ward for rooming-in. As of March 2014, 1,737 NBSUs are functional in the country.

Special Newborn Care Unit (SNCU)

SNCU is a neonatal unit in the vicinity of the labor room which is to provide special care (all care except assisted ventilation and major surgery) for sick newborns. Any facility with more than 3,000 deliveries per year should have an SNCU (most district hospitals and some sub-district hospitals would fulfil this criteria).

The minimum recommended number of beds for an SNCU at a district hospital is 12. However, if the district hospital conducts more than 3,000 deliveries per year, 4 beds should be added for each 1,000 additional deliveries. A 12 bedded unit will require 4 additional adult beds for the step down. As of March 2014, 507 SNCUs are functional in the country.

Triage of sick newborns (43)

Triage is sorting of neonates to rapidly screen sick neonates for prioritizing management. Fig. 11 summarizes the process.

A. CRITERIA FOR ADMISSION TO NBSU *(43)*

Newborn presenting with any of the following signs to a facility with neonatal stabilization unit requires admission for initial stabilization and transfer to SNCU :

- Apnea or gasping
- Respiratory distress (Rate>70/min with severe retractions/grunt)
- Hypothermia <35.4°C
- Hyperthermia (>37.5°C)
- Central cyanosis
- Shock (cold periphery with capillary filling time (CFT) 3 seconds and weak and fast pulse)
- Significant bleeding that requires blood or component transfusion

Newborns, who after assessment and stabilization, can be managed at stabilization unit*

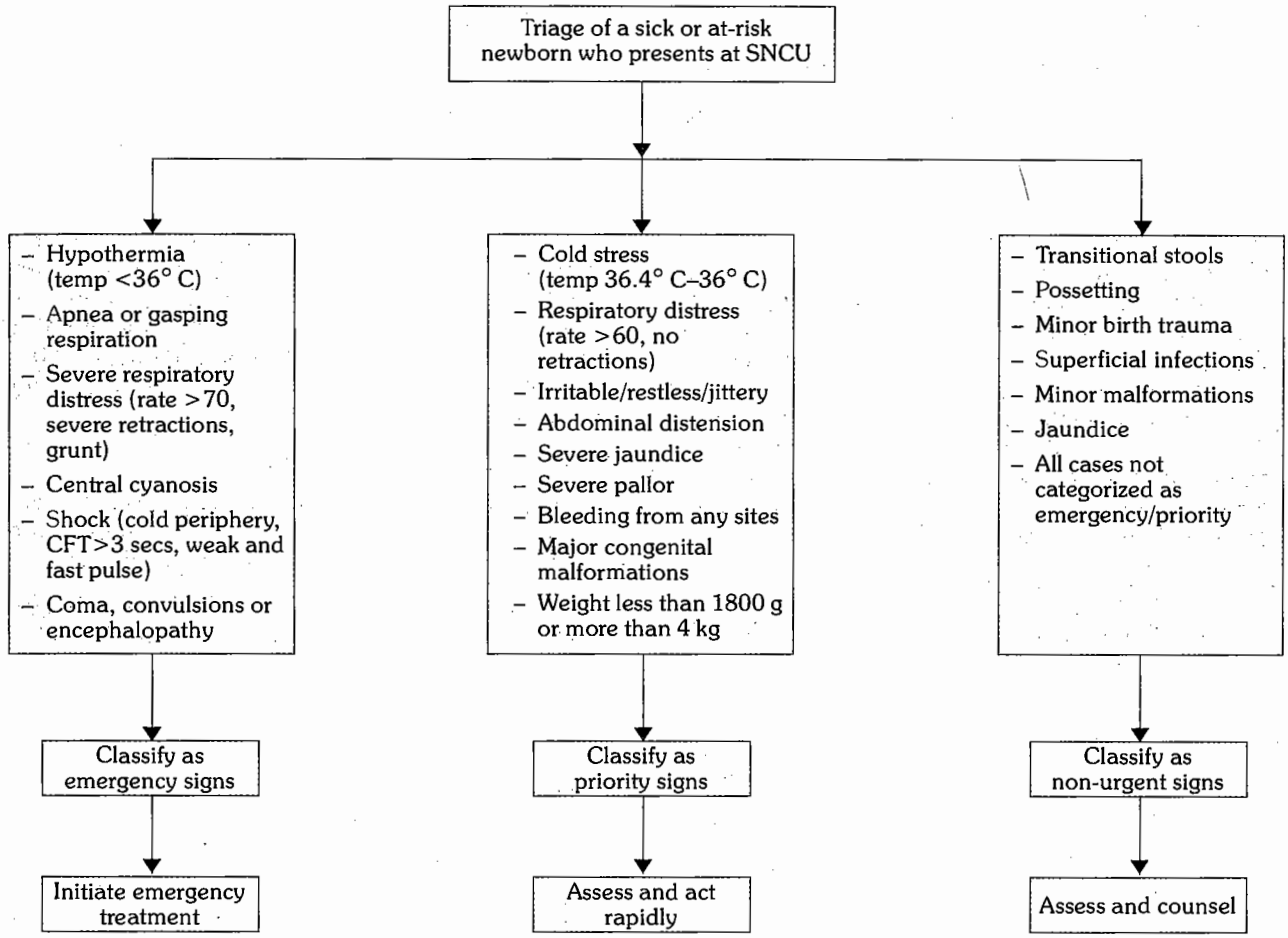
- Newborns with respiratory distress, having respiratory rate 60–70/min without grunting or retractions (for observation and oxygen therapy)
- Newborns with gestation less than 34 weeks or weight <1800 g (for observation and assisted feeding)
- Newborns with hypothermia and hyperthermia who are haemodynamically stable after initial stabilization
- Newborns with jaundice requiring phototherapy
- Neonates with sepsis who are haemodynamically stable, for observation and antibiotic therapy.

* Others would require referral to an SNCU after stabilization, if an SNCU and appropriate referral is available in the district.

B. CRITERIA FOR ADMISSION TO SNCU *(43)*

Criteria for admission to SNCU and criteria for transfer to step-down unit and discharge are as follows :

I. Any newborn with following criteria should be immediately admitted to the SNCU :
   - Birth weight <1800 g or gestation <34 weeks
   - Large baby (>4.0 kg)
   - Perinatal asphyxia
   - Apnea or gasping
   - Refusal to feed
   - Respiratory distress (rate>60/min or grunt/ retractions)
   - Severe jaundice (appears <24 hrs/stains palms and soles/lasts>2 weeks)
   - Hypothermia <35.4°C, or hyperthermia (>37.5°C)
   - Central cyanosis



Newborns classified as "Emergency" require urgent intervention and emergency measures. All such newborns will be admitted to SNCU after initial stabilization.
Newborns classified as "Priority" are sick and need rapid assessment and admission to SNCU.
Newborns classified as non-urgent do not require urgent attention, but require further assessment and counselling.

FIG. 11

- Shock (cold periphery with CFT>3 seconds, and weak and fast pulse)
- Coma, convulsions or encephalopathy
- Abdominal distension
- Diarrhoea/dysentery
- Bleeding
- Major malformations

II. Criteria for transfer from SNCU to the Step-Down
- Newborn whose respiratory distress is improving and does not require oxygen supplementation to maintain saturation
- Newborn on antibiotics for completion of duration of therapy
- Low birth weight newborn (less than 1800 g), who are otherwise stable (for adequate weight gain)
- Newborn with jaundice requiring phototherapy but otherwise stable
- Newborn admitted for any condition, but are now thermodynamically and hemodynamically stable

III. Criteria for discharge from SNCU
- Newborn is able to maintain temperature without radiant warmer
- Newborn is haemodynamically stable (normal CFT, strong peripheral pulse)
- Newborn accepting breast-feeds well
- Newborn has documented weight gain for 3 consecutive days; and the weight is more than 1.5 kg
- Primary illness has resolved

In addition to the above, mother should be confident of taking care of the newborn at home.

HOME BASED NEWBORN CARE (HBNC) (44) :

Home based newborn care is aimed at improving newborn survival. The strategy of universal access to home based newborn care must complement the strategy of institutional delivery to achieve significant reduction in postpartum and neonatal mortality and morbidity. The providers of service include anganwadi workers, ANM, ASHA and the medical officer. However, ASHA is the main person involved in home based newborn care.

The major objective of HBNC is to decrease neonatal mortality and morbidity through :

1. The provision of essential newborn care to all newborns and the prevention of complications.
2. Early detection and special care of preterm and low birth weight newborns.
3. Early identification of illness in the newborn and provision of appropriate care and referral.

4. Support the family for adoption of healthy practices and build confidence and skills of the mother to safeguard her health and that of the newborn.

The responsibilities of ASHA for home based newborn care are as follows *(44)* :

1. Mobilize all pregnant mothers and ensure that they receive the full package of antenatal care.
2. Undertake birth planning and birth preparedness with the mother and family to ensure access to safe delivery.
3. Provide newborn care through a series of home visits which include the skills for:
   a. Weighing the newborn,
   b. Measuring newborn temperature,
   c. Ensuring warmth
   d. Supporting exclusive breast-feeding by teaching the mother proper positioning and attachment for initiating and maintaining breast-feeding,
   e. Diagnosing and counselling in case of problems with breast-feeding,
   f. Promoting hand-washing,
   g. Providing skin, cord and eye care,
   h. Health promotion and counselling mothers and families on key messages on newborn care which includes discouraging unhealthy practices such as early bathing, and bottle feeding,
   i. Ensuring prompt identification of sepsis or other illnesses.
4. Assessing if the baby is high-risk (preterm or low birth weight), through the use of protocols and managing such LBW or preterm babies through
   a. Increasing the number of home visits,
   b. Monitoring weight gain,
   c. Supporting and counselling the mother and family to keep the baby warm and enabling frequent and exclusive breast-feeding,
5. Detect signs and symptoms of sepsis, provide first level care and refer the baby to an appropriate centre. If the family is unable to go, ASHA should ensure that the ANM visits sick newborn on a priority basis.
6. Recognize postpartum complications in the mother and refer appropriately.
7. Counsel the couple for family planning.
8. Provide immediate newborn care, in case of those deliveries that do not occur in institutions (home deliveries and deliveries occurring on the way to the institution).

ASHA will make visits to all newborns according to specified schedule upto 42 days of life. The schedule of visit is as follows :

a. Six visits in the case of institutional delivery – Day 3, 7, 14, 21, 28, and 42.
b. Seven visits in the case of home delivery (Day 1, 3, 7, 14, 21, 28 and 42).
c. In cases of Caesarean section delivery, where the mother returns home after 5–6 days, ASHAs are entitled to full incentive of Rs. 250 if she completes all five visits starting from Day 7 to Day 42.
d. In cases when a newborn is discharged from SNCU, ASHAs are eligible to full incentive amount of Rs. 250 for completing the remaining visits. In addition, ASHAs are also eligible for an incentive of Rs. 50 for monthly follow-up of low birth weight babies and newborns discharged from SNCU (as approved by MSG of the National Health Mission on December 6th, 2013). The low birth weight are followed up for two years and SNCU discharged babies for one year.
e. In cases where the woman delivers at her maternal house and returns to her husband's house, two ASHAs undertake the HBNC visits, i.e., one at maternal house immediately after delivery, and another one at husband's house when the new-born returns home or vice versa. In such cases the HBNC incentive of Rs. 250 can be divided into two parts in a way that each ASHA who completes 3 visits or more is entitled to Rs. 125. In these instances, if an ASHA undertakes less than 3 visits, she would not be entitled to HBNC incentive.
f. In cases of twin or triples the incentive amount for ASHA would be two time of the regular HBNC incentive of Rs. 250/- (i.e., Rs. 500/-) or three times of Rs. 250/- (i.e., Rs. 750/-) respectively.

The incentive money is paid to ASHA on 45th day subject to the following :

a. Record of birth weight in the mother and child protection card;
b. Immunization of newborn with BCG, first dose of OPV, hep B and DPT/pentavalent vaccine and entry into the mother and child protection card;
c. Registration of birth; and
d. Both mother and newborn are safe until 42nd day of delivery.

Navjat Shishu Suraksha Karyakram (NSSK)

NSSK is a programme aimed to train health personnel in basic newborn care and resuscitation. It has been launched to address care at birth issue i.e. prevention of hypothermia, prevention of infection, early initiation of breast-feeding and basic newborn resuscitation. The objective of the new initiative is to have a trained health person in basic newborn care and resuscitation unit at every delivery point *(6)*.

Integrated management of neonatal and childhood illness (IMNCI)

Integrated management of childhood illness (IMCI)

The extent of childhood morbidity and mortality caused by diarrhoea, ARI, malaria, measles and malnutrition is substantial. Most sick children present with signs and symptoms of more than one of these conditions. This overlap means that a single diagnosis may not be possible or appropriate, and treatment may be complicated by the need to combine for several conditions. An integrated approach to manage sick children is, therefore, necessary. IMCI is a strategy for an integrated approach to the management of childhood illness as it is important for child health programmes to look beyond the treatment of a single disease. This is cost effective and emphasizes prevention of disease and promotion of child health and development besides provision of standard case management of childhood illness.

In the Indian context this strategy is quite pertinent considering the recent evidence from NFHS–III report highlighting that ARI (17 per cent), diarrhoea (13 per cent), fever (27 per cent) and under–nutrition (43 per cent) were the commonest morbidities observed in the children aged under 3 years. Coverage of measles vaccination in children between 12–23 months is also low. An integrated approach to address these major childhood illnesses seems to be an effective strategy to promote child health in this country. The line of action is as shown in Fig. 12.

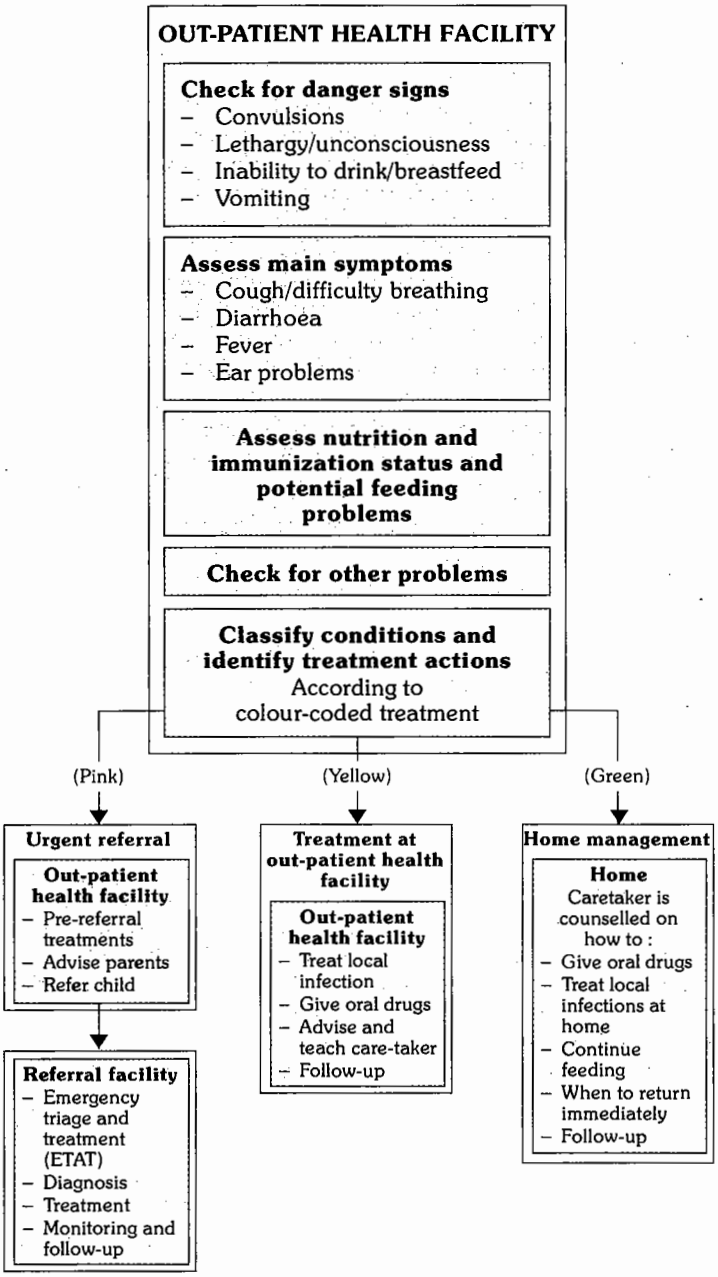


FIG. 12

The integrated case management process

Source : *(45)*

The Indian version of IMCI has been renamed as Integrated Management of Neonatal and Childhood Illness (IMNCI). It is the central pillar of child health interventions under the RCH II strategy. The major highlights of the Indian adaptation are :

a. Inclusion of 0–7 days age in the programme;
b. Incorporating national guidelines on malaria, anaemia, vitamin–A supplementation and immunization schedule;
c. Training of the health personnel begins with sick young infants upto 2 months;
d. Proportion of training time devoted to sick young infant and sick child is almost equal; and
e. is skill based.

For more details please refer to page 576, chapter 9.

IMNCI strategy is one of the main interventions under RCH-II/NRHM. It focusses on preventive, promotive and curative aspects of the programme. The objective is to implement IMNCI package at the level of household, and through ANMs at sub-centre level; through medical officers, nurse and LHVs at PHCs level.

Rashtriya Bal Swasthya Karyakram (RBSK) *(46)*

RBSK is a new initiative launched in February 2013. It includes provision for Child Health Screening and Early Intervention Services through early detection and management of 4 Ds, prevalent in children. These are defects at birth, diseases in children, deficiency conditions and development delays including disabilities. An estimated 27 crore children in the age group of 0–18 years are expected to be covered across the country in a phased manner.

Child Health Screening and Early Intervention Services under NRHM envisage to cover 30 identified health conditions for early detection, free treatment and management. Based on the high prevalence of diseases like hypothyroidism, sickle cell anaemia and beta thalassaemia in certain geographical pockets of some states/UTs, and availability of testing and specialized support facilities, these states and UTs may incorporate them as part of this initiative. The health conditions are as shown in Table 12.

TABLE 12

Identified health conditions for child health screening and early intervention services

Defects at Birth

1. Neural tube defect
2. Down's Syndrome
3. Cleft Lip and Palate / cleft palate alone
4. Talipes (club foot)
5. Developmental dysplasia of the Hip
6. Congenital cataract
7. Congenital deafness
8. Congenital heart diseases
9. Retinopathy of prematurity

Deficiencies

10. Anaemia especially severe anaemia
11. Vitamin A deficiency (Bitot's spots)
12. Vitamin D deficiency (Rickets)
13. Severe acute malnutrition
14. Goitre

Childhood Diseases

15. Skin conditions (scabies, fungal infection and eczema)
16. Otitis media
17. Rheumatic Heart Disease
18. Reactive Airway Disease
19. Dental caries
20. Convulsive disorders

Developmental delays and disabilities

21. Vision impairment
22. Hearing impairment
23. Neuro-motor impairment
24. Motor delay
25. Cognitive delay
26. Language delay
27. Behaviour disorder (Autism)
28. Learning disorder
29. Attention Deficit Hyperactivity Disorder
30. Congenital Hypothyroidism, Sickle Cell Anaemia, Beta Thalassaemia (Optional)

Source : *(46)*

Programme Implementation

1. For newborn :
   - Facility based newborn screening at public health facilities, by existing health manpower.
   - Community based newborn screening at home through ASHAs for newborn till 6 weeks of age during home visits.
2. For children 6 weeks to 6 years :
   - Anganwadi center based screening by dedicated Mobile Health Teams.
3. For children 6 years to 18 years :
   - Government and Government aided school based screening by dedicated Mobile Health Teams.

Facility based newborn screening

This includes screening of birth defects in institutional deliveries at public health facilities, especially at the designated delivery points by ANMs, Medical Officers/ Gynaecologists. Existing health service providers at all designated delivery points will be trained to detect, register report and refer birth defects to the District Early Intervention Centres in District Hospitals.

Community based newborn screening (age 0–6 weeks) for birth defects

Accredited Social Health Activists (ASHAs) during home visits for newborn care will use the opportunity to screen the babies born at home and the institutions till 6 weeks of age. ASHAs will be trained with simple tools for detecting gross birth defects. Further ASHAs will mobilise caregivers of children to attend the local Anganwadi Centers for screening by the dedicated Mobile Health Team. For performing the above additional tasks, she would be equipped with a tool kit consisting of a pictorial reference book having self-explanatory pictures for identification of birth defects. Suitable performance based incentive may also be provided to ASHAs. In order to ensure improved outcome of the screening programme by Mobile Health Teams, ASHAs will give priority to the children with low birth weight, underweight and children from households known to have any chronic illness (e.g., tuberculosis, HIV, haemoglobinopathy etc.). Line lists maintained by the ANMs and AWWs would also be used to moblise children.

Screening of children aged 6 weeks till 6 years attending Anganwadi Centers

Children in the age group 6 weeks to 6 years of age will be examined in the Anganwadi Centres by dedicated Mobile Health Teams.

Screening of children enrolled in Government and Government aided schools

For children in the age group 6 to 18 years, who will be screened in Government and Government aided schools, the block will be the hub of activity for the programme. At least three dedicated Mobile Health Teams in each block will be engaged to conduct screening of children. Villages within the jurisdiction of the block would be distributed amongst the mobile health teams. The number of teams may vary depending on the number of Anganwadi Centers, difficult to reach areas and children enrolled in the schools. The screening of children in the Anganwadi Centers would be conducted at least twice a year and at least once a year for school children to begin with.

In RCH Phase–II the other interventions of RCH Phase–I, e.g., additional ANMs, public health nurse, private anaesthetists, safe motherhood consultants, 24 hours delivery services at PHCs and CHCs, referral transport, integrated financial envelop, RCH camps, training of Dais, border district cluster strategy, and intervention for newborn care and child health (immunization, control of ARI and diarrhoea, vitamin A and iron suplementation etc.) will continue.

The quality indicators used to monitor and evaluate RCH programme through monthly reports are (47) :

1. Number of antenatal cases registered – total and at less than 12 weeks;
2. Number of pregnant women who had 3 antenatal check-ups;
3. Number of high-risk pregnant women referred;
4. Number of pregnant women who had two doses of tetanus toxoid injection;
5. Number of pregnant women under prophylaxis and treatment for anaemia;
6. Number of deliveries by trained and untrained birth attendant;
7. Number of cases with complications referred to PHC/ FRU;
8. Number of new born with birth weight recorded;
9. Number of women given 3 post natal check-ups;
10. Number of RTI/STI cases detected, treated and referred;
11. Number of children fully immunized;
12. Number of adverse reactions reported after immunization;
13. Number of cases of ARI and diarrhoea under 5 years treated, referred PHC/FRU and deaths; and
14. Number of cases motivated and followed up for contraception.

REPRODUCTIVE, MATERNAL, NEWBORN, CHILD AND ADOLESCENT HEALTH (RMNCH+A) STRATEGY, 2013

In June 2012, the Government of India, Ethiopia, USA and the UNICEF convened the "Global Child Survival Call to Action : A Promise to Keep" summit in Washington, DC to energize the global fight to end preventable child deaths through targeted interventions in effective, life-saving interventions for children. More than 80 countries gathered at the Call to Action to pledge to reduce child mortality to ≤ 20 child deaths per 1000 live births in every country by 2035 *(48)*. Eight months after the event, in February 2013, the Government of India held its own historic Summit on the Call to Action for Child Survival, where it launched "A Strategic Approach to Reproductive, Maternal, Newborn, Child, and Adolescent Health (RMNCH+A) in India." Since that time, RMNCH+A has become the heart of the Government of India's flagship public health programme, the National Health Mission *(48)*.

With support from USAID and its Maternal Child Health Integrated Programme (MCHIP), as well as from UNICEF, UNFPA, NIPI and other development partners, the Government of India has taken important steps to introduce and support RMNCH+A implementation. This approach is likely to succeed given that India already has a community based programme with presence of 8.7 lakh ASHA workers, as well as the three tiered health system in place. These provide a strong platform for delivery of services. This integrated strategy can potentially promote greater effeciency while reducing duplication of resources and efforts in the ongoing programme.

The RMNCH+A strategy is based on provision of comprehensive care through the five pillars, or thematic areas, of reproductive, maternal, neonatal, child, and adolescent health, and is guided by central tenets of equity, universal care, entitlement, and accountability. The "plus" within the strategy focusses on :

- Including adolescence for the first time as a distinct life stage;
- Linking maternal and child health to reproductive health, family planning, adolescent health, HIV, gender, preconception and prenatal diagnostic techniques;
- Linking home and community-based services to facility-based care; and
- Ensuring linkages, referrals, and counter-referrals between and among health facilities at primary (primary health centre), secondary (community health centre), and tertiary levels (district hospital).

In developing the RMNCH+A strategy, the aim is to reach the maximum number of people in the remotest corners of the country through a continuum of services, constant innovation, and routine monitoring of interventions. In rolling out the new strategy, the emphasis is on high impact interventions in each of the five thematic areas of reproductive, maternal, newborn, child, and adolescent health, and then to focus its efforts, and those of its development partners, on improving the coverage and quality of those interventions in 184 high-priority districts (HPDs) across India. Guidelines and tools were developed and policies were adjusted.

1. *High-Priority Districts:* The RMNCH+A strategy addresses India's inter-state and inter-district variations. The districts with relatively weak performance against RMNCH+A indicators were identified. Uniform and clearly defined criteria were used to identify 184 high-priority districts across all 29 states. The RMNCH+A approach is a conscious articulation of the GOI's commitment to tailoring programmes to meet the needs of previously underserved groups, including adolescents, urban poor, and tribal populations.

2. *Management tools and job aids:* The RMNCH+A 5×5 matrix identifies five high-impact interventions across each of the five thematic areas, five cross-cutting and health systems strengthening interventions, and, the minimum essential commodities across each of the thematic areas. The 5×5 matrix as shown in Fig. 13, is an important tool for explaining the strategy in simple terms, organizing technical support, and monitoring progress with the states and high-priority districts.

Reproductive Health
- Focus on spacing methods, particularly PPIUCD at high case load facilities.
- Focus on interval IUCD at all facilities including subcentres on fixed days.
- Home delivery of Contraceptives (HDC) and Ensuring Spacing at Birth (ESB) through ASHAs.
- Ensuring access to Pregnancy Testing Kits (PTK "Nischay Kits") and strengthening comprehensive abortion care services.
- Maintaining quality sterilization services.

Maternal Health
- Use MCTS to ensure early registration of pregnancy and full ANC.
- Detect high risk pregnancies and line list including severely anaemic mothers and ensure appropriate management.
- Equip delivery points with highly trained HR and ensure equitable access to EmOC services through FRUs, Add MCH wings as per need.
- Review maternal, infant and child deaths for corrective actions.
- Identify villages with high numbers of home deliveries and distribute Misoprostol to selected women in 8th month of pregnancy for consumption during 3rd stage of labour; Incentivize ANMs for home deliveries.

Newborn Health
- Early initiation and exclusive breast-feeding.
- Home based newborn care through ASHA.
- Essential Newborn Care and resuscitation services at all delivery points.
- Special Newborn Care Units with highly trained human resource and other infrastructure.
- Community level use of Gentamycin by ANM.

Child Health
- Complementary feeding, IFA supplementation and focus on nutrition.
- Diarrhoea management at community level using ORS and Zinc.
- Management of pneumonia.
- Full immunization coverage.
- Rashtriya Bal Swasthya Karyakram (RBSK); screening of children for 4Ds' (birth defects, development delays, deficiencies and disease) and its management.

Adolescent Health
- Address teenage pregnancy and increase contraceptive prevalence in adolescents.
- Introduce community based services through peer educators.
- Strengthen ARSH clinics.
- Roll out National Iron Plus Initiative including weekly IFA supplementation.
- Promote menstrual hygiene.

Health Systems Strengthening
- Cases load based deployment of HR at all levels.
- Ambulances, drugs, diagnostics, reproductive health commodities.
- Health education, demand promotion & behaviour change communication.
- Supportive supervision and use of data for monitoring and review, including scorecards based on HMIS.
- Public grievances redressal mechanism, client satisfaction and patient safety through all round quality assurance.

Cross Cutting Interventions
- Bring down out of pocket expenses by ensuring ISSK, RBSK and other free entitlements.
- ANMs & Nurses to provide specialized and quality care to pregnant women and children.
- Address social determinants of health through convergence.
- Focus on un-served and underserved villages, urban slums and blocks.
- Introduce difficult area and performance based incentives.

FIG. 13
5 × 5 matrix for high impact RMNCH+A interventions
To be Implemented with High Coverage and High Quality

Goals and Targets *(37)*

Taking into account the progress made so far in maternal and child health, it is pertinent to establish the goals and targets for the implementation phase 2012–2017, after considering the main reasons for mortality and interventions proven to have an impact on them. The 12th Five Year Plan has defined the national health outcomes and the three goals that are relevant to RMNCH+A strategic approach are as follows :

- Reduction of Infant Mortality Rate (IMR) to 25 per 1,000 live births by 2017.
- Reduction in Maternal Mortality Ratio (MMR) to 100 per 100,000 live births by 2017.
- Reduction in Total Fertility Rate (TFR) to 2.1 by 2017.

For achieving these goals, variable increase in the coverage level for key interventions are required. These are defined in the Table 13.

While the country aims to set one collective goal towards reducing preventable maternal, newborn and child deaths by 2017, it is increasingly becoming apparent that there is varied and unequal rate of progress within the states and districts. Therefore, state specific coverage targets should be established against existing baselines. The national and state 'scorecard' is being introduced as a tool to increase transparency and track progress against reproductive and maternal health and child survival indicators related with intervention coverage. For more details about the score cards please refer to page 466.

The implementation strategies of RMNCH+A *(37)*

The key interventions of RMNCH+A as a "Continuum of Care" are as shown in Fig. 14. The set of interventions are those that have high impact on reducing mortality and improving survival. Most of these interventions have been part of the previous phase of NRHM. The effectiveness of these will be determined by the coverage achieved among the affected fraction of population as also the availability, accessability, actual utilization of services and quality of services delivered.

Adolescent Health Programme *(1, 37)*

Taking cognisance of the diverse nature of adolescent health needs, a comprehensive adolescent health strategy has been developed. The priority under adolescent health include nutrition, sexual and reproductive health, mental health, addressing gender-based violence, non-communicable diseases and substance use. The strategy proposes a set of interventions (health promotion, prevention, diagnosis, treatment and referral) across levels of care. These interventions and approaches work towards building protective factors that can help adolescents and young people develop 'resilience' to resist negative behaviours and operate at four major levels: individual, family, school and community by providing a comprehensive package of information, commodities and services.

The priority interventions are as follows :

1. Adolescent nutrition; iron and folic acid supplementation.
2. Facility-based adolescent reproductive and sexual health services (ARSH) (Adolescent health clinics).
3. Information and counselling on adolescent sexual reproductive health and other health issues.
4. Menstrual hygiene.
5. Preventive health check-ups.

A. Adolescent Reproductive and Sexual Health programme (ARSH)

Adolescent Reproductive and Sexual Health programme (ARSH) focusses on reorganizing the existing public health system in order to meet service needs of adolescents. Steps

TABLE 13

Coverage targets for key RMNCH+A interventions for 2017

- Increase facilities equipped for perinatal care (designated as 'delivery points') by 100%.
- Increase proportion of all births in government and accredited private institutions at annual rate of 5.6% from the baseline of 61% (SRS 2010).
- Increase proportion of pregnant women receiving antenatal care at annual rate of 6% from the baseline of 53% (CES 2009).
- Increase proportion of mothers and newborns receiving postnatal care at annual rate of 7.5% from the baseline of 45% (CES 2009).
- Increase proportion of deliveries conducted by skilled birth attendants at annual rate of 2% from the baseline of 76% (CES 2009).
- Increase exclusive breast-feeding rates at annual rate of 9.6% from the baseline of 35% (CES 2009).
- Reduce prevalence of under-five children who are underweight at annual rate of 5.5% from the baseline of 45% (NFHS-3).
- Increase coverage of three doses of combined diphtheria-tetanus-pertussis (DTP3) (12–23 months) at annual rate of 3.5% from the baseline of 7% (CES 2009).
- Increase ORS use in under-five children with diarrhoea at annual rate of 7.2% from the baseline of 43% (CES 2009).
- Reduce unmet need for family planning methods among eligible couples, married and unmarried, at annual rate of 8.8% from the baseline of 21% (DLHS 3).
- Increase met need for modern family planning methods among eligible couples at annual rate of 4.5% from the baseline of 47% (DLH 3).
- Reduce anaemia in adolescent girls and boys (15–19 years) at annual rate of 6% from the baseline of 56% and 30%, respectively (NFHS-3).
- Decrease the porportion of total fertility contributed by adolescents (15–19 years) at annual rate of 3.8% per year from the baseline of 16% (NFHS-3).
- Raise child sex ratio in the 0–6 years age group at annual rate of 0.6% per year from the baseline of 914 (Census 2011).

Clinical

Reproductive care	*Pregnancy and child birth care*	*Newborn and childcare*
– Comprehensive abortion care – RTI/STI case management, – Postpartum IUCD and sterilization; interval IUCD procedures – Adolescent friendly health services	– Skilled obstetric care, immediate newborn care and resuscitation – Emergency obstetric care – Preventing Parent-to-Child Transmission (PPTCT) of HIV – Postpartum sterilization	– Essential newborn care – Care of sick newborn (SNCU, NBSU) – Facility-based care of childhood illnesses (IMNCI) – Care of children with severe acute malnutrition (NRC) – Immunization

Outreach/Sub-centre

Reproductive health care	*Antenatal care*	*Postnatal care*	*Child health care*
– Family planning (including IUCD insertion, OCP and condoms) – Prevention and management of STIs – Peri-conception folic acid supplementation	– Full antenatal care package – PPTCT	– Early detection and management of illnesses in mother and newborn – Immunization	– First level assessment and care for newborn and childhood illnesses – Immunization – Micro-nutrient supplementation

Family & Community

– Weekly IFA supplementation – Information and counselling on sexual reproductive health and family planning – Comminity based promotion and delivery of contraceptives – Menstrual hygiene	– Counselling and preparation for newborn care, breast-feeding, birth preparedness – Demand generation for pregnancy care and institutional delivery (JSY, JSSK)	– Home-based newborn care and prompt referral (HBNC scheme) – Antibiotic for suspected case of newborn sepsis – Infant and Young Child Feeding (IYCF), including exclusive breast-feeding and complementary feeding. – Child health screening and early intervention services (0–18 years) – Early childhood development – Danger sign recognition and care-seeking for illness – Use of ORS and Zinc in case of diarrhoea

Intersectoral : Water, sanitation, hygiene, nutrition, education, empowerment

Adolescence/Pre-pregnancy → Pregnancy → Birth → Newborn/postnatal → Childhood

FIG. 14

Continuum of care across life cycle and different levels of health system

are being taken to ensure improved service delivery for adolescents during routine sub-centre clinics and also to ensure service availability on fixed days and timings at the Primary Health Centre, Community Health Centre and District Hospital levels. Core package of services includes promotive, preventive, curative and counselling services being made available for all adolescents – married and unmarried, girls and boys through adolescent friendly health clinics. ARSH programme envisages creating an enabling environment for adolescents to seek health care services through a spectrum of programmatic approaches :

- Facility based health services–Adolescent Friendly Health Clinics;
- Counselling–Dedicated ARSH and ICTC counselling;
- Community based interventions–Outreach activities, and
- Capacity building for service providers.

i. *Adolescent Friendly Health Clinics (AFHC):* Through Adolescent Friendly Health Clinics, routine check-up at primary, secondary and tertiary levels of care is provided on fixed day clinics. At present 6,302 AFHCs are functional across the country providing services, information and commodities to more than 2.5 million adolescents for varied health related needs such as contraceptives provision, management of menstrual problems, RTI/STI management, antenatal care and anaemia.

ii. *Facility based counselling services:* Counselling services for adolescents on important issues such as nutrition, puberty, RTI/STI prevention and contraception, delaying marriage and childbearing, and concerns related to contraception, abortion services, pre-marital concerns, substance misuse, sexual abuse and mental health problems are being provided through recruitment and training of dedicated counsellors. At present 881 dedicated ARSH counsellors are providing comprehensive counselling services to adolescents across the country. In 23 States/UTs, 1439 ICTC counsellors have been enrolled to provide sexual and reproductive health counselling to adolescents.

iii. *Outreach activities:* Outreach activities are being conducted in schools, colleges, teen clubs, vocational training centres, during Village Health Nutrition Day (VHND), health melas and in collaboration with self

help groups to provide adequate and appropriate information to adolescents in spaces where they normally congregate.

B. Weekly Iron and Folic Acid Supplementation (WIFS)

Ministry of Health and Family Welfare has launched the Weekly Iron and Folic Acid Supplementation (WIFS) Programme to meet the challenge of high prevalence and incidence of anaemia amongst adolescent girls and boys. The long term goal is to break the intergenerational cycle of anaemia, the short term benefit is of a nutritionally improved human capital. The programme, implemented across the country, both in rural and urban areas, will cover 10.25 crore adolescents. The key interventions under this programme are as follows :

- Administration of supervised weekly iron-folic acid supplements of 100 mg elemental iron and 500 µg folic acid using a fixed day approach.
- Screening of target groups for moderate/severe anaemia and referring these cases to an appropriate health facility.
- Biannual de-worming (Albendazole 400 mg), six months apart, for control of helminths infestation.
- Information and counselling for improving dietary intake and for taking actions for prevention of intestinal worm infestation.

C. Menstrual Hygiene Scheme (1)

The Ministry of Health and Family Welfare has launched scheme for promotion of menstrual hygiene among adolescent girls in the age group of 10–19 years in rural areas. This programme aims at ensuring that girls have adequate knowledge and information about menstrual hygiene and have access to high quality sanitary napkins along with safe disposal mechanisms. Key activities under the scheme include :

- Community based health education and outreach in the target population to promote menstrual health;
- Ensuring regular availability of sanitary napkins to the adolescents;
- Sourcing and procurement of sanitary napkins;
- Storage and distribution of sanitary napkins to the adolescent girls;
- Training of ASHA and nodal teachers in menstrual health, and
- Safe disposal of sanitary napkins.

CARE DURING PREGNANCY AND CHILDBIRTH *(37)*

Pregnancy and childbirth are physiological events in the life of a woman. Though most pregnancies result in normal birth, it is estimated that about 15 per cent may develop complications, which cannot be predicted. Most of these complications can be averted by preventive care, skilled care at birth, early detection of risk, appropriate and timely management of obstetric complications and postnatal care.

The delivery of services during pregnancy and childbirth requires a strong element of continuum of care from community to facility level and vice versa. While the antenatal package, counselling and preparation for newborn care, breast-feeding, birth and emergency preparedness will mainly be delivered through community outreach; skilled birth attendance are to be provided at health facilities, primarily 24×7 PHC and FRU. These facilities are most likely to be the one that have been designated as "delivery points" and therefore have provision for full complement of RMNCH services. Following discharge from the health facilities, mothers and newborns will be provided postnatal care through home visits. Most of these services are already in place.

The priority interventions are as follows *(37)* :

1. Delivery of antenatal care package and tracking of high-risk pregnancies.
2. Skilled obstetric care.
3. Immediate essential newborn care and resuscitation.
4. Emergency obstetric and newborn care.
5. Postpartum care for mother and newborn.
6. Postpartum IUCD and sterilization.
7. Implementation of PC & PNDT Act.

NEWBORN AND CHILD CARE

The interventions in this phase of life mainly focus on children under 5 years of age. Given below are the priority child health interventions that are already in place under NRHM.

Priority Interventions (37) :

1. Home-based newborn care and prompt referral.
2. Facility-based care of the sick newborn.
3. Integrated management of common childhood illnesses (diarrhoea, pneumonia and malaria).
4. Child nutrition and essential micronutrients supplementation.
5. Immunization
6. Early detection and management of defects at birth, deficiencies, diseases and disability in children 0–18 years of age (Rashtriya Bal Swasthya Karyakram).

CARE THROUGH THE REPRODUCTIVE YEARS

Reproductive health needs to exist across the reproductive years and therefore access to these services is required in various life stages starting from the adolescence phase. Reproductive health services include the provision for contraceptives, access to comprehensive and safe abortion services, diagnosis and management of sexually transmitted infections, including HIV.

A new strategic direction has been developed for the family planning programme, wherein it has been repositioned to not only achieve population stabilisation but also to reduce maternal mortality as also infant and child mortality. A target-free approach based on unmet needs for contraception; equal emphasis on spacing and limiting methods; and promoting 'children by choice' in the context of reproductive health are the key approaches to be adopted for the promotion of family planning and improving reproductive health.

These services will be delivered at home, through community outreach and at all levels of health facilities and include adolescents and adults in the reproductive age group.

Priority interventions (37)

1. Community-based promotion and delivery of contraceptives.
2. Promotion of spacing methods (interval IUCD).
3. Sterilization services (vasectomies and tubectomies).

4. Comprehensive abortion care (includes MTP Act).
5. Prevention and management of sexually transmitted and reproductive infections (STI/RTI).

Delivery Points *(37)*

The provision of services for delivery care in a health facility generally serves as an important indicator to assess whether the facility is optimally functional or not. The concept of 'delivery point' emerges from this presumption. Among the health facilities designated as L1, L2 and L3, there are some facilities which are conducting deliveries above a minimum bench mark (minimum 3 normal deliveries per month at L1; minimum 10 deliveries per month, including management of complications, at L2; minimum 20–50 deliveries per month including C-section at L3). These are designated as delivery points. According to the government mandate, these facilities should be the first to be strengthened for providing comprehensive RMNCH Services. This should be supported by a referral transport system that reaches the patient within 30 minutes of receiving a call and the health facility within the next 30 minutes. The long-term goal should be to establish and operationalize Basic Emergency Obstetric Care and Comprehensive Emergency Obstetric Care Centres as per the expected delivery load in the state and district.

Maternal and Child Health (MCH) Wing *(37)*

Most health facilities, especially those at secondary and tertiary level are having high case load of pregnant women and newborn due to increase in institutional deliveries following launch of JSY and JSSK. Therefore, it has been decided that dedicated Maternal and Child Health Wings will be established in high case load facilities with adequate provision of beds. The new MCH wings will be comprehensive units (30/50/100 bedded) with antenatal waiting rooms, labour wing, essential newborn care room, SNCU, operation theatre, blood storage units and a postnatal ward and an academic wing. This will ensure provision of emergency maternal and newborn care services as well as 48 hours stay, i.e., quality postnatal care to mothers and newborns *(37)*.

SCORE CARD *(37)*

A. Health Management Information System – based dashboard monitoring system:

The choice of indicators for dashboard monitoring system are based on life cycle approach, and are as shown in Fig. 15.

1. Steps underway to include proportion
   - Pregnant women <19 yrs old to total women registered for ANC.
   - Home Based New born Care (HBNC) visit by ASHA to planned visits.
   - Children 9–11 months fully immunized to children 9–11 months due for immunization.
   - Children with diarrhoea who were treated with ORS to children reported with diarrhoea.
   - Children with diarrhoea who were treated with ORS and Zinc to children reported with diarrhoea.
   - Children discharged live from SNCUs to number of admissions in SNCUs.
   - Children with ARI who received treatment to children reported with ARI.

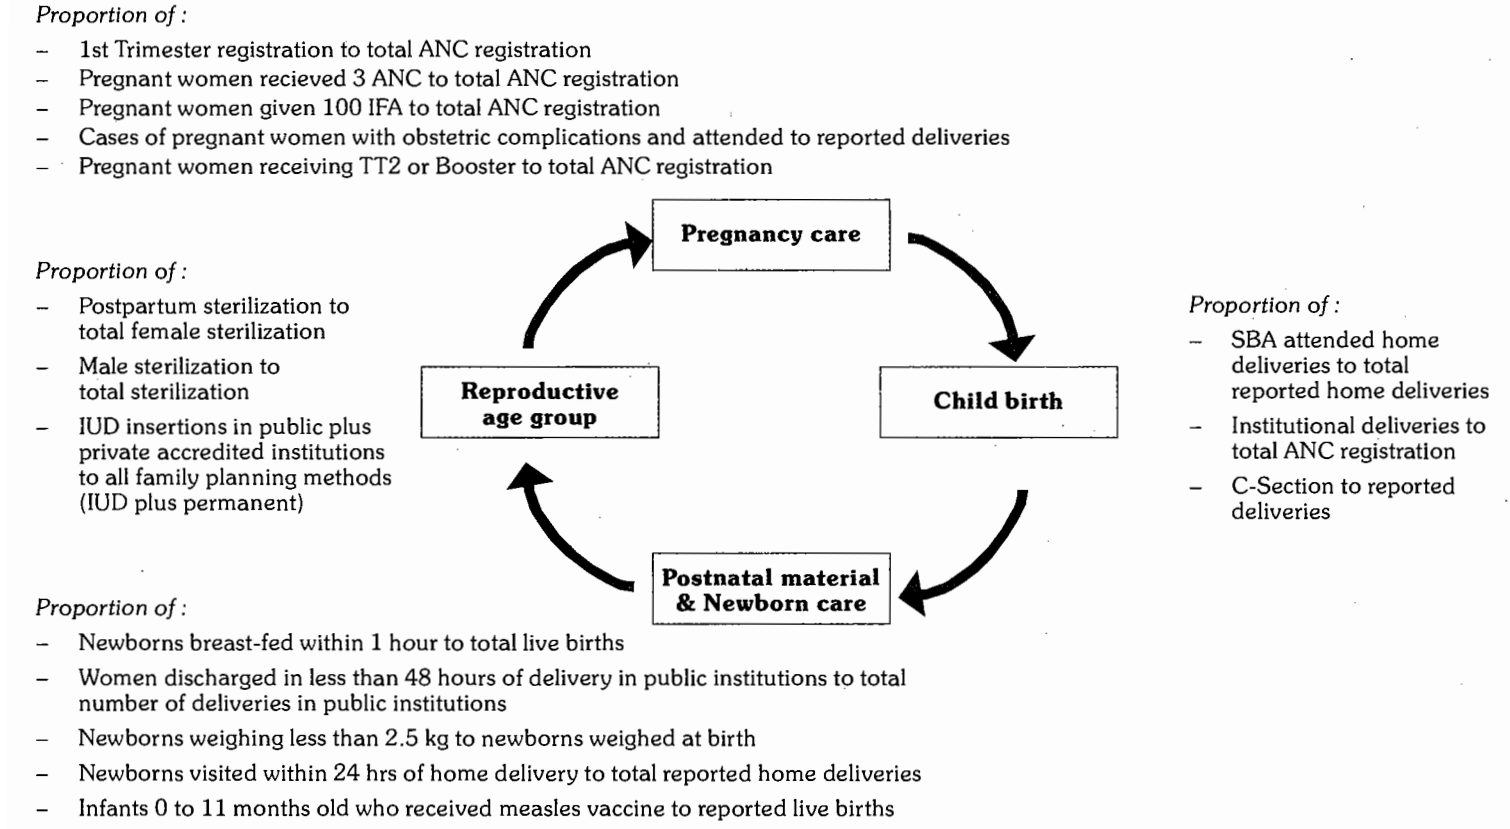

FIG. 15
Choice of indicators for dash board

2. All India average for each indicator will be taken as the reference point.
3. States scores will be determined on the basis of the national average :
   - Positive scores from 1 to 4 for those above the national average (for positive indicators) and for those below the national average (for negative indicators).
   - Negative scores –1 to –4 for those below national average (for positive indicators) and for those above national average (for negative indicators).
4. All the indicator scores for each state will be consolidated as state score (all indicators have the same weightage)
5. States have been classified into four categories based on the state scores.

B. Survey based score card *(37)*

19 survey based outcome and coverage indicators related to health, nutrition and sanitation will be used for the score card. The indicators are as shown in Table 14.

TABLE 14

Indicators for survey based score card

Mortality	– Under-five mortality rate
	– Infant mortality rate
	– Neonatal mortality rate
	– Maternal mortality ratio (per 100,000 live births)
Fertility	– Total fertility rate
	– Births to women during age 15–19 out of total births
Nutrition	– Children with birth weight less than 2.5 kg
	– Children under 3 years who are underweight
Gender	– Child sex ratio 0–6
Cross-cutting	– Full Immunization Children (12–23 months) receiving 1 dose BCG, 3 doses of DPT/OPV/hep B each and 1 measles vaccine
	– Household having access to toilet facility
	– Couple using spacing method for more than 6 months
Diarrhoea	– ORT or increased fluids for diarrhoea (among children <2 years of age who had diarrhoea in preceeding 2 weeks)
Pneumonia	– Care seeking for ARI in any health facility (Among children <2 years of age who had ARI in preceding 2 weeks)
Service Delivery	– Woman who received 4 + ANC
	– Skilled Birth Attendance (delivery by doctor, ANM/Nurse/LHV)
	– Mothers who recieved postnatal care from a doctor/nurse/LHV/ANM/other health personnel within 2 days of delivery for their last birth (%)
	– Early initiation of breast-feeding (<1hr)
	– Exlusive breast-feeding for 6 months (among 6–9 months children)

Latest available data from national surveys will be taken into consideration including Sample Registration System, Coverage Evaluation Survey, District Level Household and Facility Survey, National Family Health Survey, Census, Annual Health Survey.

All India average for each indicator will be taken as a reference point. States will be colour coded based on :

- *Mortality indicators, nutrition, fertility:* Green – less than 20% of the national average, Yellow – 20% below and above national average, Red – more than 20% of the national average.
- *Remaining Indicators:* Green – more than 20% of the national average, Yellow – 20% below and above the national average, Red – less than 20% of the national average

The scorecard will be updated as and when (every 1–2 years) new survey data is available.

INDIA NEWBORN ACTION PLAN (INAP)

In the past two decades, there has been remarkable progress in the survival of mother and children beyond the newborn period. Presently, the newborn health has captured the attention of the policy makers and two important milestones in this direction have been the National Rural Health Mission and the Reproductive, Maternal, Newborn, Child and Adolescent Health Strategy (RMNCH+A Strategy), NRHM has provided unprecedented attention and resources for newborn health. By adopting RMNCH+A strategy in 2013, the country observed a paradigm shift in its approach towards health care. Newborn health occupies centre stage in the overall strategy as all the inter-linkages between various components have the greatest impact on the mortality and morbidity rates of the newborn.

In India, Newborn Action Plan (INAP) developed in response to the global Every Newborn Action Plan (ENAP), was launched in June 2014. The plan outlines a targetted strategy for accelerating the reduction of preventable newborn deaths and stillbirths in the country. INAP defines the latest evidence on effective interventions which will not only help in reducing the burden of stillbirths and neonatal mortality, but also maternal deaths. The goal is to attain "Single Digit Neonatal Mortality rate by 2030" and Single Digit Stillbirth rate by 2030.

The INAP will be implemented within the existing RMNCH+A framework, and guided by the principles of integration, equity, gender, quality of care, convergence, accountability and partnerships. Its strength is built on its six pillars of intervention packages impacting stillbirths and newborn health, which includes : (a) Pre-conception and antenatal care; (b) Care during labour and childbirth; (c) Immediate newborn care; (d) Care of the healthy newborn; (e) Care of small and sick newborn; and (f) Care beyond newborn survival. For effective implementation, a systematic plan of monitoring and evaluation has been developed with a list of dashboard indicators *(33)*.

The interventions under the National Health Mission focussing on newborns are shown in Table 15.

TABLE 15

Interventions under National Health Mission focussing on newborns

Programme (Year)	Objectives	Status
Janani Suraksha Yojana (JSY) (2005)	Safe motherhood intervention to increase institutional delivery through demand-side financing and conditional cash transfer	– Implemented in all states and union territories (UTs) – Special focus on low-performing states
Integrated Management of Neonatal and Childhood Illnesses (IMNCI) at the community level and F-IMNCI at health facilities (2007)	Standard case management of major causes of neonatal and childhood morbidity and mortality	– Operationalised in more than 500 districts – 5.9 lakhs health and other functionaries, including physicians, nurses, AWWs, and ASHAs trained under IMNCI – 26,800 medical officers and specialists placed at the CHCs/FRUs trained under F-IMNCI
Navjat Shishu Suraksha Karyakram (NSSK) (2009)	Basic newborn care and resuscitation training programme	– 1.3 lakh health providers trained to-date
Janani Shishu Suraksha Karyakram (JSSK) (2011)	Zero out-of-pocket expenditure for maternal and infant health services through free healthcare and referral transport entitlements	– Implemented in all states and UTs – Assured service package benefits extended to sick children upto age one
Facility Based Newborn Care (FBNC) (2011)	Newborn care facilities at various levels of public health services that includes Newborn Care Corners (NBCCs) at all points of childbirth to provide immediate care; Newborn Stabilization Units (NBSUs) at CHC/FRUs for management of selected conditions and to stablize sick newborns before referral to higher centres; and Special Newborn Care Unit (SNCUs) at district/ sub-district hospitals to care for sick newborns (all types of care except assisted ventilation and major surgeries)	– 14,135 NBCCs established at delivery points to provide essential newborn care – 1,810 NBSUs established at CHCs/FRUs – 548 SNCUs established at district/sub-district hospitals or medical colleges – More than 6,300 personnel provided FBNC training – Online reporting system adapted and scaled up in seven states with 245 SNCUs made online and more than 2.5 lakhs newborns registered in the data base.
Home Based Newborn Care (HBNC) (2011)	Provision of essential newborn care to all newborns, special care of preterm and low-birth-weight newborns; early detection of illness followed by referral; and support to family for adoption of healthy practices, by ASHA worker	– Implemented in all states and UTs – Most of the ASHAs trained in newborn care – ASHAs visited more than 12 lakhs newborns in 2013
Rashtriya Bal Swasthya Karyakram (RBSK) (2013)	Screening of children with birth defects, diseases, deficiencies, and developmental delays (including disabilities)	– All children, ages 0 to 18 years targeted – More than 8 crore children screened and more than 10 lakhs children identified for tertiary care in 2013

Source : *(33)*

Strategic Intervention Packages *(33)*

The interventions are grouped in six packages, corresponding to the various life stages of the newborn. It is estimated that high coverage of available intervention packages can prevent almost three-quarters of the newborn deaths, one-third of stillbirths and half of the maternal deaths by 2025.

The interventions have been categorized as :

a. Essential [E], to be implemented universally;

b. Situational [S], implementation dependent on epidemiological context;

c. Advanced [A], implementation based on health-system capacity of the state/district.

The states are urged to develop their own action plans based on the six packages described below :

1. *Pre-conception and antenatal care*

Health interventions must start well before conception and their impact on the neonatal and stillbirth outcome requires equivalent consideration. The importance of antenatal care for improved neonatal and perinatal outcome is well established; however, coverage of a few salient interventions needs increased attention (e.g., use of long lasting insecticide treated nets and intermittent preventive treatment of malaria, antenatal syphilis screening combined with treatment and increased emphasis on early detection, and prompt treatment of complications in pregnancy such as pre-eclampsia, type-2 diabetes).

The strategic interventions for pre-conception and antenatal care for newborns are given below.

Pre-conception and antenatal care interventions package

Family and community

1. Reproductive health & family planning [E]
   - Adolescent reproductive health
   - Delaying age of marriage and first pregnancy
   - Birth spacing
2. Nutrition related interventions [E]
   - Balanced energy protein supplementation
   - Peri-conceptional folic acid
   - Maternal calcium supplementation
   - Multiple micronutrient supplementation (Iron, folic acid and iodine)
   - Nutrition counselling
3. Counselling and birth preparedness [E]
4. Prevention against malaria [S]

Outreach/Sub-centre

5. Antenatal screening for anaemia and hypertensive disorders of pregnancy (PIH, preeclampsia, eclampsia) [E]
6. Antenatal screening for malaria [S]
7. Prevention and management of mild to moderate anaemia [E]
8. Maternal tetanus immunization [E]
9. Adolescent friendly health services (nutrition and reproductive health counselling) [E]
10. Interval IUCD insertion [E]

Health facility

11. Antenatal screening and management of severe anaemia, hypertensive disorders of pregnancy (PIH, preeclampsia, eclampsia), gestational diabetes, syphilis [E]
12. Antenatal screening and management of hypothyroidism, hepatitis B, HIV, malaria [S]
13. Adolescent friendly health clinics (as per RKSK guidelines) [E]
14. Postpartum family planning services including PPIUCD insertion [E]
15. Prevention of Rh disease using anti D immunoglobulin [S]

2. *Care during labour and childbirth*

Intra-partum complications and preterm births remain a challenge to the neonatal survival. Care during labour and childbirth have the potential to reduce stillbirths by a third. It is important to emphasize that BEmOC can reduce intra-partum-related neonatal deaths by 40% and CEmOC can also reduce newborn mortality by 40%, whereas skilled attendance at birth alone without access to the emergency component has a smaller effect at 25%. Care at childbirth also has additional benefits on child survival, improved growth, reduced disability and non-communicable diseases.

Antenatal corticosteroids use to manage preterm labour not only reduces neonatal deaths by 31%, but this intervention is also associated with reduced need of specialized care for newborns, such as ventilators, etc. Antibiotics administration for pre-mature rupture of membranes (PROM) reduces early-onset postnatal sepsis. Clean birth practices especially hand-washing with soap and water by birth attendant has been found to reduce mortality due to sepsis in births at home (15%), facilities (27%), and during postnatal period (40%).

The strategic interventions for care during labour and child birth are given below :

Care during labour and childbirth

Family and community

1. Skilled birth attendance [E]
2. Clean birth practices [E]

Outreach/Sub-centre

3. Identification of complications and timely referral [E]
4. Pre-referral dose by ANM [E]
   - Antenatal corticosteriods in preterm labour
   - Antibiotics for premature rupture of membranes

Health facility

5. Emergency obstetric care [E]
   - Basic and comprehensive
6. Management of preterm labour [E]
   - Antenatal corticosteroids in preterm labour
   - Antibiotics for premature rupture of membranes

3. *Immediate newborn care*

Immediate care is the basic right of every newborn baby. This package includes interventions such as immediate drying and stimulation, provision of warmth, hygienic care, early initiation of breast-feeding, and administration of vitamin K. For babies who do not breathe at birth, neonatal resuscitation is a crucial life-saving intervention. Resuscitation training of providers in facilities reduces intrapartum-related neonatal deaths and early neonatal deaths substantially. Hypothermia is a risk factor for neonatal mortality, especially in cases of preterm and low birth weight babies. All steps should be taken to prevent and manage hypothermia, and rooming-in of babies with mother must be universally practiced. Delayed cord clamping in newborns, including pre-term babies is associated with decreased risk of anaemia and intraventricular haemorrhage. Administration of vitamin K at birth prevents haemorrhagic disease of newborn.

The strategic interventions for immediate newborn care are given below :

Immediate newborn care

Family and community

1. Delayed cord clamping [E]
2. Interventions to prevent hypothermia [E]
   - Immediate drying
   - Head covering
   - Skin-to-skin care
   - Delayed bathing
3. Early initiation and exclusive breast-feeding [E]
4. Hygiene to prevent infection [E]

Outreach/Sub-centre

5. Vitamin K at birth [E]
6. Neonatal resuscitation [E]

Health facility

7. Advanced neonatal resuscitation [E]

4. *Care of healthy newborn*

Evidence shows that community-based interventions can significantly improve child survival. A large number of ASHAs have been trained to perform various preventive and promotive health activities, such as counselling of mothers on breast-feeding, complementary feeding, immunization, care-seeking, promoting nutrition, sanitation, and safe dinking water, etc. Despite the significant increase in institutional deliveries, home deliveries persist to about 25% to 40% in pockets across states. Even in cases of institutional deliveries, most women tend to return home within a few hours after delivery. For women who stay at the institution for 48 hours or more, it is also important to provide care to the neonate at home for the remaining critical days of the first week and upto the 42nd day of life. Home visitation by ASHAs can contribute significantly to delivery of interventions with focus on the newborn period. Regular and timed contacts with the newborn are essential for ensuring continued exclusive breast-feeding, appropriate immunization, and care-seeking of children with danger signs.

The interventions for care of healthy newborn are given below :

Care of healthy newborn

Family and community

1. Home visits till six weeks by trained ASHA [E]
   - Counselling
   - Prevention of hypothermia, cord care
   - Early identification of danger signs
   - Prompt and appropriate referral
2. Exclusive breast-feeding [E]
3. Clean postnatal practices [E]

Outreach/Sub-centre

4. Immunization [E]
   - BCG
   - OPV
   - Hepatitis B
   - DPT

Health facility

All the interventions (except home visits)

5. *Care of small and sick newborn*

Specific interventions for small and sick newborns include Kangaroo mother care (KMC). KMC involves package of early and continuous skin-to-skin contact, breast-feeding support, and supportive care in stable newborns weighing less than 2000 gm. KMC can be practiced even at home, thus improving chances of newborn survival.

Strategic interventions for care of small and sick newborn include :

Care of small and sick newborn

Family and community

1. Thermal care and feeding support (for home deliveries) [E]

Outreach/Sub-centre

2. Integrated management using IMNCI and use of oral antibiotics [E]
3. Injectable Gentamicin by ANMs for sepsis [E]
   - Pre -referral
   - Completion of antibiotic course in case referral is refused/ not possible "OR" as advised by treating physician

Health facility

4. Kangaroo mother care at facility [E]
5. Full supportive care at block and district level [E]
   - NBSU at block level
   - SNCU at district level
6. Intensive care services (NICU) at regional level [A] for
   - Assisted ventilation
   - Surfactant use
   - Surgery

6. *Care beyond newborn survival*

This is a new package considering the burden of birth defects and development delays in newborns. It is of particular significance for SGA and preterm newborns, as well as newborns discharged from SNCUs.

The table below lists the interventions to care for newborns beyond their survival.

Care beyond newborn survival

Family and community	*Outreach/Sub-centre*	*Health facility*
1. Screening for birth defects, failure to thrive and developmental delays [E]	3. As before	4. Newborn screening [A]
2. Follow-up visits of [E]		5. Management of birth defects [E]
– SNCU discharged babies till 1 year of age		– Diagnosis
– small and low birth weight babies till 2 years of age		– Treatment, including surgery
		6. Follow-up of high-risk infants (discharged from SNCUs and small newborns) for
		– Developmental delay
		– Appropriate management

Monitoring and Evaluation *(33)*

A comphrehensive assessment of targets would be done in 2020, which will help plan course corrections, if any, in on-going interventions. Further, from the year 2020, the milestones will be reviewed every five years keeping in sync with ENAP – i.e., 2025, 2030, and 2035.

Following core indicators (dashboard indicators) have been selected for monitoring, based on direct relevance to the action plan framework, targets, goals, and review of current data availability.

Dashboard indicators for INAP

Level and focus areas	Indicators
Impact level indicators	– Birth registration – Stillbirth rate – Early neonatal mortality rate – Neonatal mortality rate – Percentage of neonatal deaths to under-5 deaths – Survival rate of newborns discharged from SNCU/NICU at one year of age – Cause-specific neonatal mortality
Pre-conception & antenatal care	– Births to women aged 15–19 years out of total births (teenage pregnancy) – Percentage of pregnant women who received full ANC – Percentage of pregnant women detected and treated with severe anaemia – Percentage of pregnant women detected and treated with PIH
Care during labour and child birth	– Percentage of safe deliveries (institutional + home deliveries by SBA) – Percentage of preterm births – Caesarean section rate – Percentage of women with preterm labour (< 34 weeks) receiving at least one dose of antenatal corticosteroid – Intra-partum stillbirth rate
Immediate newborn care	– Percentage of newborns breast-fed within one hour of birth – Percentage of newborns delivered at health facility receiving vitamin K at birth – Percentage of labour room staff trained in Navjat Shishu Suraksha Karyakram – Percentage of newborns weighed at birth – Percentage of low birth weight babies
Care of healthy newborn	– Percentage of newborns received complete schedule of home visits under HBNC by ASHAs – Percentage of sick newborns identified during home visits by ASHAs – Exclusive breast-feeding rate – Percentage of mothers stayed for 48 hrs in the facility – Percentage of newborn received birth dose of Hepatitis B, OPV and BCG
Care of small and sick newborn	– Percentage of district hospitals with functional SNCU – Percentage of facilities with SNCUs having functional KMC units – Percentage of female admissions is SNCU – Mortality rate in newborns with admission weight <1800 gm – Percentage of newborn deaths due to birth asphyxia – Percentage of newborns with suspected sepsis receiving pre-referral dose of gentamicin by ANM
Care beyond survival	– Percentage of newborns screened for birth defects (facility + community) – Percentage of newborns with any defect seen as birth – Percentage of newborns discharged from SNCU followed up till one year of age – Percentage of districts with functional District Early Intervention Centre (DEIC)

NATIONAL PROGRAMME FOR PREVENTION AND CONTROL OF CANCER, DIABETES, CARDIOVASCULAR DISEASES AND STROKE (NPCDCS)

India is experiencing a rapid health transition with large and rising burden of chronic non-communicable diseases (NCDs) especially cardiovascular disease, diabetes mellitus, cancer, stroke, and chronic lung diseases. It is estimated that in 2005 NCDs accounted for 53 per cent of deaths. Considering the fact that NCDs are surpassing the burden of communicable diseases in India and the existing health system is mainly focussed on communicable diseases, need for National Programme on Prevention and Control of Diabetes, Cardiovascular Diseases and Stroke was envisaged. Later on this programme was integrated with National Cancer Control Programme, and National Programme for Prevention and Control of Cancer, Diabetes, Cardiovascular Diseases and Stroke (NPCDCS) came into existence. During the 11th Five Year Plan period, 100 identified districts in 21 states have been covered under the programme *(6)*.

A. Diabetes, Cardiovascular Disease and Stroke (DCS) Component under NPCDCS

The programme focuses on the health promotion, capacity building including human resource development, early diagnosis and management of these diseases with integration with the primary health care system.

The major objectives of the programme are as follows *(4)* :

- Prevent and control common NCDs through behaviour and lifestyle changes.
- Provide early diagnosis and management of common NCDs.
- Build capacity at various levels of health care for prevention, diagnosis and treatment of common NCDs.
- Train human resource within the public health set-up *viz* doctors, paramedics and nursing staff to cope with the increasing burden of NCDs, and
- Establish and develop capacity for palliative & rehabilitative care.

The programme is to be implemented in 20,000 sub-centres and 700 community health centres (CHCs) in 100 districts across 21 States/UTs and the strategies include promoting healthy lifestyle through massive health education and mass media efforts at country level, opportunistic screening of persons above the age of 30 years, establishment of Non-Communicable Disease (NCD) Clinic at Community Health Centre (CHC) and District level, development of trained manpower and strengthening of tertiary level health facilities. For long-term sustainability of the programme, service delivery will be through existing public health infrastructure and systems. The various approaches such as mass media, community education and interpersonal communication will be used for behavioural change focusing on the following messages :

- Increased intake of healthy foods
- Increased physical activity
- Avoidance of tobacco and alcohol
- Stress management.

Activities at Sub-Centre

Health promotion for behaviour and lifestyle change will be carried out by organizing various camps, interpersonal communications, posters, banners, etc. Opportunistic screening of population above 30 years will be carried out using BP measurement and blood glucose by strip method. The suspected cases of diabetes and hypertension will be referred to CHCs of higher health facility for further diagnosis and management. For screening of diabetes, glucometer optium xceed, optium test strips and auto disabled lancets are being procured at central level and provided to the concerned states as per their requirements from time to time.

Activities at CHC

NCD clinic at CHC shall do the diagnosis by required investigations/test like blood sugar measurement, lipid profile, ultrasound, X-ray and ECG etc., management and stabilization of common CVD, diabetes and stroke cases (out- patient as well as in-patients). One of the nurses appointed under the programme shall undertake home visits for bedridden cases, supervise the work of health workers and attend monthly clinics being held in the villages on a random basis. Complicated cases of diabetes, high blood pressure etc. shall be referred from CHC to the district hospital for further investigations and management.

Activities at district hospital

NCD clinic at district hospital shall screen persons above the age of 30 years for diabetes, hypertension, cardiovascular diseases etc. to identify individuals who are at a high-risk of developing diabetes, hypertension and CVDs warranting further investigation/action. Detailed investigation will be done in respect of persons those who are at high-risk of developing NCDs on screening and those who are referred from CHCs. They shall provide regular management and annual assessment of persons suffering from cancer, diabetes and hypertension. People with established cardiovascular diseases shall also be managed at district hospital. They shall provide home based palliative care for chronic, debilitating and progressive patients. Apart from clinical services, district hospital shall be involved in promotion of healthy lifestyle through health education and counselling to the patients and their attendants.

Urban health check-up scheme for diabetes and high blood pressure

The scheme has the following objectives :

1. To screen urban slum population for diabetes and high blood pressure.
2. To create database for prevalence of diabetes and high blood pressure in urban slums.
3. To sensitize the urban slum population about healthy lifestyle.

The blood sugar and blood pressure will be checked for all ≥ 30 years and all pregnant women of all age.

The NCD cells at the centre, state and district will implement and monitor the National Programme for Prevention and Control of Cancer, Diabetes, CVD and Stroke (NPCDCS) in various states. The national NCD cell has been established at the centre.

B. Cancer component under NPCDCS

Cancer is an important public health problem in India, with nealy 10 lakh new cases occurring every year in the country. It is estimated that there are 2.8 million cases of cancer in the country at any given point of time. With the objectives of prevention, early diagnosis and treatment, the national cancer control programme was launched in 1975–76. In view of the magnitude of the problem and gaps in the availability of cancer treatment facilities across the country, the programme was revised in 1984–85 and subsequently in December 2004. During 2010, the programme was integrated with National Programme on Prevention and Control of Diabetes, Cardiovascular Disease and Stroke. The objectives of the programme are :

a. Primary prevention of cancers by health education;
b. Secondary prevention i.e. early detection and diagnosis of common cancer such as cancer of cervix, mouth, breast and tobacco related cancer by screening/self examination method; and
c. Tertiary prevention i.e. strengthening of the existing institutions of comprehensive therapy including palliative care.

The schemes under the revised programme are :

1. Regional Cancer Centre Scheme

The existing regional cancer centres are being further strengthened to act as referral centres for complicated and difficult cases at the tertiary level. One time assistance of Rs. 3 crores during the plan period is provided to Regional Cancer Centres except TMH, Mumbai and IRCH (AIIMS) for strengthening and to the CNCI, Kolkata on the approved pattern of funding.

2. Oncology Wing Development Scheme

This scheme had been initiated to fill up the geographic gaps in the availability of cancer treatment facilities in the country. Central assistance is provided for purchase of equipment, which include a cobalt unit besides other equipment. A part of the grant can be used for the civil work but the manpower is to be provided by the concerned state government/institution. The quantum of central assistance is Rs. 3 crores per institution under the scheme.

3. Decentralized NGO scheme

This scheme is meant for IEC activities and early detection of cancer. The scheme is operated by the nodal agencies and the NGOs are given financial assistance for undertaking health education and early detection activities of cancer.

4. IEC activities at central level

IEC activities at the central level are to be initiated in order to give wider publicity about the Anti Tobacco Legislation for discouraging consumption of cigarettes and other tobacco related products, and for creating awareness among masses about the ill effects of consumption of tobacco and tobacco related products. Under this scheme wider publicity would also be given about the rules being formulated for implementation of various provisions of the anti-tobacco legislation. November 7th is observed as National Cancer Awareness Day in the country.

5. Research and training

Training programmes, monitoring and research activities will be organized at the central level under this scheme. Following training manuals have been developed under the NCCP for capacity building in cancer control at district level :

a. Manual for health professionals
b. Manual for cytology
c. Manual for palliative care
d. Manual for tobacco cessation

Cancer services under national programme for prevention and control of cancer, diabetes, CVD and stroke *(6)* :

1. Common diagnostic services, basic surgery, chemotherapy and palliative care for cancer cases is being made available at 100 district hospitals.
2. Each district is being supported with Rs. 1.66 crores per annum for the following.
   - Chemotherapy drugs are provided for 100 patients at each district hospital.
   - Day care chemotherapy facilities is being established at 100 district hospitals.
   - Facility for laboratory investigations including mammography is being provided at 100 district hospitals and if not available, this can be outsourced at government rates.
3. Home based palliative care is being provided for chronic, debilitating and progressive cancer patients at 100 districts.
4. Support is being provided for contractual manpower through 1 Medical Oncologist, 1 Cytopathologist, 1 Cytopathology technician, 2 Nurses for day care.
5. 45 centres were to be strengthened as Tertiary Cancer Centres (TCCs) to provide comprehensive cancer care services at a cost of Rs. 6.00 crore each during 2011–12.

TOBACCO CONTROL LEGISLATION *(49)*

A comprehensive tobacco control legislation titled "The Cigarettes and other Tobacco Products (Prohibition of Advertisement and Regulation of Trade and Commerce, Production, Supply and Distribution) Act, 2003" was passed by the parliament in April, 2003 and notified in Gazette of India on 25th Feb, 2004. The important provisons of the Act are :

a. Prohibition of smoking in public places;
b. Prohibition of direct and indirect advertisement of cigarette and other products;
c. Prohibition of sale of cigarette and other tobacco products to a person below the age of 18 years,
d. Prohibition of sale of tobacco products near the educational institutions;
e. Mandatory depiction of statutory warnings (including pictorial warnings) on tobacco packs; and
f. Mandatory depiction of tar and nicotine contents alongwith maximum permissible limits on tobacco packs.

The rules related to prohibition of smoking in public places came into force from the 2nd October, 2008. As per rules, it is mandatory to display smoke free signages at all public places. Labelling and packaging rules mandating the depiction of specified health warnings on all tobacco product packs came into force from 31st May, 2009.

National Tobacco Control Programme *(3)* : In order to facilitate the implementation of the Tobacco Control Laws, to bring about greater awareness about the harmful effects of tobacco, and to fulfill the obligations under the WHO-Framework convention on tobacco control, Govt. of India has launched a new National Tobacco Control Programme in the 11th Five Year Plan. Pilot phase was launched in 16 districts covering 9 states in 2007–08. It now covers 42 districts in 21 states in the country. The main components of the programme are :

1. Public awareness/mass media campaigns for awareness building and for behavioural change;
2. Establishment of tobacco product testing laboratories, to build regulatory capacity, as required under COTPA, 2003;
3. Mainstreaming the programme components as a part of the health delivery mechanism under the NRHM framework;
4. Mainstream research and training on alternate crops and livelihood, with other nodal ministries;
5. Monitoring and evaluation, including surveillance, e.g. adult tobacco survey;
6. Dedicated tobacco control cells for effective implementation and monitoring of anti-tobacco initiatives;
7. Training of health and social workers, NGOs school teachers etc;
8. School programme; and
9. Provision of tobacco cessation facilities.

NATIONAL MENTAL HEALTH PROGRAMME

The National Mental Health Programme was launched during 1982 with a view to ensure availability of Mental Health Care Services for all, especially the community at risk

and underprivileged section of the population, to encourage application of mental health knowledge in general health care and social development. A National Advisory Group on mental health was constituted under the Chairmanship of the Secretary, Ministry of Health and Family Welfare for the effective implementation of the National Health Programme. Eleven institutions have been identified for imparting training in basic knowledge and skills in the field of mental health to the primary health care physicians and para-medical personnel. At present this programme covers 94 districts.

The aims of the NMHP are : (a) Prevention and treatment of mental and neurological disorders and their associated disabilities; (b) Use of mental health technology to improve general health services; and (c) Application of mental health principles in total national development to improve quality of life *(50)*.

The objectives of the programme are :

1. To ensure availability and accessibility of minimum mental health care for all in the foreseeable future, particularly to the most vulnerable and underprivileged sections of population.
2. To encourage application of mental health knowledge in general health care and in the social development.
3. To promote community participation in the mental health services development, and to stimulate efforts towards self-help in the community.

The programme strategies are :

1. Integration of mental health with primary health care through the NMHP;
2. Provision of tertiary care institutions for treatment of mental disorders;
3. Eradicating stigmatization of mentally ill patients and protecting their rights through regulatory institutions like the Central Mental Health Authority, and State Mental Health Authority.

District Mental Health Programme components are : (a) Training programmes of all workers in the mental health team at the identified nodal institute in the state; (b) Public education in mental health to increase awareness and to reduce stigma; (c) For early detection and treatment, the OPD and indoor services are provided; and (d) Providing valuable data and experience at the level of community to the state and centre for future planning, improvement in service and research.

District Mental Health Programme has now incorporated promotive and preventive activities for positive mental health which includes :

- *School mental health services :* Life skills education in schools, counselling services.
- *College counselling services :* Through trained teachers/ councellors.
- *Work place stress management :* Formal & Informal sectors, including farmers, women etc.
- *Suicide prevention services :* Counselling center at district level, sensitization workshops, IEC, help lines etc.

The National Human Rights Commission also monitors the conditions in the mental hospitals along with the government of India, and the states are acting on the recommendations of the joint studies conducted to ensure quality in delivery of mental care.

Thrust areas *(6)*

1. District mental health programme in an enlarged and more effective form covering the entire country.
2. Streamlining/modernization of mental hospitals in order to modify their present custodial role.
3. Upgrading department of psychiatry in medical colleges and enhancing the psychiatric content of the medical curriculum at the undergraduate as well as postgraduate level.
4. Strengthening the central and state mental health authorities with a permanent secretariat. Appointment of medical officers at state headquarters in order to make the monitoring role more effective.
5. Research and training in the field of community mental health, substance abuse and child adolescent psychiatric clinics.

INTEGRATED DISEASE SURVEILLANCE PROJECT

Integrated disease surveillance project is a decentralized state based surveillance system in the country. This project is intended to detect early warning signals of impending outbreaks and help initiate an effective response in a timely manner in urban and rural areas. It will also provide essential data to monitor progress of ongoing disease control programme and help allocate health resources more efficiently. The project was launched in Nov. 2004. It is a 5 year project.

The surveillance is needed to recognize cases or cluster of cases to initiate interventions to prevent transmission of disease or reduce morbidity and mortality; access the public health impact of health events or determine and measure trends; demonstrate the need for public health intervention programmes and resources and allocate resources during public health planning; monitor effectiveness of prevention and control measures; identify high-risk groups or geographical areas to target interventions and guide analytic studies; and develop hypothesis that lead to analytic studies about risk factors for disease causation, propagation and progression *(51)*.

In this project, different types of integration are proposed. These include : (a) Sharing of surveillance information of disease control programmes; (b) Developing effective partnership with health and non-health sectors in surveillance; (c) Including non-communicable and communicable diseases in the surveillance system; (d) Effective partnership of private sector and NGOs in surveillance activities; (e) Bringing academic institutions and medical colleges into the primary public health activity of disease surveillance.

The important information in disease surveillance are – who gets the disease, how many get the disease, where did they get the disease, why did they get the disease, and what needs to be done as public health response.

The components of the surveillance activity are :

(a) Collection of data

(b) Compilation of data

(c) Analysis and interpretation

(d) Follow-up action

(e) Feedback.

The prerequisite of the effective surveillance are – use of standard case definition, ensure regularity of reports and the action on reports.

The classification of surveillance in IDSP is as follows :

a. *Syndromic diagnosis* – diagnosis is made on the basis of clinical pattern by paramedical personnel and members of the community;
b. *Presumptive diagnosis* – diagnosis made on typical history and clinical examination by medical officer; and
c. *Confirmed diagnosis* – clinical diagnosis by a medical officer and or positive laboratory identification.

Syndromes under surveillance (51) :

The paramedical health staff will undertake disease surveillance based on broad categories of presentation. The following clinical syndromes will be under surveillance in IDSP :

1. Fever
   a. Less than 7 days duration without any localizing signs
   b. With rash
   c. With altered sensorium or convulsions
   d. Bleeding from skin or mucus membrane
   e. Fever more than 7 days with or without localizing signs
2. Cough more than 3 weeks duration
3. Acute flaccid paralysis
4. Diarrhoea
5. Jaundice, and
6. Unusual events causing death or hospitalization.

These syndromes are intended to pick up all priority diseases listed under regular surveillance at the level of the community under the Integrated Disease Surveillance Project.

Fever with or without localizing signs	Malaria, Typhoid, JE, Dengue, Measles
Cough more than 3 weeks	Tuberculosis
Acute flaccid paralysis	Polio
Diarrhoea	Cholera
Jaundice	Hepatitis, Laptospirosis, Dengue, Malaria, Yellow fever
Unusual syndromes	Anthrax, Plague, Emerging epidemics

The core conditions under surveillance in IDSP are as follows *(52)* :

(i) Regular Surveillance

Vector borne disease	: Malaria
Water borne disease	: Acute diarrhoeal disease (cholera)
	: Typhoid
Respiratory diseases	: Tuberculosis
Vaccine preventable diseases	: Measles
Diseases under eradication	: Polio
Other conditions	: Road traffic accidents (Link-up with police computers)
Other international commitments	: Plague
Unusual clinical syndromes (causing death/ hospitalization)	: Meningoencephalitis / Respiratory distress, Haemorrhagic fevers, other undiagnosed conditions

(ii) Sentinel Surveillance

Sexually transmitted diseases / blood borne	: HIV / HBV, HCV
Other conditions	: Water quality monitoring
	: Outdoor air quality (Large urban centres)

(iii) Regular periodic surveys

NCD risk factors	: Anthropometry, Physical activity, Blood pressure, Tobacco, Nutrition etc.

(iv) Additional state priorities

Each state may identify upto five additional conditions for surveillance.

The reporting units for disease surveillance are :

	Public Health Sector	Private health sector
Rural	CHCs, District hospitals	Sentinel private practitioners, and Sentinel hospitals.
Urban	Urban hospitals, ESI / Railway / Medical college hospitals.	Sentinel private nursing homes, sentinel hospitals, Medical colleges, Private and NGO laboratories

1. Sub-centre–health worker/ANM reports all patients fulfilling the clinical syndrome from PHC, private clinic, hospital etc.
2. PHC/CHC medical officers report as probable cases of interest, where this cannot be confirmed by laboratory tests at the peripheral reporting units, and as confirmed when the laboratory information is available as in case of blood smear +ve malaria and sputum AFB +ve tuberculosis.
3. Sentinel private practitioners, district hospitals, municipal hospitals, medical colleges, sentinel hospitals, NGOs – medical officers report as probable cases of interest.

NATIONAL GUINEAWORM ERADICATION PROGRAMME

India launched its National Guineaworm Eradicatior Programme in 1984 with technical assistance from WHO From the very beginning the programme was integrated intc the national health system at village level. With well definec strategies, an efficient information and evaluation system intersectoral coordination at all levels and close collaboratior with WHO and UNICEF, India was able to significantly reduce the disease in affected areas. The country has reported zerc cases since August 1996. In February 2000, the Internationa Commission for the Certification of Dracunculiasi Eradication recommended that India be certified free o dracunculiasis transmission *(52)*.

The following activities are continuing as pe recommendations of International Certification Team o

International Commission for Certification of Dracunculiasis Eradication, Geneva :

a. Health education activities with special emphasis on school children and women in rural areas.
b. Rumour registration and rumour investigation.
c. Maintenance of guinea-worm disease on list of notifiable disease and continuation of surveillance in previously infected areas.
d. Careful supervision of the functioning of hand pumps and other sources of safe drinking water, and provision of additional units, wherever necessary.

YAWS ERADICATION PROGRAMME *(5)*

The disease has been reported in India from the tribal communities living in hilly forest and difficult to reach areas in 49 districts of 10 states, namely Andhra Pradesh, Assam, Chhattisgarh, Gujarat, Jharkhand, Madhya Pradesh, Maharashtra, Orissa, Tamil Nadu and Uttar Pradesh. National Institute of Communicable Diseases is the nodal agency for planning, guidance, coordination, monitoring and evaluation of the programme. The programme is implemented by the State Health Directorates of Yaws endemic states utilizing existing health care delivery system with the coordination and collaboration of department of tribal welfare and other related institutions.

The number of reported cases has come down from more than 3,500 to Nil during the period from 1996 to 2004, since then no new case has been reported.

NATIONAL PROGRAMME FOR CONTROL AND TREATMENT OF OCCUPATIONAL DISEASES

Government of India launched a scheme called "National Programme for Control and Treatment of Occupational Diseases" in 1998–99. The National Institute of Occupational Health, Ahmedabad (ICMR) has been identified as the nodal agency for this programme.

The following research projects have been proposed by the government *(53)* :

1. Prevention, control and treatment of silicosis and silico-tuberculosis in agate industry.
2. Occupational health problems of tobacco harvesters and their prevention.
3. Hazardous process and chemicals, database generation, documentation, and information dissemination.
4. Capacity building to promote research, education, training at National Institute of Occupational Disease.
5. Health Risk Assessment and development of intervention programme in cottage industries with high risk of silicosis.
6. Prevention and control of occupational health hazards among salt workers in the remote desert areas of Gujarat and Western Rajasthan.

NUTRITIONAL PROGRAMME

Please refer to chapter 10, for details.

NATIONAL FAMILY WELFARE PROGRAMME

See chapter 8 page 516 for details.

NATIONAL WATER SUPPLY AND SANITATION PROGRAMME

The National Water Supply and Sanitation Programme was initiated in 1954 with the object of providing safe water supply and adequate drainage facilities for the entire urban and rural population of the country. In 1972 a special programme known as the **Accelerated Rural Water Supply Programme** was started as a supplement to the national water supply and sanitation programme. Inspite of increased financial outlay during the successive Five Year Plans, only a small dent was made on the overall problem. During the Fifth Plan, rural water supply was included in the Minimum Needs Programme of the State Plans. The Central Government is supporting the efforts of the States in identifying problem villages through assistance under Accelerated Rural Water Supply Programme. A *"problem village"* has been defined as one where no source of safe water is available within a distance of 1.6 km, or where water is available at a depth of more than 15 metres, or where water source has excess salinity, iron, fluorides and other toxic elements, or where water is exposed to the risk of cholera.

The stipulated norm of water supply is 40 litres of safe drinking water per capita per day, and at least one hand pump/spot-source for every 250 persons. Information, education and communication is an integral part of rural sanitation programme to adopt proper environmental sanitation practices including disposal of garbage, refuse and waste water, and to convert all existing dry latrines into low cost sanitary latrines. The priority is to evolve financially viable sewerage systems in big cities and important pilgrimage and tourist centres and recycling of treated effluents for horticulture, irrigation and other non-domestic purposes *(54)*.

The programme was subsequently renamed as the Rajiv Gandhi National Drinking Water Mission in 1991. In 1999–2000, Sector Reform Project was started to involve the community in planning, implementation and management of drinking water schemes which was in 2002 scaled up as the Swajaldhara Programme.

Swajaldhara (55)

Swajaldhara was launched on 25th Dec. 2002. Swajaldhara has certain fundamental reform principles, which need to be adhered to by the state governments and the implementing agencies. Swajaldhara is a community led participatory programme, which aims at providing safe drinking water in rural areas, with full ownership of the community, building awareness among the village community on the management of drinking water projects, including better hygiene practices and encouraging water conservation practices along with rainwater harvesting.

Swajaldhara has two components : Swajaldhara I (First Dhara) is for a gram panchayat or a group of panchayats (at block / tahsil level) and Swajaldhara II (Second Dhara) has district as the project area. District water and sanitation mission sanctions swajaldhara I. The panchayats and communities have the power to plan, implement, operate, maintain and manage all water supply and sanitation schemes. There is an integrated service delivery mechanism, taking up conservation measures through rain water harvesting and ground water recharge systems for sustained drinking water supply and shifting the role of government from direct service delivery to that of planning, policy

formulation, monitoring and evaluation and partial financial support. On completion of the project, gram panchayat or village water and sanitation committee manages the project.

The programme was revised from 1st April 2009 and named as National Rural Drinking Water Programme *(56)*. It is now a component of Bharat Nirman which focuses on the creation of rural infrastructure.

Bharat Nirman

Bharat Nirman was launched by the Government of India in 2005 as a programme to build rural infrastructure. While phase-I was implemented in the period of 2005–06 to 2008–09, the phase-II was implemented from 2009–10 to 2011–12. At the beginning of phase-I period, priority was given to cover water quality problem and other contaminants, e.g., arsenic and fluoride affected habitations followed by iron, salinity, nitrate.

New initiatives in 12th Five Year Plan

1. In order to raise coverage of piped water supply, toilet coverage and strengthening of institutions and systems in rural drinking water and rural sanitation sectors the Ministry has proposed a Rural Water Supply and Sanitation Project for low income states;
2. Enhancement of service levels for rural water supply from the norm of 40 lpcd to 55 lpcd for designing of system. The target being at least 50 per cent of rural population in the country to have access to water within their household premises or within 100 metres radius, with at least 30 per cent having individual household connections, as against 13 per cent today *(56)*.

Rural Sanitation Programme *(56)*

Nirmal Bharat Abhiyan (NBA)

In 2012, a paradigm shift was made in the Total Sanitation Campaign, by launching the Nirmal Bharat Abhiyan, in the 12th Five Year Plan. The objective of NBA is to achieve sustainable behavioural change with provision of sanitary facilities in entire communities in a phased manner, saturation mode with "Nirmal Grams" as outcomes.

Swachh Bharat Abhiyan

Prime Minister Shri Narendra Modi launched country's biggest cleanliness drive on 2nd October 2014. The campaign aims to accomplish a vision of clean India by 2nd October 2019.

MINIMUM NEEDS PROGRAMME

The Minimum Needs Programme (MNP) was introduced in the first year of the Fifth Five Year Plan (1974–78). The objective of the programme is to provide certain basic minimum needs and thereby improve the living standards of the people. It is the expression of the commitment of the government for the "social and economic development of the community particularly the underprivileged and underserved population". The programme includes the following components :

a. Rural Health
b. Rural Water Supply
c. Rural Electrification
d. Elementary Education
e. Adult Education
f. Nutrition
g. Environmental improvement of Urban Slums
h. Houses for landless labourers

There are two basic principles which are to be observed in the implementation of MNP : (a) the facilities under MNP are to be first provided to those areas which are at present underserved so as to remove disparities between different areas; (b) the facilities under MNP should be provided as a package to an area through intersectoral area projects, to have a greater impact.

In the field of **rural health**, the objectives to be achieved by the end of the Eighth Five Year Plan, under the minimum needs programme were : one PHC for 30,000 population in plains and 20,000 population in tribal and hilly areas; one sub-centre for a population of 5,000 people in the plains and for 3000 in tribal and hilly areas, and one community health centre (rural hospital) for a population of one lakh or one C.D. Block by the year 2000. The establishment of PHCs, sub-centres, upgradation of PHCs, and construction of buildings thereof are all included in the State sector of the minimum needs programme.

In the field of **nutrition,** the objectives are (a) to extend nutrition support to 11 million eligible persons (b) to expand "special nutrition programme" to all the ICDS projects, and (c) to consolidate the mid-day meal programme and link it to health, potable water and sanitation.

20-POINT PROGRAMME

In addition to the Five Year Plans and Programmes, in 1975, the Govt. of India initiated a special activity. This was the 20-Point programme – described as an **agenda** for national action to promote social justice and economic growth.

On August 20, 1986, the existing 20-Point Programme was restructured. Its objectives are spelt out by the Government as "eradication of poverty, raising productivity, reducing inequalities, removing social and economic disparities and improving the quality of life".

At least 8 of the 20 points are related, directly or indirectly, to health. These are :

Point 1	–	Attack on rural poverty
Point 7	–	Clean drinking water
Point 8	–	Health for all
Point 9	–	Two-child norm
Point 10	–	Expansion of education
Point 14	–	Housing for the people
Point 15	–	Improvement of slums
Point 17	–	Protection of the environment

The restructured 20–Point Programme constitutes the Charter for the country's socio-economic development. It has been described as "the cutting edge of the plan for the poor".

8 Demography and Family Planning

"Delay the first, postpone the second and prevent the third"

Demography, as understood today, is the scientific study of human population. It focuses its attention on three readily observable human phenomena : (a) *changes* in population size (growth or decline) (b) the *composition* of the population and (c) the *distribution* of population in space. It deals with five "demographic processes", namely fertility, mortality, marriage, migration and social mobility. These five processes are continuously at work within a population determining size, composition and distribution.

Community medicine is vitally concerned with population, because health in the group depends upon the dynamic relationship between the numbers of people, the space which they occupy and the skill that they have acquired in providing for their needs. The main sources of demographic statistics in India are population censuses, National Sample Surveys, registration of vital events, and adhoc demographic studies.

Demographic cycle

The history of world population since 1650 suggests that there is a demographic cycle of 5 stages through which a nation passes:

(1) FIRST STAGE (High stationary)

This stage is characterized by a high birth rate and a high death rate which cancel each other and the population remains stationary. India was in this stage till 1920.

(2) SECOND STAGE (Early expanding)

The death rate begins to decline, while the birth rate remains unchanged. Many countries in South Asia, and Africa are in this phase. Birth rates have increased in some of these countries possibly as a result of improved health conditions, and shortening periods of breast-feeding *(1)*.

(3) THIRD STAGE (Late expanding)

The death rate declines still further, and the birth rate tends to fall. The population continues to grow because births exceed deaths. India has entered this phase. In a number of developing countries (e.g., China, Singapore) birth rates have declined rapidly.

(4) FOURTH STAGE (Low stationary)

This stage is characterized by a low birth and low death rate with the result that the population becomes stationary. Zero population growth has already been recorded in Austria during 1980–85. Growth rates as little as 0.1 were recorded in UK, Denmark, Sweden and Belgium during 1980–85. In short, most industrialized countries have undergone a demographic transition shifting from a high birth and high death rates to low birth and low death rates.

(5) FIFTH STAGE : (Declining)

The population begins to decline because birth rate is lower than the death rate. Some East European countries, notably Germany and Hungary are experiencing this stage.

WORLD POPULATION TRENDS

At the beginning of the Christian era, nearly 2,000 years ago, world population was estimated to be around 250 million. Subsequent estimates of the world population, and rates of increase are given in Table 1.

TABLE 1

World population

Year	Population (million)	Average annual growth rate (per cent)
1750	791	–
1800	978	0.4
1850	1,262	0.5
1900	1,650	0.6
1950	2,526	1.1
1960	3,037	1.79
1970	3,696	1.92
1975	4,066	1.89
1980	4,432	1.72
1987	5,000	1.63
1991	5,385	1.7
1998	5,884	1.6
2000	6,054	1.4
2003	6,313	1.1
2007	6,655	1.4
2008	6,734	1.2
2010	6,908	1.23
2014	7,238	1.2

It required all the human history up to the year 1800 for the world population to reach one billion. The second billion came in 130 years (around 1930), the third billion in 30 years (around 1960), the fourth billion in 15 years (in 1974), the fifth billion in 12 years (in 1987), and the sixth billion in 12 years (1999). On October 12th 1999 world population became 6 billion. The 7th billion came in 2014 (after 15 years). It is expected to reach 8 billion by 2025 *(2)*.

About three fourths of the world's population lives in the developing countries. The population of the ten most populous countries of the world and their relative share is shown in Fig. 1. Although, in terms of population USA ranks

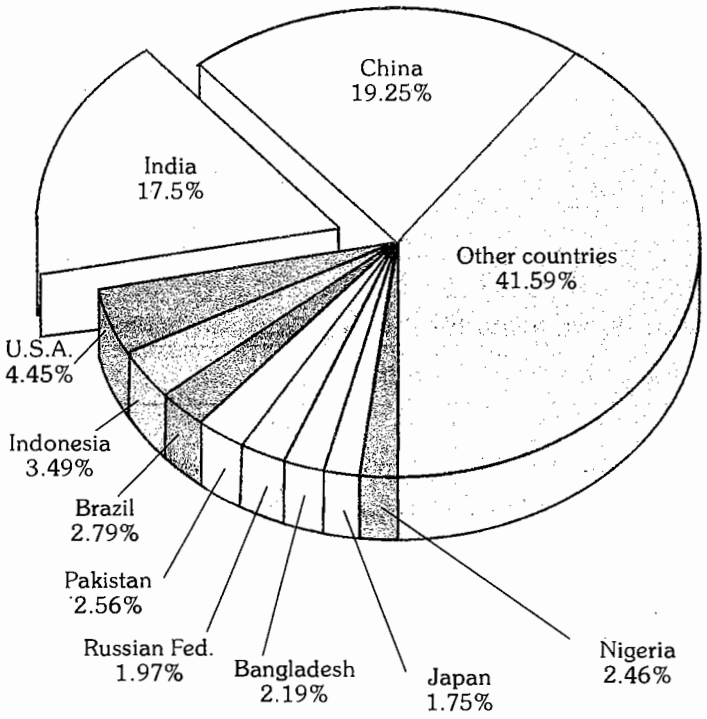

FIG. 1

Ten most populous countries of the world (2014)

Source : *(3)*

third in the world after India, there is a yawning gap of 978 million between the population of these two countries. The United Nations has estimated that world's population grew at an annual rate of 1.23 per cent during 2000–2010. China registered a much lower annual growth rate of population (0.6 per cent) during 2002–2012, as compared to India (1.4 per cent). In fact, the growth rate of China is now very much comparable to that of USA (0.9 per cent).

Three countries of SEAR, i.e. India (17.5 per cent), Indonesia (3.49 per cent) and Bangladesh (2.19 per cent) are among the most populous ten countries of the world. At present India's population is second to that of China. According to UN projections India's population will reach 1.53 billion by the year 2050, and will be the highest population in the world. The trend of population increase in South East Asia Region countries is as shown in Table 2.

TABLE 2

Trends in increase of population of SEAR countries (in million)

Country	1975	2012
India	6,207	1,236.2
Bangladesh	73.2	154.6
Bhutan	1.2	0.7
Indonesia	134.4	246.8
Maldives	0.1	0.3
Myanmar	30.1	52.7
Nepal	13.5	27.4
Sri Lanka	14.0	21.0
Thailand	41.3	66.78
Total (excluding DPR Korea)	6,514.8	1,833.35

Birth and death rates

The glaring contrasts in birth and death rates in selected countries are as shown in Table 3.

TABLE 3

Crude birth and death rates in selected developed and developing countries in 2012

Country	Crude birth rate	Crude death rate
India	21	7
Bangladesh	20	6
Pakistan	26	7
Sri Lanka	18	7
Thailand	10	8
Myanmar	17	9
Nepal	22	7
China	13	7
Japan	8	10
Singapore	10	5
UK	12	9
USA	13	8

Source : *(5)*

The world's birth rate fell below 30 for the first time around 1975 and had declined to about 20 during 2012 *(5)*. In most of the world the decline reflected falling birth rates and a global trend towards smaller families. The outstanding examples are Singapore and Thailand. In Singapore, in 40 years, the birth rate fell from 23 per thousand in 1970 to 10 in 2012; and, in Thailand from 37 to 10 during the same period (Table 4).

TABLE 4

Reduction in the crude birth and death rates in selected countries, 1970–2012

Country	Crude birth rate		Crude death rate	
	1970	2012	1970	2012
Bangladesh	45	20	20	6
Nepal	43	22	21	7
India	38	21	16	7
Sri Lanka	31	18	8	7
Thailand	37	10	10	8
Singapore	23	10	5	5
China	33	13	8	7
Pakistan	43	26	16	7

Source : *(5)*

In all these countries, key factors in fertility decline included changes in government attitudes towards growth, the spread of education, increased availability of contraception and the extension of services offered through family planning programmes, as well as the marked change in marriage patterns.

Death rates have also declined worldwide over the last decades. The global death rate declined from 11.0 (between 1975–1980) to 8 per thousand population during 2012, a reduction of 23 per cent. The decline in the crude death rate of the South-East Asia Region has been more marked, from 14.1 to 7.5 per 1000 population *(6)*.

In countries with a relative young population, crude death rates are mainly affected by infant and child mortality. With improvement in maternal and child health services, successful implementation of the expanded programme on immunization, diarrhoeal disease and acute respiratory

infection control programmes, as well as with the control of other infectious diseases, there has been marked reduction in infant and child mortality rates, which are reflected in the declining crude death rates.

Growth rates

When the crude death rate is substracted from the crude birth rate, the net residual is the current annual growth rate, exclusive of migration. The relation between the growth rate and population increase is as shown in Table 5.

TABLE 5

Relation between growth rate and population

Rating	Annual rate of growth %	Number of years required for the population to double in size
Stationary population	No growth	
Slow growth	Less than 0.5	More than 139
Moderate growth	0.5 to 1.0	139–70
Rapid growth	1.0 to 1.5	70–47
Very rapid growth	1.5 to 2.0	47–35
"Explosive" growth	2.0 to 2.5	35–28
——"——	2.5 to 3.0	28–23
——"——	3.0 to 3.5	23–20
——"——	3.5 to 4.0	20–18

Source : *(7)*

It is said that population growth rates, like railway trains, are subject to momentum. They start slowly and gain momentum. Once in motion, it takes time to bring the momentum under control. In case of the train the control factors are mass and inertia; in population, they are age distribution, marriage customs and numerous cultural, social and economic factors.

The world population growth rate was at, or near its peak, around 1970, when the human population grew by an estimated 1.92 per cent. The most recent data show a slight decline since then to 1.2 per cent in 2012.

The growth rate is not uniform in the world. There are many countries in the world (e.g., European countries) where the growth rate is less than 0.3 per cent per year. In developing countries, the growth rates are excessive – it is around 2.6 per cent in Africa, 1.1 per cent in Latin America, 0.3 per cent in Europe and industrialized countries, and 1.3 per cent in Asia. A population growing at 0.5 per cent per year will double in about 140 years, a population growing at 3 per cent per year will double in about 20–25 years (Table 5). These differences in growth rates are largely the result of fertility and mortality patterns. The salient features of population growth at a glance are as follows:

- Approximately 95 per cent of this growth is occurring in the developing countries.
- Currently, one-third of the world's population is under the age of 15, and will soon enter the reproductive bracket, giving more potential for population growth.
- The UNFPA estimates that world population is most likely to reach 10 billion people by 2050, and 20.7 billion a century later.
- The expected number of births per women, at current fertility rates (2012) is : for industrialized countries 1.7, developing countries 2.9 and for least developed countries 4.1. The global total fertility rate is 2.5.

The rampant population growth has been viewed as the greatest obstacle to the economic and social advancement of the majority of people in the underdeveloped world.

DEMOGRAPHIC TRENDS IN INDIA

Demographic indicators

Demographic characteristics provide an overview of its population size, composition, territorial distribution, changes therein and the components of changes such as nativity, mortality and social mobility. Demographic indicators have been divided into two parts – population statistics and vital statistics.

Population statistics include indicators that measure the population size, sex ratio, density and dependency ratio.

Vital statistics include indicators such as birth rate, death rate, natural growth rate, life expectancy at birth, mortality and fertility rates.

These indicators help in identifying areas that need policy and programmed interventions, setting near and far-term goals and deciding priorities, besides understanding them in an integrated structure.

With a population of 1,364 million in the year 2014, India is the second most populous country in the world, next only to China, whereas seventh in land area. With only 2.4 per cent of the world's land area, India is supporting about 17.5 per cent of the world's population. The population of India since 1901, average annual exponential growth rate (%), and the decadal growth of population (%) is as shown in Table 6.

TABLE 6

Population of India, 1901–2011

Year	Total population (in million)	Average annual exponential growth rate (%)	Decadal growth rate (%)
1901	238.4	–	–
1911	252.1	0.56	0.75
1921	251.3	(–) 0.03	(–) 0.31
1931	279.0	1.04	11.00
1941	318.7	1.33	14.22
1951	361.1	1.25	13.31
1961	439.2	1.96	21.64
1971	548.2	2.20	24.80
1981	683.3	2.22	24.66
1991	846.4	2.16	23.87
2001	1,028.6	1.7	21.52
2011	1,210.1	1.64	17.64

Source : *(8)*

India's population has been steadily increasing since 1921. The year 1921 is called the "big divide" because the absolute number of people added to the population during each decade has been on the increase since 1921 (Table 6). India's population is currently increasing at the rate of 16 million each year.

India's population numbered 238 million in 1901, doubled in 60 years to 439 million (1961); doubled again, this time in only 30 years to reach 846 million by 1991. It crossed 1 billion mark on 11 May 2000, and is projected to reach 1.53 billion by the year 2050. This will then make India the most populous country in the world, surpassing China.

With the division of some states the rank of most populous states have changed. Table 7 shows the ten most populous states in the country by rank. It is seen that Uttar Pradesh comes first with about 199.581 million people, Maharashtra comes second with 112.372 million people and Bihar comes third with 103.804 million people. These ten states account for about 71 per cent of the total population of India *(8)*.

TABLE 7

Ranking of most populous states by population size 2011

Rank	State	Population 31.3.2011 (000)	Per cent to total population of India 31-3-2011
1.	Uttar Pradesh	199,581	16.49
2.	Maharashtra	112,372	9.29
3.	Bihar	103,804	8.58
4.	West Bengal	91,347	7.55
5.	Andhra Pradesh	84,665	7.00
6.	Madhya Pradesh	72,597	6.00
7.	Tamil Nadu	72,138	5.96
8.	Rajasthan	68,621	5.67
9.	Karnataka	61,130	5.05
10.	Gujarat	60,383	4.99

Source : *(8)*

It has been estimated that with current trends, the population in India will increase from 1.210 billion to 1.4 billion during the period 2011 to 2026, an increase of 13.57 per cent in twenty five years at the rate of 1.2 per cent annually. There is a substantial difference in total fertility rate in between and within states. At one end of spectrum are southern states like Kerala, Tamil Nadu, Karnataka and Andhra Pradesh with total fertility rate at or below replacement levels. At the other end are high fertility states like Uttar Pradesh, Chhattisgarh, Uttarakhand, Rajasthan, Jharkhand, Bihar, Madhya Pradesh and Orissa, with an estimated combined total fertility rate of 4.2 in 2000. The estimated year by which some high fertility states will reach replacement level of fertility if current trend continues is as follows *(9)* :

Uttar Pradesh	–	2027
Madhya Pradesh	–	2025
Chhattisgarh	–	2022
Uttarakhand	–	2022
Bihar	–	2021
Rajasthan	–	2021
Jharkhand	–	2018
India	–	2021

It is matter of concern that these states will delay the attainment of replacement level of fertility in India until 2021, with Uttar Pradesh projected to reach this level by 2027. These high fertility states are anticipated to contribute about 50 per cent to the nation-wide increase in population. Demographic outcomes in these states will determine the timing and size of population at which India achieves population stabilization.

Age and sex composition

The age–sex composition of India's population is as shown in Table 8. In the age group 0–14 years male population is about 1.4 per cent more than female, whereas in the age group 60+, percentage of female population is 0.8 per cent more than male population. The proportion of population in the age group 0–14 years is higher in rural areas (30.5 per cent) than in urban areas (25.2 per cent), for both male and female population *(10)*.

The proportion of population below 14 years of age is showing decline, whereas the proportion of elderly in the country is increasing. This trend is to continue in the time to come. The increase in the elderly population will impose a greater burden on the already outstretched health services in the country.

TABLE 8

Per cent distribution by age and sex, India (2012)

Age group	Population percentage		
	Total	Males	Females
0–4	9.7	9.9	9.4
5–9	9.1	9.3	8.9
10–14	10.3	10.6	10.1
15–19	9.9	10.3	9.6
20–24	10.2	9.9	10.5
25–29	8.8	8.8	8.9
30–34	7.8	7.8	7.8
35–39	6.8	6.7	6.9
40–44	6.2	6.2	6.2
45–49	5.2	5.1	5.2
50–54	4.1	4.3	3.9
55–59	3.6	3.2	4.0
60–64	3.0	3.0	3.0
65–69	2.2	2.1	2.3
70–74	1.5	1.4	1.6
75–79	0.9	0.8	1.0
80–84	0.4	0.4	0.5
85+	0.3	0.2	0.3
Total	100.0	100.0	100.0

Note : * Total may not add upto 100 due to rounding off.

Source : *(10)*

Age pyramids

The age structure of a population is best represented as shown in Fig.2.

Such a representation is called an "Age Pyramid". A vivid contrast may be seen in the age distribution of men and women in India and in Switzerland. The age pyramid of India is typical of developing countries, with a broad base and a tapering top. In the developed countries, as in Switzerland, the pyramid generally shows a bulge in the middle, and has a narrower base.

Sex ratio

Sex ratio is defined as "the number of females per 1000 males". One of the basic demographic characteristics of the population is the sex composition. In any study of population, analysis of the sex composition plays a vital role. The sex composition of the population is affected by the differentials in mortality conditions of males and females, sex selective migration and sex ratio at birth. "Female deficit syndrome" is considered adverse because of social implications. A low sex ratio indicates strong male–child preference and consequent gender inequities, neglect of the girl child resulting in higher mortality at younger age, female infanticide, female foeticide, higher maternal

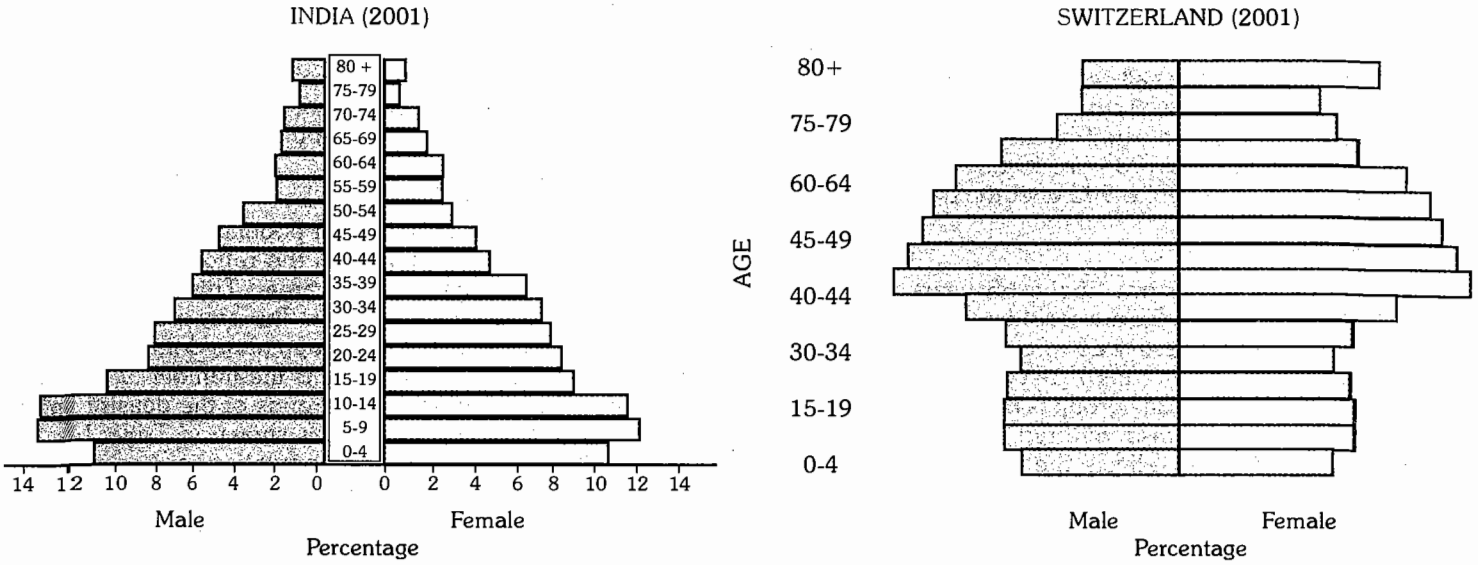

FIG. 2

Percentage distribution by age of the population of India and of the population of Switzerland.

mortality and male bias in enumeration of population. Easy availability of the sex determination tests and abortion services may also be proving to be catalyst in the process, which may be further stimulated by preconception sex selection facilities.

The trends in the sex ratio in the country from 1901 onwards are as shown in Table 9.

TABLE 9

Sex ratio in India

Year	Females per 1000 males
1901	972
1911	964
1921	955
1931	950
1941	945
1951	946
1961	941
1971	930
1981	934
1991	927
2001	933
2011	940

Source : *(8)*

The sex ratio in India has been generally adverse to women, i.e., the number of women per 1,000 men has generally been less than 1,000. Apart from being adverse to women, the sex ratio has also declined over the decades.

Sex ratio at birth : Sex ratio at birth can be affected by sex-selectivity at birth. The sex ratio at birth for India for the year 2011 has been estimated at 878. It varies from 871 in rural areas to 891 in urban areas. Among the bigger states, the sex ratio at birth varies from 1,084 in Kerala to 877 in Haryana. In the rural areas, the highest and lowest sex ratio at birth are in the states of Kerala (1077) and Haryana (880) respectively. The sex ratio in urban areas varies from 1,091 in Kerala to 871 in Haryana. Table 10 shows the variations of sex ratio at birth by residence in the bigger states of the country.

Source : *(8)*

Child sex ratio (0–6 years) : Census 2011 marks a considerable fall in child sex ratio in the age group of 0–6 years and has reached an all time low of 914 since 1961. The fall has been 13 points from 927 to 914 for the country during 2001 to 2011. In rural areas, the fall has been significant – 15 points from 934 to 919 and in urban areas it has been 4 points from 906 to 902 over the decade *(8)*.

Dependency ratio

The proportion of persons above 65 years of age and children below 15 years of age are considered to be dependant on the economically productive age group (15–64 years). The ratio of the combined age groups 0–14 years plus 65 years and above to the 15–65 years age group is referred to as the total dependency ratio. It is also referred to as the **societal dependency ratio** and reflects the need for a society to provide for their younger and older population groups. The dependency ratio can be subdivided into **young age dependency ratio** (0–14 years); and **old age dependency ratio** (65 years and more). These ratios are, however, relatively crude, since they do not take into consideration elderly or young persons who are employed or working age persons who are unemployed. It is given by the formula :

$$\text{Total dependency ratio} = \frac{\text{Children 0–14 years age + Population more than 65 years of age}}{\text{Population of 15 to 64 years}} \times 100$$

For India, the dependency ratio for the year 2005 is calculated as :

Population in 0–14 years age group – 374,143,000
Population above 65 years of age – 56,454,000
Population in 15–64 years age group – 703,805,000

$$\text{Total dependency ratio} = \frac{374143000 + 56454000}{703805000} \times 100$$

$$= 61.1 \text{ per cent}$$

The young age dependency ratio is 53.1 per cent, and old age dependency ratio is 8.02 per cent *(11)*. For the year 2010, the projected young age dependency ratio is 47.9 per cent and old age dependency ratio 7.7 per cent *(12)*.

For international comparison, the child, old and total dependency ratios are used to study the dependency burden of the population. The total dependency ratio tends to decrease in the earlier stages of development when rapid decline in fertility reduces the child population more than the increase in the older persons, but subsequently the increase in older persons far out-weighs the decline in the child population. There is a shift from child dependency to old age dependency, as fertility declines and life expectancy increases.

The rapid decline in dependency ratios, especially the child dependency ratio, has been identified to be a key factor underlying rapid economic development. The term *"demographic bonus"* connotes the period when the dependency ratio in a population declines because of decline in fertility, until it starts to rise again because of increasing longevity. This period depends on the pace of decline in fertility level of a population. If the switch to small families is fast, the demographic bonus can give a considerable push to development. If investment in health care and education for skill development are made during this period, maximum advantage is taken of the demographic transition with high economic growth rates *(11)*.

The term *"demographic burden"* is used to connote the increase in the total dependency ratio during any period of time, mostly caused by increased old age dependency ratio. This is an inevitable consequence of demographic transition, and the country has to face this problem sooner or later *(11)*.

Density of population

One of the important indices of population concentration is the density of population. It is the ratio between (total) population and surface (land) area. This ratio can be calculated for any territorial unit for any point in time, depending on the source of the population data *(11)*. In the Indian census, density is defined as the number of persons, living per square kilometre. The trends of the density in the country from 1901 onwards are as shown in Table 11. For the year 2014 the density of population per sq. km. in India was 394.

Urbanization

By definition, urban population is the number of persons residing in urban localities. The definition of urban locality varies from country to country. In Indian context, the urban areas are the "Towns (places with municipal corporation, municipal area committee, town committee, notified area committee or cantonment board); also, all places having 5,000 or more inhabitants, a density of not less than 1,000 persons per square mile or 390 per square kilometre, pronounced urban characteristics and at least three fourths of the adult male population employed in pursuits other than agriculture" *(11)*.

The population in India continues to be predominantly rural with agriculture as the main occupation for the majority of the people.

As per provisional population totals of Census – 2011, the rural population stands at 833.1 million (68.84 per cent) and urban population at 377.1 million (31.80 per cent), an increase of 3.35 per cent in urban population. In absolute numbers, rural population has increased by 90.47 million and urban population by 91.00 million in the last decade. Uttar Pradesh has the largest rural population of 155.11 million i.e. 18.62 per cent of country's rural population, whereas Maharashtra has the highest urban population of 50.83 million i.e. 13.48 per cent of the country's urban population. Fig. 3 indicates the level of urbanization in the country.

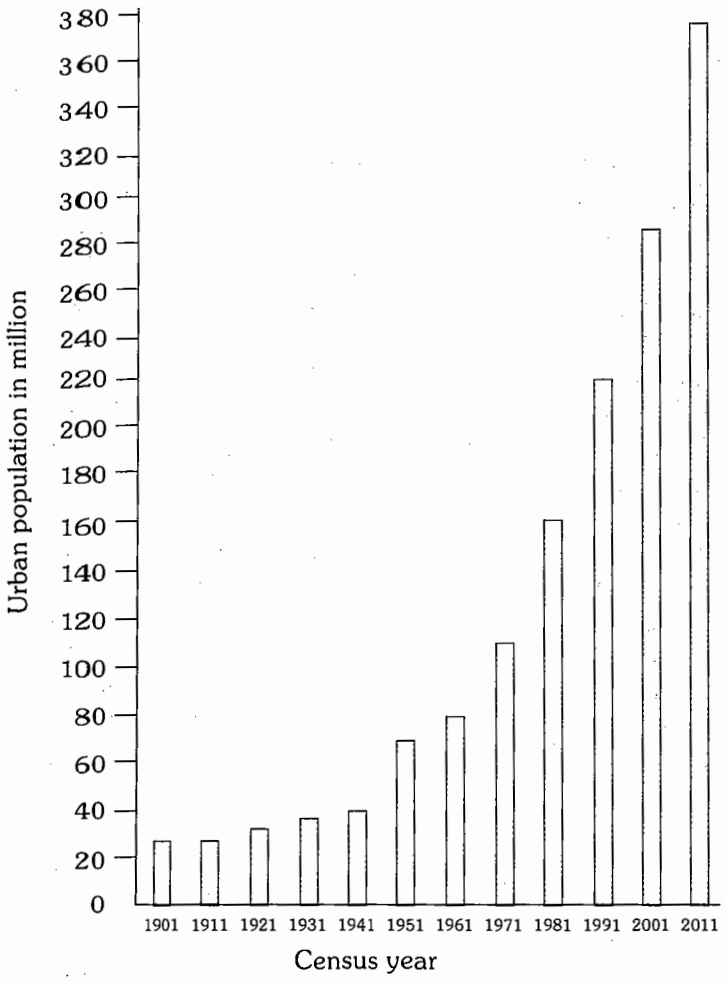

FIG. 3

INDIA – Growth of urban population 1901–2011

The increase in urban population has been attributed both to natural growth (through births) and migration from villages because of employment opportunities, attraction of better living conditions and availability of social services such as education, health, transport, entertainment etc. The continuous migration of people from country side to urban areas in India constitute a social crisis, the ramification of which may eventually impair the quality of life.

According to 2011 census, the urban-rural scenario in India is as follows *(8)* :

Administrative Units	Census 2001	Census 2011	Increase
No. of States/UTs	35	35	-
No. of Districts	593	640	47
No. of Sub-Districts	5,463	5,924	461
No. of Towns	5,161	7,935	2,774
No. of Statutory Towns	3,799	4,041	242
No. of Census Towns	1,362	3,894	2,532
No. of Villages	638,588	640,867	2,279

Family size

While in common parlance, family size refers to the total number of persons in a family, in demography, family size means the **total number of children** a woman has borne at a point in time *(13)*. The completed family size indicates the total number of children borne by a woman during her child-bearing age, which is generally assumed to be between 15 and 45 years. The **total fertility rate** gives the approximate magnitude of the completed family size.

The family size depends upon numerous factors, viz. duration of marriage, education of the couple, the number of live births and living children, preference of male children, desired family size, etc.

The question of family size is undoubtedly important from the demographic point of view. The family planning programme's campaign is currently based on the theme of a "two–child" family norm, with a view to reach the long-term demographic goal of NRR=1. Family planning involves both decision regarding the "desired family size" and the effective limitation of fertility once that size has been reached.

Table 12 shows the total fertility rates (completed family size) in India and selected countries. The decrease in family size does not appear to be due to any reduction in fertility; rather it appears to be due to the result of deliberate family planning.

TABLE 12

Total fertility rates in selected developed and developing countries : 1994 and 2012

Literacy and education

In 1948, the Declaration of Human Rights stated that everyone has a right to education. Yet, even today, this right is being denied to millions of children. Education is a crucial element in economic and social development. Without education, development can neither be broad based nor sustained. The benefits that accrue to a country by having a literate population are multidimensional. Spread of literacy is generally associated with modernization, urbanization, industrialization, communication and commerce. It forms an important input in the overall development of individuals enabling them to comprehend their social, political and cultural environment better, and respond to it appropriately. Higher levels of education and literacy lead to a greater awareness and also contribute to improvement of economic conditions, and is a pre-requisite for acquiring various skills and better use of health care facilities.

It was decided in 1991 census to use the term literacy rate for the population relating to seven years age and above. A person is deemed as literate if he or she can read and write with understanding in *any* language. A person who can merely read but cannot write is not considered literate. The same concept has been continued in census 2001 and 2011 also. The literacy rate taking in account the total population in the denominator has now been termed as *"crude literacy rate"*, while the literacy rate calculated taking into account the 7 years and above population in the denominator is called the effective literacy rate. The formula for computing crude literacy rate and effective literacy rate are as follows:

$$\text{Crude literacy rate} = \frac{\text{Number of literate persons} \times 100}{\text{Total population in a given year}}$$

$$\text{Effective literacy rate} = \frac{\text{Number of literate persons aged 7 and above} \times 100}{\text{Population aged 7 and above in a given year}}$$

A significant milestone reached in Census 2011 is that the total number of illiterates has come down from 304.1 million in 2001 to 272.9 million in 2011 showing a decline of 31.1 million. The reverse trend was noted during 1991–2001 period. The decadal increase in the number of literates among males is of 31.9 per cent points and the corresponding increase among females is of 49.1 per cent points *(8)*. These two changes are a clear indication that the gender gap in literacy is shrinking in the country. It will have far reaching consequence on the development of the society. Fig. 4 shows the literacy rates in India after independence.

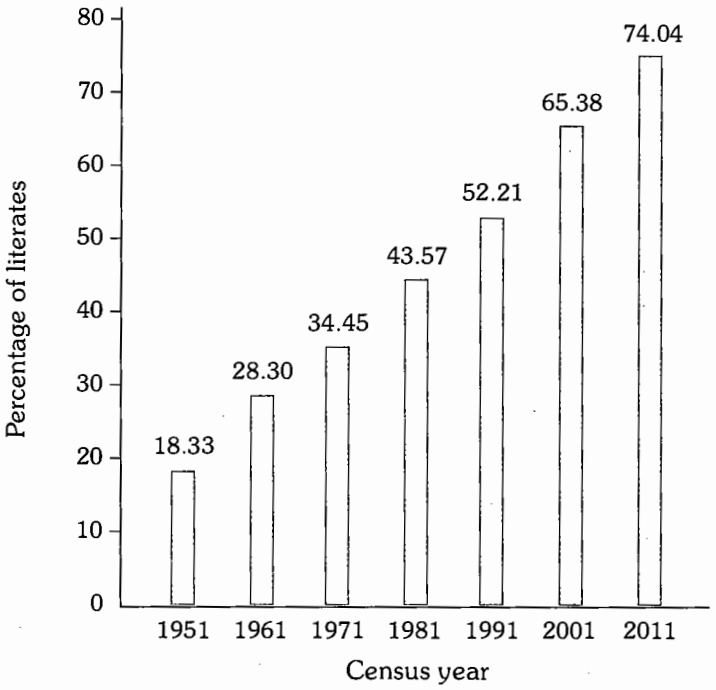

FIG. 4

Literacy rates in India 1951–2011

Source : *(15)*

The national average of literacy rate is misleading as wide variations exist between the states. Table 13 shows the literacy rates in different states in India. The national percentage of literates in the population above 7 years of age is about 74.04 with literate males about 82.14 per cent and females lagging behind with about 65.46 per cent.

Table 13 shows that Kerala continues to occupy the top rank in the country with about 93.91 per cent literates. Mizoram (91.58 per cent, and Lakshadweep (92.28 per cent) closely follow Kerala. On the other end is Bihar and Arunachal Pradesh with literacy rate of only 63.82 and 66.9 per cent respectively. The states which have literacy rates below the national average are Arunachal Pradesh, Andhra Pradesh, Bihar and Jharkhand, Jammu & Kashmir, Uttar Pradesh, Rajasthan and Odisha etc.

Source : *(8)*

Government of India has made education compulsory up to the age of 14 years in the country. Though considerable progress has been made in expanding primary education, a major concern is high drop out rates in the first few years of schooling *(2)*.

Life expectancy

Life expectancy – or expectation of life – at a given age is the average number of years which a person of that age may expect to live, according to the mortality pattern prevalent in that country. Demographers consider it as one of the best indicators of a country's level of development and of the overall health status of its population.

Life expectancy at birth has continued to increase

globally over the years. For 1950–1955, the combined life expectancy at birth for both sexes was 46.5 years. Five decades later by 2008, it was 69 years – an increase of 22.5 years. The increase has been more marked in less developed regions of the world than in the developed regions *(14)*.

Most countries in the world exhibit a sex differential in mortality favouring women – females live longer than males as shown in Table 14. Contrary to this biological expectation, the life expectancy of women in Nepal and Maldives is lower than that of men, while in Bangladesh and India it is almost equal.

Trends in life expectancy show that people are living longer, and they have a right to a long life in good health, rather than one of pain and disability. Health policy makers thus need to recognize this changing demographic pattern and plan for prevention and control of diseases associated with old age.

Tables 14 and 15 present life expectancy at birth in India and those in selected countries. Japan leads in life expectancy for both males and females,80 and 86 years respectively for the year 2014.

FERTILITY

By fertility is meant the actual bearing of children. Some demographers prefer to use the word natality in place of fertility. A woman's reproductive period is roughly from 15 to 45 years – a period of 30 years. A woman married at 15 and living till 45 with her husband is exposed to the risk of pregnancy for 30 years, and may give birth to 15 children, but this maximum is rarely achieved.

Fertility depends upon several factors. The higher fertility in India is attributed to universality of marriage, lower age at marriage, low level of literacy, poor level of living, limited use of contraceptives and traditional ways of life. National Family Health Survey–3 conducted in India during 2005–2006 provides some detailed information of fertility trends, as shown in Table 16.

TABLE 16

Source : *(17)*

Some of the factors which have engaged attention of demographers since long are discussed below.

1. Age at marriage

The age at which a female marries and enters the reproductive period of life has a great impact on her fertility. The Registrar General of India collected data on fertility on a national scale and found that females who marry before the age of 18 gave birth to a larger number of children than those who married after *(18)*. In India some demographers have estimated that if marriages were postponed from the age of 16 to 20–21, the number of births would decrease by 20–30 per cent *(18)*.

Early marriage is a long–established custom in India. As early as 1929, the Sarada Act was enacted forbidding the practice of child marriage. The census data reveals that prior to 1951, the average age at marriage for girls in India was 13 years. There is however, a gradual rise in the age at marriage in the country. The Child Marriage Restraint Act of 1978 raises the legal age at marriage from 15 to 18 years for girls, and from 18 to 21 years for boys. Studies indicate that in many States, the mean age at marriage for girls has already moved upto 20 years in 2006, and many others are very close to this. The national average for effective marriage is 21 years. The exceptions are the rural areas, where a substantial proportion of marriages continue to take place when the girl is around 16 years of age *(17)*.

2. Duration of married life

Studies indicate that 10–25 per cent of all births occur within 1–5 years of married life; 50–55 per cent of all births within 5–15 years of married life. Births after 25 years of married life are very few *(18)*. This suggests that family planning efforts should be concentrated in the first few years of married life in order to achieve tangible results.

3. Spacing of children

Studies have shown that when all births are postponed by one year, in each age group, there was a decline in total fertility. It follows that spacing of children may have a significant impact on the general reduction in the fertility rates.

4. Education

There is an inverse association between fertility and educational status. Education provides knowledge; increased exposure to information and media; builds skill for gainful employment; increases female participation in family decision making; and raises the opportunity costs of women's time. The National Family Health Survey–3 shows that the total fertility rate is 1.7 children higher for illiterate women than for women with at least a high school education (Table 16).

5. Economic status

Operational Research studies support the hypothesis that economic status bears an inverse relationship with fertility. The total number of children born declines with an increase in per capita expenditure of the household. The World Population Conference at Bucharest in fact stressed that economic development is the best contraceptive. It will take care of population growth and bring about reductions in fertility.

6. Caste and religion

Muslims have a higher fertility than Hindus. The National Family Health Survey–3 reported a total fertility rate of 3.09 among Muslims as compared to 2.65 among Hindus. The total fertility rate among Christians was found to be 2.35. Among Hindus, the lower castes seem to have a higher fertility rate than the higher castes *(17)*.

7. Nutrition

There appears to be some relationship between nutritional status and fertility levels. Virtually, all well-fed societies have low fertility, and poorly-fed societies high fertility. The effect of nutrition on fertility is largely indirect.

8. Family planning

Family planning is another important factor in fertility reduction. In a number of developing countries, family planning has been a key factor in declining fertility (Table 4). Family planning programmes can be initiated rapidly and require only limited resources, as compared to other factors.

9. Other factors

Fertility is affected by a number of physical, biological, social and cultural factors such as place of women in society, value of children in society, widow remarriage, breast-feeding, customs and beliefs, industrialization and urbanization, better health conditions, housing, opportunities for women and local community involvement. Attention to these factors requires long-term government programmes and vast sums of money.

FERTILITY–RELATED STATISTICS

Fertility may be measured by a number of indicators, as given below. Stillbirths, foetal deaths and abortions, however, are not included in the measurement of fertility in a population *(19)*.

1. Birth Rate

Birth rate is the simplest indicator of fertility and is defined as "the number of live births per 1000 estimated mid-year population, in a given year". It is given by the formula :

$$\text{Birth Rate} = \frac{\text{Number of live births during the year}}{\text{Estimated mid-year population}} \times 1000$$

The birth rate is an unsatisfactory measure of fertility because the total population is not exposed to child bearing. Therefore it does not give a true idea of the fertility of a population.

2. General Fertility Rate (GFR)

It is the "number of live births per 1000 women in the reproductive age-group (15–44 or 49 years) in a given year".

$$\text{GFR} = \frac{\text{Number of live births in an area during the year}}{\text{Mid-year female population age 15–44 (or 49) in the same area in same year}} \times 1000$$

General fertility rate is a better measure of fertility than the crude birth rate because the denominator is restricted to the number of women in the child–bearing age, rather than the whole population. The major weakness of this rate is that not all women in the denominator are exposed to the risk of childbirth.

3. General Marital Fertility Rate (GMFR)

It is the "number of live births per 1000 married women in the reproductive age group (15–44 or 49) in a given year".

$$\text{GMFR} = \frac{\text{Number of live births in a year}}{\text{Mid-year married female population in the age-group 15–49 years}} \times 1000$$

4. Age-specific Fertility Rate (ASFR)

A more precise measure of fertility is age-specific fertility rate, defined as the "number of live births in a year to 1000 women in any specified age-group". The age-specific fertility rates throw light on the fertility pattern. They are also sensitive indicators of family planning achievement.

$$\text{ASFR} = \frac{\text{Number of live births in a particular age group}}{\text{Mid-year female population of the same age-group}} \times 1000$$

5. Age-specific Marital Fertility Rate (ASMFR)

It is the number of live births in a year to 1000 married women in any specified age group.

$$\text{ASMFR} = \frac{\text{Number of live births in a particular age group}}{\text{Mid-year married female population of the same age group}} \times 1000$$

6. Total Fertility Rate (TFR)

Total fertility rate represents the average number of children a woman would have if she were to pass through her reproductive years bearing children at the same rates as the women now in each age group *(20)*. It is computed by summing the age-specific fertility rates for all ages; if 5–year age groups are used, the sum of the rates is multiplied by 5. This measure gives the approximate magnitude of "completed family size".

$$\text{TFR} = \frac{5 \times \sum_{15\text{-}19}^{45\text{-}49} \text{ASFR}}{1000}$$

7. Total Marital Fertility Rate (TMFR)

Average number of children that would be born to a married woman if she experiences the current fertility pattern throughout her reproductive span.

$$\text{TMFR} = \frac{5 \times \sum_{15\text{-}19}^{45\text{-}49} \text{ASMFR}}{1000}$$

8. Gross Reproduction Rate (GRR)

Average number of girls that would be born to a woman if she experiences the current fertility pattern throughout her reproductive span (15–44 or 49 years), assuming no mortality.

$$\text{GRR} = \frac{5 \times \sum_{15\text{-}19}^{45\text{-}49} \text{ASFR for female live births}}{1000}$$

9. Net Reproduction Rate (NRR)

Net Reproduction Rate (NRR) is defined as the number of daughters a newborn girl will bear during her lifetime assuming fixed age-specific fertility and mortality rates *(21)*.

NRR is a demographic indicator. NRR of 1 is equivalent to attaining approximately the 2–child norm. If the NRR is less than 1, then the reproductive performance of the population is said to be below replacement level.

10. Child-woman Ratio

It is the number of children 0–4 years of age per 1000 women of child-bearing age, usually defined as 15–44 or 49 years of age. This ratio is used where birth registration statistics either do not exist or are inadequate. It is estimated through data derived from censuses *(8)*.

11. Pregnancy Rate

It is the ratio of number of pregnancies in a year to married women in the ages 15–44 (or 49) years. The "number of pregnancies" includes all pregnancies, whether these had terminated as live births, stillbirths or abortions or had not yet terminated.

12. Abortion Rate

The annual number of all types of abortions, usually per 1000 women of child-bearing age (usually defined as age 15–44) *(22)*.

13. Abortion Ratio

This is calculated by dividing the number of abortions performed during a particular time period by the number of live births over the same period *(23)*.

14. Marriage Rate

It is the number of marriages in the year per 1000 population :

$$\text{Crude Marriage Rate} = \frac{\text{Number of marriages in the year}}{\text{Mid-year population}} \times 1000$$

Demographers consider this a very unsatisfactory rate, because the denominator is comprised primarily of population that is not eligible to marry. A more sensitive rate is the general marriage rate :

$$\text{General Marriage Rate} = \frac{\text{Number of marriages within one year}}{\text{Number of unmarried persons age 15–49 years}} \times 1000$$

This rate is more accurate when computed for women than for men because more men than women marry at the older ages *(8)*.

Fertility trends

Researches indicate that the level of fertility in India is beginning to decline. The crude birth rate which was about 49 per thousand population during 1901–11 has declined to about 25.0 per thousand population in 2002, and was 21.6 per thousand population in 2012. The rural urban differential has narrowed. However, the crude birth rate has continued to be higher in rural areas as compared to urban areas in the last 3 decades.

The total fertility rate has declined from 3.6 in 1991 to 2.4 in 2012. The TFR in rural areas has declined from 5.4 in 1971 to 2.6 in 2012, whereas the corresponding decline in urban areas has been from 4.1 to 1.8 during the same period. There are considerable inter-state variations in total fertility rate as shown in Fig. 5. In bigger states it varies from 1.8 in Kerala to 3.3 in Uttar Pradesh and Bihar *(10)*.

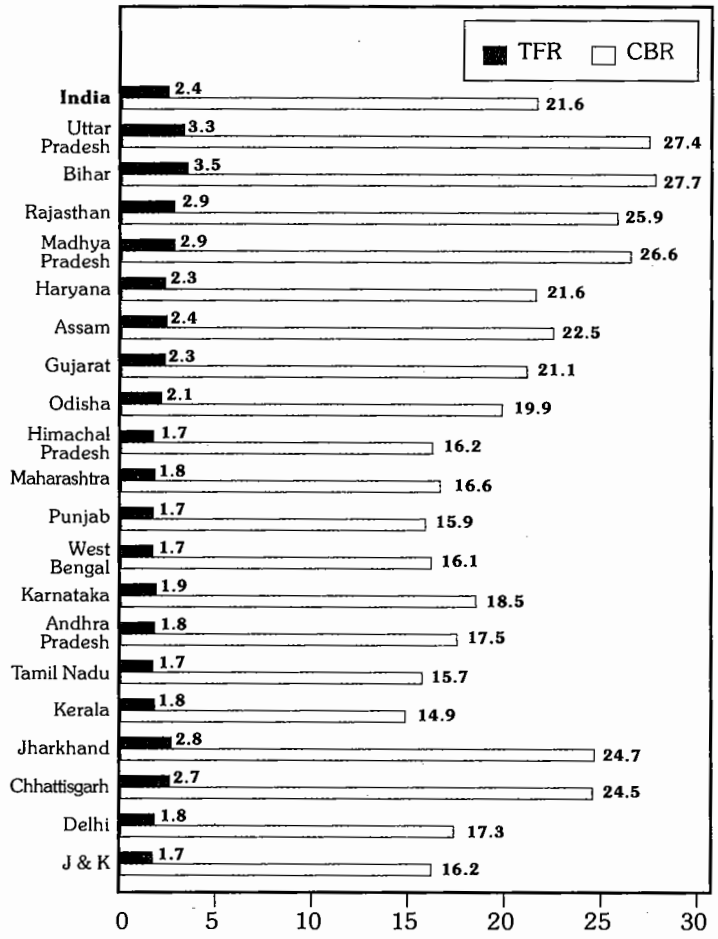

FIG. 5

Crude birth rate (2012) and Total fertility rate (2012) for major states

Source : *(10)*

Recent estimates of the fertility indicators and age-specific fertility rates in India are given in Table 17.

TABLE 17

Fertility indicators of India, 2012

Indicator	Age group	Total	Rural	Urban
Age-specific fertility rate	15–19	31.5	36.3	16.7
	20–24	191.9	210.6	140.4
	25–29	154.6	164.8	131.4
	30–34	64.5	68.3	55.6
	35–39	23.9	27.5	15.4
	40–44	8.2	10.1	3.7
	45–49	2.2	2.8	0.8
Age-specific marital fertility rate	15–19	268.2	273.8	235.3
	20–24	322.0	329.0	296.2
	25–29	180.9	187.2	165.0
	30–34	69.4	72.9	60.9
	35–39	25.8	29.4	16.7
	40–44	9.1	11.2	4.1
	45–49	2.5	3.2	0.9
Crude birth rate		21.6	23.1	17.4
General fertility rate		80.3	87.6	61.5
Total fertility rate		2.4	2.6	1.8
Gross reproduction rate		1.1	1.2	0.8
General marital fertility rate		114.9	122.9	90.2
Total marital fertility rate		4.4	4.5	3.9

Birth and death rates

The birth and death rates are important components of population growth. The birth and death rates in India are shown in Table 18. A look at Table 18 shows that whereas the death rate has considerably declined from 27.4 in 1951 to an estimated 7.0 per thousand population in 2012, the birth rate has declined niggardly from 39.9 in 1951 to an estimated 21.6 per thousand in 2012.

The Fifth Five Year (1974–79) Plan's objective was to reduce the birth rate from 35 per thousand at the beginning of the Plan to 30 per thousand by 1978–79. During 1979–84, the birth rate was stagnating around 33 per thousand with no obvious decline. During 1990, however, the birth rate showed a slight decline, to an estimated 30.2, further declining to 26.4 by the year 1998. The current picture indicates that birth and death rates are both declining in India.

TABLE 18

Birth and death rates in India

Year	Birth rate	Death rate
1941–1950	39.9	27.4
1951–1960	41.7	22.8
1961–1970	41.2	19.0
1971–1980	37.2	15.0
1981	33.9	12.5
1991	29.5	9.8
1995	28.3	9.0
1998	26.8	9.0
1999	26.1	8.7
2002	25.0	8.1
2004	24.1	7.5
2006	23.5	7.5
2008	22.8	7.4
2010	22.1	7.2
2012	21.6	7.0

Source : *(10)*

HIGH BIRTH RATE : India like other developing countries is faced with the dilemma of a high birth rate and a declining death rate. This is a vicious circle, not easy to break. The causes of high birth rate are :- (1) *Universality of marriage* : Marriages are universal and sacramental. Everyone, sooner or later (usually sooner) gets married and participates in reproduction. The individual's economic security or emotional maturity are seldom a pre-requisite to marriage. (2) *Early marriage* : Marriages are performed early. Data indicate that about 60 per cent of the girls aged 15–19 years are already married. (3) *Early puberty* : Indian girls attain puberty early, between 12 and 14 years. (4) *Low standard of living* : Where standards of living are low, birth rates are high. (5) *Low level of literacy* : The 2011 census showed that only 74.04 per cent of the population was literate. The female literacy is still lower, especially in the rural areas. (6) *Traditional customs and habits* : Customs dictate that every woman must marry and every man must have a son. Children are considered a gift of God and their birth should not be obstructed. (7) *Absence of family planning habit* : Family planning is of recent origin. It has not yet become part of the marital mores of the people.

DECLINING DEATH RATE : The declining death rate has been attributed to : (1) absence of natural checks, e.g., famines and large scale epidemics, (2) mass control of diseases, e.g., smallpox, plague, cholera, malaria etc., (3) advances in medical science, e.g., extensive use of

chemotherapeutics, antibiotics, and insecticides, (4) better health facilities, e.g., establishment of primary health centres and more treatment centres, (5) impact of national health programmes, (6) improvements in food supply, (7) international aid in several directions, and (8) development of social consciousness among the masses.

Demographers opine that further rapid decline in India's death rate may not continue in future. The reason is that most of the "easy" conquest of mortality has been accomplished through the widespread use of vaccines, antibiotics, insecticides, and other life-saving measures. The tasks that remain now are the most difficult ones such as improvements in environmental sanitation and nutrition; and control of non-communicable and genetic diseases.

Growth rate

The population growth rates in India are presented in Table 6. Prior to 1921, the population of India grew at a slow rate. This was due to the operation of natural checks (e.g., famines and epidemics) which took a heavy toll of human life. After 1921, the "great divide", the occurrence of famines and epidemics was effectively controlled through better nutrition and improved health care services, with the result that the death rate declined more steeply than the birth rate. Consequently, there was a net gain in births over deaths, leading to rapid growth in population, which rose from 1.25 per cent in 1951 to 1.96 in 1961, 2.20 in 1971, 2.22 in 1981, 2.14 in 1991, 1.93 in 2001 and 1.64 in 2011 (Table 6).

India is now the second most populous country in the world, adding 17.5 million every year to her 1210 million at the time of 2011 census. However, the most recent data indicates a decline in India's population growth rate.

The national health goal was to attain a birth rate of 21 and a death rate of 9 per thousand by 2007. This would yield an annual growth rate of 1.2 per cent, which was considered essential for the stabilization of population of India over the next 50 years or so.

FAMILY PLANNING

Definition

There are several definitions of family planning. An Expert Committee (1971) of the WHO defined family planning as "a way of thinking and living that is adopted voluntarily, upon the basis of knowledge, attitudes and responsible decisions by individuals and couples, in order to promote the health and welfare of the family group and thus contribute effectively to the social development of a country" *(25)*.

Another Expert Committee *(26)* defined and described family planning as follows : "Family planning refers to practices that help individuals or couples to attain certain objectives :

(a) to avoid unwanted births
(b) to bring about wanted births
(c) to regulate the intervals between pregnancies
(d) to control the time at which births occur in relation to the ages of the parent; and
(e) to determine the number of children in the family.

Basic human rights

The United Nations Conference on Human Rights at Teheran in 1968 recognized family planning as a basic human right. The Bucharest Conference *(27)* on the World Population held in August 1974 endorsed the same view and stated in its 'Plan of Action' that "all couples and individuals have the basic human right to decide freely and responsibly the number and spacing of their children and to have the information, education, and means to do so". The World Conference of the International Women's Year in 1975 also declared "the right of women to decide freely and responsibly on the number and spacing of their children and to have access to the information and means to enable them to exercise that right" *(28)*. Thus during the past few decades, family planning has emerged from whispers in private quarters to the focus of international concern as a basic human right, and a component of family health and social welfare.

Scope of family planning services

Family planning is not synonymous with birth control; it is more than mere birth control. A WHO Expert Committee (1970) has stated that family planning includes in its purview:- (1) the proper spacing and limitation of births, (2) advice on sterility, (3) education for parenthood, (4) sex education, (5) screening for pathological conditions related to the reproductive system (e.g., cervical cancer), (6) genetic counselling, (7) premarital consultation and examination, (8) carrying out pregnancy tests, (9) marriage counselling, (10) the preparation of couples for the arrival of their first child, (11) providing services for unmarried mothers, (12) teaching home economics and nutrition, and (13) providing adoption services *(29)*. These activities vary from country to country according to national objectives and policies with regard to family planning. This is the modern concept of family planning.

Health aspects of family planning *(29, 30, 31)*

Family planning and health have a two-way relationship. The principal health outcomes of family planning were listed and discussed by a WHO Scientific Group on the Health Aspects of Family Planning *(29)*. These can be summarized under the following headings.

Women's health

maternal mortality, morbidity of women of child–bearing age, nutritional status (weight changes, haemoglobin level, etc.) preventable complications of pregnancy and abortion.

Foetal health

foetal mortality (early and late foetal death); abnormal development.

Infant and child health

neonatal, infant and pre-school mortality, health of the infant at birth (birth weight), vulnerability to diseases.

(a) WOMEN'S HEALTH : Pregnancy can mean serious problems for many women. It may damage the mother's health or even endanger her life. In developing countries, the risk of dying as a result of pregnancy is much greater than in developed countries. The risk increases as the mother grows older and after she has had 3 or 4 children. Family planning by intervening in the reproductive cycle of women, helps them to control the number, interval and timing of pregnancies and births, and thereby reduces maternal mortality and morbidity and improves health. The health impact of family planning occurs primarily through : (i) the avoidance of unwanted pregnancies; (ii) limiting the number of births and proper spacing, and (iii) timing the

births, particularly the first and last, in relation to the age of the mother. It is estimated that guaranteeing access to family planning alone could reduce the number of maternal deaths by 25 per cent, and child mortality by 20 per cent *(11)*.

(i) *Unwanted pregnancies* : The essential aim of family planning is to prevent the unwanted pregnancies. An unwanted pregnancy may lead to an induced abortion. From the point of view of health, abortion outside the medical setting (criminal abortion) is one of the most dangerous consequence of unwanted pregnancy. Particular mention must be made of the unmarried mother who faces significantly higher health risks. There is also evidence of higher incidence of mental disturbances among mothers who have had unwanted pregnancies.

(ii) *Limiting the number of births and proper spacing* : Repeated pregnancies increase the risk of maternal mortality and morbidity. These risks rise with each pregnancy beyond the third, and increase significantly with each pregnancy beyond the fifth. The incidence of rupture of the uterus and uterine atony increases with parity as does the incidence of toxaemia, eclampsia and placenta previa. Anaemia is a common problem in mothers with many children and the rate of stillbirths tends to increase significantly with high parity. The somatic consequences of repeated pregnancies may also be exemplified in the clear association between the incidence of cancer of the cervix and high parity. Family planning is the only way to limit the size and control the interval between births with a view to improving the health of the mother.

(iii) *Timing of births* : Generally mothers face greater risk of dying below the age of 20 and above the age of 30–35. In many countries, complications of pregnancy and delivery show the same pattern of risk, with the highest rate below 20 and over 35 years of age.

(b) FOETAL HEALTH : A number of congenital anomalies (e.g., Down's syndrome) are associated with advancing maternal age. Such congenital anomalies can be avoided by timing the births in relation to the mother's age. Further, the "quality" of population can be improved only by avoiding completely unwanted births. In the present state of our knowledge, it is very difficult to weigh the overall genetic effects of family planning.

(c) CHILD HEALTH : Issues relating to family planning are highly relevant to paediatrics. It would seem that family size and birth spacing, if practised by all, will yield substantial child health benefits. These are : (a) *Child mortality* : It is well known that child mortality increases when pregnancies occur in rapid succession. A birth interval of 2 to 3 years is considered desirable to reduce child mortality. Family planning is, therefore, an important means of ensuring the survival of all children in a family. (b) *Child growth, development and nutrition* : Birth spacing and family size are important factors in child growth and development. The child is likely to receive his full share of love and care, including nutrition he needs, when the family size is small and births are properly spaced. Family planning, in other words, is effective prevention against malnutrition. (c) *Infectious diseases* : Children living in large-sized families have an increase in infection, especially infectious gastroenteritis, respiratory and skin infections.

The welfare concept

Family planning is associated with numerous misconceptions – one of them is its strong association in the minds of people with sterilization. Others equate it with birth control. The recognition of its welfare concept came only a decade and half after its inception, when it was named Family Welfare Programme.

The concept of welfare is very comprehensive and is basically related to quality of life. The Family Welfare Programme aims at achieving a higher end – that is, to improve the quality of life of the people.

Small-family norm

Small differences in the family size will make big differences in the birth rate. The difference of only one child per family over a decade will have a tremendous impact on the population growth.

The objective of the Family Welfare Programme in India is that people should adopt the "small family norm" to stabilize the country's population at the level of some 1,533 million by the year 2050 AD. Symbolized by the inverted red triangle, the programme initially adopted the model of the 3–child family. In the 1970s, the slogan was the famous *Do Ya Teen Bas*. In view of the seriousness of the situation, the 1980s campaign has advocated the 2–child norm. The current emphasis is on three themes : "Sons or Daughters – two will do"; "Second child after 3 years", and "Universal Immunization".

A significant achievement of the Family Welfare Programme in India has been the decline in the fertility rate from 6.4 in the 1950s to 2.4 in 2012. The national target was to achieve a Net Reproduction Rate of '1' by the year 2006, which is equivalent to attaining approximately the 2–child norm. All efforts are being made through mass communication that the concept of small family norm is accepted, adopted and woven into lifestyle of the people.

Eligible couples

An "eligible couple" refers to a currently married couple wherein the wife is in the reproductive age, which is generally assumed to lie between the ages of 15 and 45. There will be at least 150 to 180 such couples per 1000 population in India. These couples are in need of family planning services. About 20 per cent of eligible couples are found in the age group 15–24 years *(32)*. On an average 2.5 million couples are joining the reproductive group every year. The "Eligible Couple Register" is a basic document for organizing family planning work. It is regularly updated by each functionary of the family planning programme for the area falling within his jurisdiction.

The scenario in India as on March, 2010 is as shown in Fig. 6.

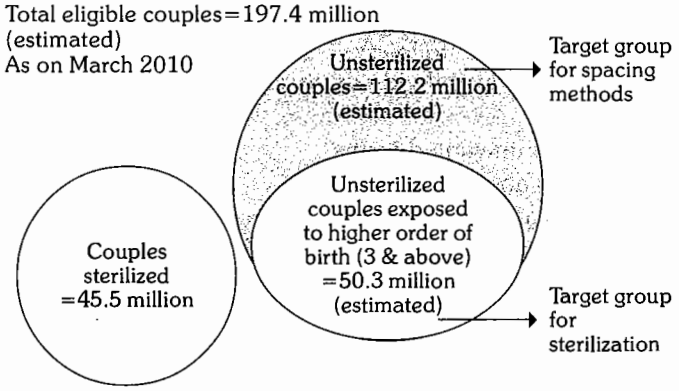

FIG. 6

Estimated eligible couples and target couples in India.

Source : *(24)*

Target couples

In order to pin-point the couples who are a priority group within the broad definition of "eligible couples", the term "target couple" was coined. Hitherto, the term target couple was applied to couples who have had 2–3 living children, and family planning was largely directed to such couples. The definition of a target couple has been gradually enlarged to include families with one child or even newly married couples *(34)* with a view to develop acceptance of the idea of family planning from the earliest possible stage. In effect, the term target couple has lost its original meaning. The term eligible couple is now more widely used and has come to stay.

Couple protection rate (CPR)

Couple protection rate (CPR) is an indicator of the prevalence of contraceptive practice in the community. It is defined as the per cent of eligible couples effectively protected against childbirth by one or the other approved methods of family planning, viz. sterilization, IUD, condom or oral pills. Sterilization accounts for over 60 per cent of effectively protected couples *(32)*. Demographers are of the view that the demographic goal of NRR=1 can be achieved only if the CPR exceeds 60 per cent.

Couple protection rate is based on the observation that 50 to 60 per cent of births in a year are of birth order 3 or more. Thus attaining a 60 per cent CPR will be equivalent to cutting off almost all third or higher order births, leaving 2 or less surviving children per couple *(33)*. Therefore, the previous National Population Policy was to attain a CPR of 42 per cent by 1990 (end of Seventh Five Year Plan), and 60 per cent by the year 2000. In short CPR is a dominant factor in the reduction of net reproduction rate.

During 2012–2013, the total number of family planning acceptors by different methods was as follows *(34A)*.

Sterilization	....	4.57	million
Vasectomy	....	0.12	million
Tubectomy	....	4.45	million
IUD insertion	....	5.41	million
Condom users	....	13.96	million
Oral pill users	....	6.2	million

However about 60 per cent eligible couples are still unprotected against conception.

During the year 2011, 40 per cent of eligible couples in the reproductive age group 15–44 years were effectively protected against conception by one or the other family planning method.

A state-wise break-up of the figures reported indicates that while some states notably Punjab, Gujarat, Maharashtra, Karnataka, Haryana and Tamil Nadu etc. are forging ahead to cover more than half of their fertility level population by contraception, the other states like Bihar, Uttar Pradesh, Assam, Rajasthan, West Bengal, Jammu and Kashmir etc. are lagging behind with low contraceptive acceptance levels.

NATIONAL POPULATION POLICY 2000

Population policy in general refers to policies intended to decrease the birth rate or growth rate. Statement of goals, objectives and targets are inherent in the population policy.

In April 1976 India formed its first – "National Population Policy". It called for an increase in the legal minimum age of marriage from 15 to 18 for females, and from 18 to 21 years for males. However, for the most part, the 1976 statement became irrelevant and the policy was modified in 1977. New policy statement reiterated the importance of the small family norm without compulsion and changed the programme title to "family welfare programme". The National Health Policy approved by the parliament in 1983 had set the long-term demographic goals of achieving a Net Reproductive Rate (NRR) of one by the year 2000 (which was not achieved).

"National Population Policy 2000" is the latest in this series. It reaffirms the commitment of the government towards target free approach in administering family planning services. It gives informed choice to the people to voluntarily avail the reproductive health care services.

The new NPP 2000 is more than just a matter of fertility and mortality rates. It deals with women education; empowering women for improved health and nutrition; child survival and health; the unmet needs for family welfare services; health care for the under-served population groups like urban slums, tribal community, hill area population and displaced and migrant population; adolescent's health and education; increased participation of men in planned parenthood; and collaboration with NGOs.

The objective of NPP 2000 is to bring the TFR to replacement level by 2010. The long term objective is to achieve requirements of suitable economic growth, social development and environment protection.

The National Socio-Demographic Goals to be achieved by the year 2010 were as follows *(35)*:

(1) Address the unmet needs for basic reproductive and child health services, supplies and infrastructure.

(2) Make school education upto the age 14 free and compulsory, and reduce drop-outs at primary and secondary school levels to below 20 per cent for both boys and girls.

(3) Reduce infant mortality rate to below 30 per 1000 live births.

(4) Reduce maternal mortality ratio to below 100 per 100,000 live births.

(5) Achieve universal immunization of children against all vaccine preventable diseases.

(6) Promote delayed marriage for girls, not earlier than age 18 and preferably after 20 years of age.

(7) Achieve 80 per cent institutional deliveries and 100 per cent deliveries by trained persons.

(8) Achieve universal access to information/counselling, and services for fertility regulation and contraception with a wide basket of choices.

(9) Achieve 100 per cent registration of births, deaths, marriage and pregnancy.

(10) Contain the spread of Acquired Immunodeficiency Syndrome (AIDS), and promote greater integration between the management of reproductive tract infections (RTI) and sexually transmitted infections (STI) and the National AIDS Control Organization.

(11) Prevent and control communicable diseases.

(12) Integrate Indian Systems of Medicine (ISM) in the provision of reproductive and child health services, and in reaching out to households.

(13) Promote vigorously the small family norm to achieve replacement levels of TFR.

(14) Bring about convergence in implementation of related social sector programmes so that family welfare becomes a people centred programme.

If the NPP 2000 was fully implemented, it was anticipated that in the year 2010 the population may be 1107 million instead of 1162 million projected by the Technical Group of Population Projections. However, the provisional population (1210 million) in 2011 is higher by about 110 million compared to the target set for the year 2010. Efforts at population stabilization will be effective only if an integrated package of essential services is directed at village and household levels. Inadequacies in the existing health infrastructure have led to a unmet need of 28 per cent of contraception services and obvious gap in coverage and outreach. The NPP 2000 is to be largely implemented and managed at panchayat and nagar palika levels in coordination with the concerned state/UT administration.

CONTRACEPTIVE METHODS

(Fertility Regulating Methods)

Contraceptive methods are, by definition, preventive methods to help women avoid unwanted pregnancies. They include all temporary and permanent measures to prevent pregnancy resulting from coitus.

The last few years have witnessed a contraceptive revolution, that is, man trying to interfere with the ovulation cycle.

It is now generally recognized that there can never be an ideal contraceptive – that is, contraceptive that is safe, effective, acceptable, inexpensive, reversible, simple to administer, independent of coitus, long-lasting enough to obviate frequent administration and requiring little or no medical supervision. Further, a method which may be quite suitable for one group may be unsuitable for another because of different cultural patterns, religious beliefs and socio-economic milieu. As there is no single method likely to meet the social, cultural, aesthetic and service needs of all individuals and communities, the search for an "ideal contraceptive" has been given up. The present approach in family planning programmes is to provide a "cafeteria choice" that is to offer all methods from which an individual can choose according to his needs and wishes and to promote family planning as a way of life.

The term conventional contraceptives is used to denote those methods that require action at the time of sexual intercourse, e.g., condoms, spermicides, etc. Each contraceptive method has its unique advantages and disadvantages. The success of any contraceptive method depends not only on its effectiveness in preventing pregnancy but on the rate of continuation of its proper use.

The contraceptive methods may be broadly grouped into two classes – spacing methods and terminal methods, as shown below :

I. Spacing methods

1. Barrier methods
   (a) Physical methods
   (b) Chemical methods
   (c) Combined methods
2. Intra-uterine devices
3. Hormonal methods
4. Post-conceptional methods
5. Miscellaneous.

II. Terminal methods

1 Male sterilization

2 Female sterilization.

BARRIER METHODS

A variety of barrier or "occlusive" methods, suitable for both men and women are available. The aim of these methods is to prevent live sperm from meeting the ovum. Barrier methods have increased in popularity quite recently because of certain contraceptive and non-contraceptive advantages. The main contraceptive advantage is the absence of side-effects associated with the "pill" and IUD. The non-contraceptive advantages include some protection from sexually transmitted diseases, a reduction in the incidence of pelvic inflammatory disease and possibly some protection from the risk of cervical cancer *(36)*. Barrier methods require a high degree of motivation on the part of the user. In general they are less effective than either the pill or the loop. They are only effective if they are used consistently and carefully.

a. PHYSICAL METHODS

1. Condom *(37, 38)*

Condom is the most widely known and used barrier device by the males around the world. In India, it is better known by its trade name NIRODH, a sanskrit word, meaning prevention. Condom is receiving new attention today as an effective, simple "spacing" method of contraception, without side effects. In addition to preventing pregnancy, condom protects both men and women from sexually transmitted diseases.

The condom is fitted on the erect penis before intercourse. The air must be expelled from the teat end to make room for the ejaculate. The condom must be held carefully when withdrawing it from the vagina to avoid spilling seminal fluid into the vagina after intercourse. A new condom should be used for each sexual act.

Condom prevents the semen from being deposited in vagina. The effectiveness of a condom may be increased by using it in conjunction with a spermicidal jelly inserted into the vagina before intercourse. The spermicide serves as additional protection in the unlikely event that the condom should slip off or tear.

Condoms can be a highly effective method of contraception, if they are used correctly at every coitus. Failure rates for the condom vary enormously. Surveys have reported pregnancy rates varying from 2–3 per 100 women–years to more than 14 in typical users *(39)*. Most failures are due to incorrect use.

The ADVANTAGES of condom are : (a) they are easily available (b) safe and inexpensive (c) easy to use; do not require medical supervision (d) no side effects (e) light, compact and disposable, and (f) provides protection not only against pregnancy but also against STD. The

DISADVANTAGES are : (a) it may slip off or tear during coitus due to incorrect use, and (b) interferes with sex sensation locally about which some complain while others get used to it. The main limitation of condoms is that many men do not use them regularly or carefully, even when the risk of unwanted pregnancy or sexually transmitted disease is high.

Condoms are manufactured in India by the Hindusthan Latex in Trivandrum, London Rubber Industries in Chennai and others. Besides commercial outlets, condoms are supplied under social marketing programme.

Female condom

The female condom is a pouch made of polyurethane, which lines the vagina. An internal ring in the close end of the pouch covers the cervix and an external ring remains outside the vagina. It is prelubricated with silicon, and a spermicide need not be used. It is an effective barrier to STD infection. However, high cost and acceptability are major problems. The failure rates during the first year use vary from 5 per 100 women-years pregnancy rate to about 21 in typical users *(40)*.

2. Diaphragm

The diaphragm is a vaginal barrier. It was invented by a German physician in 1882. Also known as "Dutch cap", the diaphragm is a shallow cup made of synthetic rubber or plastic material. It ranges in diameter from 5–10 cm (2–4 inches). It has a flexible rim made of spring or metal. It is important that a woman be fitted with a diaphragm of the proper size. It is held in position partly by the spring tension and partly by the vaginal muscle tone. This means, for successful use, the vaginal tone must be reasonable. Otherwise, in the case of a severe degree of cystocele, the rim may slip down.

The diaphragm is inserted before sexual intercourse and must remain in place for not less than 6 hours after sexual intercourse. A spermicidal jelly is always used along with the diaphragm. The diaphragm holds the spermicide over the cervix. Side-effects are practically nil. Failure rate for the diaphragm with spermicide vary between 6 to 12 per 100 women–years *(39)*.

ADVANTAGES : The primary advantage of the diaphragm is the almost total absence of risks and medical contraindications. DISADVANTAGES : Initially a physician or other trained person will be needed to demonstrate the technique of inserting the diaphragm into the vagina and to ensure a proper fit. After delivery, it can be used only after involution of the uterus is completed. Practice at insertion, privacy for this to be carried out and facilities for washing and storing the diaphragm precludes its use in most Indian families, particularly in the rural areas. Therefore, the extent of its use has never been great.

If the diaphragm is left in the vagina for an extended period, there is a remote possibility of a toxic shock syndrome, which is a state of peripheral shock requiring resuscitation *(41)*.

Variations of the diaphragm include the cervical cap, vault cap and the vimule cap. These devices are not recommended in the National Family Welfare Programme.

3. Vaginal sponge

Another barrier device employed for hundreds of years is the sponge soaked in vinegar or olive oil, but it is only recently one has been commercially marketed in USA under the trade name **TODAY** for the sole purpose of preventing conception. It is a small polyurethane foam sponge measuring 5 cm × 2.5 cm, saturated with the spermicide, nonoxynol–9. The sponge is far less effective than the diaphragm, but it is better than nothing *(42)*. The failure rate in parous women is between 20 to 40 per 100 women-years and in nulliparous women about 9 to 20 per 100 women-years *(40)*.

b. CHEMICAL METHODS

In the 1960s, before the advent of IUDs and oral contraceptives, spermicides (vaginal chemical contraceptives) were used widely. They comprise four categories *(43)*:

a) Foams : foam tablets, foam aerosols
b) Creams, jellies and pastes – squeezed from a tube
c) Suppositories – inserted manually, and
d) Soluble films – C–film inserted manually.

The spermicides contain a base into which a spermicide is incorporated. The commonly used modern spermicides are "surface-active agents" which attach themselves to spermatozoa and inhibit oxygen uptake and kill sperms *(44)*.

The main drawbacks of spermicides are : (a) they have a high failure rate (b) they must be used almost immediately before intercourse and repeated before each sex act (c) they must be introduced into those regions of the vagina where sperms are likely to be deposited, and (d) they may cause mild burning or irritation, besides messiness. The spermicide should be free from potential systemic toxicity. It should not have an inflammatory or carcinogenic effect on the vaginal skin or cervix. No spermicide which is safe to use has yet been found to be really effective in preventing pregnancy when used alone *(44)*. Therefore, spermicides are not recommended by professional advisers. They are best used in conjunction with barrier methods. Recently there has been some concern about possible teratogenic effects on foetuses, following their use. However, this risk is yet to be confirmed *(41)*.

INTRA-UTERINE DEVICES

Types of IUD

There are two basic types of IUD : **non-medicated** and **medicated**. Both are usually made of polyethylene or other polymers; in addition, the medicated or bioactive IUDs release either metal ions (copper) or hormones (progestogens).

The non-medicated or inert IUDs are often referred to as **first generation IUDs**. The copper IUDs comprise the **second** and the hormone–releasing IUDs the **third** generation IUDs. The medicated IUDs were developed to reduce the incidence of side-effects and to increase the contraceptive effectiveness. However, they are more expensive and must be changed after a certain time to maintain their effectiveness *(45)*. Fig. 7 shows different types of IUDs currently in use. In India, under the National Family Welfare Programme, Cu–T–200 B is being used. From the year 2002, Cu–T–380 A has been introduced in the programme *(46)*.

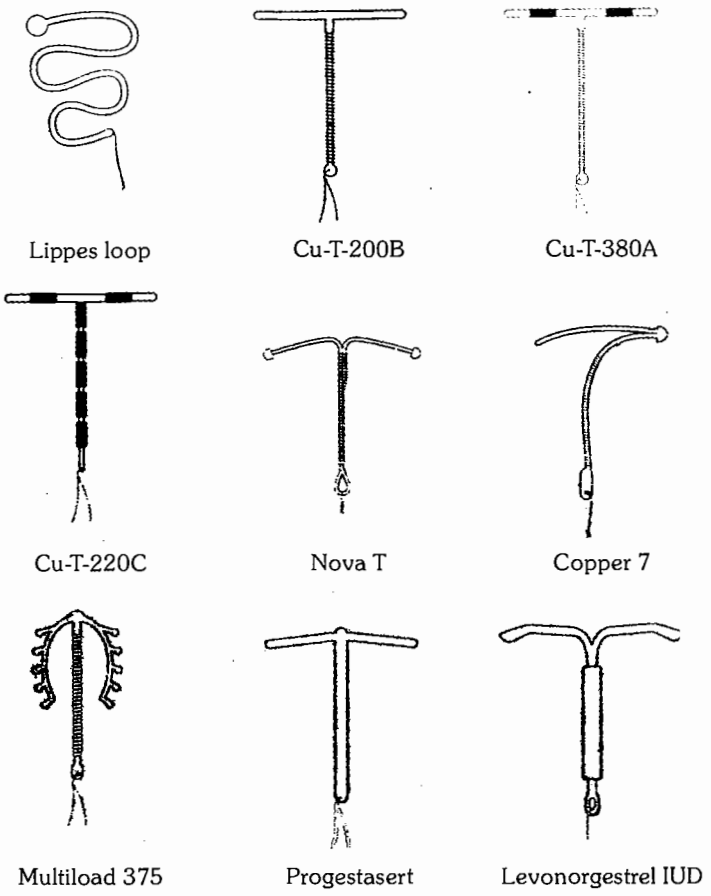

FIG. 7
Types of IUDs currently in use

FIRST GENERATION IUDs

The first generation IUDs comprise the inert or non-medicated devices, usually made of polyethylene, or other polymers. They appeared in different shapes and sizes – loops, spirals, coils, rings, and bows. Of all the models, the Lippes Loop is the best known and commonly used device in the developing countries.

Lippes Loop

Lippes Loop is double–S shaped device made of polyethylene, a plastic material that is non-toxic, non-tissue reactive and extremely durable. It contains a small amount of barium sulphate to allow X-ray observation. The Loop has attached threads or "tail" made of fine nylon, which project into the vagina after insertion. The tail can be easily felt and is a reassurance to the user that the Loop is in its place. The tail also makes it easy to remove the Loop when desired.

The Lippes Loop exists in four sizes A,B,C, and D, the latter being the largest. A larger sized device usually has a greater anti-fertility effect and a lower expulsion rate but a higher removal rate because of side-effects such as pain and bleeding. The larger Loops (C and D) are more suitable for multiparous women.

SECOND GENERATION IUDs

It occurred to a number of research workers that the ideal IUD can never be developed simply as a result of obtaining changes in the usual shape or size *(42)*. A new approach was tried in the 1970s by adding copper to the IUD. It was found that metallic copper had a strong anti-fertility effect *(47)*. The addition of copper has made it possible to develop smaller devices which are easier to fit, even in nulliparous women. A number of copper bearing devices are now commercially available :

Earlier devices :
- Copper – 7
- Copper T–200

Newer devices :
- Variants of the T device
  - (i) Cu-T–220 C
  - (ii) Cu-T–380 A or Ag
- Nova T
- Multiload devices
  - (i) ML–Cu–250
  - (ii) ML–Cu–375

The numbers included in the names of the devices refer to the surface area (in sq. mm) of the copper on the device. Nova T and Cu-T– 380 Ag are distinguished by a silver core over which the copper wire is wrapped.

The newer copper devices are significantly more effective in preventing pregnancy than the earlier copper ones or the inert IUDs. The newer copper IUDs – Multiload devices and variants of the T device – offer the further advantage of having an effective life of at least 5 years. They can be left in place safely for the time, unless specific medical or personal reasons call for earlier removal.

Advantages of copper devices

- Low expulsion rate
- Lower incidence of side-effects, e.g., pain and bleeding
- easier to fit even in nulliparous women
- better tolerated by nullipara
- increased contraceptive effectiveness
- effective as post-coital contraceptives, if inserted within 3–5 days of unprotected intercourse

THIRD GENERATION IUDs

A third generation of IUDs – based on still another principle, i.e., release of a hormone – have become available on a limited scale. The most widely used hormonal device is **progestasert**, which is a T–shaped device filled with 38 mg of progesterone, the natural hormone. The hormone is released slowly in the uterus at the rate of 65 mcg daily. It has a direct local effect on the uterine lining, on the cervial mucus and possibly on the sperms. Because the hormone supply is gradually depleted, regular replacement of the device is necessary.

Another hormonal device LNG–20 (Mirena) is a T–shaped IUD releasing 20 mcg of **levonorgestrel** (a potent synthetic steroid); it has a low pregnancy rate (0.2 per 100 women) and less number of ectopic pregnancies *(40)*. Long-term clinical experience with levonorgestrel releasing IUD has shown to be associated with lower menstrual blood loss and fewer days of bleeding than the copper devices. The levonorgestrel releasing IUD has an effective life of 10 years *(40)*. The hormonal devices would be particularly valuable for women in developing countries in whom excess blood loss caused by inert devices have been shown to result in significant anaemia. But these devices are more expensive, to be introduced on a wide scale.

Mechanism of action of IUDs

At present, the most widely accepted view is that the IUD causes a foreign–body reaction in the uterus causing cellular and biochemical changes in the endometrium and uterine fluids, and it is believed that these changes impair the viability of the gamete and thus reduce its chances of fertilization, rather than its implantation.

Medicated IUDs produce other local effects that may contribute to their contraceptive action. Copper seems to enhance the cellular response in the endometrium *(48)*. It also affects the enzymes in the uterus. By altering the biochemical composition of cervial mucus, copper ions may affect sperm motility, capacitation and survival *(48)*.

Hormone-releasing devices increase the viscosity of the cervical mucus and thereby prevent sperm from entering the cervix. They also maintain high levels of progesterone in the endometrium and thus, relatively low levels of oestrogen, thereby sustaining an endometrium unfavourable to implantation *(48)*.

Effectiveness

The IUD is one of the most effective reversible contraceptive methods. The "theoretical effectiveness" of IUD is less than that of oral and injectable hormonal contraceptives. But since IUDs have longer continuation rates than the hormonal pills or injections, the overall effectiveness of IUDs and oral contraceptives are about the same in family planning programmes *(49)*.

Table 19 shows the rates of pregnancy, expulsion and removal of some of the IUDs. It can be seen from Table 19 that copper devices are more effective than the Lippes Loop in preventing pregnancy, with fewer expulsions. Studies have shown that the effectiveness of copper devices is directly related to the amount of copper surface area (usually this is 200 or 220 sq. mm.)

TABLE 19

First year clinical trial experience in parous women

Device	Pregnancy rate (%)	Explusion rate (%)	Removal rate (%)
Lippes Loop	3	12-20	12-15
Cu-7	2-3	6	11
TCu-200	3	8	11
TCu-380A	0.5-0.8	5	14
Progesterone IUD	1.3-1.6	2.7	9.3
Levonorgestrel IUD	0.2	6	17

Source : *(40)*

Change of IUD

Inert IUDs such as Lippes Loop may be left in place as long as required, if there are no side-effects. Copper devices cannot be used indefinitely because copper corrodes and mineral deposits build up on the copper affecting the release of copper ions. They have to be replaced periodically. The same applies to the hormone–releasing devices. This is an inherent disadvantage of medicated devices when they are used in large national family planning programmes.

The Cu-T–380A is approved for use for 10 years. However, the Cu-T–380A has been demonstrated to maintain its efficacy over at least 12 years of use. The Cu-T–200 is approved for 4 years and the Nova T for 5 years. The progesterone-releasing IUD must be replaced every year because the reservoir of progesterone is depleted in 12–18 months. The levonorgestrel IUD can be used for at least 7 years, and probably 10 years. The progesterone IUD has a slightly higher failure rate, but the levonorgestrel device that releases 15–20 µg levonorgestrel per day is as effective as the new copper IUDs *(40)*.

Advantages

The IUD has many advantages : (a) simplicity, i.e., no complex procedures are involved in insertion; no hospitalization is required (b) insertion takes only a few minutes (c) once inserted IUD stays in place as long as required (d) inexpensive (e) contraceptive effect is reversible by removal of IUD (f) virtually free of systemic metabolic side-effects associated with hormonal pills (g) highest continuation rate, and (h) there is no need for the continual motivation required to take a pill daily or to use a barrier method consistently; only a single act of motivation is required. However, as with most contraceptive methods, the IUD can produce side-effects such as heavy menstruation and/or pain.

Contraindications

ABSOLUTE : (a) suspected pregnancy (b) pelvic inflammatory disease (c) vaginal bleeding of undiagnosed aetiology (d) cancer of the cervix, uterus or adnexia and other pelvic tumours (e) previous ectopic pregnancy *(50)*.

RELATIVE : (a) anaemia (b) menorrhagia (c) history of PID since last pregnancy (d) purulent cervical discharge (e) distortions of the uterine cavity due to congenital malformations, fibroids (f) unmotivated person *(45)*.

The ideal IUD candidate

The Planned Parenthood Federation of America (PPFA) has described the ideal IUD candidate as a woman :

- who has borne at least one child
- has no history of pelvic disease
- has normal menstrual periods
- is willing to check the IUD tail
- has access to follow-up and treatment of potential problems, and
- is in a monogamous relationship.

The federation does not, however, rule out women who do not conform to this profile *(51)*.

An important finding that has recently emerged is that the IUD is not a method of first choice for nulliparous women. They have more problems with IUD such as expulsions, low abdominal pain and pelvic infection, than other women. IUDs such as copper–T, which are smaller and more pliable are better suited to the small uterus of the nulliparous women, if they cannot use or accept alternative methods of contraception.

In 1985, the American College of Obstetricians and Gynaecologists stated that IUDs are "not recommended for women who have not had children or who have multiple partners, because of the risk of PID and possible infertility" *(51)*.

Timing of insertion

Although the loop can be inserted at almost anytime during a woman's reproductive years (except during pregnancy), the most propitious time for loop insertion is

during menstruation or within 10 days of the beginning of a menstrual period *(42)*. During this period, insertion is technically easy because the diameter of the cervical canal is greater at this time than during the secretory phase. The uterus is relaxed and myometrial contractions which might tend to cause expulsion are at a minimum *(44)*. In addition, the risk that a woman is pregnant is remote at this time.

The IUD insertion can also be taken up during the first week after delivery before the woman leaves the hospital ("immediate postpartum insertion"). Special care is required with insertions during the first week after delivery because of the greater risk of perforation during this time. Furthermore, immediate postpartum insertion is associated with a high expulsion rate. A convenient time for loop insertion is 6–8 weeks after delivery ("post–puerperal insertion"). Post–puerperal insertion of an IUD has several advantages. It can be combined with the follow-up examination of the women and her child. IUD insertion can also be taken up immediately after a legally induced first trimester abortion. But IUD insertion immediately after a second trimester abortion is not recommended *(45)*. Since there is a risk of infection, most physicians still do not approve of an IUD insertion after an illegal abortion *(45)*.

Follow-up

An important aspect of IUD insertion is follow-up which is sadly neglected. The objectives of the follow-up examination are : (a) to provide motivation and emotional support for the woman (b) to confirm the presence of the IUD, and (c) diagnose and treat any side-effect or complication *(51)*. The IUD wearer should be examined after her first menstrual period, for the chances of loop expulsion are high during this period; and again after the third menstrual period to evaluate the problems of pain and bleeding; and thereafter at six-month or one-year intervals depending upon the facilities and the convenience of the patient.

The IUD wearer should be given the following instructions : (a) she should regularly check the threads or "tail" to be sure that the IUD is in the uterus; if she fails to locate the threads, she must consult the doctor (b) she should visit the clinic whenever she experiences any side-effects such as fever, pelvic pain and bleeding, and (c) if she misses a period, she must consult the doctor.

SIDE-EFFECTS AND COMPLICATIONS

1. Bleeding

The commonest complaint of women fitted with an IUD (inert or medicated) is increased vaginal bleeding. It accounts for 10–20 per cent of all IUD removals *(51)*. The bleeding may take one or more of the following forms : greater volume of blood loss during menstruation, longer menstrual periods or mid-cycle bleeding *(48)*. From the woman's point of view, irregular bleeding constitutes a source of personal inconvenience; from a medical point of view, the concern is iron-deficiency anaemia. Usually bleeding or spotting between periods settles within 1–2 months *(49)*. The patient who is experiencing the bleeding episodes should receive iron tablets (ferrous sulphate 200 mg, three times daily).

Studies have shown that the greatest blood loss is caused by the larger non-medicated devices. Copper devices seem to cause less average blood loss. Menstrual blood loss is consistently lower when hormone–releasing devices are used *(45)*.

If the bleeding is heavy or persistent or if the patient develops anaemia despite the iron supplement, the IUD should be removed. Since there is often a direct relationship between the bleeding and the size and configuration of the IUD *(50)*, a change of IUD from the Lippes Loop to one of copper devices is advised. In most women, removal of the device is rapidly followed by a return to the normal menstrual pattern. If an abnormal pattern persists, a full gynaecological examination is required to ensure that there is no pelvic pathology *(45)*.

2. Pain

Pain is the second major side-effect leading to IUD removal. WHO estimates that 15–40 per cent of IUD removals appear to be for pain only *(45)*. Pain may be experienced during IUD insertion and for a few days thereafter, as well as during menstruation *(51)*. It may manifest itself in low backache, cramps in the lower abdomen and occasionally pain down the thighs. These symptoms usually disappear by the third month *(49)*.

If during insertion, the pain is particularly severe, it is possible that the device may have been incorrectly placed in the uterus or there is a disparity in size between the device and the uterine cavity. Severe pain can also indicate a uterine perforation *(45)*. Pain could also be due to infection. Pain is more commonly observed in nullipara and those who have not had a child for a number of years *(52, 53)*.

Slight pain during insertion can be controlled by analgesics such as aspirin and codein. If pain is intolerable, the IUD should be removed. In place of a Lippes Loop, a copper device can be tried. If the woman decides not to have an IUD, another method of contraception should be prescribed.

3. Pelvic infection

Pelvic inflammatory disease (PID) is a collective term that includes acute, subacute and chronic conditions of the ovaries, tubes, uterus, connective tissue and pelvic peritoneum and is usually the result of infection *(50)*. Studies suggest that IUD users are about 2 to 8 times more likely to develop PID than non-contraceptors *(54)*. Risk associated with IUD use is greater among women who have a number of sexual partners *(55)* possibly because of greater potential for exposure to STDs. The greater risk of PID with IUD use may be due to introduction of bacteria into the uterus during IUD insertion. Recent work has focused on PID as being caused by organisms ascending the IUD tail from the lower genital tract to uterus and tubes *(56)*. The organisms include Gardnerella, Anaerobic streptococci, Bacteroides, Coliform bacilli and Actinomyces. The risk of PID appears to be the highest in the first few months after IUD insertion.

The clinical manifestations of PID are vaginal discharge, pelvic pain and tenderness, abnormal bleeding, chills and fever. In many cases, the infection may be asymptomatic or low grade. Even one or two episodes of PID can cause infertility permanently blocking the fallopian tubes. Therefore, young women should be fully counselled on the risks of PID before choosing an IUD.

When PID is diagnosed, it should be treated promptly with broad–spectrum antibiotics. Most clinicians recommend removing IUD if infection does not respond to antibiotics within 24–48 hours *(48)*. The risk of PID calls for proper selection of cases for IUD insertion, better sterilization and insertion techniques, and modified devices without tails.

4. Uterine perforation

Many workers have reported uterine perforation by the IUD *(57)*. The reported incidence ranges from 1:150 to 1 : 9000 insertions *(57)*, depending upon the time of insertion, design of the IUD, technique of insertion and operator's experience. In the hands of trained physicians, it should not be higher than 0.3 per cent *(58)*. The device may migrate into the peritoneal cavity causing serious complications such as intestinal obstruction. Copper devices produce an intense tissue reaction leading to peritoneal adhesions. Perforations occur more frequently when insertions are performed between 48 hours and 6 weeks postpartum. Interestingly, the perforation may be completely asymptomatic and discovered only when searching for a missing IUD. The conclusive diagnosis of perforation is usually made by a pelvic X-ray. Evidence suggests that any IUD that has perforated the uterus should be removed because the risks of intra-abdominal inflammatory response leading to adhesions or perforation of organs within the abdominal cavity outweigh the risks associated with removal *(51)*.

5. Pregnancy

Considering all IUDs together, the actual use failure rate in the first year is approximately 3 per cent *(40)*. It differs, in different types of IUDs. About 50 per cent of uterine pregnancies occurring with the device *in situ* end in a spontaneous abortion *(51)*. Removal of the IUD in early pregnancy has been found to reduce this abortion rate by half. In women who continue the pregnancy with the device *in situ*, a 4–fold increase in the occurrence of premature births compared with other women has been reported *(45)*.

The earlier teaching that pregnancy with an IUD *in situ* is not unsafe is no longer accepted. Pregnancy with an IUD should be regarded as a potential medical complication with the dangers of infection and spontaneous abortion. The options left open are *(44)* :

(a) If the woman requests an induced abortion, this is legally available.

(b) If the woman wishes to continue with the pregnancy and the threads are visible, the device should be removed by gently pulling the threads.

(c) If the woman wishes to continue with the pregnancy and the threads are not visible, there should be careful examination for possible complications. If there are any signs of intrauterine infection and sepsis, evacuation of the uterus under broad–spectrum antibiotic cover is mandatory.

If the woman becomes pregnant with the IUD, she should be advised that only 25 per cent of pregnancies will have a successful outcome if the IUD is left in place.

6. Ectopic pregnancy

The possibility of ectopic pregnancy must be considered when an IUD user becomes pregnant. The ectopic pregnancy rate per 1000 women year in levonorgestrel IUD and Cu–T–380A is about 0.2 as compared to non-contraceptive users, where it is about 3–4.5. With progesteron IUD it is higher–about 6.8, because its action is limited to a local effect on endometrium. With levonorgestrel IUD the chances of ectopic pregnancy are less, because it is associated with a partial suppression of gonadotrophins with subsequent disruption of normal follicular growth and inhibition of ovulation in significant number of cycles *(40)*.

Women using IUDs should be taught to recognize the symptoms of ectopic pregnancy – lower abdominal pain, dark and scanty vaginal bleeding or amenorrhoea. Women at high risk of ectopic pregnancy – because of previous PID, tubal pregnancy or other ectopic pregnancy – should not use an IUD if other methods are feasible *(51)*.

7. Expulsion

Expulsion rates vary between 12–20 per cent (Table 19). Expulsion can be partial or complete. Partial expulsion is diagnosed on speculum examination by observing the stem of the IUD protruding through the cervix. Clinical skill, timing of insertion and the age and parity of the user all influence the likelihood of expulsion.

An expulsion usually occurs during the first few weeks following insertion or during menstruation. Expulsion is most common among young women, nulliparous women and women who have a postpartum insertion. Expulsion rates are somewhat lower for copper than for inert devices. As many as 20 per cent of all expulsions go undetected. In general, expulsion in itself is not a serious problem, but if expulsion is unnoticed, pregnancy may occur.

8. Fertility after removal

Fertility does not seem to be impaired after removal of a device provided there has been no episode of PID, whilst the device was *in situ (48)*. Over 70 per cent of previous IUD users conceive within one year of stopping use *(51)*. It is now established that PID is a threat to woman's fertility. There is no meaningful data available on the long-term use of IUD on subsequent fertility *(45)*.

9. Cancer and teratogenesis

There is no evidence to date that IUD use increases cancer risks. Nor is there any evidence of developmental abnormality or congenital malformations among the offspring of either former users of IUDs or those who conceive with an IUD *in situ (45)*.

10. Mortality

Mortality associated with IUD use is extremely rare and has been estimated to be one death per 100,000 woman–years of use, the deaths usually following complications such as septic spontaneous abortion or ectopic pregnancy *(45)*. In fact, IUD is safer than oral contraceptives in this regard, particularly in older or high-risk patients *(45)*.

Of all the available spacing methods of contraception, IUDs are among the most effective, with an average pregnancy rate after one year of about 3–5 per 100 typical users *(51)*. In comparison with other methods, the IUD is a relatively inexpensive form of contraception, because of its long life. Unlike use of barrier methods, IUD use is independent of the time of intercourse. IUDs have a relatively high continuation rates. Inert devices, as well as those with copper lack the systemic metabolic effects associated with oral pills. Women who cannot tolerate the adverse effects of oral pills may find the IUD an acceptable alternative. It does not interfere with lactation. However, because of expulsion and possible side-effects like menstrual irregularities, IUDs should preferably be used in settings where follow-up facilities are available. Evidence to date shows that for a fully informed woman, the IUD can provide a satisfactory, highly effective, relatively low-risk method of contraception.

HORMONAL CONTRACEPTIVES

Hormonal contraceptives when properly used are the most effective spacing methods of contraception. Oral contraceptives of the combined type are almost 100 per cent effective in preventing pregnancy. They provide the best means of ensuring spacing between one childbirth and another. More than 65 million in the world are estimated to be taking the "pill" of which about 9.52 million are estimated to be in India.

Gonadal steroids

To physicians in general medicine, the term "steroid" refers to adrenocortical hormones, while to those in gynaecology, it implies gonadal steroids, i.e., oestrogens and progestogens.

a. *Synthetic oestrogens :* Two synthetic oestrogens are used in oral contraceptives. These are *ethinyl-oestradiol* and *mestranol.* Both are effective. In fact, mestranol is inactive until converted into ethinyl oestradiol in the liver *(59).*

b. *Synthetic progestogens :* These are classified into three groups – pregnanes, oestranes and gonanes. (i) *Pregnanes* : These include megestrol, chlormadinone and medroxy–progesterone acetate. The pregnane progestogens are now not recommended in oral contraceptives because of doubts raised by the occurrence of breast tumours in beagle dogs. (ii) *Oestrones* : These are also known as 19–nortestosterones, e.g., norethisterone, norethisterone acetate, lynestrenol, ethynodiol diacetate and norethynodrel. These are all metabolized to norethisterone before becoming active. For some women, oestranes are more acceptable than gonanes. (iii) *Gonanes* : The most favoured gonane is levonorgestrel *(59).*

Classification

Hormonal contraceptives currently in use and/or under study may be classified as follows :

A. Oral pills
1. Combined pill
2. Progestogen only pill (POP)
3. Post-coital pill
4. Once–a–month (long–acting) pill
5. Male pill

B. Depot (slow release) formulations
1. Injectables
2. Subcutaneous implants
3. Vaginal rings

A. ORAL PILLS

1. Combined pill

The combined pill is one of the major spacing methods of contraception. The "original pill" which entered into the market in the early 1960s contained 100–200 mcg of a synthetic oestrogen and 10 mg of a progestogen. Since then, a number of improvements have been made to reduce the undesirable side-effects of the pill by reducing the dose of both the oestrogen and progestogen. At the present time, most formulations of the combined pill contain no more than 30–35 mcg of a synthetic oestrogen, and 0.5 to 1.0 mg of a progestogen. The debate continues about the minimum effective dose of the progestogen in the pill which will produce the least metabolic disturbances.

The pill is given orally for 21 consecutive days beginning on the 5th day of the menstrual cycle (for a few preparations 20 or 22 days are advised), followed by a break of 7 days during which period menstruation occurs. When the bleeding occurs, this is considered the first day of the next cycle. The bleeding which occurs is not like normal menstruation, but is an episode of uterine bleeding from an incompletely formed endometrium caused by the withdrawal of exogenous hormones. Therefore it is called "withdrawal bleeding" rather than menstruation. Further, the loss of blood which occurs is about half that occurring in a woman having ovulatory cycle. If bleeding does not occur, the woman is instructed to start the second cycle one week after the preceding one. Ordinarily, the woman "menstruates" after the second course of pill intake.

The pill should be taken everyday at a fixed time, preferably before going to bed at night. The first course should be started strictly on the 5th day of the menstrual period, as any deviation in this respect may not prevent pregnancy. If the user forgets to take a pill, she should take it as soon as she remembers, and that she should take the next day's pill at the usual time.

Types of pills

The Department of Family Welfare, in the Ministry of Health and Family Welfare, Government of India has made available 2 types of low-dose oral pills under the brand names of MALA–N and MALA–D. It contains Levonorgestrel 0.15 mg and Ethinyl estradiol 0.03 mg. Mala–D in a package of 28 pills (21 of oral contraceptive pills and 7 brown film coated 60 mg ferrous fumarate tablets) is made available to the consumer under social marketing at a price of Rs. 3 per packet. Mala–N is supplied free of cost through all PHCs, urban family welfare centres, etc. Some of the combined pills are as shown in Table 20.

TABLE 20
Some combination oral contraceptives

Name	Progestin	(mg)
(A) *With EE 0.02 mg*		
Loestrin 1/20	Norethisterone acetate	1.00
Femilon	Desogestrel	0.15
(B) *With EE 0.03 mg*		
Eugynon 30	Levonorgestrel	0.25
Microgynon, Ovral L Triquilar (Varying E E and levonorgestrel) Primovlar 30, Mala D,	Levonorgestrel	0.15
Choice	Norgestrel	0.30
Novelon	Desogestrel	0.15
Yasmin	Drospirenone	3.00
(C) *With EE 0.05 mg and less progestogenic*		
Eugynon 50, Duoluton, Ovral G	Norgestrel	0.50
Ovral, Primovlar 50	Levonorgestrel	0.25
Minovlar Ed, Orlest	Norethisterone acetate	1.00
Orthonovin 1/50	Norethisterone	1.00
(D) *With EE 0.05 mg and more progestogenic*		
Orgalutin	Lynestrenol	2.50
Norlestrin 2.5/50	Norethisterone acetate	2.50
Gynovlar 21	-Do-	3.00
Anovlar 21	-Do-	4.00

2. Progestogen-only pill (POP)

This pill is commonly referred to as "minipill" or "micropill". It contains only progestogen, which is given in small doses throughout the cycle. The commonly used progestogens are norethisterone and levonorgestrel.

The progestogen-only pills never gained widespread use because of poor cycle control and an increased pregnancy rate *(60)*. However, they have a definite place in modern-day contraception. They could be prescribed to older women for whom the combined pill is contraindicated because of cardiovascular risks. They may also be considered in young women with risk factors for neoplasia *(61)*. The evidence that the progestogens may lower the high-density lipoproteins may be of some concern.

3. Post-coital contraception

Post-coital (or "morning after") contraception is recommended within 72 hours of an unprotected intercourse. Two methods are available :

(a) *IUD* : The simplest technique is to insert an IUD, if acceptable, especially a copper device within 5 days.

(b) *Hormonal* : More often a hormonal method may be preferable. In India Levonorgestrel 0.75 mg tablet is approved for emergency contraception. It is used as one tablet of 0.75 mg within 72 hours of unprotected sex and the 2nd tablet after 12 hours of 1st dose.

or

Two oral contraceptive pills containing 50 mcg of ethinyl estradiol within 72 hours after intercourse, and the same dose after 12 hours.

or

Four oral contraceptive pills containing 30 or 35 mcg of ethinyl estradiol within 72 hours and 4 tablets after 12 hours.

or

Mifepristone 10 mg once within 72 hours.

Post-coital contraception is advocated as an emergency method; for example, after unprotected intercourse, rape or contraceptive failure. Opinion is divided about the effect on foetus, should the method fail. Although the failure rate for post-coital contraception is less than 1 per cent, some experts think a woman should not use the hormonal method unless she intends to have an abortion, if the method fails. There is no evidence that foetal abnormalities will occur. But some doubts remain *(62)*.

4. Once-a-month (long-acting) pill

Experiments with once-a-month oral pill in which quinestrol, a long-acting oestrogen is given in combination with a short-acting progestogen, have been disappointing *(63)*. The pregnancy rate is too high to be acceptable. In addition, bleeding tends to be irregular.

5. Male pill

The search for a male contraceptive began in 1950 *(64)*. Research is following 4 main lines of approach : (a) preventing spermatogenesis (b) interfering with sperm storage and maturation (c) preventing sperm transport in the vas, and (d) affecting constituents of the seminal fluid. Most of the research is concentrated on interference with spermatogenesis. An ideal male contraceptive would decrease sperm count while leaving testosterone at normal levels. But hormones that suppress sperm production tend to lower testosterone and affect potency and libido.

A male pill made of gossypol – a derivative of cotton-seed oil, has been very much in the news. It is effective in producing azoospermia or severe oligospermia, but as many as 10 per cent of men may be permanently azoospermic after taking it for 6 months. Further gossypol could be toxic. Animal studies show a narrow margin between effective and toxic doses. At present it does not seem that gossypol will ever be widely used as a male contraceptive *(65)*.

MODE OF ACTION OF ORAL PILLS

The mechanism of action of the combined oral pill is to prevent the release of the ovum from the ovary. This is achieved by blocking the pituitary secretion of gonadotropin that is necessary for ovulation to occur. Progestogen-only preparations render the cervical mucus thick and scanty and thereby inhibit sperm penetration. Progestogens also inhibit tubal motility and delay the transport of the sperm and of the ovum to the uterine cavity *(63)*.

EFFECTIVENESS

Taken according to the prescribed regimen, oral contraceptives of the combined type are almost 100 per cent effective in preventing pregnancy *(50)*. Some women do not take the pill regularly, so the actual rate is lower. In developed countries, the annual pregnancy rate is less than 1 per cent but in many other countries, the pregnancy rate is considerably higher *(63)*.

Under clinical trial conditions, the effectiveness of progestogen-only pills is almost as good as that of the combination products. However, in large family planning programmes, the effectiveness and continuation rates are usually lower than in clinical trials. The effectiveness may also be affected by certain drugs such as rifampicin, phenobarbital and ampicillin *(63)*.

RISKS AND BENEFITS

Historically oral contraceptives were introduced in the early 1960s. During the first decade of their use, investigations focused on the benefit of pregnancy prevention and risk of abnormal cycle bleeding. During the 1970s, following their widespread use it became apparent that the oral contraceptives had some adverse effects principally on the cardiovascular system (e.g., myocardial infarction, deep vein thrombosis, etc.) and that these effects were associated with the oestrogen component of the pill. This led to a reduction of the oestrogen content of the pill until the current 30-35 mcg oral pills were developed. Until 1980, there was little mention of the untoward effects of progestogens.

As we entered the third decade of oral pill use in 1980s, more information about the hazards and benefits of the pill were available from two large British prospective studies – the Royal College of General Practitioners' study and the Oxford University Family Planning Association's study, both of which started in 1968 *(65, 66, 67)*. This section summarizes the risks and benefits of the pill as of date.

a. Adverse effects

1. Cardiovascular effects

Data from the earlier case control studies *(68, 69)* and the Oral Contraceptive Study of the RCGP *(68)* and the Oxford

Study in UK *(66, 67)* provided conclusive evidence that the use of the combined pill was associated with an excess mortality. Women who had used the pill were reported to have a 40 per cent higher death rate than women who had never taken the pill. Virtually, all the excess mortality was due to cardiovascular causes, that is myocardial infarction, cerebral thrombosis and venous thrombosis, with or without pulmonary embolus *(70, 71)*. The risk increased substantially with age and cigarette smoking (Table 21). The evidence was convincing that the cardiovascular complications were positively associated with the oestrogen content of the pill.

TABLE 21

Circulatory disease mortality rates per 100,000 women–years by age, smoking status and oral contraceptive use

Age	Mortality ever users	Rate controls
15–24 Years		
Non–smokers	0.0	0.0
Smokers	10.5	0.0
25–34 Years		
Non–smokers	4.4	2.7
Smokers	14.2	4.23
35–44 Years		
Non–smokers	21.5	6.4
Smokers	63.4	15.2
45 + Years		
Non–smokers	52.4	11.4
Smokers	206.7	27.9

Source : *(72)*

The above findings led to the progressive reduction of the oestrogen content to the minimum levels necessary to maintain contraceptive effect. Inspiteof this reduction, it became clear by 1980 that some of the untoward vascular effects (e.g., hypertension) persisted, in addition to metabolic effects which are attributed to the progestogen content of the pill. It became clear that progestogen levels must also be minimal to avoid the complications of pill use.

2. Carcinogenesis

A review prepared by WHO *(73)* concluded that there was no clear evidence of a relationship, either positive or negative between the use of combined pill and the risk of any form of cancer. However, the WHO Multicentre case-control study on the possible association between the use of hormonal contraceptives and neoplasia indicated a trend towards increased risk of cervical cancer with increasing duration of use of oral contraceptives; this finding is being further explored *(74)*.

3. Metabolic effects

A great deal of attention has been focused recently on the metabolic effects induced by oral contraceptives. These have included the elevation of blood pressure, the alteration in serum lipids with a particular effect on decreasing high-density lipoproteins, blood clotting and the ability to modify carbohydrate metabolism with the resultant elevations of blood glucose and plasma insulin *(75)*. These effects are positively related to the dose of the progestogen component *(76)*. Family planning specialists have voiced a growing concern that the adverse effects associated with oral contraceptives could be a potential long–range problem for the users in that they may accelerate atherogenesis and result in clinical problems such as myocardial infarction and stroke.

4. Other adverse effects

(i) *Liver disorders* : The use of the pill may lead to hepatocellular adenoma and gall bladder disease. Cholestatic jaundice can occur in some pill users. (ii) *Lactation* : Preparations containing a relatively high amount of oestrogen adversely affect the quantity and constituents of breast milk *(74)*, and less frequently cause premature cessation of lactation. In a WHO study *(74)* users of the combined pill experienced a 42 per cent decline in milk volume after 18 weeks, compared with a decline of 12 per cent for users of progestogen-only minipills and 0.16 per cent for controls using non-hormonal preparations. Women taking oral contraceptives, no matter what type, excrete small quantities of hormones in their breast milk, but little is known about the long-term impact, if any, on the child *(71)*. (iii) *Subsequent fertility*: In general, oral contraceptive use seems to be followed by a slight delay in conception *(77)*. The proportion of women becoming pregnant within 2 months of discontinuing the pill may range from 15–35 per cent *(78)*. It is not known whether the prolonged use of the pill beyond 5–10 years affects subsequent fertility. (iv) *Ectopic pregnancies* : These are more likely to occur in women taking progestogen-only pills, but not in those taking combined pills. (v) *Foetal development* : Several reports have suggested that oral pills taken inadvertently during (or even just before) pregnancy might increase the incidence of birth defects of the foetus, but this is not yet substantiated *(79)*.

5. Common unwanted effects

(i) *Breast tenderness* : Breast tenderness, fullness and discomfort have been observed in women taking oral pills. Breast engorgement and fullness are said to be dependent on progestogen; pain and tenderness are attributed to oestrogen. (ii) *Weight gain* : About 25 per cent of users complain of weight gain. It is usually less than 2 kg, and occurs during the first 6 months of use. This is attributed to water retention, in which case restriction of salt intake is usually effective. (iii) *Headache and migraine* : Migraine may be aggravated or triggered by the pill. Women, whose migraine requires treatment with vasoconstrictors such as ergotamine, should not take oral pills. (iv) *Bleeding disturbances* : A small minority of women using oral contraceptives may complain of break-through bleeding or spotting in the early cycles. A few women may not have a withdrawal bleeding at the end of a cycle. Women should be forewarned of these possibilities.

b. Beneficial effects

The single most significant benefit of the pill is its almost 100 per cent effectiveness in preventing pregnancy and thereby removing anxiety about the risk of unplanned pregnancy. Apart from this, the pill has a number of non–contraceptive health benefits *(80)*. Both the Royal College of General Practitioners' and the Oxford Family Planning Association's long-term prospective studies of pill use in Britain have shown that using the pill may give protection against at least 6 diseases: benign breast disorders including fibrocystic disease and fibroadenoma, ovarian cysts, iron–deficiency anaemia, pelvic inflammatory disease, ectopic pregnancy and ovarian cancer.

Contraindications

(a) *Absolute* : Cancer of the breast and genitals; liver disease; previous or present history of thromboembolism; cardiac abnormalities; congenital hyperlipidaemia; undiagnosed abnormal uterine bleeding.

(b) *Special problems requiring medical surveillance* : Age over 40 years; smoking and age over 35 years; mild hypertension; chronic renal disease; epilepsy; migraine; nursing mothers in the first 6 months; diabetes mellitus; gall bladder disease; history of infrequent bleeding, amenorrhoea, etc. *(63)*.

Duration of use

The pill should be used primarily for spacing pregnancies in younger women. Those over 35 years should go in for other forms of contraception. Beyond 40 years of age, the pill is not to be prescribed or continued because of the sharp increase in the risk of cardiovascular complications *(63)*.

Medical supervision *(81)*

Women taking oral contraceptives should be advised annual medical examinations. An examination before prescribing oral pills is required (a) to identify those with contraindications, and (b) those with special problems that require medical intervention or supervision. A check-list (Table 22) has been developed for screening women who can be given oral pills by the health workers.

TABLE 22

Check-list for prescription of oral contraceptives

Check the following by history and examination	Yes	No
Above 40 years of age	....	....
Above 35 years of age and a heavy smoker	....	....
Seizures	....	....
Severe pain in the calves or thighs	....	....
Symptomatic varicose veins in the legs	....	....
Severe chest pains	....	....
Unusual shortness of breath after examination	....	....
Severe headaches and/or visual disturbances	....	....
Lactating (yes = for less than 6 months)	....	....
Intermenstrual bleeding and/ or bleeding after sexual intercourse	...	....
Amenorrhoea	....	....
Abnormally yellow skin, eyes	....	....
Blood pressure (yes = above 140 mm Hg systolic and/or 90 mm Hg diastolic)	....	....
Mass in the breast	....	....
Swollen legs (oedema)	....	....
Instructions : If all the above are negative, the woman may be given oral contraceptives. If any are positive, she must first be seen by a doctor.

B. DEPOT FORMULATIONS

The need for depot formulations which are highly effective, reversible, long-acting and oestrogen-free for spacing pregnancies in which a single administration suffices for several months or years cannot be stressed. The injectable contraceptives, subdermal implants and vaginal rings come in this category.

1. Injectable contraceptives

There are two types of injectable contraceptives. Progestogen-only injectables and the newer once-a-month combined injectables. The formulation and injection schedules of injectable contraceptives are as shown in Table 23.

A. PROGESTOGEN-ONLY INJECTABLES

Thus far, only two injectable hormonal contraceptives – both based on progestogen – have been found suitable. They offer more reliable protection against unwanted pregnancies than the older barrier techniques. These are :

a. DMPA (Depot-medroxyprogesterone acetate)
b. NET-EN (Norethisterone enantate)
c. DMPA-SC

a. DMPA *(82)*

Depot-medroxyprogesterone acetate (DMPA or Depo-provera) has been in use since 1960s. The standard dose is an intramuscular injection of 150 mg every 3 months. It gives protection from pregnancy in 99 per cent of women for at least 3 months. It exerts its contraceptive effect primarily by suppression of ovulation. However, it also has an indirect effect on the endometrium and direct action on the fallopian tubes and on the production of cervical mucus, all of which may play a role in reducing fertility. DMPA has been found to be a safe, effective and acceptable contraceptive which requires a minimum of motivation or none at all. Another advantage is that it does not affect lactation. Therefore in the experience of several countries, DMPA has proved acceptable during the postpartum period as a means of spacing pregnancies. However, the side-effects of DMPA (viz. weight increase, irregular menstrual bleeding and prolonged infertility after its use) are disadvantages limiting the age groups for which the drug could regularly be used. As now practiced in a number of countries, this contraceptive should find good use among multiparae of age over 35 years who have already completed their families.

b. NET-EN

Norethisterone enantate (NET-EN) has been in use as a contraceptive since 1966. However, it has been less extensively used than DMPA. It is given intramuscularly in a dose of 200 mg every 60 days. Contraceptive action appears to include inhibition of ovulation, and progestogenic effects on cervical mucus. A slightly higher (0.4) pregnancy rate (failure rate) has been reported as compared to DMPA.

Administration

The initial injection of both DMPA and NET-EN should be given during the first 5 days of the menstrual period. This timing is very important to rule out the possibility of pregnancy. Both are given by deep intramuscular injection into the gluteus maximus. The injection site should never be massaged following injections. *(83)*. Although compliance

TABLE 23

Formulations and injection schedules of injectable contraceptives

Common trade names	Formulation	Injection type and schedule
Progestin - Only Injectables		
Depo-Provera®, Megestron®, Contracep®, Depo-Prodasone®	Depot medroxyprogesterone acetate (DMPA) 150 mg	One intramuscular (IM) injection every 3 months
depo-subQ provera 104® (DMPA-SC)	DMPA 104 mg	One subcutaneous injection every 3 months
Noristerat®, Norigest®, Doryxas®	Norethisterone enanthate (NET-EN) 200 mg	One IM injection every 2 months
Combined Injectable (progestin + estrogen)[1]		
Cyclofem®, Ciclofeminina®, Lunelle®[2]	Medroxyprogesterone acetate 25 mg + Estradiol cypionate 5 mg (MPA/E_2C)	One IM injection every month
Mesigyna®, Norigynon®	NET-EN 50 mg + Estradiol valerate 5 mg ($NET\text{-}EN/E_2V$)	One IM injection every month
Deladroxale®, Perlutal®, Topasel®, Patectro®, Deproxone®, Nomagest®	Dihydroxyprogesterone (algestone) acetophenide 150 mg + Estradiol enanthate 10 mg	One IM injection every month
Anafertin®, Yectames®	Dihydroxyprogesterone (algestone) acetophenide 75 mg + Estradiol enanthate 5 mg	One IM injection every month
Chinese Injectable No. 1®	17α-hydroxyprogesterone caproate 250 mg + Estradiol valerate 5 mg	One IM injection every month, except 2 injections in first month

[1] Also called monthly injectables.
[2] The U.S. Food and Drug Administration approved Lunelle, but it is currently not available in the United States.

Source : *(82)*

with regular injection intervals should be encouraged, both DMPA and Net–EN may be given two weeks early or two weeks late *(84)*.

c. DMPA–SC 104 mg *(82)*

A new lower-dose formulation of DMPA, *depo-subQ provera 104* (also called DMPA–SC), is injected under the skin rather than in the muscle. It contains 104 mg of DMPA rather than the 150 mg in the intramuscular formulation. Like the intramuscular formulation, DMPA–SC is given at 3-month intervals.

DMPA–SC is just as effective as the formulation injected into the muscle, and the patterns of bleeding changes and amount of weight gain are similar.

Injections of DMPA–SC are given in the upper thigh or abdomen. DMPA–SC should not be injected intramuscularly, and the intramuscular formulation should not be injected subcutaneously. The intramuscular formulation cannot be diluted to make the lower-dose subcutaneous formulation.

Side-effects

Both DMPA and NET–EN have similar side effects, the most common being disruption of the normal menstrual cycle, manifested by episodes of unpredictable bleeding, at times prolonged and at other times excessive. In addition, many women using DMPA or NET–EN may become amenorrhoeic. The unpredictable bleeding may be very inconvenient to the user; and amenorrhoea can be alarming, causing anxiety. Studies showed that women discontinuing DMPA became pregnant some 5.5 months (average) after the treatment period. At 2 years, more than 90 per cent of previous users became pregnant *(83)*. A study is in progress in India to examine the return of fertility among women who discontinued NET–EN. The potential long-term effects of DMPA and NET–EN are not yet known.

Contraindications

These include cancer of the breast; all genital cancers; undiagnosed abnormal uterine bleeding; and a suspected malignancy. Women usually should not start using a progestin-only injectable if they have high blood pressure (systolic ≥ 160 mm Hg or diastolic ≥ 100), certain conditions of the heart, blood vessels, or liver including history of stroke or heart attack and current deep vein thrombosis. Also, a woman breast-feeding a baby less than 6 weeks old should not use progestin-only injectables *(82)*.

The particular advantage of DMPA and NET–EN is that they are highly effective, long-lasting and reversible contraceptives. Check-lists have been developed for auxiliaries primarily for the screening of women who can be given injectable contraceptives without being examined by the physician; they can also be utilized in follow-up visits.

B. COMBINED INJECTABLE CONTRACEPTIVES

These injectables contain a progestogen and an oestrogen. They are given at monthly intervals, plus or minus three days. Combined injectable contraceptives act mainly by suppression of ovulation. The cervical mucus is affected, mainly by progestogen, and becomes an obstacle to sperm penetration. Changes are also produced in endometrium which makes it unfavourable for implantation if fertilization occurs, which is extremely unlikely.

In clinical trials, Cyclofem/Cycloprovera and Mesigyna have both been found to be highly effective with 12 month failure rates of 0.2 per cent or less for Cyclofem/Cycloprovera and 0.4 per cent for Mesigyna. The side-effects are similar to progestogen only injectables, but are much less. Data on return to ovulation and fertility are limited.

The contraindications are confirmed or suspected pregnancy; past or present evidence of thromboembolic disorders; cerebrovascular or coronary artery disease; focal migraine; malignancy of the breast; and diabetes with

vascular complications. Combined injectables are not suitable for women who are fully breast feeding until 6 months postpartum. It is less suitable for women with risk factors for oestrogen.

2. Subdermal implants

The Population Council, New York has developed a subdermal implant known as **Norplant** for long-term contraception. It consists of 6 silastic (silicone rubber) capsules containing 35 mg (each) of levonorgestrel *(85)*. More recent devices comprise fabrication of levonorgestrel into 2 small rods, **Norplant (R)–2**, which are comparatively easier to insert and remove. The silastic capsules or rods are implanted beneath the skin of the forearm or upper arm. Effective contraception is provided for over 5 years. The contraceptive effect of Norplant is reversible on removal of capsules. A large multicentre trial conducted by International Committee for Contraception Research (ICCR) reported a 3–year pregnancy rate of 0.7. The main disadvantages, however, appear to be irregularities of menstrual bleeding and surgical procedures necessary to insert and remove implants.

3. Vaginal rings

Vaginal rings containing levonorgestrel have been found to be effective. The hormone is slowly absorbed through the vaginal mucosa, permitting most of it to bypass the digestive system and liver, and allowing a potentially lower dose. The ring is worn in the vagina for 3 weeks of the cycle and removed for the fourth *(86)*.

POST-CONCEPTIONAL METHODS

(Termination of pregnancy)

Menstrual regulation

A relatively simple method of birth control is "menstrual regulation". It consists of aspiration of the uterine contents 6 to 14 days of a missed period, but before most pregnancy tests can accurately determine whether or not a woman is pregnant *(44)*. Cervical dilatation is indicated only in nullipara or in apprehensive subjects. No after-care is necessary as a rule.

The immediate complications are uterine perforation and trauma. Late complications (after 6 weeks) include a tendency to abortion or premature labour, infertility, menstrual disorders, increase in ectopic pregnancies and Rh–immunization *(87)*.

Some regard menstrual regulation as very early abortion, others view it as a treatment for delayed periods. Menstrual regulation differs from abortion in 3 respects *(88)* : (a) the lack of certainty if a pregnancy is being terminated. Microscopic examination of the aspirated material can confirm pregnancy *post facto*, but it is not obligatory (b) the lack of legal restrictions, and (c) the increased safety of the early procedure.

Menstrual induction

This is based on disturbing the normal progesterone–prostaglandin balance by intrauterine application of 1–5 mg solution (or 2.5–5 mg pellet) of prostaglandin F2. Within a few minutes of the prostaglandin impact, performed under sedation, the uterus responds with a sustained contraction lasting about 7 minutes, followed by cyclic contractions continuing for 3–4 hours. The bleeding starts and continues for 7–8 days *(87)*.

Oral abortifacient

Mifepristone (RU 486) in combination with misoprostol is 95 per cent successful in terminating pregnancies of upto 9 week's duration with minimum complications. The commonly used regimen is mifepristone 200 mg orally on day 1, followed by misoprostol 800 mcg vaginally either immediately or within 6–8 hours. Commercially it comes as MTP kit having combipack tablets of mifepristone 200 mg one tablet and misoprostol 200 mcg 4 tablets (800 mcg).

The other regimen is a dose of mifepristone 600 mg on day one, followed by 400 mcg orally of misoprostol on day three.

The patient should return for a follow-up visit approximately 14 days after the administration of mifepristone to confirm by clinical examination or ultra-sonographic scan that a complete termination of pregnancy has occurred. Patients who have an ongoing pregnancy at this visit have a risk of foetal malformation resulting from the treatment. Surgical termination is recommended to manage medical abortion treatment failures.

Contraindications

Administration of mifepristone and misoprostol is contraindicated in following conditions : (1) History of allergy or known hypersensitivity to mifepristone, misoprostol or other prostaglandin; (2) Confirmed or suspected ectopic pregnancy or undiagnosed adnexal mass; (3) IUD in place; (4) Chronic adrenal failure; (5) Haemorrhagic disorder or concurrent anticoagulant therapy; (6) Inherited porphyria; and (7) If a patient does not have adequate access to medical facilities equipped to provide emergency treatment of incomplete abortion and blood transfusion.

ABORTION

Abortion is theoretically defined as termination of pregnancy before the foetus becomes viable (capable of living independently). This has been fixed administratively at 28 weeks, when the foetus weighs approximately 1000 g. Abortion is sought by women for a variety of reasons including birth control. In fact, in some countries (e.g., Hungary) the legal abortions exceed live births.

Abortions are usually categorized as spontaneous and induced. Spontaneous abortions occur once in every 15 pregnancies *(89)*. They may be considered "Nature's method of birth control". Induced abortions, on the other hand, are deliberately induced – they may be legal or illegal. Illegal abortions are hazardous; they are usually the last resort of women determined to end their pregnancies at the risk of their own lives.

Abortion hazards

It is estimated that of the 210 million pregnancies that occur each year, about 80 million are unintended. In 2008, 21.6 million unsafe abortions were estimated to have occurred, causing about 47,000 deaths. Almost 14 unsafe abortions per 1000 women aged 15–44 years takes place. In developing countries the rate is 16 per 1000 women and least developed countries about 27 per 1000 women in age group 15–44 years. The high unsafe abortion rate exists in parallel to low overall contraceptive use *(90)*.

In India an ICMR study documented that the rates of safe (legal) and unsafe (illegal) abortion were 6.1 and 13.5 per

1000 pregnancies respectively. It is evident that perhaps two thirds of all abortions take place outside authorized health service by unauthorized and often unskilled persons *(91)*.

The EARLY COMPLICATIONS of abortion include haemorrhage, shock, sepsis; uterine perforation, cervical injury, thromboembolism and anaesthetic and psychiatric complications. The LATE SEQUELAE include infertility, ectopic gestation, increased risk of spontaneous abortion and reduced birth weight.

Data indicates that the seventh and eighth week of gestation is the optimal time for termination of pregnancy *(92)*. Studies indicate that the risk of death is 7 times higher for women who wait until the second trimester to terminate pregnancy. The Indian Law (MTP Act, 1971) allows abortion only up to 20 weeks of pregnancy.

Legalization of abortion

During the last 25 years there have been gradual liberalization of abortion laws throughout the world. Until 1971, abortions in India were governed exclusively by the Indian Penal Code 1860 and the Code of Criminal Procedure 1898, and were considered a crime except when performed to save the life of a pregnant woman. The Medical Termination of Pregnancy Act was passed by the Indian Parliament in 1971 and came into force from April 1, 1972 (except in Jammu and Kashmir, where it came into effect from November 1, 1976). Implementing rules and regulations initially written in 1971 were revised again in 1992 *(95)*. The Medical Termination of Pregnancy Act is a health care measure which helps to reduce maternal morbidity and mortality resulting from illegal abortions. It also affords an opportunity for motivating such women to adopt some form of contraception.

THE MEDICAL TERMINATION OF PREGNANCY ACT 1971

The Medical Termination of Pregnancy Act, 1971 lays down :

1. The conditions under which a pregnancy can be terminated.
2. The person or persons who can perform such terminations, and
3. The place where such terminations can be performed.

1. The conditions under which a pregnancy can be terminated under the MTP Act. 1971 :

There are 5 conditions that have been identified in the Act :

a. *Medical* – where continuation of the pregnancy might endanger the mother's life or cause grave injury to her physical or mental health.
b. *Eugenic* – where there is substantial risk of the child being born with serious handicaps due to physical or mental abnormalities.
c. *Humanitarian* – where pregnancy is the result of rape.
d. *Socio-economic* – where actual or reasonably foreseeable environments (whether social or economic) could lead to risk of injury to the health of the mother, and
e. *Failure of contraceptive devices* – The anguish caused by an unwanted pregnancy resulting from a failure of any contraceptive device or method can be presumed to constitute a grave mental injury to the health of the mother. This condition is a unique feature of the Indian law and virtually allows abortion on request, in view of the difficulty of proving that a pregnancy was not caused by failure of contraception.

The written consent of the guardian is necessary before performing abortion in women under 18 years of age, and in lunatics even if they are older than 18 years.

2. The person or persons who can perform abortion

The Act provides safeguards to the mother by authorizing only a Registered Medical Practitioner having experience in gynaecology and obstetrics to perform abortion where the length of pregnancy does not exceed 12 weeks. However, where the pregnancy exceeds 12 weeks and is not more than 20 weeks, the opinion of two Registered Medical Practitioners is necessary to terminate the pregnancy.

3. Where abortion can be done

The Act stipulates that no termination of pregnancy shall be made at any place other than a hospital established or maintained by Government or a place approved for the purpose of this Act by Government.

Abortion services are provided in hospitals in strict confidence. The name of the abortion seeker is kept confidential, since abortion has been treated statutorily as a personal matter.

MTP RULES (1975)

Rules and Regulations framed initially were altered in October 1975 to eliminate time–consuming procedures involved in MTP and to make services more readily available. These changes have occurred in 3 administrative areas *(93, 94)*.

1. Approval by Board

Under the new rules, the Chief Medical Officer of the district is empowered to certify that a doctor has the necessary training in gynaecology and obstetrics to do abortions. The procedure of doctors applying to Certification Boards was removed.

2. Qualification required to do abortion

The new rules allow for registered medical practitioners to qualify through on the spot training :

> "If he has assisted a RMP in the performance of 25 cases of medical termination of pregnancy in an approved institution".

The doctor may also qualify to do MTPs under the new rules if he has one or more of the following qualifications which are similar to the old rules :

(a) 6 months housemanship in obstetrics and gynaecology.
(b) a postgraduate qualification in OBG.
(c) 3 years of practice in OBG for those doctors registered before the 1971 MTP Act was passed.
(d) 1 year of practice in OBG for those doctors registered on or after the date of commencement of the Act.

3. The place where abortion is performed

Under the new rules, non–governmental institutions may also take up abortions provided they obtain a licence from the Chief Medical Officer of the district, thus eliminating the requirement of private clinics obtaining a Board licence.

Impact of liberalization of abortion

Although abortion has been greatly liberalized, the annual number of legal abortions are about 6.1 per 1000 pregnancies, whereas the illegal abortions performed in the country are about 13.5 per 1000 pregnancies. In other words, illegal abortions are still rife although it is now more than 40 years since MTP Act was promulgated.

An amendment to the MTP Act in the year 2003 includes decentralization of power for approval of places as MTP centres, from state to district level with the aim of enlarging the network of safe MTP centres, and MTP service providers. The strategy at the community level is : (a) spread awareness regarding safe MTP in the community and the availability of services thereof ; (b) Enhance access to confidential counselling for safe MPT; train ANMs, AWWs, and link workers/ASHAs to provide such counselling; and (c) Promote post-abortion care through ANMs, AWWs, link workers/ASHAs while maintaining confidentiality. At the facility level the strategy is : (1) To provide manual Vaccum Aspiration facility at all CHCs and at least 50 per cent of PHCs that are being strengthened for 24 hour deliveries; (2) Provide comprehensive and high quality MTP services at all FRUs; and (3) Encourage private and NGO sectors to establish quality MTP services *(9)*.

Repeated abortion is not conducive to the health of the mother. It has to be ensured that abortion does not replace the traditional methods of birth control. The numerous abortion hazards which are inherent should serve as a warning that abortions under the best of circumstances can never be as safe as efficient contraception.

MISCELLANEOUS

1. Abstinence

The only method of birth control which is completely effective is complete sexual abstinence. It is sound in theory; in practice, an oversimplification. It amounts to repression of a natural force and is liable to manifest itself in other directions such as temperamental changes and even nervous breakdown. Therefore, it can hardly be considered as a method of contraception to be advocated to the masses.

2. Coitus interruptus

This is the oldest method of voluntary fertility control. It involves no cost or appliances. It continues to be a widely practised method. The male withdraws before ejaculation, and thereby tries to prevent deposition of semen into the vagina. Some couples are able to practise this method successfully, while others find it difficult to manage. The chief drawback of this method is that the precoital secretion of the male may contain sperm, and even a drop of semen is sufficient to cause pregnancy. Further, the slightest mistake in timing the withdrawal may lead to the deposition of a certain amount of semen. Therefore, the failure rate with this method may be as high as 25 per cent.

Hitherto, the alleged side-effects (e.g., pelvic congestion, vaginismus, anxiety neurosis) were highly magnified. Today, expert opinion is changing in this respect. If the couple prefers it, there should be no objection to its use. It is better than using no family planning method at all. It is conceded that coitus interruptus along with abstinence and abortion played a major role in reducing birth rates in the developed world during the 18th and 19th centuries *(44)*.

3. Safe period (rhythm method)

This is also known as the *"calendar method"* first described by Ogino in 1930. The method is based on the fact that ovulation occurs from 12 to 16 days before the onset of menstruation (see Fig. 8). The days on which conception is likely to occur are calculated as follows :

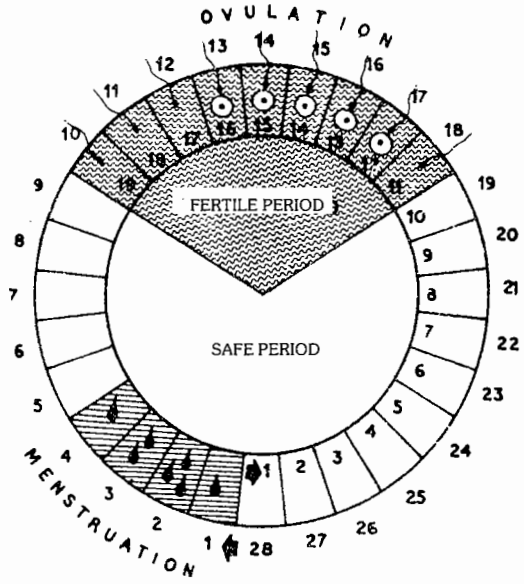

FIG. 8
Safe period in a 28–day cycle

The shortest cycle minus 18 days gives the first day of the fertile period. The longest cycle minus 10 days gives the last day of the fertile period. For example, if a woman's menstrual cycle varies from 26 to 31 days, the fertile period during which she should not have intercourse would be from the 8th day to the 21st day of the menstrual cycle, counting day one as the first day of the menstrual period. Fig. 8 shows the fertile period and the safe period in a 28-day cycle.

However, where such calculations are not possible, the couple can be advised to avoid intercourse from the 8th to the 22nd day of the menstrual cycle, counting from the first day of the menstrual period *(95)*.

The drawbacks of the calendar method are : (a) a woman's menstrual cycles are not always regular. If the cycles are irregular, it is difficult to predict the safe period (b) it is only possible for this method to be used by educated and responsible couples with a high degree of motivation and cooperation (c) compulsory abstinence of sexual intercourse for nearly one half of every month – what may be called "programmed sex" (d) this method is not applicable during the postnatal period, and (e) a high failure rate of 9 per 100 woman–years *(39)*. The failures are due to wrong calculations, inability to follow calculations, irregular use and "taking chances".

Two medical complications have been reported to result from the use of safe period; ectopic pregnancies and embryonic abnormalities. Ectopic pregnancies may follow conception late in the menstrual cycle and displacement of the ovum; embryonic abnormalities may result from conception involving either an over-aged sperm or over-aged ovum. If this is correct, the safe period may not be an absolutely safe period *(96)*.

4. Natural family planning methods

The term "natural family planning" is applied to three methods: (a) basal body temperature (BBT) method (b) cervical mucus method, and (c) symptothermic method. The principle is the same as in the calendar method, but here the woman employs self-recognition of certain physiological signs and symptoms associated with ovulation as an aid to ascertain when the fertile period begins. For avoiding pregnancy, couples abstain from sexual intercourse during the fertile phase of the menstrual cycle; they totally desist from using drugs and contraceptive devices. This is the essence of natural family planning.

(a) Basal body temperature method (BBT)

The BBT method depends upon the identification of a specific physiological event – the rise of BBT at the time of ovulation, as a result of an increase in the production of progesterone. The rise of temperature is very small, 0.3 to 0.5 degree C. When no ovulation occurs (e.g., as after menarche, during lactation) the body temperature does not rise. The temperature is measured preferably before getting out of bed in the morning. The BBT method is reliable if intercourse is restricted to the post–ovulatory infertile period, commencing 3 days after the ovulatory temperature rise and continuing up to the beginning of menstruation. The major drawback of this method is that abstinence is necessary for the entire pre-ovulatory period. Therefore, few couples now use the temperature method alone *(97)*.

(b) Cervical mucus method

This is also known as *"billings method"* or *"ovulation method"*. This method is based on the observation of changes in the characteristics of cervical mucus. At the time of ovulation, cervical mucus becomes watery clear resembling raw egg white, smooth, slippery and profuse. After ovulation, under the influence of progesterone, the mucus thickens and lessens in quantity. It is recommended that the woman uses a tissue paper to wipe the inside of vagina to assess the quantity and characteristics of mucus. To practice this method the woman should be able to distinguish between different types of mucus. This method requires a high degree of motivation than most other methods. The appeal and appropriateness of this method in developing countries such as India, especially among lay people, is dubious.

(c) Symptothermic method

This method combines the temperature, cervical mucus and calendar techniques for identifying the fertile period. If the woman cannot clearly interpret one sign, she can "double check" her interpretation with another. Therefore, this method is more effective than the "Billings method".

To sum up, natural family planning demands discipline and understanding of sexuality. It is not meant for everybody. The educational component is more important with this approach than with other methods. The opinion of the Advisory Group to WHO's Special Programme of Research in Human Reproduction is that the current natural family planning methods have very little application particularly in developing countries *(98)*.

5. Breast-feeding

Field and laboratory investigations have confirmed the traditional belief that lactation prolongs postpartum amenorrhoea and provides some degree of protection against pregnancy *(99)*. No more than 5–10 per cent of women conceive during lactational amenorrhoea, and even this risk exists only during the month preceding the resumption of menstruation *(100)*. However, once menstruation returns, continued lactation no longer offers any protection against pregnancy *(101)*. By and large, by 6 months after childbirth, about 20–50 per cent of women are menstruating and are in need of contraception *(102)*.

6. Birth control vaccine

Several immunological approaches for men and women are being investigated. The most advanced research involves immunization with a vaccine prepared from beta sub-unit of human chorionic gonadotropin (hCG), a hormone produced in early pregnancy. Immunization with hCG would block continuation of the pregnancy. Antibodies appeared in about 4–6 weeks and reached maximum after about 5 months and slowly declined reaching zero levels after a period ranging from 6–11 months. The immunity can be boosted by a second injection. Two types of pregnancy vaccines employing variants of the beta sub-unit of hCG are now about to go into clinical trial *(51)*. Research on birth control vaccines continues. The uncertainties are great *(86)*.

TERMINAL METHODS

(Sterilization)

Voluntary sterilization is a well–established contraceptive procedure for couples desiring no more children. Currently female sterilizations account for about 85 per cent and male sterilizations for 10–15 per cent of all sterilizations in India (*103*), inspite of the fact that male sterilization is simpler, safer and cheaper than female sterilization.

Sterilization offers many advantages over other contraceptive methods – it is a one-time method; it does not require sustained motivation of the user for its effectiveness; provides the most effective protection against pregnancy; the risk of complications is small if the procedure is performed according to accepted medical standards; and it is most cost-effective. It has been estimated that each procedure averts 1.5 to 2.5 births per woman *(104)*.

Guidelines for sterilization

Sterilization services are provided free of charge in Government institutions. Guidelines have been issued from time to time by the Government covering various aspects of sterilization. These are *(105, 106)*:

a. The age of the husband should not ordinarily be less than 25 years nor should it be over 50 years.

b. The age of the wife should not be less than 20 years or more than 45 years.

c. The motivated couple must have 2 living children at the time of operation.

d. If the couple has 3 or more living children, the lower limit of age of the husband or wife may be relaxed at the discretion of the operating surgeon, and

e. It is sufficient if the acceptor declares having obtained the consent of his/her spouse to undergo sterilization operation without outside pressure, inducement or coercion, and that he/she knows that for all practical purposes, the operation is irreversible, and also that the spouse has not been sterilized earlier.

Male sterilization *(107, 108)*

Male sterilization or vasectomy being a comparatively simple operation can be performed even in primary health centres by trained doctors under local anaesthesia. When carried out under strict aseptic technique, it should have no risk of mortality. In vasectomy, it is customary to remove a piece of vas at least 1 cm after clamping. The ends are ligated and then folded back on themselves and sutured into position, so that the cut ends face away from each other. This will reduce the risk of recanalization at a later date. It is important to stress that the acceptor is not immediately sterile after the operation, usually until approximately 30 ejaculations have taken place *(44)*. During this intermediate period, another method of contraception must be used. If properly performed, vasectomies are almost 100 per cent effective.

Following vasectomy, sperm production and hormone output are not affected. The sperm produced are destroyed intraluminally by phagocytosis. This is a normal process in the male genital tract, but the rate of destruction is greatly increased after vasectomy. Vasectomy is a simpler, faster and less expensive operation than tubectomy in terms of instruments, hospitalization and doctor's training. Cost-wise, the ratio is about 5 vasectomies to one tubal ligation.

COMPLICATIONS

The very few complications that may arise are :

(a) *Operative* : The early complications include pain, scrotal haematoma and local infection. Wound infection is reported to occur in about 3 per cent of patients. Good haemostasis and administration of antibiotics will reduce the risk of these complications.

(b) *Sperm granules* : Caused by accumulation of sperm, these are a common and troublesome local complication of vasectomy. They appear in 10–14 days after the operation. The most frequent symptoms are pain and swelling. Clinically the mass is hard and the average size approximately 7 mm. Sperm granules may provide a medium through which re-anastomosis of the severed vas can occur. The sperm granules eventually subside. It has been reported that using metal clips to close the vas may reduce or eliminate this problem.

(c) *Spontaneous recanalization* : Most epithelial tubes will recanalize after damage, and the vas is no exception. The incidence of recanalization is variously placed between 0 to 6 per cent. Its occurrence is serious. Therefore, the surgeon should explain the possibility of this complication to every acceptor prior to the operation, and have written consent acknowledging this fact. In a study, the wives of 6 out of 14,047 men who had vasectomies in the UK became pregnant between 16 months and 3 years later *(109)*. Therefore, the patient should be urged to report for a regular follow-up, may be up to 3 years.

(d) *Autoimmune response* : Vasectomy is said to cause an autoimmune response to sperm. Blocking of the vas causes reabsorption of spermatozoa and subsequent development of antibodies against sperm in the blood. Normally 2 per cent of fertile men have circulating antibodies against their own sperm. In men who have had vasectomies, the figure can be as high as 54 per cent. There is no reason to believe that such antibodies are harmful to physical health. It is likely that the circulating antibodies can cause a reduction in subsequent fertility despite successful reanastomosis of the vas *(43)*.

(e) *Psychological* : Some men may complain of diminution of sexual vigour, impotence, headache, fatigue, etc. Such adverse psychological effects are seen in men who have undergone vasectomy under emotional pressure. That is why it is important to explain to each acceptor the basis of the operation and give him sufficient time to make up his mind voluntarily and seriously to have the operation done.

Causes of failure *(108)*

The failure rate of vasectomy is generally low, 0.15 per 100 person–years. The most common cause of failure is due to the mistaken identification of the vas. That is, instead of the vas, some other structure in the spermatic cord such as thrombosed vein or thickened lymphatic has been taken. Histological confirmation has, therefore, been recommended on all vasectomy specimens by some authors in developed countries. In developing countries, histological confirmation is ruled out because of lack of facilities for such an examination. A simpler method has been recommended, that is, microscopic examination of a smear prepared by gentle squeezing of the vas on a glass slide and staining with Wright's stain. The vas can be identified by the presence of columnar epithelial cells that line the lumen of the vas. In some cases, failure may be due to spontaneous recanalisation of vas. Sometimes there may be more than one vas on one side. Pregnancy could also result from sexual intercourse before the disappearance of sperms from the reproductive tract.

Post-operative advice

To ensure normal healing of the wound and to ensure the success of the operation, the patient should be given the following advice :

1. The patient should be told that he is not sterile immediately after the operation; at least 30 ejaculations may be necessary before the seminal examination is negative *(44)*.
2. To use contraceptives until aspermia has been established.
3. To avoid taking bath for at least 24 hours after the operation.
4. To wear a T–bandage or scrotal support *(langot)* for 15 days : and to keep the site clean and dry.
5. To avoid cycling or lifting heavy weights for 15 days; there is, however, no need for complete bed rest.
6. To have the stitches removed on the 5th day after the operation.

No scalpel vasectomy

No scalpel vasectomy is a new technique that is safe, convenient and acceptable to males. This new method is now being canvassed for men as a special project, on a voluntary basis under the family welfare programme. Under

the project, medical personnel all over the country are to be trained. Availability of this new technique at the peripheral level will increase the acceptance of male sterilization in the country. The project is being funded by the UNFPA *(9)*.

Female sterilization

Female sterilization can be done as an interval procedure, postpartum or at the time of abortion. Two procedures have become most common, namely laparoscopy and minilaparotomy.

(a) Laparoscopy

This is a technique of female sterilization through abdominal approach with a specialized instrument called "laparoscope". The abdomen is inflated with gas (carbon dioxide, nitrous oxide or air) and the instrument is introduced into the abdominal cavity to visualize the tubes. Once the tubes are accessible, the Falope rings (or clips) are applied to occlude the tubes. This operation should be undertaken only in those centres where specialist obstetrician–gynaecologists are available. The short operating time, shorter stay in hospital and a small scar are some of the attractive features of this operation.

Patient selection : Laparoscopy is not advisable for postpartum patients for 6 weeks following delivery; however, it can be done as a concurrent procedure to MTP. Haemoglobin per cent should not be less than 8. There should be no associated medical disorders such as heart disease, respiratory disease, diabetes and hypertension. It is recommended that the patient be kept in hospital for a minimum of 48 hours after the operation.

The cases are required to be followed-up by health workers (F) LHVs in their respective areas once between 7–10 days after the operation, and once again between 12 and 18 months after the operation.

Complications : Although complications are uncommon, when they do occur they may be of a serious nature requiring experienced surgical intervention. Puncture of large blood vessels and other potential complications have been reported as major hazards of laparoscopy.

Laparoscopic sterilizations have become very popular in India. Nearly 41.4 per cent of all female sterilizations during 2010–11 were through laparoscopic method *(24)*.

(b) Minilap operation

Minilaparotomy is a modification of abdominal tubectomy. It is a much simpler procedure requiring a smaller abdominal incision of only 2.5 to 3 cm conducted under local anaesthesia. The minilap/Pomeroy technique is considered a revolutionary procedure for female sterilization. It is also found to be a suitable procedure at the primary health centre level and in mass campaigns. It has the advantage over other methods with regard to safety, efficiency and ease in dealing with complications. Minilap operation is suitable for postpartum tubal sterilization.

Evaluation of contraceptive methods

Contraceptive efficacy is generally assessed by measuring the number of unplanned pregnancies that occur during a specified period of exposure and use of a contraceptive method. The two methods that have been used to measure contraceptive efficacy are the Pearl index and life-table analysis.

The **Pearl index** is defined as the number of "failures per 100 woman-years of exposure (HWY)." This rate is given by the formula :

$$\text{Failure rate per HWY} = \frac{\text{Total accidental pregnancies}}{\text{Total months of exposure}} \times 1200$$

In applying the above formula, the total accidental pregnancies shown in the numerator must include every known conception, whatever its outcome, whether this had terminated as live births, still-births or abortions or had not yet terminated. The factor 1200 is the number of months in 100 years. The total months of exposure in the denominator is obtained by deducting from the period under review of 10 months for a full-term pregnancy, and 4 months for an abortion *(96)*.

A failure rate of 10 per HWY would mean that in the lifetime of the average woman about one–fourth or 2.5 accidental pregnancies would result, since the average fertile period of a woman is about 25 years *(96)*.

In designing and interpreting a use–effectiveness trial, a minimum of 600 months of exposure is usually considered necessary before any firm conclusion can be reached *(96)*.

With most methods of contraception, failure rates decline with duration of use. The Pearl index is usually based on a specific exposure (usually one year) and, therefore, fails to accurately compare methods at various durations of exposure. This limitation is overcome by using the method of life-table analysis.

Life-table analysis : Life-table analysis calculates a failure rate for each month of use. A cumulative failure rate can then compare methods for any specific length of exposure. Women who leave a study for any reason other than unintended pregnancy are removed from the analysis, contributing their exposure until the time of the exit.

Element of success in family planning programme

The main strategy of family planning programme is to offer to client easy access to a wide range of affordable contraceptive method through multiple service delivery channels in a good quality, reliable fashion. The key points are as follows : *(1) Make services accessible :* Offering services through a variety of delivery points makes methods available to more potential users; *(2) Make services affordable :* Partnerships between public and private-sector services encourage clients to pay what they can, while public programmes serve the poor for free or for low fees; *(3) Offer client-centered care :* Planning and providing services with the clients in mind help to make sure their needs are met and their preferences are honoured; *(4) Rely on evidence-based technical guidance :* Up-to-date service delivery guidelines, tools, and job aids can help translate research findings into better practice; *(5) Communicate effectively :* Communication grounded in behaviour theory and sensitive to local norms motivates clients to seek services and helps them make good family planning choices; *(6) Assure contraceptive security :* A strong logistics system and a long-term plan for contraceptive security ensure that a variety of methods, and the supplies and equipment to provide them, are always available; *(7) Work for supportive policies :* Showing how family planning contributes to development goals makes the case for continued support for family

planning programme; *(8) Coordinate* : When governments, donor agencies, and implementing partners work together, they streamline efforts and avoid duplication; *(9) Build a high-performing staff* : Programme can keep workers motivated and on the job by creating a good working environment, matching skills with tasks, and rewarding a job well done; *(10) Secure adequate budget, use it well* : Spending wisely, doing more with less, and finding ways to recover costs can help ensure financial sustainability; *(11) Base decisions on evidence* : Research, monitoring, and evaluation yield important information to guide decision-making, and they need not be expensive; *(12) Lead strongly, manage well* : Strong leadership helps programmes navigate change. Good management solves operational problems; and *(13) Integrate services appropriately* : Programmes can address a wider range of health needs by integrating services where appropriate and offering referrals where it is not.

Unmet need for family planning *(110)*

The concept that eventually became unmet need for family planning was first explored in 1960s, when data from surveys of contraceptive knowledge attitude and practices (KAP) showed a gap between some women's reproductive intention and their contraceptive behaviour. The term that came to popular use describing this group was "KAP–gap". One of the first published use of the term "unmet need" appeared in 1977. In 1978, based on World Fertility Survey data from five Asian countries, Charles Westoff published first comparative estimates of unmet need for limiting births.

Many women who are sexually active would prefer to avoid becoming pregnant, but nevertheless are not using any method of contraception (including use by their partner). These women are considered to have an "unmet need" for family planning. The concept is usually applied to married women. However, it can apply to sexually active fecund women and perhaps to men, but its measurement has been limited to married women only. Unmet need can be a powerful concept for family planning. It poses a challenge to family planning programme – to reach and serve millions of women whose reproductive attitude resembles those of contraceptive user – but who are, for some reason or combination of reasons, not using contraceptives.

Among the most common reason for unmet need are inconvenient or unsatisfactory services, lack of information, fears about contraceptive side-effects and opposition from husband or relatives. Unmet need is defined on the basis of women's response to survey questions.

According to the National Family Health Survey–3, the unmet need for family planning is highest (27.1 per cent) among women below 20 years age and is almost entirely for spacing the births rather than for limiting the births. It is also relatively high for women in age group 20–24 years (21.1 per cent) with about 75 per cent of the need being for spacing the births. The unmet need for contraception among women aged 30 years and above are mostly for limiting the births.

Unmet need for family planning is higher in rural areas than in urban areas. It also varies by women's education (within range of 10.4–13.6 per cent) and religion (hindu and christian women have a lower unmet need than muslim women). Table 24 shows some of the characteristics of unmet need for family planning in India *(17)*.

TABLE 24

Percentage of currently married women with unmet need for family planning in India by selected background characteristics
(NFHS–3, 2005–06)

Background characteristics	Unmet need for family planning		
	For spacing	For limiting	Total
Age			
15-19	25.1	2.0	27.1
20-24	14.9	6.2	21.1
25-29	6.0	9.9	16.0
30-34	2.1	9.0	11.0
35-39	0.5	6.9	7.4
40-44	0.1	4.2	4.3
45-49	0.1	1.8	1.9
Residence			
Urban	4.5	5.2	9.7
Rural	6.9	7.2	14.1
Education			
No education	5.5	8.1	13.6
<5 years complete	5.2	5.2	10.4
5-7 years complete	7.3	5.2	12.5
8-9 years complete	7.7	5.7	13.5
10-11 years complete	7.0	5.2	12.1
12 or more years complete	6.0	4.7	10.7
Religion			
Hindu	5.8	6.1	11.9
Muslim	8.6	10.2	18.8

Highest	3.9	4.1	8.1
Total	6.2	6.6	12.8

Source : *(17)*

The National Family Health Survey–3 results show that although current use of contraception has increased and the extent of unmet need has declined in most of the states in India, there is a need for considerable improvement in the coverage and quality of family planning services, especially in the four large states of Uttar Pradesh, Bihar, Madhya Pradesh and Rajasthan.

According to the DLHS-III (2007–08), about 20.5 per cent of currently married women in India have an unmet need for family planning. The unmet need for spacing the births is about 7.2 per cent and need for limiting births is 13.3 per cent *(112)*.

Contraception and adolescence *(113)*

Adolescence is the period between puberty and the end of physiological maturation, which occurs between ages 15–19 years. Pregnancy in adolescence constitutes about 11 per cent of all pregnancies in most developing countries and in some developed countries such as the USA. For the

year 2014, WHO puts the global adolescent birth rate at 49 per 1000 girls of that age, country rates range from one to 229 births per 1000 girls. This indicates a marked decrease since 1990 *(111)*. These are often "at risk" pregnancies. Many are undesired, and occur in unmarried adolescents who then resort to legal or illegal abortion, performed under unsatisfactory medical conditions. This has serious health and even life-threatening consequences for these young women – the ensuing mortality and morbidity (especially secondary sterility) are quite considerable.

Prevention of undesired pregnancies and of sexually transmitted diseases in young people through educational programmes dealing with responsible sexual behaviour is a major public health challenge. Adolescents are ambivalent about family planning : to request contraception is to "reveal" one's sexuality. For this reason, adolescent girls sometimes choose the risk of an undesired pregnancy and of an abortion.

BARRIER METHODS : Condoms make barrier method worthwhile, because they protect those adolescents, with occasional different sexual partners, against STD and AIDS. However, condoms must be properly used, and it depends on the man's behaviour. Young men seem to be increasingly aware of the importance of safeguarding their own health and that of their partners. Cervical caps and diaphragms, on the other hand, are inappropriate for adolescents since they require foreseeing of intercourse and complicated manipulations, to which young people are loath.

HORMONAL CONTRACEPTION : Hormonal methods are perfectly suitable for adolescents, who generally do not suffer from such problems as cardiovascular contraindications. In fact, these are probably the most adequate methods, since they are completely reversible, and in no way modify the future fertility of these young women. In developed countries, pills are usually preferred, but trimestrial or monthly injections are also appropriate. Implants, with their five year term, cover too long a period for certain adolescents.

IUD : IUD are theoretically contraindicated, because of the risk of pelvic infection and of secondary sterility. However, an adolescent is better protected by an IUD than by illegal repeated abortions. This method has the advantage of being discrete and avoiding demanding routines.

OTHER METHODS : Periodic abstinence is not easy when cycles are irregular and intercourse is unforeseen, and with new partners. In certain countries, however, they are practically the only method taught, for religious reasons, and poor protection is preferable to no protection at all. Similarly, withdrawal is not very suitable method, since young men are usually not very skillful.

Spermicides are not contraindicated, but have two disadvantages – they are costly, and are not effective against STD and AIDS.

As a major chunk of the world population is under 25 years age group. An extremely large number of young people will, therefore, be entering their reproductive years at that time. The demographic future of the world will depend on them, on how well informed they are, and on their sense of responsibilities.

DELIVERY SYSTEM

Since family planning is essentially a component of the health care system, the primary responsibility for the delivery of services rests with the Government through its health care system at the Centre and in the States.

At the Centre

The Family Welfare Programme is a centrally sponsored scheme, and the states receive 100 per cent assistance from the central government. Since the entire cost is virtually borne by the central government, the central government controls the planning, and financial management of the programme (e.g., establishment of clinics, pattern of staffing, expenditure); training, research and evaluation, and most important, the formulation of an overall policy for the programme. The current policy is to promote family planning on the basis of voluntary and informed acceptance with full community participation. The emphasis is on a 2–child family. Recently there have been two major changes in the approach to delivery of family planning services : first, a greater emphasis on spacing methods, side by side with terminal methods, and secondly to take the services to every door–step and motivate families to adopt the small family norm.

The administrative apparatus consists of a separate Department of Family Welfare, which was created in 1966 in the Central Ministry of Health and Family Welfare. The Secretary to the Government of India in the Ministry of Health and Family Welfare is in over all charge of the Department of Family Welfare. He is assisted by a **Special Secretary** and Joint Secretaries. The special secretary supervises the programme implementation and coordinates the various activities. There is now an **Advisor** (Mass Media and Communication) – an officer of the rank of an Additional Secretary. The National Institute of Health and Family Welfare acts as an apex technical institute for promoting health and family welfare in the country through education, training services, research and evaluation. There is a Central Family Welfare Council consisting of all the State Health Ministers to review the implementation of the programme. A Population Advisory Council headed by the Union Health Minister, Members of Parliament, and persons from the fields related to population control was set up in 1982. This body acts like a "think tank" to analyze the implementation of the programme and advise the government suitably. A cabinet sub–committee headed by the Prime Minister has also been formed for periodic review of the progress of the family welfare programme. Family planning is no longer viewed as the sole responsibility of the Health Ministry, but will devolve on all ministries connected with human resources and development. This is an important breakthrough in current thinking.

At the state level

Under the Indian constitution, the state governments are responsible for the administration and implementation of the Family Welfare Programme. Since most of the crucial policy decisions are made by the central government, the pattern of organization and many features of the delivery system are fairly well–standardized in the States.

The organizational set-up at the State level consists of a State Family Welfare Bureau, which is part of the State Health and Family Welfare Directorate. At present, 25 State Family Welfare Bureaus are functioning in the country.

In 1979, the offices of the Family Welfare and National Malaria Eradication Programme were merged into one office and named as Regional Office for Health and Family Welfare. These regional offices have been set up to maintain

liaison with state governments and give technical assistance to them in connection with the implementation of the Family Welfare Programme and other important health programmes. To co-ordinate the family welfare activities between the state governments and the central government, one Family Welfare Cell has been sanctioned for each State.

At the district level

At the district level, the set-up consists of a District Family Welfare Bureau consisting of 3 divisions – an administrative division headed by the District Family Welfare Officer; mass education and media division, in charge of District Mass Education and Media Officer, and an evaluation division, in charge of a Statistical Officer. These are supported by 1,083 Urban Family welfare centres and 871 Urban Health Posts. Presently there are 4 types of Urban Health Posts–type A for areas with population less than 5,000, type B for areas with population between 5,000–10,000, type C for population between 10,000–25,000, and type D for areas with population between 25,000–50,000. If the population is more than 50,000, then it is to be divided into sectors of 50,000 population and Health Posts provided. Type A, B and C Health Posts are attached to a hospital for providing referral and supervisory services. Type D Health Post is attached to a hospital for sterilization, MTP and referral *(34)*. Only type D health post have a post of medical officer.

The 10 city family welfare bureaus are entrusted with the responsibility of coordination, monitoring and supervision etc. of the family welfare services provided by various institutions in the city.

Presently there are three types of Urban Family Welfare Centres. Type I is for population between 10,000–25,000, type II is for population between 25,000–50,000, and type III is for above 50,000 population *(34)*. These are manned by 2 para-medical staff in type I and II centres and by 6 persons including medical officer in type III centres.

The Urban family welfare centres and health posts provide comprehensive integrated services of MCH and family planning. The staff pattern is different for different types of health posts and urban family welfare centres.

At the community health centre

Community health centre is established and maintained by the state governments. Presently it is manned by four medical specialists i.e. surgeon, physician, gynaecologist and paediatrician, supported by 21 paramedical and other staff. It has 30 in-door beds with one OT, X-ray, labour room and laboratory facilities and serves as a referral centre for four PHCs. According to Indian Public Health Standards, the community health centre is to be manned by 6 medical specialists including an anaesthetist and an eye surgeon supported by 24 paramedical and other staff with inclusion of two nurse midwives. It provides, apart from other emergency obstetric care, full range of family planning services including laproscopic services and safe abortion services. At present as of March 2014, 5,363 community health centres are functional in the country *(114)*.

At the primary health centre

Since more than 68.2 per cent of India's population lives in the rural areas an adequate network of service centres has been extended to the rural areas. A Rural Family Welfare Centre with a medical officer and supporting staff forms an integral part of the primary health centre. A total of 5,435 Rural Family Welfare Centres were established in the country at all block level PHCs sanctioned upto 1.4.1980. Most of the states have integrated these centres into their primary health care system and after this date family planning services are being provided through integrated facilities at PHCs *(115)*. As of March 2014, 25,020 primary health centres were functioning in the country. Each centre is supported by sub-centres. The total number of sub-centres functioning are 152,326 *(114)*.

When fully staffed (by 3 medical officers including one lady doctor and supporting personnel) the PHC is expected to provide fairly comprehensive "essential health care" including family planning care. The medical officers are usually trained to provide MTP and sterilization services. The programme of insertion of copper-T IUDs has been intensified. It is intended that laparoscopic services which have become very popular will be made more widely available at the PHC.

The sub-centres are to provide the main thrust of the programme. Each subcentre is staffed by one male and one female health worker. They are responsible for providing rudimentary health and MCH care; family planning motivation, supplies and services in spacing methods.

Various studies conducted have highlighted that the existing infrastructure is not being optimally utilized because of its inadequacy to provide proper services. To improve matters **popular committees** have been set up at all levels by some states to involve people in the programme and in exercising vigilance over the work of various functionaries.

At the village level

Two schemes are being implemented at the village level to improve the outreach of services and increase local participation: **(a) The Village Health Guides** : An innovative approach has been the creation of a band of village Health Guides (mostly women), one for each village or a population of 1000. They are made responsible for spreading knowledge and information to the eligible couples and providing them with supplies of Nirodh and oral pills. About 3.23 lakh health guides are already in position. **(b) Trained dais :** The national target is to provide one trained dai per 1000 population. They conduct safe deliveries in rural areas. They also act as family planning counsellors and motivators, supplementing the delivery system. **(c) ASHA :** 8.89 lakh ASHAs have been selected so far and 8.06 lakh have been provided with drug kits *(112)*. At present the village health guides, trained dais and ASHAs are the lynchpins of the family planning delivery system in India.

New initiatives *(112)*

1. *Home Delivery of Contraceptives (HDC)*
   a. A new scheme has been launched to utilize the services of ASHA to deliver contraceptives at the doorstep of beneficiaries. The scheme was launched in 233 pilot districts of 17 States on 11 July 2011 and is now expanded to the entire country from 17th December 2012.
   b. ASHA is charging a nominal amount from beneficiaries for her effort to deliver contraceptives at doorstep i.e. Rs. 1 for a pack of 3 condoms. Rs.1 for a cycle of OCPs and Rs. 2 for a pack of one tablet of ECP.

2. *Ensuring Spacing at Birth (ESB)*

   a. Under a new scheme launched by the Government of India, services of ASHAs to be utilized for counselling newly married couples to ensure spacing of 2 years after marriage and couples with 1 child to have spacing of 3 years after the birth of 1st child. The scheme is operational in 18 States (EAG, North-Eastern and Gujarat and Haryana). ASHA would be paid following incentives under the scheme :
      - Rs. 500/- to ASHA for delaying first child birth by 2 years after marriage.
      - Rs. 500/- to ASHA for ensuring spacing of 3 years after the birth of 1st child.
      - Rs.1000/- in case the couple opts for a permanent limiting method upto 2 children only.

   b. Ministry of Health & Family Welfare has introduced short term IUCD (5 years effectively), Cu IUCD 375 under the National Family Planning programme. Training of State level trainers has already been completed and process is underway to train service providers upto the sub-centre level.

   c. A new method of IUCD insertion (post-partum IUCD insertion) has been introduced by the Government.

   d. Promoting Post-partum Family Planning services at district hospitals by providing for placement of dedicated Family Planning Counsellors and training of personnel.

3. *Pregnancy Testing Kits*

Nischay-Home based pregnancy test kits (PTKs) was launched under NRHM in 2008 across the country. The PTKs are being made available at sub-centres and to the ASHAs to facilitate the early detection and decision making for the outcomes of pregnancy.

The public sector provides a wide range of contraceptive services for limiting and spacing of births at various levels of health system as described in Table 25.

Government of India is promoting "Fixed Day Static Services" (FDS) approach in sterilization services within the public health system with the aim of increasing access to sterilization services. States are being provided technical and financial support for the development of human resources and upgradation of health facilities for the functioning of FDS. In the states with high unmet need for limiting methods, sterilization camps will continue till the time FDS is implemented effectively. The frequency of sterilization services at different health facilities at FDS is as follows *(9)* :

District hospital	– weekly
Sub-district hospital	– weekly
CHC/Block PHC	– fortnightly
24x7 PHC/PHC	– monthly

Community Needs Assessment Approach *(116)*

Till recently, the achievements of family welfare programme were assessed on the basis of the targets given from the centre for individual contraceptives. This led to a situation where the achievement of the contraceptive targets had become the ends by themselves. Over the years it became apparent that there were many drawbacks in the top down target approach in which types and quantity of contraceptive need to be canvassed was decided by the higher authorities. Firstly, the user preference was not

TABLE 25

Family planning services in public health sector

Family planning method	Service provider	Service location	Service strategy and promotional schemes
Spacing Methods			
IUCD 380 A	Trained & certified ANMs, LHVs, SNs and Doctors	Sub-centre & higher levels	• On demand • Camp approach • Revised Compensation Scheme
Oral contraceptive pills (OCPs)	Trained ASHAs, ANMs, LHVs, SNs and Doctors	At door step (in pilot districts), Village level Subcentre & higher levels	• On demand • Village Health Nutrition Days
Condoms	Trained ASHAs, ANMs, LHVs, SNs and Doctors	At door step (in pilot districts), Village level Subcentre & higher levels	• On demand • Village Health Nutrition Days
Limiting Methods			
Minilap	Trained & certified MBBS Doctors & Specialist Doctors	PHC & higher levels	• Fixed Day Static Approach • Camp approach • Revised Compensation Scheme
Laparoscopic sterilization	Trained & certified Specialist Doctors (OBG & General Surgeons)	Usually CHC & higher levels	• National Family Planning Insurance Scheme
NSV (No Scalpel Vasectomy)	Trained & certified MBBS Doctors & Specialist Doctors	PHC & higher levels	
Emergency Contraception			
Emergency contraceptive pills (ECPs)	Trained ASHAs, ANMs, LHVs, SNs and Doctors	At door step (in pilot districts) Village level, Subcentre & higher levels	• On demand • Village Health Nutrition Days

ANM : Auxiliary Nurse Midwife; LHV : Lady Health Visitor; SN : Staff Nurse; ASHA : Accredited Social Health Activist.

Source : *(112)*

reflected in the targets. If the contraceptive required in accordance with the user was not available, the targets were not likely to be achieved. There was no authentic system of feedback regarding which type of contraceptive was to be promoted in a particular area or among a particular age group. Secondly, the quality of the services became secondary. For example, if in an attempt to fulfil targets for the number of IUD insertions, the quality of care is compromised (especially while screening women for pre-existing reproductive tract infections and sexually transmitted diseases before IUD insertion) the acceptability of IUD programme would receive a serious setback and discontinuation rate will be high. Thirdly, people may be tempted to resort to false reporting to claim fulfilment of the target. In other words, contraceptive targets and cash incentives resulted in the inflation of performance statistics and deterioration in the quality of services.

Government of India deliberated objectively on the utility of retaining the practice of targets at national and state levels. In the year 1995–96, one district in each of 18 states (including a pilot project in Kerala and Tamil Nadu) were made target free. Later on the practice of fixing up of targets for individual contraceptive method was given up from April 1996. This does not mean a licence to do no work. The population goals remain the same as before. Health workers are expected to consult families and local community in the beginning of the year in order to assess their needs and preference and then work-out for themselves the programme and workload for the coming year. The requirement for each village needs to be worked out to arrive at the workload for the ANM, this becomes the target for the ANM for the year. The workload of different ANMs under one PHC when added up would determine the workload for the PHC. Similarly requirements at the district level would be worked out by adding up the requirements at all the PHCs.

Later on it was found that due to complex calculations required the health workers were unable to fix the performance norms for themselves. Therefore, it was decided to modify and rename the target free manual as *Community Needs Assessment Approach Manual.*

Involvement of private sector

The family planning programme, to be successful, will have to be extended beyond the government delivery system to include the private sector. Grants-in-aid are provided to voluntary organizations and industrial organizations for running family welfare centres and postpartum centres. The scheme for involvement of private medical practitioners in the family welfare programme has been extended to practitioners of integrated medicine. Government has also created nation–wide retail outlets for selling subsidized condoms.

Incentives and dis-incentives

The use of incentives and dis-incentives to encourage couples to practise family planning has become a common strategy in many developing countries. Financial compensation of individuals undergoing sterilization was first introduced in 1966; over the years, it has been gradually increased. The acceptors now receive a one–time payment of Rs.600 for conventional tubectomy, Rs. 1100 for vasectomy and Rs. 145 for laparoscopic tubectomy, and Rs. 75 are given to IUD receptors. Motivators also receive a small amount (Rs.150 for tubectomy and Rs. 200 for vasectomy). State government employees, who undergo sterilization after two or three children are eligible for a special increment (two increments after 2 children and one after 3 children). Central government employees get one increment after sterilization. It is under the scheme introduced in Dec. 1979 to promote small family norm, provided the employee is below 50 years of age and his spouse below 45 years. They get special leave (14 days for women and 7 days for men). No maternity leave is allowed after 3 children.

In the event of death following sterilization, recanalization, or IUD insertion, ex-gratia payment of Rs. 50,000 has been authorised to be paid to the surviving spouse, natural heir, etc. Rs. 30,000 per case of incapacitation and Rs. 20,000 per case of cost of treatment of serious post-operative complications *(9)*.

The State Governments have been requested to : issue Green Cards to individual acceptors of terminal methods after two children as a mark of recognition and for priority attention in schemes where preferential treatment was feasible. Cash awards have been instituted for the best performing states, the amount of which will be spent on promoting family welfare activities *(117)*.

Family welfare linked health insurance scheme *(9)*

Government of India has introduced a family planning insurance scheme for acceptors of sterilization and indemnity cover for doctors performing sterilization procedures in both government and accredited private/ NGO/corporate health facilities. The insurance scheme will be operated by the ICICI.

Compensation in the event of death :

In the event of death following sterilization (inclusive of death during process of sterilization operation) in hospital or within 7 days from the date of discharge from the hospital, the compensation available is Rs. 2 lakh. Death following sterilization within 8–30 days from the date of discharge from the hospital, the compensation is Rs. 50,000 and the compensation for failure of sterilization operation is Rs. 30,000 and Rs 25,000 for medical complication occuring within 60 days of sterilization operation (to be reimbursed on the basis of actual expenditure incurred, not exceeding Rs 25,000) *(91)*.

All the doctors and health facilities rendering family planning services, conducting such operations shall stand indemnified against claims arising out of failure of sterilization, death or medical complications resulting there-from up to a maximum amount of Rs 2 lacs per doctor/ health facility per case. The cover would also include the legal costs and actual modality of defending the prosecuted doctor/ health facility in court, which would be borne by the insurance company within certain limits *(118)*.

Postpartum Programme *(119)*

An All India Hospital Postpartum Programme (AIHPP) was introduced in 1969. It is a hospital-based, maternity centred approach to family planning. The primary objective of the postpartum programme is to improve the health of the mother and children through MCH and Family Welfare programme which includes antenatal, neonatal, and postnatal services; immunization services to children and mothers; and prophylaxis against anaemia and blindness. The programme is based on the following rationale :

a. That women who have recently delivered are of proven fertility, and are at risk to become pregnant again rapidly
b. At the time of delivery and during the lying-in period, they are generally more receptive to adopt one or the other family planning method.

The postpartum programme offers necessary facilities to such women. It has proved to be an efficient way of delivering family planning services. The programme now covers 550 medical institutions at national, state and district levels inclusive of 100 medical colleges and 2 post-graduate institutions. A scheme of PAP smear test facilities has been sanctioned for all medical colleges.

With a view to provide MCH and family welfare services in rural and semi-urban areas, as well as to improve the health of mothers and children, the postpartum programme has been extended to sub-divisional and sub-district hospitals. 1,012 such centres are functioning in the country *(115)*.

Population education

Population education has been defined as "an educational programme which provides for a study of the population situation in the community, nation and world with the purpose of developing in the students rational and responsible attitudes and behaviour towards that situation" *(119)*. The content of population education programme is influenced by the specific national situation as well as by political and educational goals *(120)*.

In the Indian context, the concept of population education is designed to bring home to the students, both at school and university level the consequences of uncontrolled population growth; the benefits of a small family norm; the economics, sociology and statistics of population growth, its distribution and its relation to the levels of living.

SOCIOLOGY OF FAMILY PLANNING

The institution of family is as old as man himself. It is the basic social cell. The need for its discipline has only recently dawned because of changing economic, social and cultural patterns in the world – and above all, because of concern of what might be called "quality of life" criteria. Sociologists and economists have shown that it will be difficult to raise the living standards of the people while population growth continues unchecked. The gains of the five year developmental plans are being absorbed by the rapidly growing population for basic consumption, e.g., food, shelter, clothing, education and medical care.

Attitude surveys have shown that awareness of family planning is very widespread and over 60 per cent people have attitudes favourable to restricting or spacing births *(27)*. People are generally in favour of family planning, and there is no organized opposition to it. Inspite of this, the rate of contraceptive use by couples in the developing countries is very low. This is the crux of the family planning problem. Studies have shown that the population problem is complicated by deep–rooted religious and other beliefs, attitudes and practices favouring larger families (e.g., strong preference for male children). The common beliefs are – that children are the gift of God; the number of children is determined by God; children are a poor man's wealth; children are an asset to which parents can look forward in periods of dependency caused by old age or misfortune, etc. Most of these beliefs stem from ignorance and lack of communication.

The problem of family planning is, therefore, essentially the problem of social change. Contraceptive technology is no short cut to the problem. What is more important is to stimulate social changes affecting fertility such as raising the age of marriage, increasing the status of women, education and employment opportunities, old age security, compulsory education of children, accelerating economic changes designed to increase the per capita income, etc. It is now axiomatic that economic development is the best contraceptive. The experience of all countries which have had a successful population control show that the best motivation is economic, a desire to improve standard of living. The solution to the problem is one of mass education and communication, so that people may understand the benefits of a small family.

VOLUNTARY ORGANIZATIONS

Voluntary organizations have played a major role in population control programmes since the beginning. They are involved in every possible way so as to complement governmental efforts to promote Family Welfare Programme. Apart from educational and motivational efforts, their activities include running of Family Welfare Centres, post–partum centres, ANM training schools, population research centres and other innovative projects.

Some of the well-known voluntary agencies in India are the Family Planning Association of India, the Family Planning Foundation and the Population Council of India. Others include the Indian Red Cross, the Indian Medical Association, Rotary Clubs, Lions Clubs, Citizens Forum, Christian Missionaries and Private Hospitals.

At the international level, the International Planned Parenthood Federation is the world's largest private voluntary organization supporting family planning services in developing countries. It is an international federation of independent Family Planning Associations with headquarters in London. Others with long experience in this field include the United Nations Fund for Population Activities (UNFPA), the US Agency for International Development (USAID), the Population Council, Ford Foundation, the Pathfinder Fund and World Bank besides WHO and UNICEF. The international agencies are assisting in funding family planning research, services, training and information programmes designed to reduce the family size.

NATIONAL FAMILY WELFARE PROGRAMME

India launched a nation–wide family planning programme in 1952, making it the first country in the world to do so, though records show that birth control clinics have been functioning in the country since 1930. The early beginnings of the programme were modest with the establishment of a few clinics and distribution of educational material, training and research. During the Third Five Year Plan (1961–66), family planning was declared as "the very centre of planned development". The emphasis was shifted from the purely "clinic approach" to the more vigorous "extension education approach" for motivating the people for acceptance of the "small family norm". The introduction of the Lippes Loop in 1965 necessitated a major structural reorganization of the programme, leading to the creation of a separate Department of Family Planning in 1966 in the Ministry of Health. During the years 1966–1969, the programme took firmer roots. The family planning infrastructure (e.g., primary health centres, sub-centres,

urban family planning centres, district and State bureaus) was strengthened. During the Fourth Five Year Plan (1969–74), the Government of India gave "top priority" to the programme. The Programme was made an integral part of MCH activities of PHCs and their sub-centres. In 1970, an All India Hospital Postpartum Programme and in 1972, the Medical Termination of Pregnancy (MTP) Act were introduced. During the Fifth Five Year Plan (1975–80) there have been major changes. In April 1976, the country framed its first "National Population Policy". The disastrous forcible sterilization campaign of 1976 led to the Congress defeat in the 1977 election. In June 1977, the new (Janata) Government that came into power formulated a new population policy, ruling out compulsion and coercion for all times to come. The Ministry of Family Planning was renamed "Family Welfare".

Although the performance of the programme was low during 1977–78, it was a good year in as much as the programme moved into new healthier directions. The 42nd Amendment of the Constitution has made "Population control and Family Planning" a concurrent subject, and this provision has been made effective from January 1977. The acceptance of the programme is now purely on voluntary basis. The launching of the Rural Health Scheme in 1977 and the involvement of the local people (e.g., Health Guides, trained Dais, Opinion leaders) in the family welfare programme at the grass–root level were aimed at accelerating the pace of progress of the programme. India was a signatory to the Alma Ata Declaration in 1978. The acceptance of the primary health care approach to the achievement of HFA/2000 AD led to the formulation of a National Health Policy in 1982. The National Health Policy was approved by the Parliament in 1983. It laid down the long–term demographic goal of NRR=1 by the year 2000 – which implies a 2–child family norm – through the attainment of a birth rate of 21 and a death rate of 9 per thousand population, and a couple protection rate of 60 per cent by the year 2000. The Sixth and Seventh Five Year Plans were accordingly set to achieve these goals. The National Health Policy also called for restructuring the health care delivery system to achieve HFA/2000 AD, and family planning has been accorded a central place in health development.

The Universal Immunization Programme aimed at reduction in mortality and morbidity among infants and younger children due to vaccine preventable diseases was started in the year 1985–86. The oral rehydration therapy was also started in view of the fact that diarrhoea was a leading cause of death among children. Various other programmes under MCH were also implemented during the Seventh Five Year Plan. The objective of all these programmes were convergent and aimed at improving the health of the mothers and young children, and to provide them facilities for prevention and treatment of major diseases. During 1992 these programmes were integrated under Child Survival and Safe Motherhood (CSSM) Programme.

The process of integration of related programmes initiated was taken a step further during 1994 when the International Conference on Population and Development in Cairo recommended implementation of Unified Reproductive and Child Health Programme (RCH). It is obviously sensible that integrated RCH programme would help in reducing cost of inputs to some extent because overlapping of expenditure would no longer be necessary and outcome will be better. Accordingly, during Ninth Five Year Plan the RCH Programme integrates all the related programmes of the Eighth Five Year Plan. The concept of RCH is to provide need based, client oriented, demand driven, high quality integrated services.

The Government of India evolved a more detailed and comprehensive National Population Policy 2000 (see page 493) to promote family welfare.

The investment on family welfare programme during successive plan–periods is tabulated below *(121)*. It can be seen that from a modest sum of 0.65 crores during the first plan, the investment has reached a colossal amount of Rs. 136,147 crores during the Eleventh Plan period.

Expenditure under the programme from the first to Eleventh five year plans

Period	Expenditure (Rs. in crores)
First plan (1951–56)	0.65
Second plan (1956–61)	5.00
Third plan (1961–66)	27.00
Annual plan (Inter plan 1966–69)	82.90
Fourth plan (1969–74)	285.80
Fifth plan (1974–79)	285.60
Annual plan (1978–79)	101.80
Annual plan (1979–80)	116.20
Sixth plan (1980–85)	1,309.00
Seventh plan (1985–90)	2,868.00
Annual plan (1990–91)	675.00
Annual plan (1991–92)	749.00
Eighth plan (1992–97)	6,195.00
Ninth plan (1997–2002)	14,170.00
Tenth plan (2002–2007)	58,920.30
Eleventh plan (2007–2012)	136,147.00

EVALUATION OF FAMILY PLANNING

Evaluation is defined as a "process of making judgements about selected objectives and events by comparing them with specified value standards for the purpose of deciding alternative course of action". The purpose of evaluation is to improve the design and delivery of family planning services.

Five types of evaluation have been defined by a WHO Expert Committee in 1975 *(30)* on evaluation of family planning in health services :

1. Evaluation of need

That is, health, demographic and socio-economic needs for family planning. For example, the current status of maternal mortality in a given area is an indicator of the need for family planning.

2. Evaluation of plans

That is, an assessment of the feasibility and adequacy of programme plans.

3. Evaluation of performance

(a) *Services* : Clinic services, mobile services, post-partum services, contraceptive distribution, follow up services, education and motivation activities.

(b) *Response* : Number of new acceptors, characteristics of acceptors.

(c) *Cost analysis.*

(d) *Other activities* : Administration, manpower, data system, etc.

4. Evaluation of effects

Changes in knowledge, attitudes, motivation and behaviour.

5. Evaluation of impact

A WHO Study Group in 1976 *(122)* proposed the following indices for evaluating the impact : (a) Family size (number of living children (b) desired number of additional children (c) birth interval (d) age of the mother at birth of first child and last child (e) birth order, and (f) number of abortions. To this may be added, changes in birth rate and growth rate.

Evaluation is a technical activity that requires trained personnel, statistical facilities and adequate flow of data and information.

The Family Welfare Programme in India has come a long way and holds forth the promise that in the not very distant future it may be accepted as a way of life by most people. Although birth control continues to occupy the same important position in the programme as it used to be in the earlier days the programme now aims at achieving a higher end – and that is, to improve, in conjunction with other development programmes, the quality of life of the people *(121)*.

9 Preventive Medicine in Obstetrics, Paediatrics and Geriatrics

"The test of any civilization is the measure of consideration and care which it gives to its weaker members"

In any community, mothers and children constitute a priority group. In sheer numbers, they comprise approximately 71.14 per cent of the population of the developing countries. In India, women of the child-bearing age (15 to 44 years) constitute 22.2 per cent, and children under 15 years of age about 35.3 per cent of the total population. Together they constitute nearly 57.5 per cent of the total population. By virtue of their numbers, mothers and children are the major consumers of health services, of whatever form.

Mothers and children not only constitute a large group, but they are also a "vulnerable" or special-risk group. The risk is connected with child-bearing in the case of women; and growth, development and survival in the case of infants and children. Whereas 50 per cent of all deaths in the developed world are occurring among people over 70, the same proportion of deaths are occurring among children during the first five years of life in the developing world. Global observations show that in developed regions maternal mortality ratio averages at 16 per 100,000 live births; in developing regions the figure is 440 for the same number of live births *(1)*. From commonly accepted indices, it is evident that infant, child and maternal mortality rates are high in many developing countries. Further, much of the sickness and deaths among mothers and children is largely preventable. By improving the health of mothers and children, we contribute to the health of the general population. These considerations have led to the formulation of special health services for mothers and children all over the world.

The problems affecting the health of mother and child are multifactorial. Despite current efforts, the health of mother and child still constitutes one of the most serious health problems affecting the community, particularly in the developing countries. The present strategy is to provide mother and child health services as an integrated package of "essential health care", also known as **primary health care** which is based on the principles of equity, intersectoral coordination and community participation. The primary health care approach combines all elements in the local community necessary to make a positive impact on the health status of the population, including the health of mothers and children.

Mother and child – one unit

Mother and child must be considered as one unit. It is because: (1) during the antenatal period, the foetus is part of the mother. The period of development of foetus in mother is about 280 days. During this period, the foetus obtains all the building materials and oxygen from the mother's blood; (2) child health is closely related to maternal health. A healthy mother brings forth a healthy baby; there is less chance for a premature birth, stillbirth or abortion; (3) certain diseases and conditions of the mother during pregnancy (e.g., syphilis, german measles, drug intake) are likely to have their effects upon the foetus; (4) after birth, the child is dependant upon the mother. At least up to the age of 6 to 9 months, the child is completely dependant on the mother for feeding. The mental and social development of the child is also dependant upon the mother. If the mother dies, the child's growth and development are affected (maternal deprivation syndrome); (5) in the care cycle of women, there are few occasions when service to the child is not simultaneously called for. For instance, postpartum care is inseparable from neonatal care and family planning advice; (6) the mother is also the first teacher of the child. It is for these reasons, the mother and child are treated as one unit.

Obstetrics, Paediatrics and Preventive and Social Medicine

In the past, maternal and child health services were rather fragmented, and provided piecemeal "personal health services" by different agencies, in different ways and in separate clinics. The current trend in many countries is to provide integrated MCH and family planning services as compact family welfare service. This implies a close relationship of maternity health to child health, of maternal and child health to the health of the family; and of family health to the general health of the community. In providing these services, specialists in obstetrics and child health (paediatrics) have joined hands, and are now looking beyond the four walls of hospitals into the community to meet the health needs of mothers and children aimed at positive health. In the process, they have linked themselves to preventive and social medicine, and as a result, terms such as "social obstetrics", "preventive paediatrics" and "social paediatrics" have come into vogue.

OBSTETRICS

Obstetrics is largely preventive medicine. The aim of obstetrics and preventive medicine is the same, viz. to ensure that throughout pregnancy and puerperium, the mother will have good health and that every pregnancy may

culminate in a healthy mother and a healthy baby. The age-old concept that obstetrics is only antenatal, intranatal and postnatal care, and is thus concerned mainly with technical skills, is now considered as a very narrow concept, and is being replaced by the concept of **community obstetrics** which combines obstetrical concerns with concepts of primary health care.

SOCIAL OBSTETRICS

The concept of **social obstetrics** has gained currency in recent years. It may be defined as the study of the interplay of social and environmental factors and human reproduction going back to the preconceptional or even premarital period. The social and environmental factors which influence human reproduction are a legion, viz. age at marriage, child bearing, child spacing, family size fertility patterns, level of education, economic status, customs and beliefs, role of women in society, etc. A study of these factors is an important aspect of social obstetrics. The social obstetric problems in India, differ from the social obstetric problems in the developed countries, because of various differing social, economic, cultural and other factors. While accepting the influence of environmental and social factors on human reproduction, social obstetrics has yet another dimension, that is the influence of these factors on the organization, delivery and utilization of obstetric services by the community. In other words, social obstetrics is concerned with the delivery of comprehensive maternity and child health care services including family planning so that they can be brought within the reach of the total community *(2)*.

Preventive paediatrics

Paediatrics which is synonymous with child health is that branch of medical science that deals with the care of children from conception to adolescence, in health and disease. Paediatrics is one of the first clinical subjects to link itself to preventive medicine. Like obstetrics, paediatrics has a large component of preventive and social medicine. There is no other discipline so comprehensive as paediatrics that teaches the value of preventive medicine. Recent years have witnessed further specialization within the broad field of paediatrics viz. preventive paediatrics, social paediatrics, neonatology, perinatology, developmental paediatrics, paediatric surgery; paediatric neurology, and so on.

Preventive paediatrics comprises efforts to avert rather than cure disease and disabilities. It has been broadly divided into *antenatal paediatrics* and *postnatal paediatrics*. The aims of preventive paediatrics and preventive medicine are the same: prevention of disease and promotion of physical, mental and social well-being of children so that each child may achieve the genetic potential with which he/she is born. To achieve these aims, hospitals for children have adopted the strategy of "primary health care" to improve child health care through such activities as growth monitoring, oral rehydration, nutritional surveillance, promotion of breast-feeding, immunization, community feeding, regular health check-ups, etc. Primary health care with its potential for vastly increased coverage through an integrated system of service delivery is increasingly looked upon as the best solution to reach millions of children, especially those who are most in need of preventive and curative services.

Social paediatrics

The challenge of the time is to study child health in relation to community, to social values and to social policy. This has given rise to the concept of social paediatrics. Social paediatrics has been defined as "the application of the principles of social medicine to paediatrics to obtain a more complete understanding of the problems of children in order to prevent and treat disease and promote their adequate growth and development, through an organized health structure *(3)*." Social paediatrics, like social obstetrics, covers a wide responsibility. It is concerned not only with the social factors which influence child health but also with the influence of these factors on the organization, delivery and utilization of child health care services. In other words, social paediatrics is concerned with the delivery of comprehensive and continuous child health care services and to bring these services within the reach of the total community. Social paediatrics also covers the various social welfare measures – local, national and international – aimed to meet the total health needs of a child.

Preventive and social medicine, with its involvement in total community care, and expertise in epidemiology and in the methodology of collection and utilization of data relating to the community and the environment, makes an indispensable contribution to social obstetrics and social paediatrics in the :

1. collection and interpretation of community statistics, delineating groups "at risk" for special care;
2. correlation of vital statistics (e.g., maternal and infant morbidity and mortality rates, perinatal and child mortality rates) with social and biological characteristics such as birth weight, parity, age, stature, employment etc. in the elucidation of aetiological relationships;
3. study of cultural patterns, beliefs and practices relating to childbearing and childrearing, knowledge of which might be useful in promoting acceptance and utilization of obstetric and paediatric services by the community;
4. to determine priorities and contribute to the planning of MCH services and programmes, and
5. for evaluating whether MCH services and programmes are accomplishing their objectives in terms of their effectiveness and efficiency.

Hitherto, obstetrics, paediatrics and preventive and social medicine were operating in watertight compartments. The emergence of social paediatrics, social obstetrics and their association with preventive and social medicine are certainly new developments in contemporary medicine. In some Universities, a chair of social paediatrics has also been established. The increasing coming together of these disciplines augurs well for the provision of comprehensive mother and child health care and family planning services as a compact family welfare service.

Maternity cycle

The stages in maternity cycle are :

(i) Fertilization
(ii) Antenatal or prenatal period
(iii) Intranatal period
(iv) Postnatal period
(v) Inter-conceptional period.

Fertilization takes place in the outer part of the fallopian tube. Segmentation of the fertilized ovum begins at once and proceeds at a rapid rate. The fertilized ovum reaches the uterus in 8 to 10 days. Cell division proceeds at a rapid rate. By a process of cell division and differentiation, all the organs and tissues of the body are formed. The periods of growth have been divided as follows :

1. Prenatal period :
   - (a) Ovum – 0 to 14 days
   - (b) Embryo – 14 days to 9 weeks
   - (c) Foetus – 9th week to birth
2. Premature infant – from 28 to 37 weeks
3. Birth, full term – average 280 days.

MCH problems

MCH problems cover a broad spectrum. At one extreme, the most advanced countries are concerned with problems such as perinatal problems, congenital malformations, genetic and certain behavioural problems. At the other extreme, in developing countries, the primary concern is reduction of maternal and child mortality and morbidity, spacing of pregnancies, limitation of family size, prevention of communicable diseases, improvement of nutrition and promoting acceptance of health practices. Currently, the main health problems affecting the health of the mother and the child in India, as in other developing countries, revolve round the triad of *malnutrition, infection* and the consequences of *unregulated fertility (4)*. Associated with these problems is the scarcity of health and other social services in vast areas of the country together with poor socio-economic conditions.

1. MALNUTRITION

Malnutrition is like an iceberg; most people in the developing countries live under the burden of malnutrition. Pregnant women, nursing mothers and children are particularly vulnerable to the effects of malnutrition. The adverse effects of maternal malnutrition have been well documented–maternal depletion, low birth weight, anaemia, toxemias of pregnancy, postpartum haemorrhage, all leading to high mortality and morbidity. The effects of malnutrition are also frequently more serious during the formative years of life. Previously it was thought that malnutrition was largely concentrated in school age children, and in toddlers. Now it is realized that the *intrauterine period* of life is a very important period from the nutritional standpoint. Infants born with adequate birth weight have relatively low mortality even under poor environmental conditions. The next critical period of childhood is the *period of weaning*. Severe malnutrition coincides with the age at which babies are usually weaned. Susceptibility to infection and severity of illness are significantly less in well nourished, than in malnourished children. Nutrition protection and promotion is, therefore, an essential activity of MCH care.

Measures to improve the nutritional status of mothers and children may be broadly divided into *direct* and *indirect* nutrition interventions *(4)*. *Direct interventions* cover a wide range of activities, viz. supplementary feeding programmes, distribution of iron and folic acid tablets, fortification and enrichment of foods, nutrition education, etc. *Indirect nutrition* interventions have still wider ramifications because they are not specifically related to nutrition. These include measures such as control of communicable diseases through immunization, improvement of environmental sanitation, provision of clean drinking water, family planning, food hygiene, education and primary health care. Nutritional surveillance is becoming increasingly important for identifying subclinical malnutrition, as it tends to be overlooked in both the mother and the child. The primary health worker (community worker) can play a vital role in improving the nutritional status of mothers and children.

2. INFECTION

Maternal infections may cause a variety of adverse effects such as foetal growth retardation, low birth weight, embryopathy, abortion and puerperal sepsis. In industrial societies, the risk of the mother acquiring infections during pregnancy is relatively low, but in underdeveloped areas, the mother is exposed to significantly higher risks. Many women are infected with HIV, hepatitis B, cytomegalo viruses, herpes simplex virus or toxoplasma during pregnancy. Furthermore, as many as 25 per cent of the women in rural areas suffer at least one bout of urinary infection *(5)*.

As far as the baby is concerned, infection may begin with labour and delivery and increase as the child grows older. Children may be ill with debilitating diarrhoeal, respiratory and skin infections for as much as a *third* of *their first year of life*. In some regions, the situation is further aggravated by such chronic infections as malaria and tuberculosis. The occurrence of multiple and frequent infections may precipitate in the children a severe protein-energy malnutrition and anaemia. When the child becomes ill, traditions, beliefs and taboos enter into play; the indirect effect of infections may be more important than the direct one in traditional societies *(5, 6)*.

Prevention and treatment of infections in mother and children is a major and important part of normal MCH care activity. It is now widely recognized that children in developing areas need to be immunized against six infections – tuberculosis, diphtheria, whooping cough, tetanus, measles and polio. Many countries, including India, have adopted the WHO Expanded Programme on Immunization as part of everyday MCH care. Tetanus toxoid application during pregnancy has also been taken up. Education of mothers in medical measures such as oral rehydration in diarrhoea and febrile diseases is being tried. In addition, a good knowledge and practice of personal hygiene and appropriate sanitation measures, particularly in and around the home, are essential pre-requisites for the control of the most common infections and parasitic diseases.

3. UNCONTROLLED REPRODUCTION

The health hazards for the mother and the child resulting from unregulated fertility have been well recognized – increased prevalence of low birth weight babies, severe anaemia, abortion, antepartum haemorrhage and a high maternal and perinatal mortality, which have shown a sharp rise after the 4th pregnancy. Statistics have shown that in almost every country in the world, a high birth rate is associated with a high infant mortality rate and under-five death rate (Table 1).

TABLE 1

Selected rates by country for crude birth rates, infant mortality rates and under-five mortality rates (2012)

Country	Crude birth rate per 1000 population	IMR per 1000 live births	Under–five mortality rate per 1000 live births
India	21.6	44	56
Pakistan	26	69	86
Bangladesh	20	33	41
Thailand	12	11	13
Sri Lanka	18	8	10
China	13	12	14
Switzerland	10	4	4
UK	12	5	4
USA	13	6	7
Singapore	10	2	3
Japan	8	2	3

Source : *(7)*

Because family planning has a striking impact on the health of the mother and the child, a number of countries have integrated family planning in the MCH care activities. The introduction of new types of IUD; easier and safer techniques of pregnancy termination and female sterilization; oral pills and long-acting injectable medroxy-progesterone acetate (MPA) have contributed a good deal in the utilization of family planning services. In some countries, MCH programmes are extending their scope to include family-life education in schools. There is also an increasing acceptance of the role of traditional midwives and community health workers, with suitable training for the extension of family planning services to remote rural areas.

Maternal and child health

The term "maternal and child health" refers to the promotive, preventive, curative and rehabilitative health care for mothers and children. It includes the sub-areas of maternal health, child health, family planning, school health, handicapped children, adolescence, and health aspects of care of children in special settings such as day care *(4)*.

The specific objectives of MCH are (a) reduction of maternal, perinatal, infant and childhood mortality and morbidity; (b) promotion of reproductive health; and (c) promotion of the physical and psychological development of the child and adolescent within the family. The ultimate objective of MCH services is lifelong health *(4)*.

Pregenancy detection

The simple way to confirm pregnancy in the first trimester is to conduct a urine examination using a pregnancy test kit. The kit detects pregnancy on the basis of presence of human chorionic gonadotrophin hormone in the urine. The test is performed soon after a missed period and is simple to perform. The pregnancy test should be offered to any women who is in reproductive age group and comes with a history of amenorrhoea or symptoms of pregnancy. The Government of India has made "Nischay" pregnancy test kit available across the country. Other test kits are also available in the market. The kit is provided to ASHA or other link workers and the women should be advised appropriately on the result of the test *(8)*.

ANTENATAL CARE

Antenatal care is the care of the woman during pregnancy. The primary aim of antenatal care is to achieve at the end of a pregnancy a healthy mother and a healthy baby. Ideally this care should begin soon after conception and continue throughout pregnancy. In some countries, notification of pregnancy is required to bring the mother in the prevention care cycle as early as possible.

Objectives

The objectives of antenatal care are :

(1) To promote, protect and maintain the health of the mother during pregnancy.
(2) To detect "high-risk" cases and give them special attention.
(3) To foresee complications and prevent them.
(4) To remove anxiety and dread associated with delivery.
(5) To reduce maternal and infant mortality and morbidity.
(6) To teach the mother elements of child care, nutrition, personal hygiene, and environmental sanitation.
(7) To sensitize the mother to the need for family planning, including advice to cases seeking medical termination of pregnancy; and
(8) To attend to the under-fives accompanying the mother.

The above objectives are achieved by the following programme of health care services :

(1) Antenatal visits

Ideally the mother should attend the antenatal clinic once a month during the first 7 months; twice a month, during the next month; and thereafter, once a week, if everything is normal. A high proportion of mothers in India are from lower socio-economic group, and many of them are working women. Attendance at the antenatal clinic may mean loss of daily wages. Consequently, it is difficult for them to attend the antenatal clinic so often. In these cases, a minimum of 4 visits covering the entire period of pregnancy should be the target, as shown below :

The suggested schedule is as follows *(8)* :

1st visit – within 12 weeks, preferably as soon as the pregnancy is suspected, for registration of pregnancy and first antenatal check-up.
2nd visit – between 14 and 26 weeks
3rd visit – between 28 and 34 weeks.
4th visit – between 36 weeks and term.

It is advisable for the woman to visit medical officer at the PHC for an antenatal check-up during the period of 28–34 weeks (3rd visit). Besides this, she may be advised to avail investigation facilities at the nearest PHC/CHC/FRU.

Registration of pregnancy within 12 weeks is the primary responsibility of the ANM. Opportunities such as Village Health Nutrition Day should be availed to ensure early registration of pregnancy and antenatal check-up.

Early pregnancy detection is important for the following reasons *(8)* :

1. It facilitates proper planning and allows for adequate care to be provided during pregnancy for both the mother and the foetus.

2. Record the date of last menstrual period and calculate the expected date of delivery.
3. The health status of the mother can be assessed and any medical illness that she might be suffering from can be detected. Also to obtain and record the baseline information on blood pressure, weight, haemoglobin etc.
4. It helps in timely detection of complications at an early stage and helps to manage them appropriately by referral as and where required.
5. It also helps to confirm if the pregnancy is wanted and if not, then refer the women at the earliest to a 24 hours PHC or FRU that provides safe abortion services. The health personnel should be alert to the possibility of sex selective abortion as such abortions are illegal.
6. Early detection of pregnancy and provision of care from the initial stage facilitates a good interpersonal relationship between the care giver and the pregnant woman.

Estimation of number of pregnancies in a specified area and pregnancy tracking *(8)*

To ensure complete registration, it is essential that the ANM should know the estimated number of pregnancies to be registered annually in her area. Calculating the expected number of annual pregnancies in the area will help her judge how good her pregnancy registration is. In case the number of pregnancies registered is less than that of the estimated pregnancies, she needs to track down the pregnancies she has missed, with the help of ASHAs and AWWs. Estimating the number of pregnancies will also help her judge whether she has an adequate stock of the supplies required to provide routine ANC (such as TT injections, IFA tablets and ANC record forms) and tackle any complications that arise during this period.

The number of expected pregnancies per year :

The ANM must know the population size and birth rate of the area under her jurisdiction. The expected number of live births may be calculated as shown below :

$$\text{Expected no. of live births (Y)/year} = \frac{\text{Birth rate (per 1000 population)} \times \text{population of the area}}{1000}$$

As some pregnancies may not result in a live birth (i.e. abortions and stillbirths may occur), the expected number of live births would be an under-estimation of the total number of pregnancies. Hence, a correction factor of 10% is required, i.e. add 10% to the figure obtained above.

So, the total number of expected pregnancies

$$(Z) = Y + 10\% \text{ of } Y$$

As a thumb rule, in any given month, approximately half the number of pregnancies estimated above should be in records.

Example of estimation of the number of pregnancies annually

Birth rate	= 25/1000 population
Population under the sub-centre	= 5000
Therefore, expected number of live births	= (25×5000)/1000
	= 125 births
Correction factor (pregnancy wastage)	= 10% of 125
	= say 13
Therefore, total no. of expected pregnancies in a year	= 125 + 13 = 138

In any month, the ANM should have about 69 pregnancies registered with her.

If the number of women registered is less than expected, the ANM should approach community leaders and key people to ensure that the pregnant women are registered and come for ANC. ASHA and link worker should visit every house in the area and ensure that all pregnant women are registered. Some women may be receiving ANC from the private sector. Ensure that their names together with the names of the facilities where they are registered are mentioned in the antenatal register.

The ANM must keep track of all pregnant women in her area. In case a registered women does not turn-up for her ANC check-up, ANM must follow her and counsel her for the regular ANC check-up. An antenatal check-up after a missed appointment should include all the components of the missed visit(s) as well as those that correspond to the present visit. For example, the woman should be given her TT injection and supply of IFA tablets, her weight and blood pressure should be checked besides being screened for complications.

A policy decision has been taken for a name-based tracking system whereby pregnant women and children can be tracked for their ANCs and immunization along with a feedback system for the ANM, ASHA etc. This has been done to ensure that all pregnant women receive their ANCs and PNCs, and children receive full immunization. This will also help in tracking and ensuring ANC/PNC for missed/left out cases.

PREVENTIVE SERVICES FOR MOTHERS (ANTENATAL CHECK-UP)

A. The first visit, irrespective of when it occurs, should include the following components :

I. **History-taking**

During the first visit, a detailed history of the woman needs to be taken to : (1) Confirm the pregnancy (first visit only); (2) Identify whether there were complications during any previous pregnancy/confinement that may have a bearing on the present one; (3) Identify any current medical/surgical or obstetric condition(s) that may complicate the present pregnancy; (4) Record the date of 1st day of last menstrual period and calculate the expected date of delivery by addding 9 months and 7 days to the 1st day of last menstrual period. (5) Record symptoms indicating complications, e.g. fever, persisting vomiting, abnormal vaginal discharge or bleeding, palpitation, easy fatigability, breathlessness at rest or on mild exertion, generalized swelling in the body, severe headache and blurring of vision, burning in passing urine, decreased or absent foetal movements etc; (6) History of any current systemic illness, e.g., hypertension, diabetes, heart disease, tuberculosis, renal disease, epilepsy, asthma, jaundice, malaria, reproductive tract infection, STD, HIV/AIDS etc. Record family history of hypertension, diabetes, tuberculosis, and thalassaemia. Family history of twins or congenital malformation; and (7) History of drug allergies and habit forming drugs.

II. **Physical examination**

1. *Pallor :* Presence of pallor indicates anaemia. The woman should be examined for pallor at each visit. Examine woman's conjunctiva, nails, tongue, oral mucosa and palms. Pallor should be co-related with haemoglobin estimation.

2. *Pulse :* The normal pulse rate is 60 to 90 beats per minute. If the pulse rate is persistently low or high, with or without other symptoms, the woman needs medical attention.
3. *Respiratory rate :* It is important to check the respiratory rate, especially if the woman complaints of breathlessness. Normal respiratory rate is 18–20 breaths per minute.
4. *Oedema :* Oedema (swelling), which appears in the evening and disappears in the morning after a full night's sleep, could be a normal manifestation of pregnancy. Any oedema of the face, hands, abdominal wall and vulva is abnormal. Oedema can be suspected if a woman complains of abnormal tightening of any rings on her fingers. She must be referred immediately for further investigations. If there is oedema in association with high blood pressure, heart disease, anaemia or proteinuria, the woman should be referred to the medical officer.
5. *Blood pressure :* Measure the woman's blood pressure at every visit. This is important to rule out hypertensive disorders of pregnancy. Hypertension is diagnosed when two consecutive readings taken four hours or more apart show the systolic blood pressure to be 140 mmHg or more and/or the diastolic blood pressure to be 90 mmHg or more. High blood pressure during pregnancy may signify Pregnancy-Induced Hypertension (PIH) and/or chronic hypertension. If the woman has high blood pressure, check her urine for the presence of albumin. The presence of albumin (+2) together with high blood pressure is sufficient to categorize her as having pre-eclampsia. Refer her to the MO immediately. If the diastolic blood pressure of the woman is above 110 mmHg, it is a danger sign that points towards imminent eclampsia. The urine albumin should be estimated at the earliest. If it is strongly positive, the woman should be referred to the FRU IMMEDIATELY. If the woman has high blood pressure but no urine albumin, she should be referred to the MO at 24×7 PHC. A woman with PIH, pre-eclampsia or imminent eclampsia requires hospitalization and supervised treatment at a 24-hour PHC/FRU.
6. *Weight :* A pregnant woman's weight should be taken at each visit. The weight taken during the first visit/ registration should be treated as the baseline weight. Normally, a woman should gain 9–11 kg during her pregnancy. Ideally after the first trimester, a pregnant woman gains around 2 kg every month. If the diet is not adequate, i.e. if the woman is taking less than the required amount of calories, she might gain only 5–6 kg during her pregnancy. An inadequate dietary intake can be suspected if the woman gains less than 2 kg per month. She needs to be put on food supplementation. The help of the AWW should be taken in this matter, especially for those categories of women who need it the most. Low weight gain usually leads to Intrauterine Growth Retardation and results in the birth of a baby with a low birth weight. Excessive weight gain (more than 3 kg in a month) should raise suspicion of pre-eclampsia, twins (multiple pregnancy) or diabetes. Take the woman's blood pressure and test her urine for proteinuria and sugar. If the blood pressure is high and the urine is positive for protein or sugar, refer her to medical officer.
7. *Breast examination :* Observe the size and shape of the nipples for the presence of inverted or flat nipples.

III. **Abdonimal examination**

Examine the abdomen to monitor the progress of the pregnancy and foetal growth. The abdominal examination includes the following :

1. *Measurement of fundal height :* Enlargement of the uterus and the height of the uterine fundus is as shown in Fig. 1.
   a. 12 weeks – Uterine fundus just palpable per abdomen.
   b. 20 weeks – Fundus flat at the lower border of umbelicus.
   c. 36 weeks – Fundus felt at the level of xiphisternum.

   The duration of pregnancy should always be expressed in terms of completed weeks. In the first half of pregnancy the size of the uterus is of the greatest value in confirming the calculated duration of pregnancy.
2. *Foetal heart sounds :* The foetal heart sounds can be heard after 6th month. The rate varies between 120 to 140 per minute. They are usually best heard in the midline; after the 28th week, their location may change because of the position and lie of the foetus.
3. *Foetal movements :* Foetal movements can be felt by the examiner after 18–22nd week by gently palpating the abdomen.
4. *Foetal parts :* These can be felt about the 22nd week. After the 28th week, it is possible to distinguish the head, back and limbs.
5. *Multiple pregnancy :* This must be suspected if the uterus is larger than the estimated gestational age or palpation of multiple foetal parts.
6. *Foetal lie and presentation :* Relevant only after 32 weeks of pregnancy.
7. Inspection of abdominal scar or any other relevant abdominal findings.

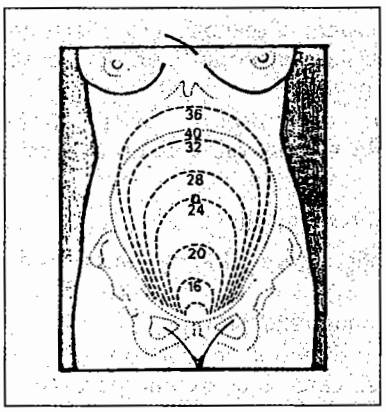

FIG. 1

Uterine fundal height at various stages of pregnancy (numbers indicate weeks of pregnancy)

IV. **Assessment of gestation age** *(9)*

Measurement of gestational age has changed over the time. As the dominant effect of gestational age on survival and long-term impairment has become apparent over the last 30 years, perinatal epidemiology has shifted from measuring birth weight alone to focusing on gestational age. The most accurate "gold standard" for assessment is routine early ultrasound assessment together with foetal measurements ideally in the first trimester. Gestational age

assessment based on the date of last menstrual period (LMP) was previously the most widespread method used and remains the only available method in many settings. Many countries now use "best obstetric estimate", combining ultrasound and LMP as an approach to estimate gestational age. It can have a large impact on the number of preterm births reported.

Any method using ultrasound requires skilled technicians, equipment and for maximum accuracy, first trimester antenatal clinic attendance. These are not common in low-income settings, where majority of preterm births occur. Alternative approaches to LMP in these settings include fundal height, clinical assessment of the newborn after birth or birth weight as a surrogate.

V. **Laboratory investigations**

The following laboratory investigations are carried out at the facilities indicated below :

a. At the sub-centre :
   - Pregnancy detection test
   - Haemoglobin examination
   - Urine test for presence of albumin and sugar
   - Rapid malaria test.

b. At the PHC/CHC/FRU :
   - Blood group, including Rh factor
   - VDRL/RPR
   - HIV testing
   - Rapid malaria test (if unavailable at SC)
   - Blood sugar testing
   - HBsAg for hepatitis B infection.

Essential components of every antenatal check-up :

1. Take the patient's history.
2. Conduct a physical examination–measure the weight, blood pressure and respiratory rate and check for pallor and oedema.
3. Conduct abdominal palpation for foetal growth, foetal lie and auscultation of foetal heart sound according to the stage of pregnancy.
4. Carry out laboratory investigations, such as haemoglobin estimation and urine tests for sugar and proteins.

Interventions and counselling

1. Iron and folic acid supplementation and medication as needed
2. Immunization against tetanus
3. Group or individual instruction on nutrition, family planning, self care, delivery and parenthood
4. Home visiting by a female health worker/trained dai
5. Referral services, where necessary.
6. Inform the woman about Janani Suraksha Yojana and other incentives offered by the government.

RISK APPROACH (10)

The central purpose of antenatal care is to identify "high risk" cases (as early as possible) from a large group of antenatal mothers and arrange for them skilled care, while continuing to provide appropriate care for all mothers. These cases comprise the following :

1. Elderly primi (30 years and over)
2. Short statured primi (140 cm and below)
3. Malpresentations, viz breech, transverse lie, etc.
4. Antepartum haemorrhage, threatened abortion
5. Pre-eclampsia and eclampsia
6. Anaemia
7. Twins, hydramnios
8. Previous still-birth, intrauterine death, manual removal of placenta
9. Elderly grandmultiparas
10. Prolonged pregnancy (14 days–after expected date of delivery)
11. History of previous caesarean or instrumental delivery
12. Pregnancy associated with general diseases, viz. cardiovascular disease, kidney disease, diabetes, tuberculosis, liver disease, malaria, convulsions, asthma, HIV, RTI, STI, etc.
13. Treatment for infertility.
14. Three or more spontaneous consecutive abortions.

The "risk approach" is a managerial tool for improved MCH care. Its purpose is to provide better services for all, but with special attention to those who need them most. Inherent in this approach is maximum utilization of all resources, including some human resources that are not conventionally involved in such care – traditional birth attendants, community health workers, women's groups, for example. The risk strategy is expected to have far–reaching effects on the whole organization of MCH/FP services and lead to improvements in both the coverage and quality of health care, at all levels, particularly at primary health care level.

MAINTENANCE OF RECORDS

A Mother and Child Protection Card should be duly completed for every woman registered. It contains a registration number, identifying data, previous health history and main health events etc. The case record should be handed over to the woman. She should be instructed to bring the record with her during all subsequent check-ups/visits and also to carry it along with her at time of delivery. This card has been developed jointly by the Ministry of Health and Family Welfare (MOHFW) and Ministry of Women and Child Development (MOWCD) to ensure uniformity in record keeping. This will also help the service provider to know the details of previous ANCs/PNCs both for routine and emergency care. The information contained in the card should also be recorded in the antenatal register as per the Health Management Information System (HMIS) format.

HOME VISITS

Home visiting is the backbone of all MCH services. Even if the expectant mother is attending the antenatal clinic regularly, it is suggested that she must be paid at least one home visit by the Health Worker Female or Public Health Nurse. More visits are required if the delivery is planned at home. The mother is generally relaxed at home. The home visit will win her confidence. The home visit will provide an opportunity to observe the environmental and social conditions at home and also an opportunity to give prenatal advice.

(2) Prenatal advice

A major component of antenatal care is antenatal or prenatal advice. The mother is more receptive to advice concerning herself and her baby at this time than at other

times. The "talking points" should cover not only the specific problems of pregnancy and child-birth but overflow into family and child health care.

(i) *DIET* : Reproduction costs energy. A pregnancy in total duration consumes about 60,000 kcal, over and above normal metabolic requirements. Lactation demands about 550 kcal a day. Further, child survival is correlated with birth weight. And birth weight is correlated to the weight gain of the mother during pregnancy. On an average, a normal healthy woman gains about 9–11 kg of weight during pregnancy. Several studies have indicated that weight gain of poor Indian women averaged 6.5 kg during pregnancy *(11)*. Thus pregnancy imposes the need for considerable extra calorie and nutrient requirements. If maternal stores of iron are poor (as may happen after repeated pregnancies) and if enough iron is not available to the mother during pregnancy, it is possible that foetus may lay down insufficient iron stores. Such a baby may show a normal haemoglobin at birth, but will lack the stores of iron necessary for rapid growth and increase in blood volume and muscle mass in the first year of life. Stresses in the form of malaria and other childhood infections will make the deficiency more acute, and many infants become severely anaemic during early months of life. A balanced and adequate diet is therefore, of utmost importance during pregnancy and lactation to meet the increased needs of the mother, and to prevent "nutritional stress".

(ii) *PERSONAL HYGIENE* : Of equal importance is advice regarding personal hygiene. (a) *Personal cleanliness* : The need to bathe every day and to wear clean clothes should be explained. The hair should also be kept clean and tidy. (b) *Rest and sleep* : 8 hours sleep, and at least 2 hours rest after mid-day meals should be advised. (c) *Bowels*: Constipation should be avoided by regular intake of green leafy vegetables, fruits and extra fluids. Purgatives like castor oil should be avoided to relieve constipation. (d) *Exercise*: Light household work is advised, but manual physical labour during late pregnancy may adversely affect the foetus. (e) *Smoking*: Smoking should be cut down to a minimum. Expectant mothers who smoke heavily produce babies much smaller than the average – it is because nicotine has a vasoconstrictor influence in the uterus and induces a degree of placental insufficiency. The adverse effects of smoking range from low birth-weight to an increased risk of perinatal death of the infant *(12)*. Women who smoke during pregnancy give birth to babies which on an average weigh 170g less at term than the babies of non-smokers. The perinatal mortality amongst babies whose mothers smoked during pregnancy is between 10–40 per cent higher than in non-smokers. (f) *Alcohol* : Evidence is mounting that alcohol can cause a range of fertility problems in women. Moderate to heavy drinkers who became pregnant have greater risk of pregnancy loss *(13)*, and if they do not abort, their children may have various physical and mental problems *(14)*. Heavy drinking has been associated with a fetal syndrome (FAS) which includes intrauterine growth retardation and developmental delay. More recently, it has been shown that the consumption of even moderate amount of alcohol during pregnancy is associated with an increased risk of spontaneous abortion *(15)*. (g) *Dental care*: Advice should also be given about oral hygiene. (h) *Sexual intercourse*: This should be restricted especially during the last trimester.

(iii) *DRUGS* : The use of drugs that are not absolutely essential should be discouraged. Certain drugs taken by the mother during pregnancy may affect the foetus adversely and cause foetal malformations. The classical example is thalidomide, a hypnotic drug, which caused deformed hands and feet of the babies born. The drug proved most serious when taken between 4 to 8 weeks of pregnancy. Other examples are LSD which is known to cause chromosomal damage, streptomycin which may cause 8th nerve damage and deafness in the foetus, iodide-containing preparations which may cause congenital goitre in the foetus *(16)*. Corticosteroids may impair foetal growth, sex hormones may produce virilism, tetracyclines may affect the growth of bones and enamel formation of teeth. Anaesthetic agents including pethidine administered during labour can have depressant effect on the baby and delay the onset of effective respiration. Later still in the puerperium, if the mother is breast-feeding, there are certain drugs which are excreted in breast milk. A great deal of caution is required in the drug-intake by pregnant women *(17)*.

(iv) *RADIATION* : Exposure to radiation is a positive danger to the developing foetus. The most common source of radiation is abdominal X-ray during pregnancy. Case cohort studies have shown that mortality rates from leukaemia and other neoplasms were significantly greater among children exposed to intrauterine X-ray. This is in addition to congenital malformations such as microcephaly. The X-ray examination in pregnancy should be carried out only for definite indications, X-ray dosage kept to minimum. Furthermore, in all women of child-bearing age among whom there is a possibility of pregnancy, elective X-ray should be avoided in the two weeks preceeding the menstrual period.

(v) *WARNING SIGNS* : The mother should be given clear-cut instructions that she should report immediately in case of the following warning signals : (a) swelling of the feet (b) fits (c) headache (d) blurring of the vision (e) bleeding or discharge per vagina, and (f) any other unusual symptoms.

(vi) *CHILD CARE* : The art of child care has to be learnt. Special classes are held for mothers attending antenatal clinics. Mother-craft education consists of nutrition education, advice on hygiene and childrearing, cooking demonstrations, family planning education, family budgeting, etc.

(3) Specific health protection

(i) *ANAEMIA* : Surveys in different parts of India indicate that about 50 to 60 per cent of women belonging to low socio-economic groups are anaemic in the last trimester of pregnancy *(11)*. The major aetiological factors being iron and folic acid deficiencies. It is well known that anaemia per se is associated with high incidence of premature births, postpartum haemorrhage, puerperal sepsis and thromboembolic phenomena in the mother. The Government of India has initiated a programme in which 100 mg of elemental iron and 500 mcg of folic acid are being distributed daily for 100 days to pregnant women through antenatal clinics, primary health centres and their subcentres.

(ii) *OTHER NUTRITIONAL DEFICIENCIES* : The mother should be protected against other nutritional deficiencies that may occur, particularly protein, vitamin and mineral especially vit A and iodine deficiency. In some MCH Centres fresh milk is supplied free of cost to all expectant mothers; where this is not possible, skimmed milk should be given. Capsules of vitamin A and D are also supplied free of cost.

(iii) *TOXEMIAS OF PREGNANCY* : The presence of albumine in urine and an increase in blood pressure

indicates toxemias of pregnancy. Their early detection and management are indicated. Efficient antenatal care minimizes the risk of toxemias of pregnancy.

(iv) *TETANUS* : If the mother was not immunized earlier, 2 doses of adsorbed tetanus toxoid should be given – the first dose at 16–20 weeks and the second dose at 20–24 weeks of pregnancy. The minimum interval between the 2 doses should be one month. No pregnant woman should be denied even one dose of tetanus toxoid, if she is seen late in pregnancy. For a woman who has been immunized earlier, one booster dose will be sufficient. When such a booster has been given, it will provide necessary cover for subsequent pregnancies, during the next 5 years. It is advised not to inject tetanus toxoid at every successive pregnancy because of the risk of hyperimmunization and side-effects.

(v) *SYPHILIS* : Syphilis is an important preventable cause of pregnancy wastage in some countries. Pregnancies in women with primary and secondary syphilis often end in spontaneous abortion, stillbirth, perinatal death, or the birth of a child with congenital syphilis. Syphilitic infection in the pregnant woman is transmissible to the foetus. Neurological damage with mental retardation is one of the most serious consequences of congenital syphilis. When the mother is suffering from syphilis, infection of the foetus does not occur before the 4th month of pregnancy; it is most likely to occur after the 6th month by which time the Langhan's cell layer has completely atrophied *(18)*. Infection of the foetus is most likely to occur when the mother is suffering from primary or secondary stages of syphilis than late syphilis.

It is routine procedure in antenatal clinics to test blood for syphilis at the first visit. Since the mother can subsequently get infected with syphilis, the ideal procedure would be to test blood for syphilis both early and late in pregnancy *(18)*. Congenital syphilis is easily preventable. Ten daily injections of procaine penicillin (600,000 units) are almost always adequate *(18)*.

(vi) *GERMAN MEASLES* : The best estimate of the total risk comes from the long-term prospective study carried out in Great Britain. When rubella was contracted in the first 16 weeks of pregnancy, foetal death or death during the first year of life occurred in the offspring of 17 per cent of the pregnancies. Among survivors who were followed upto age 8 years, 15 per cent had major defects, of which cataract, deafness and congenital heart diseases were the most common. Minor defects were found in an additional 16 per cent. It appears that the risk of all degrees of malformation may remain in the region of 20 per cent upto the 20th week *(19)*.

Ideally we should prevent infection during pregnancy by preventing and controlling the disease in the general population. In many countries, this is being attempted by vaccination of all school-aged children with rubella vaccine. Supplementing the community control of infection is the vaccination of all women of childbearing age who are sero-negative. Before vaccinating, it is advisable that pregnancy be ruled out and effective contraception be maintained for 8 weeks after vaccination because of the possible risk to the foetus from the virus.

(vii) *Rh STATUS* : The foetal red cells may enter the maternal circulation in a number of different circumstances, during labour, caesarean section, therapeutic abortion, external cephalic version, and apparently spontaneously in the late pregnancy. The intrusion of these cells, if the mother is Rh-negative and the child is Rh-positive, provokes an immune response in her so that she forms antibodies to Rh which can cross the placenta and produce foetal haemolysis. The same response may be produced to a greater degree by a transfusion of Rh-positive blood. In a pregnant woman, isoimmunization mainly occurs during labour, so that the first child although Rh-positive, is unaffected except where the mother has been already sensitized. In the second or subsequent pregnancies, if the child is Rh-positive, the mother will react to the smallest intrusion of foetal cells by producing antibodies to destroy foetal blood cells causing haemolytic disease in the foetus. Clinically haemolytic disease takes the form of *hydrops foetalis, icterus gravis neonatorum* (of which kernicterus is often a sequel) and congenital haemolytic anaemia.

It is a routine procedure in antenatal clinics to test blood for Rhesus type in early pregnancy. If the woman is Rh-negative and the husband is Rh-positive, she is kept under surveillance for determination of Rh-antibody levels during antenatal care. The blood should be further examined at 28 weeks and 34–36 weeks of gestation for antibodies. Rh anti-D immunoglobulin should be given at 28 weeks of gestation so that sensitization during the first pregnancy can be prevented. If the baby is Rh-positive, the Rh anti D immunoglobulin is given again within 72 hours of delivery. It should also be given after abortion. Post maturity should be avoided. Whenever there is evidence of haemolytic process in foetus-in-utero, the mother should be shifted to an equipped centre specialized to deal with Rh problems. The incidence of haemolytic disease due to Rh factor in India is estimated to be approximately one for every 400 to 500 live births.

(viii) *HIV INFECTION* : HIV may pass from an infected mother to her foetus, through the placenta or to her infant during delivery or by breast-feeding. About one-third of the children of HIV–positive mothers get infected through this route. The risk of transmission is higher if the mother is newly infected or if she has already developed AIDS. Voluntary prenatal testing for HIV infection should be done as early in pregnancy as possible for pregnant women who are at great risk (if they or their partner has a number of sexual partners; has a sexually transmitted disease; uses illicit injectable drugs etc.). Universal confidential voluntary screening of pregnant women in high-prevalence areas may allow infected women to choose therapeutic abortion, make an informed decision on breast-feeding, or receive appropriate care. Screening should not be used as a substitute for primary prevention through community-wide education on safe sexual practice, making condoms readily available and preventing parenteral transmission *(20)*.

(ix) *HEPATITIS B INFECTION* : Spread of infection from HBV carrier mothers to their babies appears to be a factor for the high prevalence of HBV infection in some regions. The mechanism of perinatal infection is uncertain. Most infections appear to occur at birth. Transmission of the virus to the baby after delivery is likely if both surface antigen and e antigen are positive. Vertical transmission can be blocked by immediate post-delivery administration of B immunoglobulin and hepatitis B vaccine. Please refer to page 534 for details.

(x) *PRENATAL GENETIC SCREENING* : Prenatal genetic screening includes screening for chromosomal abnormalities associated with serious birth defects, screening for direct evidence of congenital structural anomalies, and screening for haemoglobinopathies and other inherited conditions detectable by biochemical assay. Universal genetic screening

is generally not recommended. Screening for chromosomal abnormalities and for direct evidence of structural anomalies is performed in pregnancy in order to make the option of therapeutic abortion available when severe defects are detected. Typical examples are screening for trisomy 21 (Down's syndrome) and severe neural tube defects. Women aged 35 years and above, and those who already have an afflicted child are at higher risk.

(4) Mental preparation

Antenatal care does not mean only palpation, blood and urine examination and pelvic measurements. These are no doubt important aspects of antenatal care. Mental preparation is as important as physical or material preparation. Sufficient time and opportunity must be given to the expectant mothers to have a free and frank talk on all aspects of pregnancy and delivery. This will go a long way in removing her fears about confinement. The "mothercraft" classes at the MCH Centres help a great deal in achieving this objective.

(5) Family planning

Family planning is related to every phase of the maternity cycle. The mother is psychologically more receptive to advice on family planning than at other times. Educational and motivational efforts must be initiated during the antenatal period. If the mother has had 2 or more children, she should be motivated for puerperal sterilization. In this connection, the All India Postpartum Programme services are available to all expectant mothers in India *(21)*.

(6) Paediatric component

It is suggested that a paediatrician should be in attendance at all antenatal clinics to pay attention to the under-fives accompanying the mothers.

INTRANATAL CARE

Childbirth is a normal physiological process, but complications may arise. Septicaemia may result from unskilled and septic manipulations, and *tetanus neonatorum* from the use of unsterilized instruments. The need for effective intranatal care is therefore indispensable, even if the delivery is going to be a normal one. The emphasis is on the cleanliness. It entails – clean hands and fingernails, a clean surface for delivery, clean cord care i.e., clean blade for cutting the cord and clean tie for the cord, no application on cord stump, and keeping birth canal clean by avoiding harmful practices. Hospitals and health centres should be equipped for delivery with midwifery kits, a regular supply of sterile gloves and drapes, towels, cleaning materials, soap and antiseptic solution, as well as equipment for sterilizing instruments and supplies. There are delivery kits available with the items needed for basic hygiene for delivery at home, where a midwife with a midwifery kit is not likely to be present. The aims of good intranatal care are :

(i) thorough asepsis
(ii) delivery with minimum injury to the infant and mother
(iii) readiness to deal with complications such as prolonged labour, antepartum haemorrhage, convulsions, malpresentations, prolapse of the cord, etc.
(iv) Care of the baby at delivery – resuscitation, care of the cord, care of the eyes, etc.

Domiciliary care

Mothers with normal obstetric history may be advised to have their confinement in their own homes, provided the home conditions are satisfactory. In such cases, the delivery may be conducted by the Health Worker Female or trained dai. This is known as "domiciliary midwifery service."

The advantages of the domiciliary midwifery service are : (1) the mother delivers in the familiar surroundings of her home and this may tend to remove the fear associated with delivery in a hospital, (2) the chances for cross infection are generally fewer at home than in the nursery/hospital, and (3) the mother is able to keep an eye upon her children and domestic affairs; this may tend to ease her mental tension.

Domiciliary midwifery is also not without disadvantages : (1) the mother may have less medical and nursing supervision than in the hospital, (2) the mother may have less rest, (3) she may resume her domestic duties too soon, and (4) her diet may be neglected. Strictly speaking, many homes in India are unsuitable for even a normal delivery. The argument that childbirth is a natural event and should take place at home does not guarantee that everything will be normal.

Since 72.2 per cent of India's population live in rural areas, most deliveries will have to take place in the home with the aid of Female Health Workers or trained dais. Domiciliary out–reach is a major component of intranatal health care : The Female Health Worker, who is a pivot of domiciliary care, should be adequately trained to recognize the 'danger signals' during labour and seek immediate help in transferring the mother to the nearest Primary Health Centre or Hospital. The danger signals are :

(1) sluggish pains or no pains after rupture of membranes
(2) good pains for an hour after rupture of membranes, but no progress
(3) prolapse of the cord or hand
(4) meconium-stained liquor or a slow irregular or excessively fast foetal heart
(5) excessive 'show' or bleeding during labour
(6) collapse during labour
(7) a placenta not separated within half an hour after delivery
(8) post-partum haemorrhage or collapse, and
(9) a temperature of 38 deg C or over during labour. There should be a close liaison between domiciliary and institutional delivery services.

Institutional care

About one per cent of deliveries tend to be abnormal, and four per cent "difficult", requiring the services of a doctor. Institutional care is recommended for all 'high-risk" cases, and where home conditions are unsuitable.

The mother is allowed to rest in bed on the first day after delivery. From the next day, she is allowed to be up and about. The current practice is to discharge the woman after 5 days lying-in period after a normal delivery.

Rooming-in

Keeping the baby's crib by the side of the mother's bed is called "rooming-in". This arrangement gives an opportunity for the mother to know her baby. Mothers interested in breast feeding usually find there is a better chance for success with rooming-in. Rooming-in also allays the fear in

the mother's mind that the baby is not misplaced in the central nursery. It also builds up her self-confidence.

POSTNATAL CARE

Care of the mother (and the newborn) after delivery is known as postnatal or postpartal care. Broadly this care falls into two areas: care of the mother which is primarily the responsibility of the obstetrician; and care of the newborn, which is the combined responsibility of the obstetrician and paediatrician. This combined area of responsibility is also known as perinatology.

Care of the mother

The objectives of postpartal care are :

(1) To prevent complications of the postpartal period.
(2) To provide care for the rapid restoration of the mother to optimum health.
(3) To check adequacy of breast-feeding.
(4) To provide family planning services.
(5) To provide basic health education to mother/ family.

Complications of the postpartal period

Certain complications may arise during the postpartal period which should be recognized early and dealt with promptly. These are (1) *Puerperal sepsis* : This is infection of the genital tract within 3 weeks after delivery. This is accompanied by rise in temperature and pulse rate, foul-smelling lochia, pain and tenderness in lower abdomen, etc. Puerperal sepsis can be prevented by attention to asepsis, before and after delivery. This is particularly important in domiciliary midwifery service. (2) *Thrombophlebitis* : This is an infection of the veins of the legs, frequently associated with varicose veins. The leg may become tender, pale and swollen. (3) *Secondary haemorrhage* : Bleeding from vagina anytime from 6 hours after delivery to the end of the puerperium (6 weeks) is called secondary haemorrhage, and may be due to retained placenta or membranes. (4) *Others* : Urinary tract infection and mastitis, etc. It is extremely important to look for these complications in the postpartal period and prevent or treat them promptly.

Restoration of mother to optimum health

The second objective of postpartal care is to provide care whereby, the woman can recuperate physically and emotionally from her experience of delivery. The broad areas of this care fall into three divisions :

PHYSICAL

(1) *Postnatal examinations* : Soon after delivery, the health check-ups must be frequent, i.e., twice a day during the first 3 days, and subsequently once a day till the umbilical cord drops off. At each of these examinations, the FHW checks temperature, pulse and respiration, examines the breasts, checks progress of normal involution of uterus, examines lochia for any abnormality, checks urine and bowels and advises on perineal toilet including care of the stitches, if any. The immediate postnatal complications, viz puerperal sepsis, thrombophlebitis, secondary haemorrhage should be kept in mind. At the end of 6 weeks, an examination is necessary to check-up involution of uterus which should be complete by then. Further visits should be done once a month during the first 6 months, and thereafter once in 2 or 3 months till the end of one year. In rural areas only limited postnatal care is possible. Efforts should be made by the FHWs to give at least 3 to 6 postnatal visits. The common conditions found on examination during the late postnatal period are subinvolution of uterus, retroverted uterus, prolapse of uterus and cervicitis. Postnatal examination offers an opportunity to detect and correct these defects.

(2) *Anaemia* : Routine haemoglobin examination should be done during postnatal visits, and when anaemia is discovered, it should be treated. In some cases, it may be necessary to continue treatment for a year or more.

(3) *Nutrition* : Though a malnourished mother is able to secrete as much breast milk as a well nourished one, she does it at the cost of her own health. The nutritional needs of the mother must be adequately met. Often the family budget is limited; the mother should be shown the means how she can eat better with less money.

(4) *Postnatal exercises* : Postnatal exercises are necessary to bring the stretched abdominal and pelvic muscles back to normal as quickly as possible. Gradual resumption of normal house-hold duties may be enough to restore one's figure.

PSYCHOLOGICAL : The next big area of postnatal care involves a consideration of the psychological factors peculiar to the recently delivered woman. One of the psychological problems is fear which is generally borne of ignorance. Other problems are timidity and insecurity regarding the baby. If a woman is to endure cheerfully the emotional stresses of childbirth, she requires the support and companionship of her husband. Fear and insecurity may be eliminated by proper prenatal instruction. The so called postpartum psychosis is perhaps precipitated by birth; and it is rather uncommon.

SOCIAL : It has been said that the most important thing a woman can do is to have a baby. This is only part of the truth. The really important thing is to nurture and raise the child in a wholesome family atmosphere. She, with her husband, must develop her own methods.

Breast-feeding

Postnatal care offers an excellent opportunity to find out how the mother is getting along with her baby, particularly with regard to feeding. For many children, breast milk provides the main source of nourishment in the first year of life. In some societies, lactation continues to make an important contribution to the child's nutrition for 18 months or longer. In the world's more affluent societies, breast-feeding appears to have become a lost art and the feeding bottle has usurped the breast. When the standard of environmental sanitation is poor and education low, the content of the feeding bottle is likely to be as nutritionally poor as it is bacteriologically dangerous. It is therefore very important to advise the mothers to avoid the feeding bottle.

A great asset in India is that an average Indian mother, although poor in nutritional status, has a remarkable ability to breast-feed her infant for prolonged periods, sometimes extending to nearly 2 years and beyond. Longitudinal and cross-sectional studies indicate that poor Indian women secrete as much as 400 to 600 ml of milk per day during the first year (Table 2). No other food is required to be given until 6 months after birth. At the age of 6 months, breast milk should be supplemented by additional foods rich in protein and other nutrients (e.g., animal milk, soft-cooked mashed vegetables, etc.). These are called supplementary foods which should be introduced very gradually in small amounts.

TABLE 2

Output of breast milk at different stages of lactation

Months of lactation	Number examined	Per day mean–output of breast milk (ml)
0–2	20	530
3–4	18	640
5–6	14	730
7–8	14	660
9–10	17	600
11–12	30	525
13–15	11	515
16–18	29	440
19–24	14	400
25–36	12	425
37–38	4	345

Family planning

It has already been stressed that family planning is related to every phase of maternity cycle. Every attempt should be made to motivate mothers when they attend postnatal clinics or during postnatal contacts to adopt a suitable method for spacing the next birth or for limiting the family size as the case may be. Postpartum sterilization is generally recommended on the 2nd day after delivery. Although lactation confers some protection against conception, it cannot be depended upon; contraceptives have to be supplied immediately postpartum. To ask the mother to come at the time of her first menstruation may be too late. A contraceptive must therefore be used, that will not affect lactation in the early postpartum period. In this connection, IUD and conventional (non–hormonal) contraceptives are the choices during the first 6 months following delivery. In general, combined or sequential oral "pills" should be avoided in a lactating mother as they do suppress lactation. Fortunately, evidence is accumulating that progestogens alone have little or no effect on lactation. The injection of medroxy-progesterone acetate (MPA) after delivery has been found to be successful in ensuring spacing of pregnancy without suppressing lactation; however, because of its side-effects (e.g., irregular uterine bleeding, prolonged infertility) some countries have limited its use to multiparae at ages 35 and over, or who have already completed their families. MPA is not recommended for general use.

Basic health education

Health education during the postnatal period should cover the following broad areas : (a) hygiene – personal and environmental (b) feeding for mother and infant (c) pregnancy spacing (d) importance of health check-up, and (e) birth registration.

CARE OF CHILDREN

This section focuses on children in the age group 0–14 years. This is the most important age group in all societies, not because they constitute about 40 per cent of the total population, but because there is a renewed awareness that the determinants of chronic disease in later life and health behaviour are laid down at this stage *(22)*. Family influences and education are of the highest importance, and these experiences ultimately influence patterns of their future life–styles, occupational skills, and even political attitudes and leadership. The childhood period is also a vital period because of the so called socialization process, that is, transmission of attitudes, customs and behaviour. In addition, of course, they are vulnerable to disease, death and disability owing to their age, sex, place of living, socio-economic class and a host of other variables. Certain specific biological and psychological needs must be met to ensure the survival and healthy development of the child and future adult.

It is customary to divide the childhood into the following age-periods :

1. Infancy (upto 1 year of age)
   a. Neonatal period (first 28 days of life)
   b. Post neonatal period (28th day to 1 year)
2. Pre-school age (1–4 years)
3. School age (5–14 years)

Antenatal paediatrics

Fifty years ago, the main purpose of antenatal care was the prevention of maternal mortality. With the fall in the maternal mortality to about 0.2 per 1000 live births, attention has shifted to the child – first to decrease perinatal mortality, secondly to prevent perinatal morbidity; and more recently to the "foetus at risk". This has given rise to the concept of antenatal paediatrics. Recent technical developments such as amniocentesis, ultrasonography, faetoscopy and chorion biopsy have contributed significantly to the diagnosis of congenital abnormalities and inborn errors of metabolism *(23, 24)*. This knowledge has led to the recognition that causation and possible prevention may lie in intra-uterine life. The emphasis has greatly changed in the care of the child with the prevention of disorders (e.g., low birth weight, foetal disorders and neonatal asphyxia) assuming greater importance.

Antenatal care should, appropriately, begin even before the mother conceives and enters the maternity cycle; this care comprising such measures as genetic counselling for prospective parents; limitation and proper spacing of births with intervals of 2–3 years; delaying a young woman's first pregnancy until she is physically and socially mature enough to cope with it; ensuring adequate maternal nutrition; protection of the unborn against intrauterine infections and other adverse influences. In a developing country such as India, all this may not be possible, but certainly some elements, such as improvement of maternal nutrition, family planning and counselling could go a long way in ensuring maternal and foetal health.

INFANCY

Infants (0–1 year) constitute about 2.92 per cent of the total population in India. Of the 136 million children born each year in the world, 90 per cent are in the third world. Although the chances of survival of these newborns has improved by 50 per cent in the last 20 years, the first few hours, days and months of their lives are still an obstacle race. From the time of birth, 20–30 per cent of babies are under-weight. That makes them vulnerable to infection and disease. About 40 per cent of total infant mortality occurs in the first month of life. Then comes the weaning period, when one out of four surviving children receives neither the quality nor the quantity of food needed to replace the substances provided by mother's milk. The result is that more and more children in developing countries reach adulthood with their health already largely impaired. An infant mortality rate of

58 per thousand, as compared to 5 per thousand in the developed countries, places India in the unenviable position of being among the less developed in the world. Many low-cost measures are available for saving life of millions of children, like immunization, breast feeding, birth spacing, growth monitoring, improved weaning, oral rehydration. Attention is focused on these elements of child health care in developing countries.

NEONATAL CARE

A flow chart of the optimum care of the newborn is as shown in Fig. 2. This aspect of family health services has been termed neonatology. This branch of medicine is, perhaps, more than any other, dependant on teamwork in which disciplines of obstetrics and gynaecology, paediatrics, preventive and social medicine, community health services and nursing have an important part to play, if any impact is to be made on the vast problems of perinatal and neonatal mortality and morbidity. The paediatrician has a key role as a coordinator and guide for the whole team.

Early neonatal care

The first week of life is the most crucial period in the life of an infant. In India, 61.3 per cent of all infant deaths occur within the first month of life. Of these, more than half may die during the first week of birth. This is because the new born has to adapt itself rapidly and successfully to an alien external environment. The risk of death is the greatest during the first 24–48 hours after birth. The problem is more acute in rural areas where expert obstetric care is scarce, and the home environmental conditions in which the baby is born, are usually unsatisfactory.

The objective of early neonatal care is to assist the newborn in the process of adoption to an alien environment, which involves :

(i) establishment and maintenance of cardio–respiratory functions
(ii) maintenance of body temperature
(iii) avoidance of infection
(iv) establishment of satisfactory feeding regimen, and
(v) early detection and treatment of congenital and acquired disorders, especially infections.

Congenital infections caused by toxoplasmosis, rubella, human (alpha) herpes-virus 1 or 2, human (beta) herpes virus, and syphilis (TORCHES synonyms) is associated with high mortality rate in the neonates *(25)*.

Immediate care

1. CLEARING THE AIRWAY

Establishment and maintenance of cardio-respiratory functions (e.g., breathing) is the most important thing the moment the baby is born, and everything else is secondary. To help establish breathing, the airways should be cleared of mucus and other secretions. Positioning the baby with his head low may help in the drainage of secretions. This process can be assisted by gentle suction to remove mucus and amniotic fluid. Resuscitation becomes necessary if natural breathing fails to establish within a minute, as in the case of babies who have already been subject to hypoxia during labour. In these cases, resuscitation may require more active measures such as suction, application of oxygen mask, intubation and assisted respiration. All labour wards should be equipped with resuscitation equipment including oxygen. If the heart has stopped beating for 5 minutes, the baby is probably dead.

2. APGAR SCORE

The Apgar score is taken at 1 minute and again at 5 minutes after birth. Today it is considered as negligence to omit Apgar scoring of a newborn infant, especially low birth weight babies *(26)*. It requires immediate and careful observation of the heart rate, respiration, muscle tone, reflex response and colour of the infant. Each sign is given a score of 0, 1 or 2 (Table 3). It provides an immediate estimate of the physical condition of the baby. A perfect score should be 9 or 10; 0–3 indicates that the baby is severely depressed and 4–6 moderately depressed. A score below 5 needs prompt action. Infants with low Apgar scores at 5 minutes of age are subject to a high-risk of complications and death during the neonatal period *(26)*.

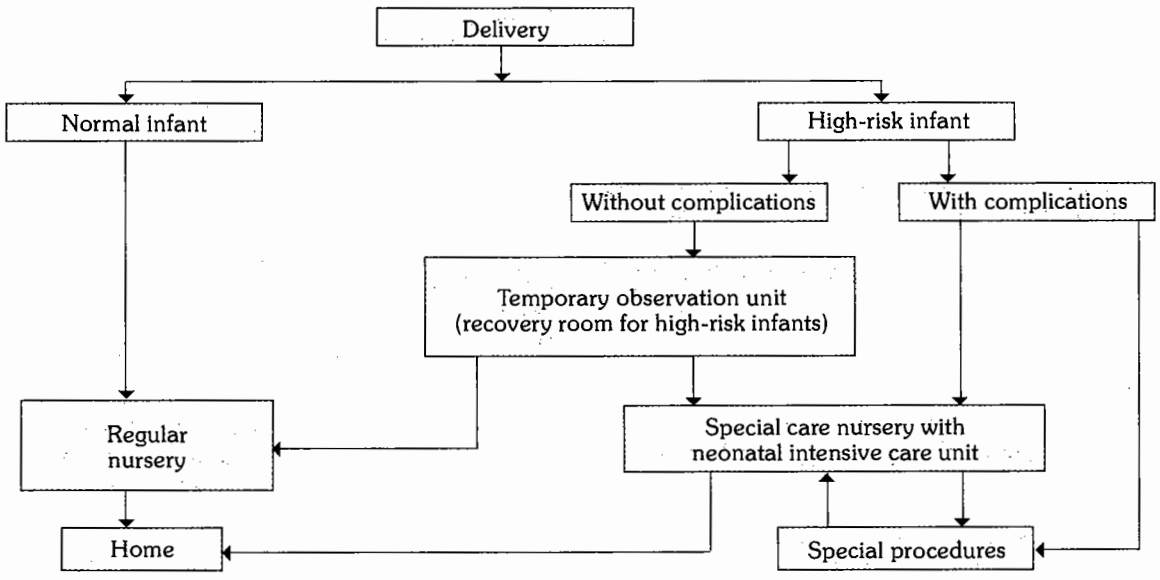

FIG. 2
Flow chart of optimum newborn care

TABLE 3

Apgar score

Sign	Score 0	1	2
Heart rate	Absent	Slow (below 100)	Over 100
Respiratory effort	Absent	Slow Irregular	Good crying
Muscle tone	Flaccid	Some flexion of extremities	Active movements
Reflex response	No response	Grimace	Cry
Colour	Blue, pale	Body pink Extremities blue	Completely pink
Total score = 10	Severe depression 0–3	Mild depression 4–6	No depression 7–10

3. CARE OF THE CORD

In the case of the normal infant, the umbilical cord should be cut and tied when it has stopped pulsating. The advantage is that the baby derives about 10 ml of extra blood, if the cord is cut after pulsation ceases. This is particularly important in India, where anaemia is frequent. Care must be taken to prevent tetanus of the newborn by using properly sterilized instruments and cord ties. It is essential to apply an antiseptic preparation on the cord stump and the skin around the base. The cord should be kept as dry as possible. It dries and shrivels up and separates by aseptic necrosis in 5–8 days.

4. CARE OF THE EYES

Before the eyes are open, the lid margins of the newborn should be cleaned with sterile wet swabs, one for each eye from inner to outer side. Instil a drop of freshly prepared silver nitrate solution (1 per cent) to prevent gonococcal conjunctivitis, alternatively, a single application of tetracycline 1 per cent ointment can be given. Any discharge from the eye of an infant is pathological and calls for immediate treatment.

Ophthalmia Neonatorum : A variety of organisms are implicated – *N. gonorrhoea, C. trachomatis* (commonest), staphylococcus, streptococcus, Candida spp, etc. The most serious cause of conjunctivitis of the newborn is infection with *N. gonococcus* as it can rapidly cause blindness. *C. trachomatis* is also an important cause of neonatal conjunctivitis. Since gonococcal ophthalmia neonatorum has become much less frequent than conjunctivitis due to other acquired organisms, application of topical neomycin might be more useful *(27)*.

As a preventive measure, specific maternal genital tract infection should be treated effectively prior to, or during pregnancy, and specific care should be taken while conducting face or breech delivery.

5. CARE OF THE SKIN

When a baby is a few hours old, the first bath is given with soap and warm water to remove vernix, meconium and blood clots. Some prefer to apply warm oil before the bath. The first bathing is done by the nursing staff. Thereafter no further bathing is necessary until the day before discharge. If culturally acceptable, the first bathing may be delayed for 12–24 hours after birth to avoid cooling the body temperature *(28)*.

6. MAINTENANCE OF BODY TEMPERATURE

The normal body temperature of a newborn is between 36.5 to 37.5°C. A newborn baby is projected out of warm womb of the mother into an environment which may be 10 to 20°C cooler especially in winter months in India.

A newborn has little thermal control and can lose body heat quickly. Immediately after birth; most of the heat loss occurs through evaporation of the amniotic fluid from the body of the wet child. As much as 75 per cent of the heat loss can occur from the head. It is important that immediately after birth the child is quickly dried with a clean cloth and wrapped in warm cloth and given to the mother for skin-to-skin contact and breast-feeding. Practices such as separating the baby from the mother for the first 12–24 hours of life are harmful. Pre-term and low birth weight babies lose heat more easily through their thin skin as they have less sub-cutaneous fat for insulation. Putting the newborn on a cold surface such as metallic tray, rubber sheeting or weighing scale should be avoided, and the child should be kept away from cold walls, open windows and from draught *(29)*.

7. BREAST-FEEDING

Breast-feeding should be initiated within an hour of birth instead of waiting several hours as is often customary. Although there is little milk at that time, it helps to establish feeding and a close mother–child relationship, known as "bonding".

The first milk which is called "colostrum" is the most suitable food for the baby during this early period because it contains a high concentration of protein and other nutrient the body needs; it is also rich in anti-infective factors which protect the baby against respiratory infections and diarrhoeal diseases. Supplementary feeds are not necessary. The regular milk comes on the third to sixth day after birth. The baby should be allowed to breast-feed whenever it wants. Feeding the baby on demand helps the baby to gain weight. It is very important to advise mother to avoid feeding bottles.

Neonatal examinations

a. FIRST EXAMINATION

The first examination is made soon after birth, and preferably in the delivery room. This examination is (a) to ascertain that the baby has not suffered injuries during the birth process; (b) to detect malformations especially those requiring urgent treatment; and (c) to assess maturity.

The following abnormalities found on examination should be immediately attended to : (a) cyanosis of the lips and skin; (b) any difficulty in breathing; (c) imperforated anus; (d) persistent vomiting; (e) signs of cerebral irritation such as twitchings, convulsions, neck rigidity, bulging of anterior fontanel, and (g) temperature instability.

b. SECOND EXAMINATION

The second examination should be made preferably by a paediatrician within 24 hours after birth. This examination should form the first stage of a continual process of health care surveillance. It is a detailed systematic examination from head to foot, conducted in good light. The following protocol will be found useful for such an examination *(30)*.

1. Body size
   Body weight; crown–heel length, head and thoracic perimeters
2. Body temperature

3. Skin :
   Observe for cyanosis of lips and skin; jaundice; pallor; generalized erythema; vesicular and bullous lesions.
4. Cardio-respiratory activities :
   Cardiac murmurs; absence of femoral pulse; central cyanosis, a respiratory rate of over 60 per minute; thoracic cage retraction on inspiration.
5. Neuro–behavioural activity :
   (i) Posture : neck retraction; frog-like posture; hyper-extension of all limbs; hyperflexion of all limbs; asymmetrical posture (ii) Muscle tone : tendon reflexes; cry; movements.
6. Head and face :
   Hydrocephalus; large fontanelles; prominent scalp vein (i) Eyes : cataract; coloboma; conjunctivitis (ii) Ears : dysmorphism; accessary auricles; pre-auricular pits (iii) Mouth and lips : Hare lip; cleft palate.
7. Abdomen :
   Signs of distension; abnormal masses; imperforate anus.
8. Limbs and joints :
   Deformities of joints; congenital dislocation of the hips; extra digits
9. Spine :
   Neural tube defects
10. External genitalia :
    Male : Hypospadius; undescended testis; hydrocele;
    Female : fused labia; enlarged clitoris.

The infected newborn *(31)*

Neonatal infection is particularly frequent in Africa. It is the main cause of neonatal mortality in many developing countries. Contributing factors are related to the environment (traditional practices, poor hygiene), the course of pregnancy (premature rupture of membranes) and constitutional fragility (prematurity, small–for–date, dysmaturity). Transplacental contamination is one of the important cause of infection in new-borns. Early detection of newborns at risk of transplacental infection is important, so that close monitoring and preventive action may be implemented.

NEONATAL TETANUS : It can be prevented by vaccination of pregnant women and sero-vaccination of newborns in case of at-risk delivery. These measures have proved effective in those countries where they are systematically applied.

CONGENITAL SYPHILIS : The frequency of congenital syphilis is on rise in some large African cities. Diagnosis is essentially based on the evidence of syphilis in the mother, since clinical signs of congenital syphilis often do not occur at once. In case of doubt and if there is risk of inadequate subsequent medical surveillance of the baby, treatment with 2.4 to 4.8 million U of Benzathine Penicillin may be recommended.

NEWBORN WITH AN HBV-POSITIVE MOTHER : Chronic carriers of hepatitis virus are extremely frequent in some countries. Babies may be infected at birth when the mother is a carrier of this virus. The risk of transmission is somewhere around 20 per cent when the mother has the HBs antigen only, and around 90 per cent when she also has the HBe antigen. Transmission occurs through the blood and the genital secretions and therefore affects the newborn during the immediate perinatal period and throughout infancy. It is not a contraindication of breast-feeding.

If the newborn is infected, there is a risk that he/she will become a chronic carrier, and tend to develop active chronic hepatitis, cirrhosis or primary cancer of liver during adulthood. 50 per cent of severe cases of infantile hepatitis before age one year are the outcome of untreated perinatal transmission.

It is possible to prevent perinatal transmission by seroprophylaxis combined with vaccination – an intra-muscular injection of 0.5 ml of hepatitis B immunoglobulin along with hepatitis B vaccine within 24 hours of birth. The vaccine must be repeated at 6, 10 and 14 weeks of age.

This prophylaxis has proved effective. The real problem is to detect mothers who are chronic carriers of the HBs antigen, and the high cost of prevention.

NEWBORN WITH AN HIV-POSITIVE MOTHER : The rapidity of the propagation of HIV infection is a source of great concern. About 30 per cent babies born to HIV-positive mothers get infected. Transmission of infection mostly occurs at the end of the pregnancy, and it is not influenced by the type of delivery. The virus has been isolated in breast-milk. Although there is probably a risk of transmission of infection through breast-milk, prohibiting breast-feeding is debatable, as it is so essential for the survival of newborn in developing countries. The risk of transmission depends on the severity of the mother's case. It is higher from mothers with AIDS, but may also occur from seropositive cases. Unfortunately, unlike hepatitis B, there is no prevention available for newborns at present. The question of whether to perform BCG vaccination arises – it is contraindicated in infected children, and therefore, should not be performed in the offspring of HIV positive mothers until it is determined whether the baby is infected or not. This is only feasible at the end of several months when the maternal antibodies are completely eliminated *(31)*.

MEASURING THE BABY

Measurements of birth-weight, length (height) and head circumference are the simplest and one of the reliable means by which the health and maturity of a baby is evaluated.

1. Birth-weight

The birth-weight should be taken preferably within the first hour of life, before significant post-natal weight loss has occurred *(32)*. The naked baby should be placed on a clean towel on the scale pan. In home delivery, weight is taken by placing the baby in a sling bag using a salter weighing scale. The child is weighed to the nearest 100 g according to the standard method for weight measurement.

The average birth-weight of infants is lower in many developing countries than it is in developed countries. There are reasons to believe that this difference is not of genetic origin but is due largely to maternal malnutrition.

2. Length (height)

This need not be taken immediately if the baby's condition gives rise to any anxiety, but should be recorded within the first 3 days. Length can be taken most accurately with a measuring board (infantometer) with a fixed head piece on which the infant lies supine with its legs fully extended and the feet flexed at right angles to the lower legs. Two people are needed to hold the baby correctly. The sliding board is moved firmly against the feet before the reading is taken. Length is taken to the nearest 0.1 cm.

3. Head circumference

This measurement may change slightly during the first 3 days owing to moulding during labour. It is taken with a tape measure at the maximum circumference of the head in the occipito-frontal diameter.

The purpose of taking these measurements are :

(i) to assess the baby's size against known standards for the population
(ii) to compare the size with estimated period of gestation
(iii) to provide a baseline against which subsequent progress can be measured.

Anthropometric measurements may be classified as *(33)* :

(a)	Weight	:	kg
(b)	Length	:	total height, sitting height, heel knee-length
(c)	Perimeters	:	head, chest, abdomen, arm, calf
(d)	Diameters	:	biacromial, bicristal, biepicondylar, bistyloid, bicondylar
(e)	Skinfold thickness	:	triceps, biceps, superiliac subscapular.

NEONATAL SCREENING

The object of screening newborns is primarily to detect infants with treatable genetic, developmental and other abnormalities, and secondarily, to provide their parents with genetic counselling. The Apgar score and routine clinical examinations are simple screening tests which should be carried out on all newborn infants. 10 to 15 ml of cord blood should be collected at birth and saved in the refrigerator for 7 days for typing, coombs' testing and other tests if needed. Recent years have witnessed development of numerous tests for screening congenital metabolic disorders, inherited haemoglobinopathies and red cell disorders. Since these diseases are rare, general screening of the population for them is neither justified nor technically possible. However, only a few tests qualify for a screening programme. The most common disorders which are screened are discussed below.

(a) *Phenylketonuria (PKU)* : PKU is a rare (incidence 1 in 10,000–20,000 births) disorder of amino acid metabolism. This is an autosomal recessive trait in babies who are homozygous with a deficiency in the enzyme phenylalanine hydrozylase (PAH) which normally converts phenylalanine to tyrosin. The deficiency results in raised serum phenylalanine concentrations causing mental retardation and tendency to seizures if the child does not receive low phenylalanine diet. Mass screening of blood phenylalanine in neonates is performed in many countries by the Guthrie test. It is possible to test for all three types of metabolic error, namely PKU, galactosaemia and maple syrup urine disease by taking blood from the 6–10 days old baby by heel prick and collecting 3 or 4 separate drops of it on thick absorbent filter paper. The treatment of PKU consists of a diet free of phenylalanine. Careful dietary management in affected children results in normal physical and mental development. (b) *Neonatal hypothyroidism* : This is the most common disorder that is screened. Congenital hypothyroidism leads to serious sequelae, including severe mental retardation, which can be prevented if medical treatment is given within the first 1–2 months of life. The test involves measuring the radio-immuno-assays of the thyroid hormone T4 or the thyroid-stimulating hormone (TSH). By examining the cord blood of newborns, potential victims of IDD could be identified and proper prevention can be taken at such an early stage of life. (c) *Coombs' test* : This is done routinely on infants of all Rh-negative mothers. (d) *Sickle cell or other haemoglobinopathies* : Agar-gel electrophoresis is done on infants whose mothers have sickle cell or other haemoglobinopathies, e.g., thalassaemia, G6PD. (e) *Congenital dislocation of hip* : The test consists of manipulating the hip of the child from the adducted to abducted position while the thigh is flexed. A positive or abnormal result is indicated by a click or snap being produced during the test. The test is carried out on all babies at 6–14 days after birth, and at monthly intervals until the child is 4 months old. Diagnosis within a week or two of birth means that treatment can be completed before the infant could normally have reached the stage of standing. Failure to diagnose the condition will expose the child to a whole series of difficult operations in later life *(20)*.

The requirements for effective screening for inborn errors are discussed in detail in chapter 4.

Identification of "at-risk" infants

The number of infants (and children 1–5 years of age) in a community, or attending a child health clinic, may be so large that it may not be possible to give sufficient time and attention to all of them. It is therefore necessary to identify particularly those "at-risk" and give them special intensive care, because it is these "at-risk" babies that contribute so largely to perinatal, neonatal and infant mortality. The basic criteria for identifying these babies include :

1. birth weight less than 2.5 kg
2. twins
3. birth order 5 and more
4. artificial feeding
5. weight below 70 per cent of the expected weight (i.e., II and III degrees of malnutrition)
6. failure to gain weight during three successive months
7. children with PEM, diarrhoea
8. working mother/one parent.

Late neonatal care

The remaining three weeks of the neonatal period carry the common and serious hazards of infection and failure of satisfactory nutrition. Diarrhoea and pneumonia take a heavy toll of life in infants exposed to an unsatisfactory environment. The case fatality rate of what would normally be trivial episodes can increase dramatically when elementary care is not given.

LOW BIRTH WEIGHT

The birth weight of an infant is the single most important determinant of its chances of survival, healthy growth and development.

There are two main groups of low birth weight babies – those born prematurely (short gestation) and those with foetal growth retardation. In countries where the population of low birth weight infants is less, short gestation period is the major cause. In countries where the proportion is high (e.g. India), the majority of cases can be attributed to foetal growth retardation.

By international agreement low birth weight has been defined as a birth weight of less than 2.5 kg (upto and

including 2499 g), the measurement being taken preferably within the first hour of life, before significant postnatal weight loss has occurred *(33)*. Apart from birth weight, babies can also be classified into 3 groups according to gestational age, using the word "preterm", "term" and "postterm", as follows *(32)* :

a. *Preterm* : Babies born before the end of 37 weeks gestation (less than 259 days).
b. *Term* : Babies born from 37 completed weeks to less than 42 completed weeks (259 to 293 days) of gestation.
c. *Postterm* : Babies born at 42 completed weeks or any time thereafter (294 days and over) of gestation.

A LBW infant then, is any infant with a birth weight of less than 2.5 kg regardless of gestational age. It includes two kinds of infants :

PRETERM BABIES (9, 33A)

Preterm is defined as babies born alive before 37 weeks of pregnancy are completed. There are sub-categories of preterm birth, based on gestational age :

- extremely preterm (<28 weeks)
- very preterm (28 to <32 weeks)
- moderate to late preterm (32 to 37 weeks).

These are babies born too early. Their intrauterine growth may be normal. That is, their weight, length and development may be within normal limits for the duration of gestation. Given good neonatal care, these babies may catch up growth and by 2 to 3 years of age will be of normal size and performance.

INCIDENCE

More than 1 in 10 of the world's babies born in 2010 were born prematurely, making an estimated 15 million preterm births (defined as before 37 weeks of gestation) of which more than 1 million died as a result of their prematurity. Prematurity is now the second-leading cause of death in children under 5 years, and the single most important cause of death in the critical first month of life. For the babies who survive, many face a lifetime of significant disability.

Causes of preterm births *(9)*

Preterm birth is a syndrome with a variety of causes which can be classified into two broad subtypes: (1) spontaneous preterm birth (spontaneous onset of labor or following prelabor premature rupture of membranes (pPROM) and (2) provider-initiated preterm birth (defined as induction of labor or elective caesarean birth before 37 completed weeks of gestation for maternal or fetal indications (both "urgent" or "discretionary"), or other non-medical reasons.

Spontaneous preterm birth is a multi-factorial process, resulting from the interplay of factors causing the uterus to change from quiescence to active contractions and to birth before 37 completed weeks of gestation. The precursors to spontaneous preterm birth vary by gestational age, social and environmental factors, but the cause of spontaneous preterm labor remains unidentified in upto half of all cases. Maternal history of preterm birth is a strong risk factor and most likely driven by the interaction of genetic, epigenetic and environmental risk factors.

Elevated risk of preterm birth also demands increased attention to maternal health, including the antenatal diagnosis and management of NCDs and other conditions known to increase the risk of preterm birth. Premature babies, in turn, are at greater risk of developing NCDs, like hypertension and diabetes, and other significant health condition later in life, creating an intergenerational cycle of risk. The link between prematurity and an increased risk of NCDs takes on an added public health importance when considering the reported increase in the rates of both worldwide. Table 4 summarizes the types of preterm births and the risk factors involved.

TABLE 4

Types of preterm birth and risk factors involved

Type:	Risk Factors:	Examples:
Spontaneous preterm birth:	Age at pregnancy and pregnancy spacing	Adolescent pregnancy, advanced maternal age, or short inter-pregnancy interval
	Multiple pregnancy	Increased rates of twin and higher order pregnancies with assisted reproduction
	Infection	Urinary tract infections, malaria, HIV, syphilis, bacterial vaginosis.
	Underlying maternal chronic medical conditions	Diabetes, hypertension, anaemia, asthma, thyroid disease
	Nutritional	Undernutrition, obesity, micronutrient deficiencies
	Lifestyle/ work related	Smoking, excess alcohol consumption, recreational drug use, excess physical work/activity
	Maternal psychological health	Depression, violence against women
	Genetic and other	Genetic risk, e.g., family history, Cervical incompetence
Provider-initiated preterm birth:	Medical induction or caesarean birth for: obstetric indication, Foetal indication	There is an overlap for indicated provider-initiated preterm birth with the risk factors for spontaneous preterm birth.
	Other-Not medically indicated	

Source : *(9)*

SMALL–FOR–DATE (SFD) BABIES :

These may be born at term or preterm. They weigh less than the 10th percentile for the gestational age. These babies are clearly the result of retarded intrauterine foetal growth.

Computation : The percentage of LBW babies is computed as :

$$\frac{\text{Live-born babies with birth weight less than 2.5 Kg}}{\text{Total number of live births}} \times 100$$

The factors associated with intrauterine growth retardation are multiple and interrelated to mother, the placenta or to the foetus. The maternal factors include malnutrition, severe anaemia, heavy physical work during pregnancy, hypertension, malaria, toxaemia, smoking, low economic status, short maternal stature, very young age,

high parity and close birth spacing, low education status etc. *(34)*. The placental causes include placental insufficiency and placental abnormalities. The foetal causes include foetal abnormalities, intrauterine infections, chromosomal abnormality and multiple gestation.

SFD babies have a high risk of dying not only during the neonatal period but during their infancy, thus significantly raising the rate of infant and perinatal mortality and contribute greatly to immediate and long term health problems. Most of them become victims of protein-energy malnutrition and infections.

In the developing countries, adverse prenatal and post-natal development of the child is associated with 3 interrelated conditions : malnutrition, infection and unregulated fertility which are often due to poor socio-economic and environmental conditions.

IMPORTANCE

LBW is one of the most serious challenges in maternal and child health in both developed and developing countries. Its public health significance may be ascribed to numerous factors – its high incidence; its association with mental retardation and a high risk of perinatal and infant mortality and morbidity (half of all perinatal and one-third of all infant deaths are due to LBW); human wastage and suffering; the very high cost of special care and intensive care units and its association with socio-economic underdevelopment *(35)*.

LBW is the single most important factor determining the survival chances of the child. Many of them die during their first year. The infant mortality rate is about 20 times greater for all LBW babies than for other babies. The lower the birth weight, the lower is the survival chance. Many of them become victims of protein–energy malnutrition and infection. LBW is thus an important guide to the level of care needed by individual babies. LBW also reflects inadequate nutrition and ill-health of the mother. There is a strong and significant positive correlation between maternal nutritional status and the length of pregnancy and birth weight. A high percentage of LBW therefore points to deficient health status of pregnant women, inadequate prenatal care and the need for improved care of the newborn.

PREVENTION

Experts opine that the rates of LBW babies could be reduced to not more than 10 per cent in all parts of the world *(36)*. It is clear from the multiplicity of causes that there is no universal solution. Interventions have to be cause–specific. Main attention has been given in recent years to ways and means of preventing LBW through good prenatal care and intervention programmes, rather than "treatment" of LBW babies born later.

DIRECT INTERVENTION MEASURES

The incidence of LBW can be reduced if pregnant women "at risk" are identified and steps are taken to reduce the risk. For this approach the women need to be identified early in pregnancy. To achieve this goal, the mothers health card – which is simple and can be used by primary health care worker – has been found very useful. The risk factors are : mother's malnutrition, heavy work load, diseases and infections and high blood pressure. Added to malnutrition, too many and too frequent pregnancies contribute to the continued depletion of her body. Both malnutrition and morbidity due to infections during pregnancy are amenable to correction or can be prevented. Some of the direct interventions are as follows :

(i) *Increasing food intake* : Studies have shown that even a relatively small dietary improvement in the malnourished pregnant mother, even during the last trimester, can result in a significant improvement in the birth weight of an infant. In Southern India, treatment of anaemic mothers led to an increase in birth weight of offspring. Direct intervention covers a wide range of activities, viz supplementary feeding, distribution of iron and folic acid tablets, fortification and enrichment of foods, etc. (ii) *Controlling infections* : Many maternal infections go unrecognized. They should be diagnosed and treated (e.g., malaria, urinary tract infection, infections due to cytomegalovirus, toxoplasmosis, rubella and syphilitic infection) or otherwise prevented. These infections can affect foetal growth in several ways. (iii) *Early detection and treatment of medical disorders* : These include hypertension, toxemias, and diabetes.

INDIRECT INTERVENTION

Family planning, avoidance of excessive smoking, improved sanitation measures, and measures aimed at improving the health and nutrition of young girls, each have a role to play. These measures can be expected to be more effective and to have lasting effects only if, at the same time there are improvements in the socio-economic and environmental conditions and in the distribution of health and social services especially in the under-served areas. Government support could be provided through such measures as maternity leave with full wages and child benefits.

Fig. 3 summarizes the integrated services delivery package for maternal and newborn care.

TREATMENT

From the point of view of treatment, LBW babies can be divided in to 2 groups : (a) those under 2 kg and (b) those between 2–2.5 kg. The first group requires first class modern neonatal care (which is hardly available globally) in an intensive care unit until the weight reaches that of the second group. The second group may need an intensive care unit for a day or two.

KANGAROO MOTHER CARE

Kangaroo mother care for low birth-weight babies was introduced in Colombia in 1979 by Drs. Hector Martinez and Edzar Rey as a response to, inter alia, high infection and mortality rates due to overcrowding in hospitals. It has since been adopted across the developing world and has become essential element in the continuum of neonatal care. The four components of kangaroo mother care are all essential for ensuring the best care option, especially for low birth-weight babies. They include skin-to-skin positioning of a baby on the mother's chest; adequate nutrition through breast-feeding; ambulatory care as a result of earlier discharge from hospital; and support for the mother and her family in caring for the baby *(37)*.

The intensive care comprises of:- (a) *Incubatory* care, that is, adjustment of temperature, humidity and oxygen supply. There is increasing evidence that low levels of oxygen in a baby's blood stream (hypoxia) can produce cerebral palsy. Therefore, continuous monitoring of the level of oxygen in baby's blood stream is now carried out in the best incubatory care units. If the oxygen is excessive, it may lead to retrolental fibroplasia. (b) *Feeding* : Breast-feeding is rarely possible – the baby cannot suck. However, breast milk

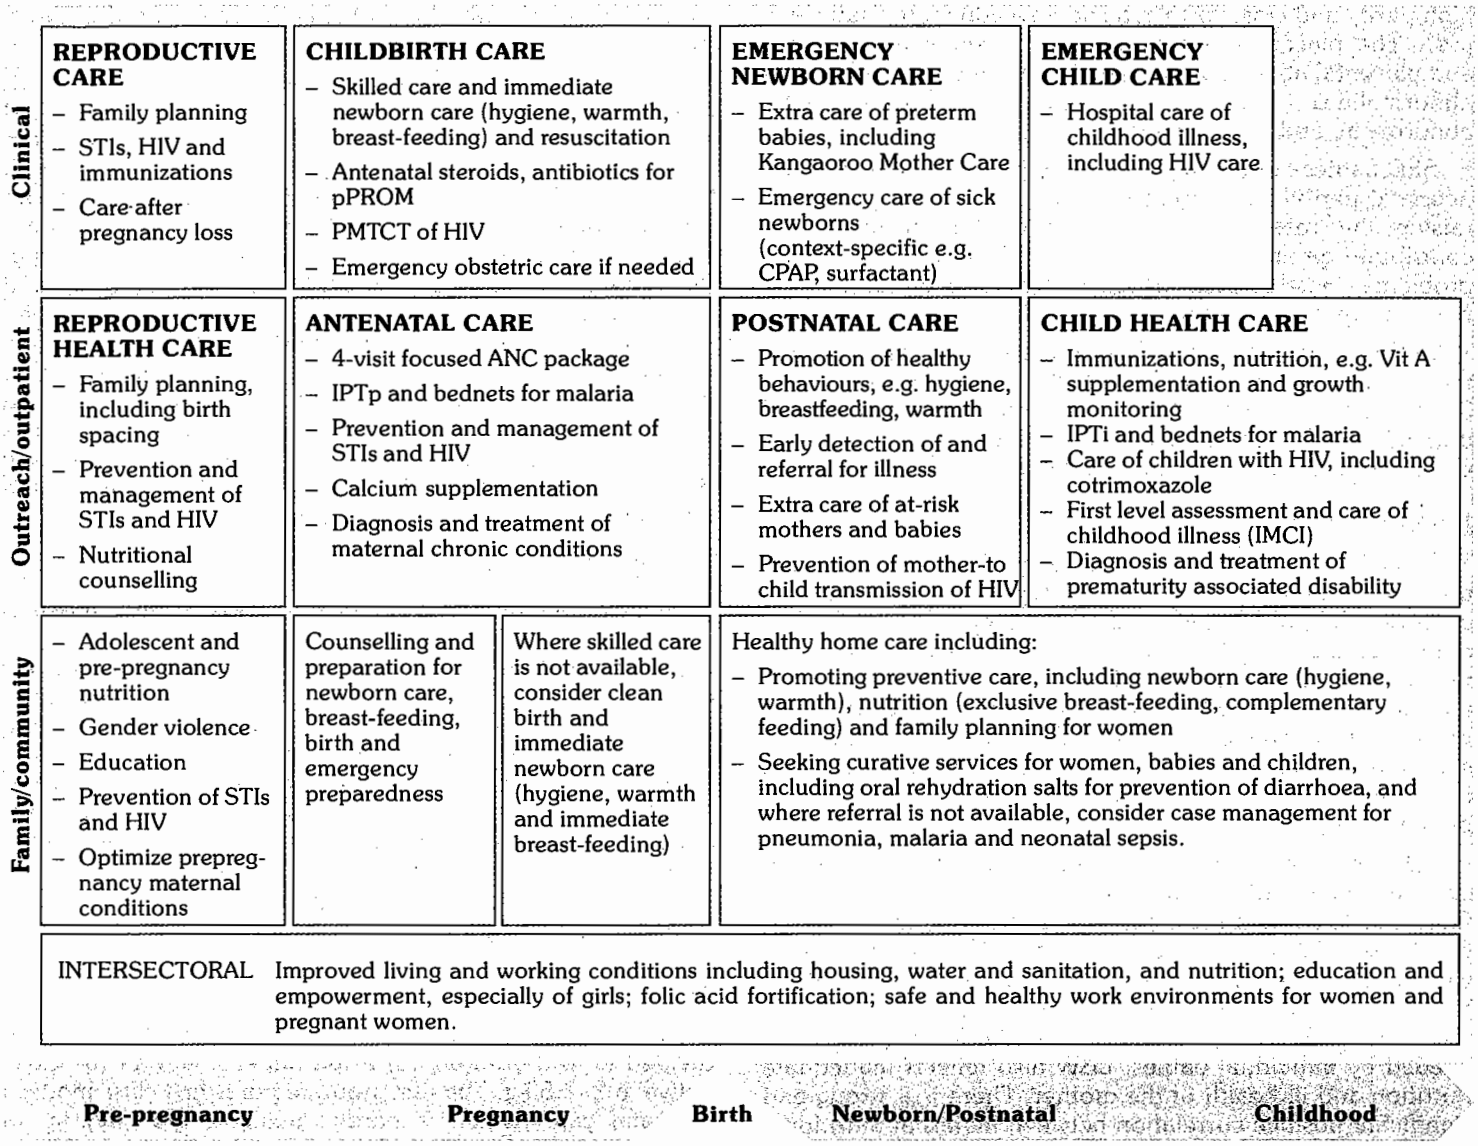

FIG. 3

Integrated service delivery packages for maternal, newborn and child health

Source : *(9)*

should be used if available. Feeding is often by nasal catheter. (c) *Prevention of infection* : Infection presents the greatest hazard. Death may occur within a few hours following respiratory infection. Prevention of infection is therefore, one of the most important functions of an intensive care unit.

The leading causes of death in low birth weight babies are :

a. atelectasis
b. malformation
c. pulmonary haemorrhage
d. intracranial bleeding, secondary to anoxia or birth trauma
e. pneumonia and other infections.

Facility based newborn care services like newborn care corner, newborn stablization unit and special newborn care unit have improved the management of low birth weight babies. Some of these units are linked to obstetric units capable of monitoring the foetus. The development of perinatal intensive care units has been associated with a decline in neonatal mortality.

FEEDING OF INFANTS

A detailed discussion of the feeding of infants is outside the scope of this book. However, a brief mention may be made of some of the important aspects of the problem.

(1) Breast-feeding

Under any circumstances, breast milk is the ideal food for the infant. No other food is required by the baby until 6 months after birth. Under normal conditions, Indian mothers secrete 450 to 600 ml of milk daily with 1.1 gm protein per 100 ml. The energy value of human milk is 70 kcals per 100 ml.

A child who is breast-fed has greater chances of survival than a child artificially fed. Prolonged breast feeding does protect the infant from early malnutrition and some infections. The data suggests that infant mortality rates in developing countries are 5–10 times higher among children who have not been breast-fed or who have been breast-fed for less than 6 months. Despite the marked advantages of breast-feeding, its popularity has declined significantly in many parts of the world.

Advantages of breast-feeding

Among the advantages of breast milk are the following : (1) it is safe, clean, hygienic, cheap and available to the infant at correct temperature (2) it fully meets the nutritional requirements of the infant in the first few months of life (3) it contains antimicrobial factors such as macrophages, lymphocytes, secretory IgA, anti-streptococcal factor, lysozyme and lactoferrin which provide considerable protection not only against diarrhoeal diseases and necrotizing enterocolitis, but also against respiratory infections in the first months of life (4) it is easily digested and utilized by both the normal and premature babies (5) it promotes "bonding" between the mother and infant (6) sucking is good for the baby – it helps in the development of jaws and teeth (7) it protects babies from the tendency to obesity (8) it prevents malnutrition and reduces infant mortality (9) it provides several biochemical advantages such as prevention of neonatal hypocalcaemia and hypomagnesemia *(38)* (10) it helps parents to space their children by prolonging the period of infertility and (11) special fatty acids in breast milk lead to increased intelligence quotients and better visual acuity. A breast-fed baby is likely to have an IQ of around 8 points higher than a non-breast fed baby *(39)*.

Early initiation of breast-feeding lowers the mother's risk of postpartum haemorrhage and anaemia, boosts mother's immune system, delays next pregnancy and reduces the insulin of diabetic mothers. It protects mothers from ovarion and breast cancers and osteoporosis *(39)*.

It is neither necessary nor desirable to train a baby to "feed by the clock". It should be explained to the mother, however, that intervals between feeds are necessary for herself and for the baby, though they may vary between 1 to 4 hours, according to the baby's needs, size, strength of sucking and the mother's milk supply.

(2) Artificial feeding

The main indications for artificial feeding are failure of breast milk, prolonged illness or death of the mother. It is crucial for the baby to be fed "breast-milk substitutes" – e.g., dried whole milk powder, fresh milk from a cow or other animal, or commercial formulae.

PRINCIPLES OF ARTIFICIAL FEEDING

In planning an artificial feed, the nutritional needs of infants should be kept in view. These include :

1. Infants require an average of 100 kcal of energy per kg of body weight per day, i.e., about 150 ml of milk per kg of body weight each day.
2. The estimated protein requirement is about 2 g/kg of body weight during the first 6 months; it declines to about 1.5 g/kg by the end of one year. This works out to 13–14 g protein daily during the first year of life. In terms of calories, 8 to 10 per cent of calories are given as protein
3. The carbohydrate requirement is about 10 g/kg of body weight daily
4. After 4 months of age, undiluted boiled and cooled milk should be given
5. Infants need feeding at frequent intervals about 6–8 times a day; older babies 5 times a day
6. During illness (e.g., fevers) the calorie need is increased, and it should be met.

(a) *DRIED MILK :* The safest milk is undoubtedly dried whole milk, which is scientifically prepared for infant feeding. It is free from bacteria; there is little danger from flies; it does not become sour and is simple to reconstitute. It is usually fortified with vitamins. But it is expensive and, therefore, beyond the reach of many Indian families.

(b) *COW'S MILK :* A cheaper alternative which is well within the reach of many Indian families is cow's milk, which in fact is widely used for infant feeding. Most health workers give very conflicting advice on the use of cow's milk for infant feeding. A small minority of over-enthusiastic paediatricians recommend undiluted cow's milk right from the birth, forgetting the fact that human milk is made for the human baby and cow's milk for the calf. Both cannot be equated. Most authorities in India and abroad including the World Health Organization have persistently recommended dilution of cow's milk during the first 2 months in order to reduce the solute load on neonatal kidneys. The Government of India in the Ministry of Health and Family Welfare in the "Manual for Health Worker (Female) Vol. I (1978) have also recommended dilution of cow's milk during the first two months. A suggested schedule for infant feeding with cow's milk is given in Table 5.

TABLE 5

Quantities per feeding – assuming five feedings per day

	Infant's weight (kg)			
	3	4	5	6
Cow's milk (ml)	70	100	150	180
Water (ml)	20	20	0	0
Sugar (g)	5	10	10	10
kcal	64	103	135	153
Protein (g)	2.1	3.0	4.5	5.4
– Place milk, water, and sugar in pan				
– bring to boil, then cool				
– pour into feeding utensil				

Source : *(40)*

Artificial feeding is a hazardous procedure in poor homes because of the dangers of contamination and over-dilution of the feed.

The composition of cow's milk and human milk is given in Table 6.

Table 6 shows that cow's milk and human milk are dissimilar in many respects. The differences may be seen as great as the difference between "brain" and "brawn", (a) *PROTEIN :* One of the striking difference is the low protein content of human milk; this is about 3 times less than in cow's milk and lower than in most mammals. The proteins in human breast milk and in cow's milk are completely different. Human milk contains more cystine, essential for the prematures, and less methionine than cow's milk. It is rich in taurine, indispensable for infants, but which they, unlike adults, are unable to synthesize. Breast milk is almost completely digested and utilized for growth, whereas much of cow's milk protein is excreted by the infant undigested producing whitish curdy stool. Breast milk contains other proteins whose functions are not nutritive, but anti-infective, e.g., IgG, lysogyme, living cells, etc. Human milk is virtually a "living" fluid. (b) *FATS :* Mother's milk is especially rich in fats, which represents between 35–50 per cent of total energy value. There are two main ways in which the fats of human milk differ from those of other milks – first, levels of essential polyunsaturated fatty acids, especially linoleic acid and alpha–linolenic acid are higher in human milk than in cow's milk; secondly, the fats of human milk are easier for the baby

TABLE 6

Comparison between breast milk during the 1st month of lactation and unprocessed cow milk

Constituent	Breast milk grammes per litre	Cow milk grammes per litre
PROTEINS :	11	33
– Casein	4	28
– Soluble proteins	7	5
Lactalbumin	3.5	1.5 to 1.8

to digest and absorb than are those of cow's milk. With cow's milk, unabsorbed fatty acids tend to bind with calcium and prevent it from being absorbed. Although there is less calcium in human milk than in cow's milk, it is much better absorbed, (c) *CARBOHYDRATES :* Human milk contains more lactose than most other milks. It may be specially useful for the growing brain. In the intestine, lactose helps the "right" kind of bacteria (i.e., *Lactobacillus bifidus*) to grow. Lactobacillus and lactose help to keep the intestinal contents acidic, which inhibits the growth of harmful bacteria. Lactose plays an important role in maintaining low electrolyte concentration. (d) *VITAMINS AND MINERALS :* If the mother takes adequate amount of vitamins, there is no reason why the child should have a vitamin supplement. The earlier teaching that human milk was deficient in vitamin D is no longer accepted. Vitamin D is present in human milk in water–soluble form. Human milk contains more vitamin A and vitamin C than cow's milk. Another factor which was supposed to be deficient in human milk was iron, but again recent work has shown that iron contained in human milk has a high level of bioavailability, thanks to complex phenomena (the action of lactoferrin, acidity of the digestive track, presence of appropriate proportions of zinc and copper). The coefficient of uptake of the iron in breast milk may be as high as 70 per cent, whereas it is only 30 per cent for cow's milk and infant formulas *(41)*, and no iron supplement is necessary for the baby reared on human milk. Human milk is richer in copper, selenium and cobalt than cow's milk. It contains less sodium than cow's milk and does not put any unnecessary strain on the infant's kidneys. The calcium/phosphorus ratio is high, so that the uptake of calcium is better than cow's milk. The high phosphorus content of cow's milk causes this mineral to be assimilated to the detriment of calcium. It has the added disadvantage of combining with certain fatty acids to form non-soluble calcium soaps.

WEANING : Weaning is not sudden withdrawal of child from the breast. It is a gradual process starting around the age of 6 months, because the mother's milk alone is not sufficient to sustain growth beyond 6 months. It should be supplemented by suitable foods rich in protein and other nutrients. These are called "supplementary foods". These are usually cow's milk, fruit juice, soft cooked rice, suji, dhal and vegetables. The weaning period is the most crucial period in child development, for during the weaning process children are particularly exposed to the deleterious synergistic interaction of malnutrition and infection. Weaning, if not done properly, is often followed by diarrhoea and months of growth failure leading to kwashiorkor, marasmus and immunodeficiency marked by recurrent and persistent infections which may be fatal. A knowledge of weaning foods and practices is an important aspect of preventive and social paediatrics. At the age of one year, the child should receive solid foods consisting of cereals, pulses, vegetables and fruits. There is now enough evidence to show that children can be properly weaned by local foods of a kind usually consumed by the older children and adults in their families. Efforts should therefore be made to design and promote the use of adequate home-made weaning foods.

Baby friendly hospitals initiatives

Since 1993 WHO's efforts to improve infant and young child nutrition have focused on promoting breast feeding. It has been calculated that breast feeding could prevent deaths of at least one million children a year. A new "baby-friendly hospital initiative" (BFHI), created and promoted by WHO and UNICEF, has proved highly successful in encouraging proper infant feeding practices, starting at birth *(42)*. BFHI is supported by the major professional medical and nursing bodies in India. The global BFHI has listed ten steps which the hospital must fulfil. This includes: (1) Have a written breast-feeding policy that is routinely communicated to all health care staff; (2) Train all health care staff in skills necessary to implement this policy; (3) Inform all pregnant women about the benefits and management of breast-feeding; (4) Help mothers initiate breast-feeding within one half-hour of birth; (5) Show mother, how to breast-feed and maintain lactation, even if they should be separated from their infants; (6) Give newborn infants no food or drink other than breast milk, not even sips of water, unless medically indicated; (7) Practice rooming-in – that is, allow mothers and infants to remain together 24 hours a day; (8) Encourage breast-feeding on demand; (9) Give no artificial teats or pacifiers (also called dummies or soothers) to breast-feeding infants; and (10) Foster the establishment of breast-feeding support groups and refer mothers to them on discharge from the hospital or clinic. The "Baby friendly" hospitals in India are also expected to adopt and practice guidelines on other interventions critical for child survival including antenatal care, clean delivery practices, essential newborn care, immunization and ORT *(43)*.

National guidelines on infant and young child feeding

In view of the vulnerability of young infant to the risk of breast milk substiutes, the Government of India enacted the

Infant Milk Substitutes, Feeding Bottles and Infant Food (Regulation of Production, Supply and Distribution) Act 1992. It came into force on 1st Aug. 1993. It prohibits the promotion of infant food, infant milk substitutes and feeding bottles as Government of India is committed to promote breast-feeding.

The new norms of infant and young child feeding i.e., exclusive breast-feeding for the first 6 months (replacing the 4–6 months age range of earlier guidelines), introduction of complementary foods at 6 months while continuing breast-feeding upto the age of 2 years or beyond; replaces the previous policy. The infant milk substitutes, feeding bottles and infant foods (Regulation of Production, Supply and Distribution) Amendment Act 2003, was passed and came into action since 1st January 2004 *(39)*. Goals set to be achieved by year 2007 were :

1. Intensify nutrition and health education to improve infant and child feeding and caring practices so as to (a) bring down the prevalence of under-weight children under three years from the current level of 47 per cent to 40 per cent; (b) reduce prevalence of severe undernutrition in children in the 0–6 years age group by 50 per cent;
2. Enhance early institution of breast feeding (colostrum feeding) from the current level of 15.8 per cent to 50 per cent;
3. Enhance the exclusive breast-feeding rate for the first six months from the current rate of 55.2 per cent (for 0–3 months) to 80 per cent; and
4. Enhance the complementary feeding rate at six months from the current level of 33.5 per cent to 75 per cent.

GROWTH AND DEVELOPMENT

1. Definition

A phenomenon peculiar to the paediatric age group is growth and development. The term growth refers to increase in the physical size of the body, and development to increase in skills and functions. Growth and development are considered together because the child grows and develops as a whole. Growth and development include not only physical aspect, but also intellectual, emotional and social aspects. Normal growth and development take place only if there is optimal nutrition, if there is freedom from recurrent episodes of infections, and if there is freedom from adverse genetic and environmental influences. MCH care is concerned with the process of growth and development, which is the foundation of human life. It is the nature of this process of physical and psychological growth and development of the child which is crucial for health or ill-health, for life or death.

Determinants of growth and development

It is beyond the scope of this book to delve into the subject of growth and development which indeed is a vast one, except to make a passing reference to some of the more important factors influencing it. Briefly these are : (1) *GENETIC INHERITANCE :* Genetic factors influence growth and development, especially height and weight, mental and social development and personality. (2) *NUTRITION :* Nutrition influences growth and development before as well as after birth. In fact, retardation of growth rate is an indication of malnutrition. When the diet is improved the child begins to grow in height and weight. (3) *AGE :* Growth rate is maximum during foetal life, during the first year of life and then again at puberty. At other periods, growth is slower. (4) *SEX :* At about the age of 10 to 11 years, female children show a sudden increase in height and weight. This growth spurt corresponds to puberty. In male children, the growth spurt occurs a little later, i.e., between 12 and 13 years. (5) *PHYSICAL SURROUNDINGS :* Sunshine, good housing, lighting and ventilation have their effects on growth and development (6) *PSYCHOLOGICAL FACTORS*: Love, tender care and proper child–parent relationship do affect the social, emotional and intellectual development of children. (7) *INFECTIONS AND PARASITOSIS :* Certain infections of the mother during pregnancy (e.g., rubella, syphilis) affect the intrauterine growth of the foetus. Infections after birth (e.g., diarrhoea, measles) slow down growth and development, especially in the malnourished child. The intestinal parasites (e.g., roundworms) by consuming considerable quantities of nutrients hamper growth and development. (8) *ECONOMIC FACTORS :* The standard of living of the family is an important factor. Children from well-to-do families have better height and weight. The economic factor is connected with the nutrition and living of the people. (9) *OTHER FACTORS*: These comprise the birth order of the child, birth spacing, birth weight in single and multiple pregnancies, education of the parents, etc. In short, a normal childhood implies proper physical, mental and emotional development, and is a prerequisite for a full adult life. The study of normal development and its determinants is the basis for paediatric education.

The process of growth from birth to age 20 may be represented diagrammatically in 3 curves (Fig. 4) which shows the level accomplished (as a percentage of development between birth and maturity). These curves are so drawn that height at age 20 corresponds to 100 on the vertical scale. It will be seen from Fig. 4 that the growth of the brain is spectacular during the pre-school age.

2. Normal growth

CONCEPT OF NORMALITY

When speaking of human growth and development, mention must be made of the difficulty of defining normality. A normal child may be defined as one whose characteristics fall within the range of measurements accepted as normal for the majority of children in the same (or reference) age group. Conventionally, these limits – the limits of normal variation – are assumed to include two standard deviations above and below the mean (i.e., between the 3rd and the 97th centiles). This presupposes the availability of accurate measurement techniques of growth, and a satisfactory set of reference values or standards for comparison.

As far as physical development is concerned, we have measurement techniques. For example, we measure growth in terms of kilograms and centimetres. But very great difficulties are encountered in connection with psychomotor, emotional and social development; most measurement techniques are based on observations such as "milestones of development."

Methods of assessment *(44, 45)*

In children, the parameters of growth generally used are : weight, height (or length in infants), and head and chest circumferences. These characteristics are measured and compared with the reference standards. Three methods are generally used for making comparisons : (i) The first method is based on mean (or median) values. The median, rather than mean is used where possible because of the skewed distribution of most anthropometric measurements.

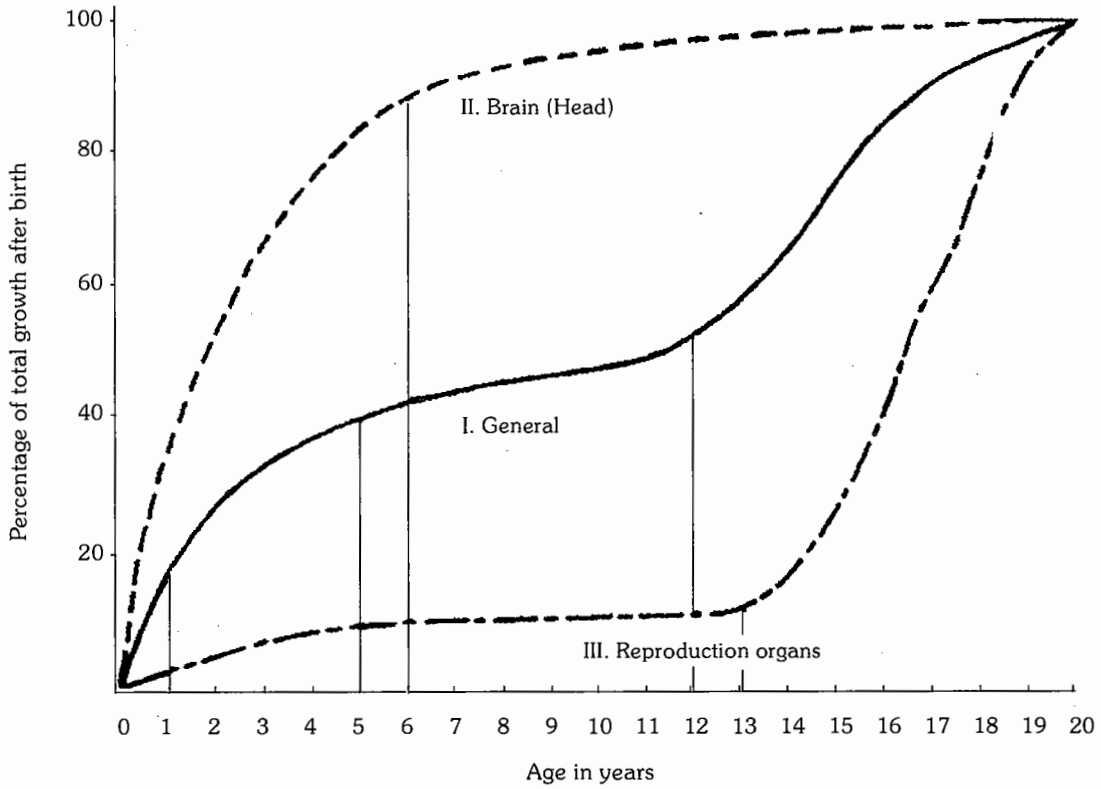

FIG. 4
Growth after birth

A variation of 2 standard deviations from either side of the mean (or median) is considered as within normal limits. (ii) The second method is by means of percentile or (centiles). Percentiles are easier to understand than standard deviations. Percentiles refer to the percentage of individuals falling below a particular level. By definition 3 per cent of children are below the 3rd percentile, and a further 3 per cent are above the 97th percentile. The remaining 94 per cent of individuals who fall between these two lines (i.e. between 3rd and 97th percentiles) should therefore be regarded as being within the range of "normal." However, the 6 per cent of the children outside this range may not necessarily be "abnormal", particularly if their growth is parallel with their centile lines. A measurement outside 3 standard deviation (above 99th and below 1st centile) is more likely to indicate a significant degree of abnormality. (iii) Thirdly, it is also possible to assess the growth of a child by such indices as weight for length, and weight for height. These are age-independent indices.

The assessment of growth may be longitudinal or cross-sectional. Longitudinal assessment of growth entails measuring the same child at regular intervals. This provides valuable data about a child's progress. Cross-sectional studies are also essential to compare a child's growth with that of his peers. Cross-sectional comparisons involve large number of children of the same age. These children are measured and the range of their measurements (e.g., weight, height) is plotted, usually on percentile charts.

Reference values

For national and international comparisons and for monitoring, reference or "standard" values of growth are essential. The well known reference standards are : *(i) Harvard (or Boston) standards (46) :* These are based on observations made on children in Boston from 1930 to 1956. They have been carefully compiled longitudinally on a large series of children, mostly from North European origin. They became widely used throughout the world. *(ii) WHO reference values (47, 48) :* The Harvard values were replaced by WHO reference values for weight and height. These values were based on extensive cross-sectional data assembled by the United States National Centre for Health Statistics (NCHS) which were considered the best available for international use. The WHO reference values are used for children upto 5 years of age since the influence of ethnic or genetic factors on young children at this age period is considered insignificant, given the similar socio-economic environment. *(iii) Indian standards (49) :* The Indian Council of Medical Research (ICMR) undertook a nationwide cross-sectional study during the year 1956 and 1965 to establish the much needed reference standards of growth and development of Indian children, for the country as a whole, as well as for each of the states in the country. As the Indian data are based on measurements of children belonging to the lower socio-economic groups which form the majority of Indian communities, the values cannot be considered as representing standard values *(50)*.

The use of local standards of reference is not recommended unless these are based on well–nourished and healthy samples of local population. Further, local standards do not permit international comparisons *(51)*. It was the opinion of WHO that countries or regions might eventually develop their own reference standards; in the interim, the WHO reference value should provide an effective substitute *(47)*.

Reference versus standard values

A distinction must be made between reference values and standard values. If the values are derived from a population

racially different from the population under study, such values should be considered as reference values only and not as standard values *(52)*. That is, reference values cannot be used as standard values applicable to a population racially different. For example, it would be absurd to apply the Harvard standards of growth to Pigmies and Eskimos who are racially different *(51)*.

Surveillance of growth and development

Surveillance of growth and development is a specific function of the mother and child health services. It is an important component of the routine anticipatory care of children. The main purpose of growth surveillance is to identify those children who are not growing normally. Surveillance also reflects the effectiveness of other components of child care such as nutrition, sanitation and control of infection. Surveillance of growth and development covers the following aspects :

PHYSICAL GROWTH

1. Weight-for-age

Measurement of weight and rate of gain in weight are the best single parameters for assessing physical growth. A single weight record only indicates the child's size at the moment; it does not give any information about whether a child's weight is increasing, stationary or declining. This is because, normal variation in weight at a given age is wide. What is important is careful repeated measurement at intervals, ideally monthly, from birth to 1 year, every two months during the second year and every 3 months thereafter upto 5 years of age, since this age group is at greatest risk from growth faltering. By comparing the measurements with reference standards of weight of children of the same age (Table 7), the trend of growth becomes obvious. This is best done on growth chart. Serial weighing is also useful to interpret the progress of growth when the age of the child is not known. Thus, without the aid of a growth chart, it is virtually impossible to detect changes in the rate of growth, such as sudden loss of weight or halt in gain. Each baby should have its own growth chart.

A baby should gain at least 500 gram wt. per month in the first three months of life. That is the minimum. The children who gain less weight are malnourished. It is usual for babies to gain about 1 kg a month, especially in the first 3 months. Healthy babies, on an average double their birth weight by 5 months, and treble it by the end of first year and quadruple by the age of two. During the first year, weight increases by about 7 kg. After that the increase in weight is not so fast – only about 2.5 kg during the second year and from then until puberty by about 2 kg per year. The weight and height gain patterns in India are as shown in Table 8.

In different parts of India, the average birth weight is between 2.7 and 2.9 kg *(54)*. The Indian infant manages to grow well upto the age of 3–4 months, even at the expense of its malnourished mother. Thereafter, the growth falters due to lack of supplementary feeding *(55)*. However, Indian children from well-to-do families display growth patterns as good as their counterparts in the Western world *(49)*.

TABLE 8

Average weight and height increase during the first 5 years

Age	Increments
	Weight increments per week
0 – 3 months	200 g
4 – 6 months	150 g
7 – 9 months	100 g
10 – 12 months	50 – 75 g
	Weight increments per year
1 – 2 years	2.5 kg
3 – 5 years	2.0 kg
	Length increments per year
1st year	25 cm
2nd year	12 cm
3rd year	9 cm
4th year	7 cm
5th year	6 cm

60	14.1	18.3	24.2	13.7	18.2	24.9

Source : *(53)*

Weight-for-age is often used to classify malnutrition and determine its prevalence. Jelliffe suggested that 80 per cent of the median weight-for-age of the reference be the cut-off point below which children could be considered malnourished.

2. Height (length)-for-age

Height should be taken in a standing position without foot wear. If the height machine is not available, the measuring scale fixed to the wall can be employed. This arrangement is suitable for children 2 years and above. The measuring scale should be capable of measuring to an accuracy of 0.1 cm *(48)*. A very great effort should be made to measure children accurately. Errors in the measurement of a young child may lead to significant errors in the classification of the nutritional status. The WHO standards (2006) for height-for-age are as shown in Table 9.

The length of a baby at birth is about 50 cm. It increases by about 25 cm during first year, and by another 12 cm during the second year. During growth spurt, boys add something like 20 cm in their height, and girls gain about 16 cm. The spurt is followed by a rapid slowing of growth. Indian girls reach 98 per cent of their final height on an average by the age of 16.5 years, and boys reach the same stage by the age of 17.75 years. With the exception of a few ethnic groups, there is evidence showing that all children have a similar growth potential.

Height is a stable measurement of growth as opposed to body weight. Whereas weight reflects only the present health status of the child, height indicates the events in the past also. The use of growth (height) centile chart is particularly valuable in studying the trend of height curve.

Low height for age : This is also known as nutritional stunting or dwarfing. It reflects past or chronic malnutrition. The cut-off point commonly taken for the diagnosis of stunting is 90 per cent of the United States NCHS height-for-age values *(56)*. Waterlow recorded the use of 2SD below the median reference as the cut-off point.

3. Weight-for-height

Height and weight are interrelated. Weight in relation to height is now considered more important than weight alone. It helps to determine whether a child is within range of "normal" weight for his height. For example, a child on the 75th centile of both his height and weight is neither overweight nor underweight, but a child on the 75th centile of his weight chart and the 25th centile of his height chart is clearly overweight.

Low weight for height : This is also known as nutritional wasting or emaciation (acute malnutrition). It is associated with an increased risk of mortality and morbidity *(56)*. A child who is less than 70 per cent of the expected weight-for-height is classed as severely wasted.

The WHO has compiled reference value for children giving weight according to height. For details see reference 53.

Weight records

Weight records are generally kept by all infant clinics; the aim is the prevention of underfeeding, and in the developing world, the weight chart is an important tool in the prevention of malnutrition.

4. Head and chest circumference

At birth the head circumference is about 34 cm. It is about 2 cm more than the chest circumference. By 6 to 9 months, the two measurements become equal, after which the chest circumference overtakes the head circumference. In severely malnourished children, this overtaking may be delayed by 3 to 4 years due to poor development of the thoracic cage. In a ICMR study *(49)*, the crossing over of chest and head circumference did not take place until the age of two years and six months. This has been attributed to growth retardation in poor Indian children.

Besides increase in height and weight, the term "growth" also includes various physiological events which occur at predictable periods such as, dentition, ossification of bones and secondary sexual characteristics.

BEHAVIOURAL DEVELOPMENT

A closely related development is behavioural development. It is assessed in four fields :

TABLE 9

2006 – WHO standards for length/height-for-age of boys and girls upto the age of 5 years (cm)

Age (months)	Boys			Girls		
	– 2SD	Median	+ 2SD	–2SD	Median	+2SD
0	46.1	49.9	53.7	45.4	49.1	52.9
4	59.7	63.9	68.0	57.8	62.1	66.4

60	100.7	110.0	119.2	99.9	109.4	118.9

Source : *(53)*

1. Motor development
2. Personal-social development
3. Adaptive development
4. Language development

The developmental landmarks or milestones of development provide an estimate of the time when the child can be expected to attain certain skills or points in development. Since the milestones are averages, each child is bound to differ from the other. For instance, some children sit up and speak earlier than others. Table 10 shows some of the normal developmental milestones and ages at which these are reached in the Indian context. When a child takes longer time to cross these milestones, the possibility of his being mentally handicapped should not be overlooked.

The behavioural development of the child is a complex affair. The work of ethnologists and sociologists show how quickly the child's behaviour conform to the models adult society offers them. For proper behaviour development, the child must be assured emotional and moral stability, that is, a home where he will find bonds of affection, regular discipline and parents who accept him and provide him with models of balanced conduct. Many children will not find themselves in ideal conditions. They consequently have trouble with behaviour, speech, sleep and appetite and these problems will have to be anticipated, diagnosed and treated.

THE GROWTH CHART

The growth or "road-to-health" chart (first designed by David Morley and later modified by WHO) is a visible display of the child's physical growth and development. It is designed primarily for the longitudinal follow-up (growth monitoring) of a child, so that changes over time can be interpreted.

It is important to note that in the weight-for-age chart, the height of the child is not taken into consideration. This is because weight is the most sensitive measure of growth, and any deviation from "normal" can be detected easily by comparison with **reference curves**. A child can lose weight, but not height. In short, the growth chart offers a simple and inexpensive way of monitoring weight gain, and in fact child health over time.

1. WHO child growth standards, 2006 *(53)*

In 1993 the WHO undertook a comprehensive review of the uses and interpretation of anthropometric references. The review concluded that the NCHS growth references, which had been recommended for international use since the late 1970s, did not adequately represent early childhood growth and that new growth curves were necessary. A Multicentre Growth Referenece Study (MGRS) was undertaken between 1997 and 2003 in Brazil, Ghana, India, Norway, Oman and USA and primary growth data and related information were gathered from 9,440 healthy breast-fed infants and young children (0 to 60 months boys and girls) from widely diverse ethnic background and cultural settings. In addition their mothers followed health practices such as breast feeding their children, and not smoking during and after pregnancy.

The new standards were generated for boys and girls aged 0–60 months – percentile and Z–score curves for length/height-for-age, weight-for-age, weight-for-length, weight-for-height and BMI-for-age. The last standard is an addition of the set of indicators previously available as part of the NCHS/WHO reference.

As expected, there are notable differences with the NCHO/WHO reference that vary by age, sex, anthropometric measure and specific percentile or Z–score curve. Differences are particularly important in infancy. Stunting will be greater throughout childhood when assessed using the new WHO standards compared to the NCHS/ WHO reference. The growth pattern of breast-fed infant will result in a substantial increase in rates of underweight during the first half of infancy and a decrease thereafter. For wasting, the main difference is during infancy when wasting rate will be substantially higher using the new WHO standards. With respect to overweight, use of the new standards will result in a greater prevalence that will vary by age, sex and nutritional status of the index population.

The new WHO standards depict normal early childhood growth under optimal environmental conditions and can be used to assess children everywhere, regardless of ethnicity, socio-economic status and type of feeding.

Fig. 5 and 6 show the comparison of WHO with NCHS weight-for-age reference curve from birth to 5 years of age for boys and girls respectively *(53)*.

TABLE 10

Milestones of development

The 'milestones' given here are approximations and to assess any individual child, all types of growth development and behaviour must be taken into account.

Age	Motor development	Language development	Adaptive development	Socio-personal development
6-8 weeks	–	–	–	Looks at mother and smiles
3 months	Holds head erect	–	–	–
4-5 months	–	listening	begins to reach out for objects	recognizes mother
6-8 months	sits without support	experimenting with noises	transfers objects hand to hand	enjoys hide and seek
9-10 months	crawling	increasing range of sounds	releases objects	suspicious of strangers
10-11 months	stands with support	first words		
12-14 months	walks wide base		builds	
18-21 months	walks narrow base beginning to run	joining words	beginning to explore	
24 months	runs	short sentences		dry by day

2. Growth chart used in India

India has adopted the new WHO Child Growth Standards (2006) in February 2009, for monitoring the young child growth and development within the National Rural Health Mission and the ICDS. The same standards will be used for research too in future.

These standards are available for both boys and girls below 5 years of age. With these new standards the child care workers will know when the nutrition and care needs of the child is being compromised and it will enable them to take timely corrective action at different levels.

A joint "Mother and Child Protection Card" has been developed, as shown in Fig. 7 and 8, which provides space for recording the family identification and registration, birth record, pregnancy record, institutional identification, care during pregnancy, preparation for delivery, registration under Janani Suraksha Yojana, details about immunization procedures, breast-feeding and introduction of supplementary food, milestones of the baby, birth spacing and reasons for special care. The chart is easily understood by the health workers and the mother, with a visual record of the health and nutritional status of the child. It is kept by the mother and brought to the health centre at each visit.

The growth chart shows normal zone of weight for age, undernutrition (below – 2 SD) and severely underweight zone (below – 3 SD). In some states like Maharashtra, the growth chart contains normal weight for age zone and undernutrition zone of grade one, second, third and fourth. It is the direction of growth that is more important than the position of dots on the line. The importance of the direction of growth is illustrated at the left hand, upper corner of the chart. Flattening or falling of the child's weight curve signals growth failure, which is the earliest sign of the protein-energy malnutrition and may precede clinical signs by weeks and months. Such a child needs special care. The objective in child care is to keep the child in normal zone.

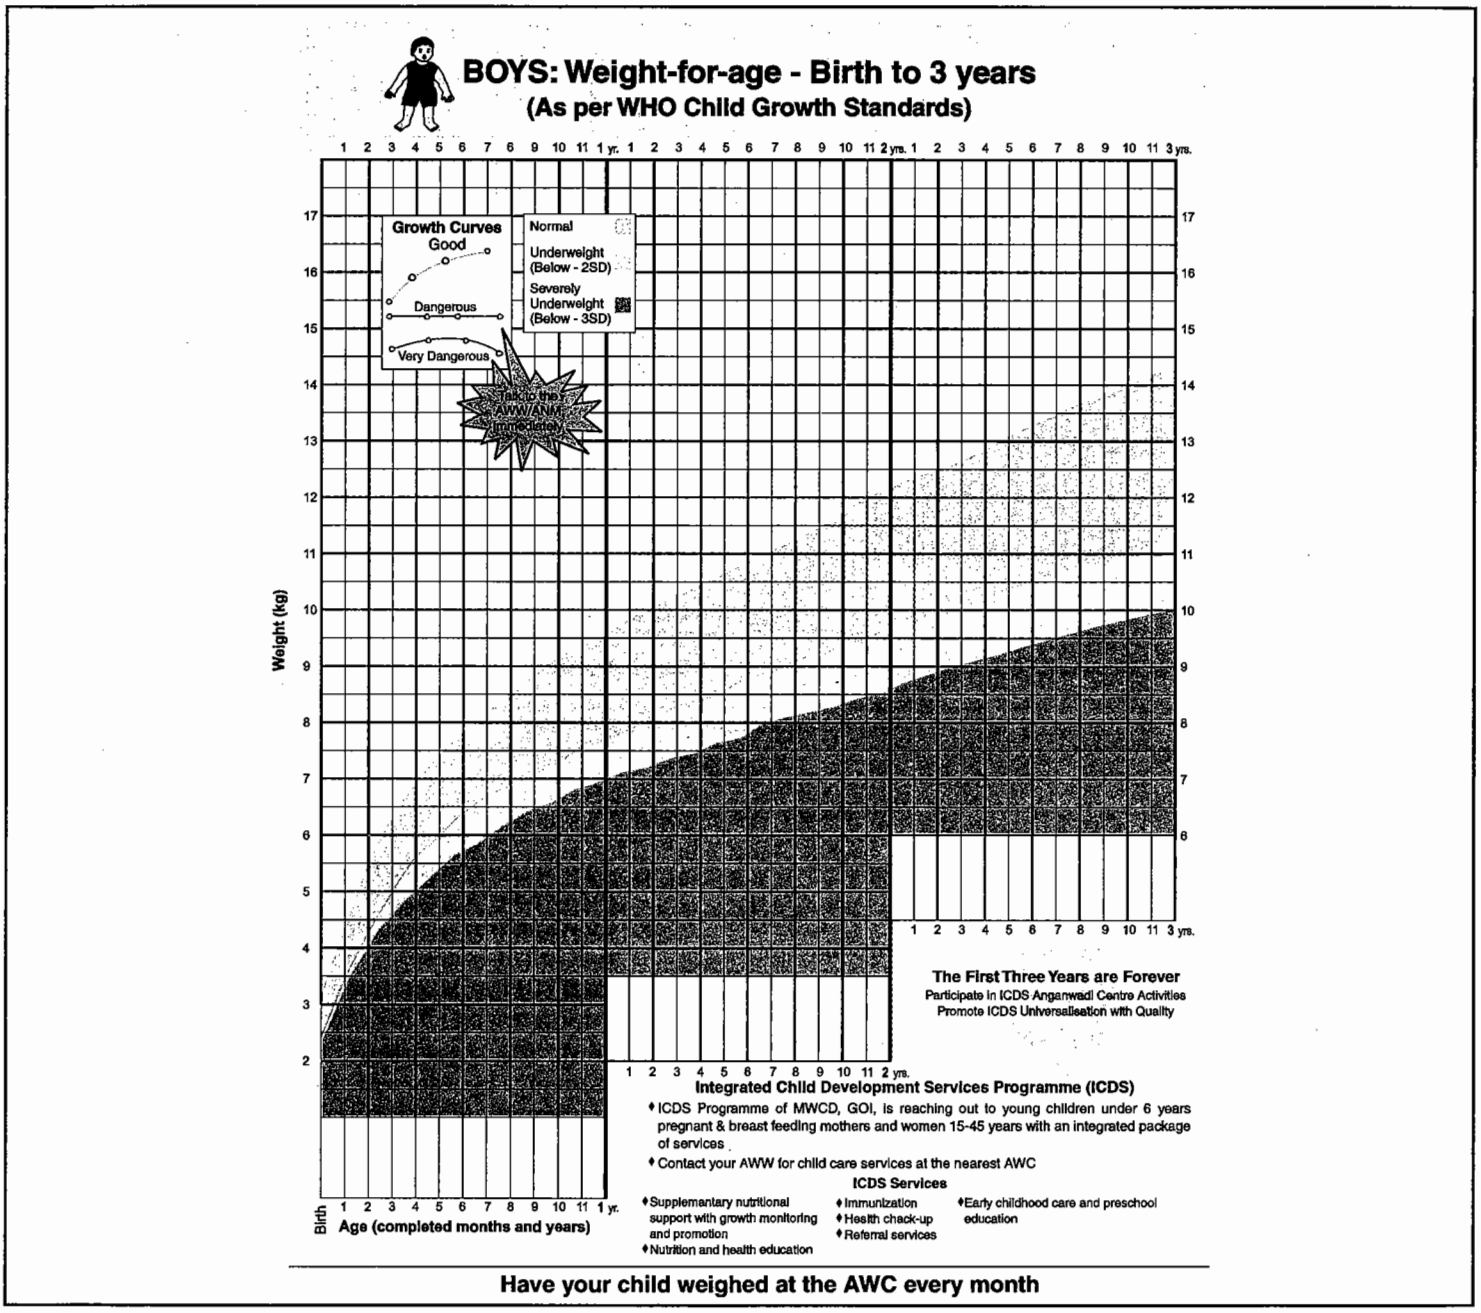

FIG. 7
ICDS growth chart for boys

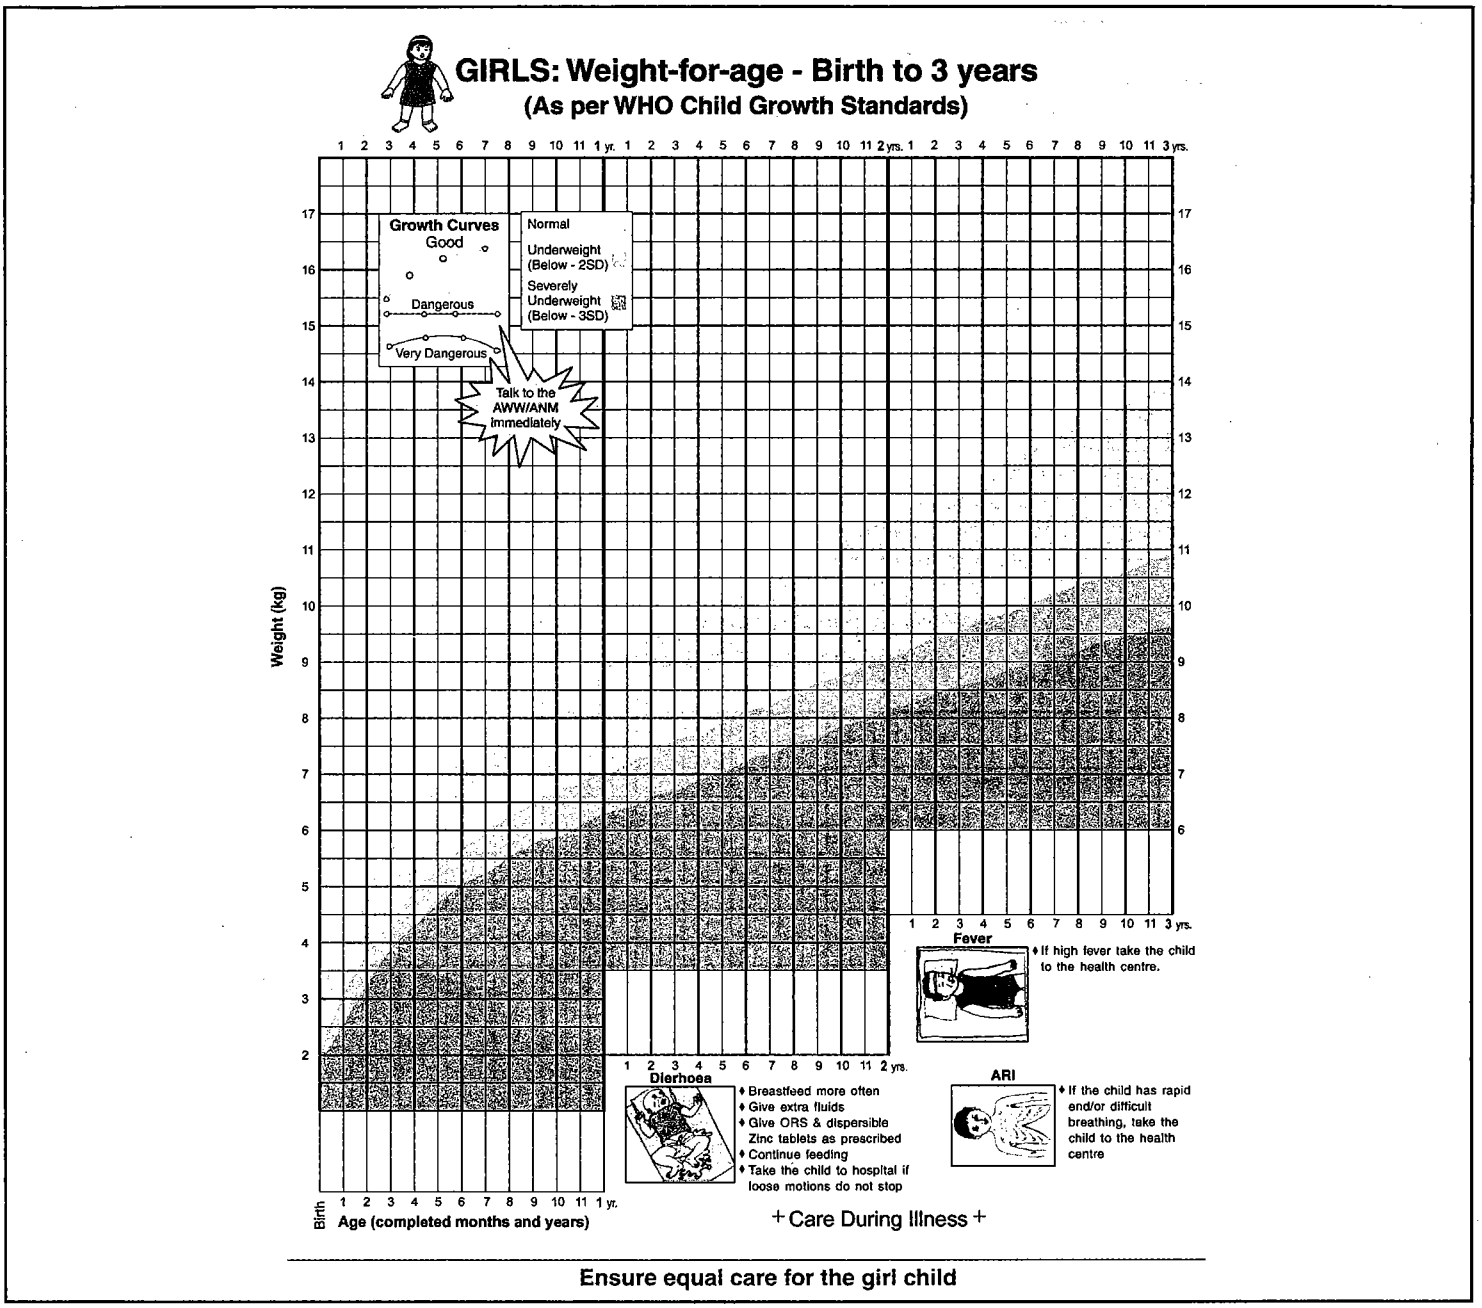

FIG. 8

ICDS growth chart for girls

Uses of growth chart

A growth chart has many potential uses :

1. for **growth monitoring** which is of great value in child health care
2. **diagnostic tool:** for identifying "high-risk" children. For example, malnutrition can be detected long before signs and symptoms of it become apparent
3. **planning and policy making:** by grading malnutrition, it provides an objective basis for planning and policy making in relation to child health care at the local and central levels
4. **educational tool:** because of its visual character, the mother can be educated in the care of her own child and encourage her to participate more actively in growth monitoring
5. **tool for action:** it helps the health worker on the type of intervention that is needed; it will help to make referrals easier
6. **evaluation:** it provides a good method to evaluate the effectiveness of corrective measures and the impact of a programme or of special interventions for improving child growth and development, and
7. **tool for teaching:** it can also be used for teaching, for example, the importance of adequate feeding; the deleterious effects of diarrhoea.

The growth chart has been described as a passport to child health care *(57)*. It has won international recognition and is now a standard method of monitoring children's health and nutritional status.

Alternative methods of growth monitoring

Growth charting is only one method of growth monitoring. There are other indicators such as height-for-

age, weight-for-height, and arm circumference. The last two are independent of age and are particularly useful when age is not known.

CARE OF THE PRE-SCHOOL CHILD

Children between 1–4 years of age are generally called pre-school age children or toddlers. In the history of health services of many developing countries, their social and health needs were realized rather late. Today, more than ever before, the pre-school age child has become a focus for organized medical–social welfare activities, and their death rate is considered a significant indicator of the social situation in a country.

The pre-school age is distinguished by the following characteristics :

1. Large numbers

Pre-school age children (1–4 years) represent about 9.7 per cent of the general population in India. A large majority of these children live in rural and tribal areas and in urban slums. By virtue of their numbers, they are entitled to a large share of health and social services. Further, children are the human resources of the future. Their development is in the interest of the total national development; therefore, they need special attention. Unfortunately, pre-school age children are comparatively less attended to.

2. Mortality

The pre–school age (1–4 years) mortality in India is 2.3 per cent of all deaths. This high mortality which is largely due to infection and malnutrition is characteristic of this age group in underprivileged areas. Malnutrition was shown to be an underlying cause in 3.4 per cent of all deaths in young children and associated cause in no less than 46 per cent *(42)*.

3. Morbidity

The data on the extent of morbidity of pre-school children are scarce. Some hospital records and a few surveys suggest that children in this age group are usually victims of PEM accompanied by retarded growth and development. Surveys indicate that the main morbidity problems are malnutrition and infections. The prevalence of severe protein-energy malnutrition ranged between 5–6 per cent, and mild protein energy malnutrition about 40 per cent. PEM is often associated with other nutritional deficiency such as anaemia, xerophthalmia, etc. Diarrhoea, diphtheria, tetanus, whooping cough, measles and other eruptive fevers, skin and eye infections, and intestinal parasitic infestations are usually common under the existing environmental conditions. Atleast 5 per cent of the pre-school age children belonging to poor socio-economic groups show signs of vitamin A deficiency. Accidents are also becoming frequent, especially burns and trauma from home accidents, and to an increasing degree, traffic accidents. Some childhood diseases and conditions do not kill their victims, but cause serious disability (e.g., blindness, paralysis); and some diseases become manifest later in life (e.g., heart disease and mental retardation). In many developing countries, periods of illness take up 25–30 per cent of the child's life and each represents either loss of weight or failure to gain weight. These episodes are well documented by several authors *(56)*.

4. Growth and development

The importance of the first 5 or 6 years of life of a child for its growth and development is well known. Any adverse influences operating on children during this period (e.g., malnutrition and infection) may result in severe limitations in their development, some of which at least are irreversible. The concept of vulnerability calls for preventive care and special actions to meet the biological and psychological needs inherent in the process of human growth and development *(36)*.

5. Accessibility

While the infant may be easily reached, the toddler is hard to reach, and it is therefore difficult to look after his health. Special inputs are needed (e.g., day care centres, play group centres, children's clubs) to reach the toddler and to bring him into the orbit of health care. Operation research all over the world has demonstrated that parents are unlikely to travel more than 5–8 kms to obtain medical care. For the toddler who needs to be carried, the distance may be reduced even further.

6. Prevention in childhood of health problems in adult life

Results of research indicate how events in early life (e.g. child's diet, infections) affect its health when it becomes an adult, and how many conditions can be prevented through early action, for example, dental diseases in adulthood. Early treatment of streptococcal infection can prevent rheumatic heart disease. Longitudinal studies suggest that the foundations of obesity, hypertension, cardiovascular diseases, and certain mental disorders may be laid in early life. Some of the chronic orthopaedic ailments of the adult are probably connected with anomalies in the development or minor uncorrected infirmities of the infant (e.g. talipes, congenital dislocation of the hip). Many of the measures subsequently undertaken to treat these disorders often do not fully succeed.

Since young children are "vulnerable" to social and health hazards which can retard or arrest their physical and mental development during these critical years, they deserve special attention by the administration, general population and the family.

CHILD HEALTH PROBLEMS

The problems facing the health worker in the developing world are vast and are nowhere more evident than in the field of childcare. The main health problems encountered in the child population comprise the following.

1. low birth weight
2. malnutrition
3. infections and parasitosis
4. accidents and poisoning
5. behavioural problems.

1. Low birth weight

This has been discussed in detail earlier.

2. Malnutrition

Malnutrition is the most widespread condition affecting the health of children. Scarcity of suitable foods, lack of purchasing power of the family as well as traditional beliefs and taboos about what the baby should eat, often lead to an insufficient balanced diet, resulting in malnutrition. A childhood mortality study in the Americas showed that no less than 50 per cent of the children who died before the age of 5 years were found to have malnutrition as underlying or

associated cause of death, the peak of this mortality being in the post–neonatal period. During 2006–12, more than 15 per cent of the world's children under the age of 5 years were underweight for their age. The proportion ranged from 1.4 per cent of children in developed countries to 24 per cent in developing countries *(58)*. In India, the National Family Health Survey (NFHS) 2005–06 included survey of the nutritional status of young children. Both chronic and acute undernutrition were found to be high in all the 7 states for which reports have been received, namely, Haryana, Karnataka, Maharashtra, Orissa, Tamil Nadu, Uttar Pradesh and Goa.

At present in India 43.5 per cent children under 5 years age are underweight. This includes 43 per cent moderate to severe cases, 16 per cent severe malnutrition, of these, 20 per cent have moderate to severe wasting and 48 per cent moderate to severe stunting *(58)*.

Malnutrition makes the child more susceptible to infection, recovery is slower and mortality is higher. Undernourished children do not grow to their full potential of physical and mental abilities. Malnutrition in infancy and childhood leads to stunted growth. It also manifests by clinical signs of micronutrient and vitamin deficiencies. Prevention and appropriate treatment of diarrhoea, measles and other infections in infancy and early childhood are important to reduce malnutrition rates as infection and malnutrition often make vicious cycle. Exclusive breast-feeding in first 6 months of life is very important.

Specific nutritional deficiencies

(a) Protein-energy malnutrition

Protein-energy malnutrition (PEM) has been identified as a major health and nutrition problem in India. It occurs particularly in weaklings and children in the first years of life. It is characterized by low birth weight if the mother is malnourished, poor growth in children and high level of mortality in children between 12 and 24 months, and is estimated to be an underlying cause in 30 per cent of deaths among children under age 5.

As many as 37 per cent of the children in the developing world have low height for their age i.e. stunting, and 10 per cent children have low weight for height. The rate of low height for age reflects the cumulative effects of undernutrition and infections since birth or even before birth; high rates are often suggestive of bad environmental conditions and/or early malnutrition. On the other hand, a greater frequency of low weight for height, often reflects current severe undernutrition or disease.

(b) Micronutrient malnutrition

Micronutrient malnutrition refers to a group of conditions caused by deficiency of essential vitamins and minerals such as vitamin A, calcium, iodine, iron and zinc. It is estimated that about 2 billion people are affected by this type of malnutrition. Vitamin A deficiency is still the most common cause of preventable childhood blindness world-wide; iodine deficiency causes goitre, cretinism and brain damage; and anaemia results from insufficient iron intake.

Nutritional anaemia : It affects all age groups, including pre-school children, school children and elders. Even mild anaemia reduces resistance to fatigue. It has a profound effect on psychological and physical behaviour.

Vitamin A deficiency and nutritional blindness : Young children are at greater risk of developing xerophthalmia, partly because their vitamin A requirements are proportionately greater than those of any other group and partly because they suffer most from infections. The result is that severe, blinding corneal destruction is most frequently seen in children between the age of six months and six years. Vitamin A deficiency is in fact, the single most frequent cause of blindness among pre-school children in developing countries. Some 20 per cent children with this deficiency are at increased risk of death from common infections, and around 2 per cent are blinded or suffer serious sight impairment.

Iodine deficiency : Iodine deficiency disorders pose a public health problem as about 1.5 billion people are living in environments lacking this mineral. As a result at least 30,000 babies are stillborn each year and over 120,000 are born mentally retarded, physically stunted, deaf–mute or paralysed. Even when children are born otherwise healthy, lack of iodine may still cause mental dullness and apathy.

Nutritional deficiencies not only lead to severe illnesses, entailing long and costly treatment, but also influence physical development, psychic behaviour and susceptibility to infection.

3. Infectious and parasitic diseases

Young children fall an easy prey to infectious diseases. The leading childhood diseases are : diarrhoea, respiratory infections, measles, pertussis, polio, neonatal tetanus, tuberculosis, and diphtheria. It is known that a child may get affected several times in a year; the incidence increases with the aggravation of a state of malnutrition. Of about 4 million deaths a year from acute respiratory infections in the developing world, a quarter are linked to malnutrition, and a further quarter associated with complications of measles, pertussis, malaria and HIV/AIDS. During 2012, about 9 per cent of under-five mortality worldwide was due to diarrhoeal diseases, about 17 per cent due to ARI, about 1 per cent deaths were due to measles and about 7 per cent due to malaria. In India, during the year 2013, 4,090 cases of diphtheria, 15,768 cases of measles, 36,661 cases of pertussis, and 528 cases of neonatal tetanus were reported *(59)*. The actual figures may be several times higher since there is considerable under-reporting. This is so, for example, in the case of eruptive fevers, malaria, intestinal parasites such as ascariasis, hookworm, giardiasis and amoebiasis etc. which are common because of poor environmental sanitation and paucity of potable drinking water. The prevention and treatment of children's illnesses may interrupt the transmission of infection in the community.

These few facts, which are merely examples and could be multiplied, show that the prevention and treatment of infections and parasitosis of children are bound to have important long-term consequences.

4. Accidents and poisoning

In the developed world, accidents and poisoning have become a relatively more important child health problem. There is every reason to believe that accidents among children are frequent in the developing countries also, especially burns and trauma as a result of home accidents and, to an increasing degree, traffic accidents. Children and young adolescents are particularly vulnerable to domestic accidents – including falls, burns, poisoning and drowning.

5. Behavioural problems

Behavioural disturbances are notable child health problem, the importance of which is increasingly recognized in most countries. Children abandoned by their families present severe social and health problems. Over 60,000 children are abandoned each year in India *(60)*.

6. Other factors affecting the health of children

a. Maternal health

A major determinant of child health is the health of his/her mother. Child health is adversely affected (the risk begin to appear even before birth) if the mother is malnourished, if she is under 18 years (too young) or over 35 (too old), if her last child was born less than 2 years ago (too close), if she has already more than 4 births (too many) and if she is deprived of basic pregnancy care. A healthy mother brings forth a healthy baby, with better chances of survival.

b. Family

In pre-school years, the child is very much an organic part of the immediate family. Whatever happens to him or her affects the other members of the family, and vice versa. Therefore, "child health" has to be "family health". It depends upon the family's physical and social environment, which includes its lifestyle, customs, culture, traditional habits, and the childbearing and childrearing practices are greatly influenced by this. The family and social environment has a considerable influence on the development of speech, personality and the intellectual potentials of the small child. Other factors are the family size, the family relationships, and family stability. Infancy and early childhood is the time when the child contracts common contagious illness from contact with others (older brothers and sisters, playmates, school–mates). Data shows that the number of episodes of infectious diarrhoea increases with the size of the family. Studies also show an increase in the prevalence of malnutrition in families with more than 4 children. In short, fewer children would mean better nutrition, better health care, less morbidity and lower infant mortality.

c. Socio-economic circumstances

The socio-economic situation in which the family is placed is a very important factor in child health. In every region of the world, the physical and intellectual development of children varies with the family's socio-economic level. Under-privileged children of the same age are smaller, lighter and less advanced in psychomotor and intellectual performance, compared to children of privileged group. A detailed analysis of socio-economic factors shows the part played by the parents' education, profession and income, their housing, the urban or rural, industrialized or non–industrialized nature of the population.

Poverty, illiteracy (especially mothers' illiteracy) and sickness create a viscious circle spanning from one generation to the next, and from which it is difficult for the individual to escape. The differences in health between rich and poor, which can be observed in all age-groups are particularly striking among children.

d. Environment

After the first week of a child's life, the environmental factors play a very great role as determinants of infant and childhood morbidity and mortality. Tetanus infection of the newborn may take a heavy toll of the newborn in the first few weeks of life. Diarrhoea, pneumonia and other infections – bacterial, viral and parasitic – are extremely common in children exposed to insanitary and hostile environment. The stages at which these infections occur vary according to the ecological conditions, home and family hygiene, local epidemiological conditions and the extent to which they come into contact with earth, water and above all with adults and other children. An insufficient supply of safe water, inadequate disposal of human excreta and other waste, an abundance of insects and other disease carriers are among the environmental factors continuously menacing family health.

Another important factor which influences child development is environmental stimulations. Children also develop skills if they are given the opportunity. Stimulation, particularly the interaction with people who take interest and talk to them helps children to develop. Other sources of environmental stimulation are the radio, TV and illustrated magazines.

e. Social support and health care

Other factors affecting the health status of children include community and social support measures, ranging from creches and day care facilities to organized health care systems.

RIGHTS OF THE WOMEN AND CHILDREN

Women and children are the most vlunerable section of the society. It is, therefore, vital to improve their health and well-being in order to achieve complete development of overall human resources.

One of the core function assigned to the WHO in its Constitution of 1948 was to "promote maternal and child health and welfare". By the 1950s, national health plans and policy documents from development agencies invariably stressed that mothers and children were vulnerable groups and, therefore, priority "targets" for public health action. The notion of mother and children as vulnerable group was also central to the primary health care movement launched at Alma-Ata in 1978. The plight of mothers and children soon came to be seen as much more than a problem of bioligical vulnerability. The 1987 Call to Action for Safe Motherhood explicitly framed it as "deeply rooted in the adverse social, cultural and economic environment of the society, and specially the environment that societies create for women". Women's relative lack of decision-making power and their unequal access to employment, finances, education, basic health care and other resources are considered to be the root causes of their ill-health, and that of their children. The unfairness of this situation has made it obvious that the health of mothers and children is an issue of rights, entitlements and day to day struggle to secure these entitlements. The milestones in this establishment of the rights of women and children are as shown in Fig. 9 *(61)*.

RIGHTS OF THE CHILD

One of the most encouraging signs of our times is the awakening of the public to the needs and rights of children. The needs of children and our duties towards them are enshrined in our Constitution; the relevant articles are :

a. Article 24 prohibits employment of children below the age of 14 in factories;

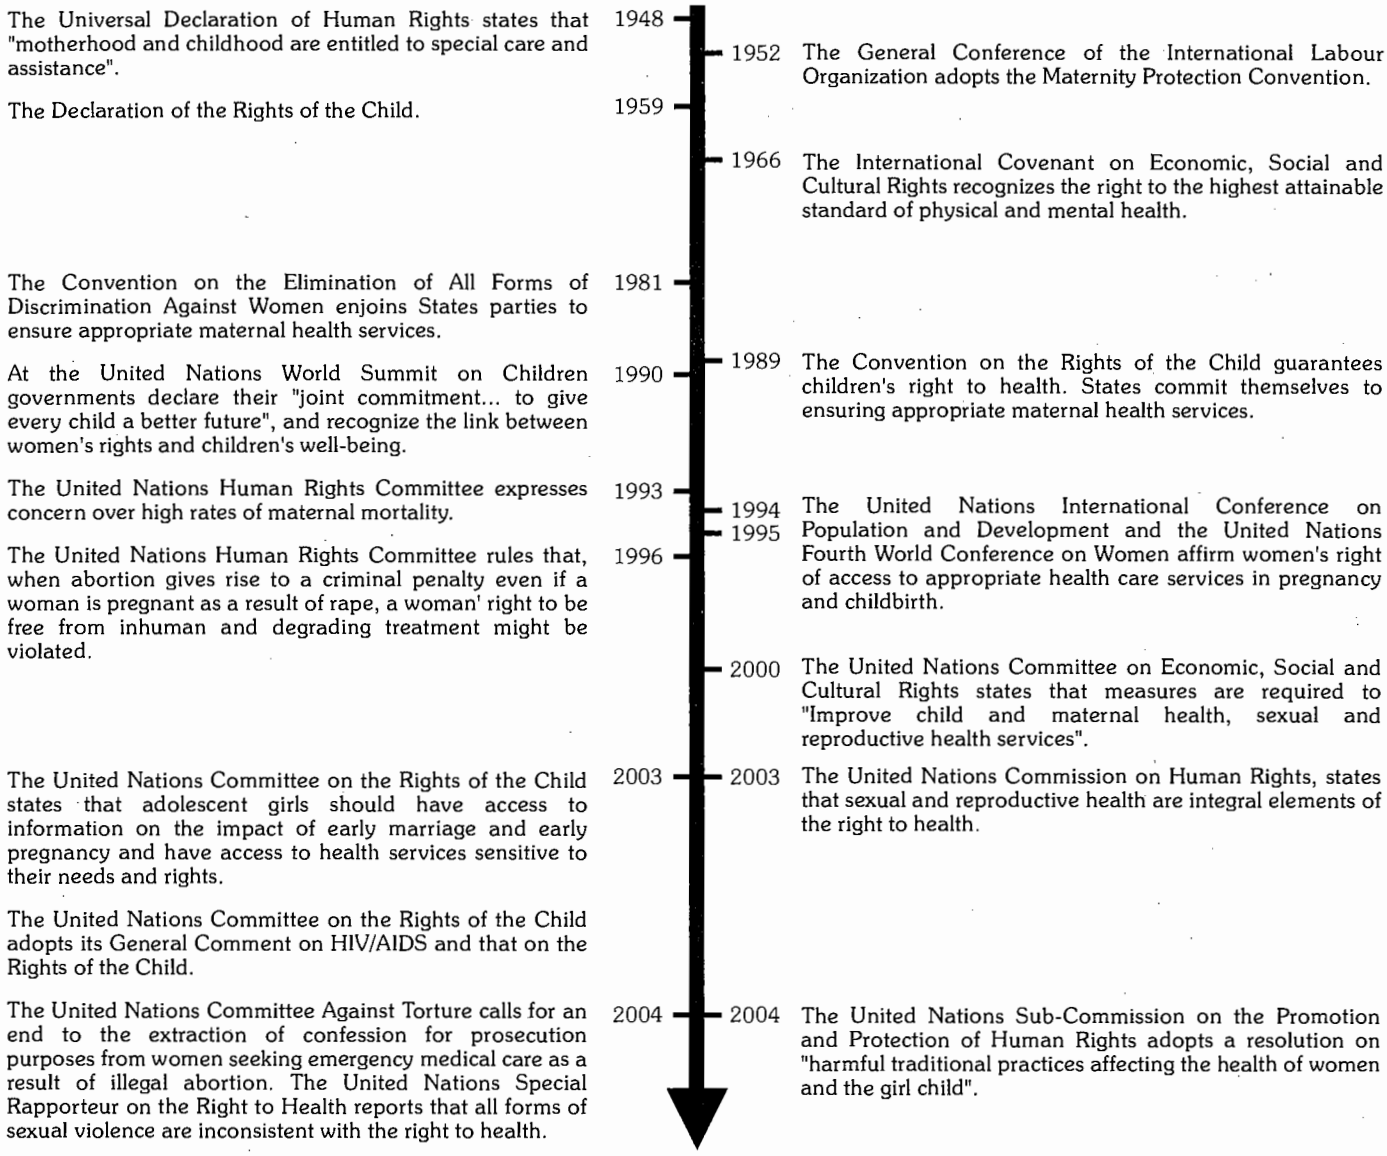

FIG. 9

Milestones in the establishment of the rights of women and children

b. Article 39 prevents abuse of children of tender age, and

c. Article 45 provides for free and compulsory education for all children until they complete the age of 14 years.

In the country's Five Year Plans, special attention has been given to the welfare of children particularly the weaker sections. Various schemes have been introduced and implemented to achieve this goal. However, despite constitutional provisions, organized efforts for stepping up child welfare services did not take place until 1959.

UN DECLARATION OF THE RIGHTS OF THE CHILD

The year 1959 ushered in a new era in child welfare. To meet the special needs of the child, the General Assembly of the United Nations adopted on 20th November 1959, the Declaration of the Rights of the Child. India was a signatory to this Declaration. The Rights of the Child are :

1. Right to develop in an atmosphere of affection and security and, wherever possible, in the care and under the responsibility of his/her parents.
2. Right to enjoy the benefits of social security, including nutrition, housing and medical care.
3. Right to free education.
4. Right to full opportunity for play and recreation.
5. Right to a name and nationality.
6. Right to special care, if handicapped.
7. Right to be among the first to receive protection and relief in times of disaster.
8. Right to learn to be a useful member of society and to develop in a healthy and normal manner and in conditions of freedom and dignity.
9. Right to be brought up in a spirit of understanding, tolerance, friendship among people, peace and universal brotherhood; and
10. Right to enjoy these rights, regardless of race, colour, sex, religion, national or social origin.

UNIVERSAL CHILDREN'S DAY

November 14 is observed as Universal Children's Day. It was started by the International Union for Child Welfare and

the UNICEF. In 1954, the UN General Assembly passed a formal resolution establishing Universal Children's Day and assigned to UNICEF the responsibility for promoting this annual day.

A non-governmental organization (Defence for Children International, Geneva) was set up in 1979 (during the International Year of the Child) to ensure ongoing, systematic international action specially directed towards promoting and protecting the Rights of the Child.

The 1990 World Summit for children agreed on a series of specific social goals for improving the lives of the children including measurable progress against malnutrition, preventable diseases and illiteracy. The vital vulnerable years of childhood should be given a first call on society's concerns and capacities. A child has only one chance to develop normally, and the protection of that one chance, therefore, demands the kind of commitment that will not be superseded by other priorities. The following are the goals that have been accepted by almost all nations.

Social goals for the year 2000 *(62)*

The end-of-century goals agreed to by the nations following the 1990 World Summit for children were :

1. A one-third reduction in 1990 under-five death rates (or to 70 per 1000 live births, whichever is less)
2. A halving of 1990 maternal mortality rates
3. A halving of 1990 rates of malnutrition among the world's under-five (to include the elimination of micronutrient deficiencies, support for breast–feeding by all maternity units, and a reduction in the incidence of low birth weight to less than 10 per cent
4. Achievement of 90 per cent immunization among under-ones, eradication of polio, elimination of neonatal tetanus, a 90 per cent reduction in measles cases and a 95 per cent reduction in measles deaths (compared to pre-immunization level)
5. A halving of child deaths caused by diarrhoeal disease
6. A one-third reduction of child deaths from acute respiratory infections
7. Basic education for all children and completion of primary education by at least 80 per cent girls as well as boys
8. Clean water and safe sanitation for all communities
9. Acceptance in all countries of the Convention on the Rights of Child, including improved protection for children in especially difficult circumstances; and
10. Universal access to high quality family planning information and services in order to prevent pregnancies that are too early, too closely spaced, too late or too many.

NATIONAL POLICY FOR CHILDREN

Keeping in view the constitutional provisions and the United Nations Declaration of the Rights of the Child, the Government of India adopted a National Policy for Children in August 1974. The Policy declares :

> *"It shall be the policy of the State to provide adequate services to children, both before and after birth and through the period of growth, to ensure their full physical, mental and social development. The State shall progressively increase the scope of such services so that, within a reasonable time, all children in the country enjoy optimum conditions for their balanced growth".*

According to the Declaration, the development of children has been considered an integral part of national development. The Policy recognizes children as the "nation's supremely important asset" and declares that the nation is responsible for their "nurture and solicitude". It further spells out various measures to be adopted and priorities to be assigned to children's programmes with a focus on areas like child health, child nutrition and welfare of the handicapped and destitute children.

A high level National Children's Board with the Prime Minister as Chairman was established. It provides a forum where problems relating to child welfare and their purposeful development into useful members of society are evolved, reviewed and coordinated into an effective programme *(68)*.

Following the enunciation of the National Policy for Children, a number of programmes were introduced by the Government of India, viz. The ICDS Scheme, programmes of supplementary feeding, nutrition education and production of nutritious food, constitution of the "National Children's Fund" under the Charitable Endowments Act, 1980, institution of National Awards for Child Welfare, Welfare of the Handicapped *(63)*.

Review of existing policies and legislations *(64)*

The Constitution of India follows the principle of protective discrimination and thereby commits itself to safeguard the rights of children through policies, laws and action. These commitments are reflected through the national polices which are as follows :

1. *National Policy for Children, 1974* provides the conceptual basis for an integrated approach to address the whole child and commits the State to provide adequate services to children, both before and after birth and through the period of growth, to ensure their full physical, mental and social development.
2. *National Policy on Education, 1986* and its *National Plan of Action,* which has a full section on early childhood care and education. It clearly recognizes the holistic nature of child development, and that ECCE is the crucial foundation for human resource development and cumulative lifelong learning. It is viewed as a feeder and support programme for universal elementary education – especially for first generation learners, and an important support service for working mothers and girls.
3. *The National Children's Fund* was created during the international year of the child in 1979 under the Charitable Endowment Fund Act, 1890. The fund provides financial assistance to voluntary agencies for implementing programmes for the welfare of children including rehabilitation of destitute children.
4. *National Health Policy, 2002* accords primacy to preventive and first line curative care at primary health level, and emphasizes convergence, and strategies to change care behaviours in families and communities.
5. *National Charter for Children, 2003* intends to secure for every child its inherent right to be a child and enjoy a healthy and happy childhood, to address the

root causes that negate the healthy growth and development of children, and to awaken the conscience of the community in the wider societal context to protect children from all forms of abuse, while strengthening the family, society and the nation.

The national charter for children affirms India's commitment to the child. However, it does not declare India's acceptance of children's entitlements as their rights. The national policy for children, 1974 still stands as the official policy commitment to children of India. With India's accession to the UNCRC and its two optional protocols rights based framework has been accepted as the guiding frame for policy measures and programming for children. This is clearly reflected in the national plan of action for children, 2005.

6. *Commission for the Protection of Child Rights Act, 2005* provides for the constitution of a national commission and state commissions for protection of child rights and children's courts for providing speedy trial of offences against children or of violation of child rights and for matters connected therewith or incidental thereto.
7. *National Plan of Action for Children, 2005* articulates clearly the rights, perspective, and agenda for the development of children. It provides a robust framework within which to promote the development and protection of children. The guiding principles of the NPA are :
   a. To regard the child as an asset and a person with human rights;
   b. To address issues of discriminiation emanating from biases of gender, class, caste, race, religion and legal status in order to ensure equality;
   c. To accord utmost priority to the most disadvantaged, poorest of the poor and the least served child in all policy and programme interventions; and
   d. To recognize the diverse stages and settings of childhood, and address the needs of each, providing all children the entitlements that fulfill their rights and meet their needs in each situation.

Time targets in the NPAC 2005 extend to 2012, the end-year of the Eleventh Plan. The NPAC 2005 has identified 12 key priority areas for the highest and most sustained attention in terms of outreach, programme interventions and resource allocations. These are :

- Reducing infant mortality rate
- Reducing maternal mortality rate
- Reducing malnutrition among children
- Achieving 100% civil registration of births.
- Universalization of early childhood care and development and quality education for all children achieving 100% access and retention in schools, including pre-schools.
- Complete abolition of female foeticide, female infanticide and child marriage and ensuring the survival, development and protection of the girl child.
- Improving water and sanitation coverage in both rural and urban areas.
- Addressing and upholding the rights of children in difficult circumstances.
- Securing for all children all legal and social protection, from all kinds of abuse, exploitation and neglect.
- Complete abolition of child labour with the aim of progressively eliminating all forms of economic exploitation of children.
- Monitoring, review, and reform of policies, programmes and laws to ensure protection of children's interest and rights.
- Ensuring child participation and choice in matters and decisions affecting their lives.

A new alienation of children from their rights has arisen with the plight of children affected by HIV/AIDS. Since the finalization of the NPAC the issues of these children have also been accepted as key priorities by MWCD and therefore found a place in the Eleventh Plan among critical concerns that need to be addressed.

8. *Integrated Child Protection Scheme (ICPS) (65, 66)*

   During the year 2009-10, the Ministry of Women and Child Development launched a new centrally sponsored scheme called "Integrated Child Protection Scheme" (ICPS) with a view to create a safe and secure environment in the country for the comprehensive development of children who are in need of care and protection, children in conflict and in contact with law (either as a victim or as a witness or due to any other circumstances), children of migrant families, children of prisoners, prostitutes, working children, street children, trafficked or sexually exploited children, child drug abusers, child beggars etc.

   The objectives of the scheme are : (1) Improve access to and quality of child protection services; (2) Raise public awareness about child rights; (3) Clearly articulated responsibilities and accountability for child protection; (4) Establish structures at all government levels for delivery of statutory and support services to children in difficult circumstances; and (5) Setting-up of an evidence based monitoring and evaluation system.

The services provided under ICPS are as follows :

(1) Emergency outreach service through 'Child line', dedicated number is 1098. It is a 24-hour toll free telephone service available to all children in distress.

(2) Open shelters for children in need, in urban and semi-urban areas.

(3) Family based non-institutional care through sponsorship, foster-care, adoption, cradle baby centres and after-care.

(4) Institutional services through shelter homes, children homes, observation homes, special homes, and specialized services for children with special needs.

(5) Web-enabled child protection management system including website for missing children.

(6) General grant-in-aid for need based interventions.

The growing vulnerability of children in urban settlements, including those caught in the shifting frame of migratory and transient labour are also now in the MWCD portfolio. Their distress and the difficult circumstances of their childhoods merit special measures of development and protection.

Goals and targets set by Government of India for child health under various national and international commitments are as follows *(64)* :

CHILD HEALTH GOALS/TARGETS

Common Minimum Programme	To raise public spending on health to at least 2-3% of GDP over the next five years and focus on primary health care ...special attention will be paid to the poorer sections in the matter of health care.
Eleventh Five Year Plan 2007–12	Reduction of infant mortality rates to 28 per thousand live births by 2012. To raise the sex ratio for age group 0–6 from 927 in 2001 to 935 by 2011–12 and to 950 by 2016–17.
National Plan of Action for Children, 2005	– To reduce infant mortality rate to below 30 per 1000 live births by 2010. – To reduce child mortality rate to below 31 per 1000 live births by 2010. – To reduce neonatal mortality rate to below 18 per 1000 live births by 2010. – To explore possibilities of covering all children with plan for health insurance.
Millenium Development Goals (MDG)	– Reduce by two-thirds, between 1990 and 2015, the under-five mortality rate (Goal 4). – Reduce by three-quarters, between 1990 and 2015, the maternal mortality rate – Combat HIV/AIDS, malaria and other diseases.
National Health Policy, 2002	– To achieve an acceptable standard of good health among the population by increasing access to decentralized public health system and by establishing or upgrading the infrastructure in the existing institutions. – Reduce IMR to 30/1000 and MMR to 100/lakh by 2010. – Eradicate polio and yaws, and eliminate leprosy by 2005. – Improve nutrition and reduce proportion of LBW babies from 30% to 10% by 2010. – Reduce mortality by 50% on account of TB, malaria and other vector and water borne diseases by 2010. – Reduce prevalence of blindness to 0.5% by 2010. – Achieve zero level growth of HIV, AIDS by 2007.

DELIVERING THE MCH SERVICES

MCH (mother and child health) is not a new speciality. It is a method of delivering health care to special group in the population which is especially vulnerable to disease, disability or death. These groups (i.e., children under the age 5 years and women in the reproductive age group (15–44 years) comprise about 32.4 per cent of the total population in India.

The MCH services encompass the curative, preventive and social aspects of obstetrics, paediatrics, family welfare, nutrition, child development and health education. The **specific objectives** of MCH are :

1. reduction of morbidity and mortality rates for mothers and children
2. promotion of reproductive health, and
3. promotion of the physical and psychological development of the child within the family.

Through concern with child development and the health education of parents and children, the ultimate objective of MCH services is life-long health.

Sub-areas

The components of MCH include the following sub-areas

a. maternal health
b. family planning
c. child health
d. school health
e. handicapped children
f. care of the children in special settings such as day care centres.

The content of MCH care will vary according to the demographic, social and economic patterns. Factors such as urbanization, rural migration, changing patterns of women's work and status have far-reaching effects on childbearing and child-rearing. It is now generally accepted that the MCH services should always be flexible and based on, and adapted to the local needs and resources of the community it serves; they should be moulded to the local traditions, cultures and other environmental characteristics and cannot be modelled on patterns copied from other countries. Health care, social legislation and social support measures also will have to be adapted to these changing needs and problems of the community.

MCH care is now conceived of as all activities which promote health and prevent or solve health problems of mother and children, irrespective of whether they are curative, diagnostic, preventive or rehabilitative, and whether they are carried out in health centres or in the home by primary health care workers, traditional dais, or highly trained specialists.

Recent trends in MCH care

Maternal and child care was traditionally designed and provided in the form of vertical programmes with "standard" technical content based on models from a few developed countries. Applied in different socio-economic situations, such vertical programmes have been unable to provide more than minimum coverage because of their cost, and they have scarcely been of a kind to solve the priority problems of the majority of mothers and children. The emergence of some new concepts is now changing the organization and management of MCH care in increasing number of countries *(67)*. These are discussed below :

1. Integration of care

Conventional MCH services tended to be fragmented into antenatal care, postnatal care, infant care, family planning etc. The various components were dealt with separately by different staff or departments. This approach has changed over the years. The trend now is an "integrated" approach. This integration is based on the fact that it is inconvenient for the mother to go to one place to receive care for herself,

to another for care for her children, and yet another for family planning services.

An integrated approach implies that all those involved in maternity care from the obstetrician down to the local dai, must work as a team. Obstetric and paediatric units should be closely linked so that there can be regular contact between obstetricians, paediatricians, community physicians, health and social workers so that services for the care of the mother and the child in the hospital and community be planned and reviewed including teaching and research. This approach helps to promote continuity of care as well as improves efficiency and effectiveness of MCH care.

2. Risk approach

A promising means of improving the coverage and efficiency of MCH care and family planning is the "risk approach". This is a managerial tool for better use of scarce resources. It is based on the early detection of mothers and children with high-risk factors. All mothers and children with high risk factors are given additional and more skilled care including hospitalization, while at the same time essential care is provided for the rest of the mothers and children so that every one gets care appropriate to their need.

It is also possible to assess the "degrees" of risk of each factor, by scoring according to their (a) *magnitude* – i.e., extent and severity; (b) *treatability* – responsiveness to treatment and control; (c) *cost-effect* – in terms of alleviating human suffering; and (d) *community attitude* – social concern. Such an approach when applied on a community–wide basis enables the determination of priority activities, within the MCH programme based on the "degrees" of risk.

Application of the risk approach to the problems of mothers and children is a departure from past or traditional practices to promote the health of mothers and children.

3. Manpower changes

The special category of "maternal and child health worker" (e.g., auxiliary-nurse-midwives, health visitors) at the peripheral level is gradually being phased out. A wide range of workers are now considered necessary for maternal and child health work. They include :

(i) *Professionals :* Specialists

(ii) *Field workers :* Multi-purpose workers, Health Guides, dais (traditional birth attendants), balsevikas, Anganwadi workers, extension workers, ASHA etc

(iii) *Voluntary workers :* Members of women's organizations

Taking for example, the local dais in the past were not generally recognized by the national health authorities, who thought that their services were inimical to the safety of the mother and child. The current trend is to assist them perform safe deliveries through training and supervision. In India, where 70 per cent of population lives in rural areas, there are not enough obstetricians to attend to all deliveries. Therefore, a trained dai or midwife is absolutely essential in every village. The same thing can be said about paediatrics. It is now recognized that obstetric and paediatric services can only be improved by cooperation and liaison with these practitioners.

4. Primary health care

Primary health care is now recognized as a way of making essential health care available to all. It has all the elements necessary to make a positive impact on the health of mothers and children – i.e., MCH care, family planning, control of infections, education about health problems and how to prevent them, and measures to ensure nutritious food – all closely related. Primary health care emphasizes family oriented care and support, and community self–reliance in health matters. MCH care is an indispensable priority element of primary health care in every country.

Targets for MCH Services

From time to time Government of India has suggested MCH goals with quantifiable time bound targets for achievement. Table 11 shows the MCH indicators with their goal period and the current level of achievement.

Organization of MCH/FP services

The mother and child health, and family planning services were integrated in the Fourth Five Year Plan for better effectiveness. They both are now an integral part of primary health care, which places emphasis on community participation and intersectoral coordination. The National Health Policy 2002 and National Population Policy 2000 has

TABLE 11

MCH goals and current level of achievement (India)

Indicator	Current level	Goals and target period: Twelfth Plan (2012-2017)	Goals and target period: National Population Policy 2000 (2010)
A. Family Planning Indicators			
Crude birth rate	21.6 (2012)	-	21
Total fertility rate	2.4 (2013)	2.1	2.1
Couple protection rate (%)	55.0 (2009-10)	65	Meet all needs
B. Mortality indicators per 1000			
Infant mortality	44 (2013)	25	< 30
Neonatal mortality	31 (2012)	20	
Maternal mortality per 100,000	178 (2010-12)	100	100
Under–5 mortality	56 (2012)	-	-
C. Services (% coverage)			
Infants (fully immunized)	77.3 (2012)	-	100
– Measles	74	-	-
– DPT_3	72	-	-
– $Polio_3$	70	-	-
– BCG	87	-	-
– $HepB_3$	70	-	-
Pregnant women TT	87.0	-	-
Antenatal care coverage % (2008-12) at least once	74.0	-	100
at least four times	37.0		
Institutional deliveries	47.0 (2010-12)	-	80
Deliveries by trained personnel	52.0 (2008-12)	-	100
D. Prevalence of low-birth-weight babies	28 (2008-12)	-	-

Source : *(7)*

provided the necessary directives for reorienting and restructuring the health services, based on primary health care approach with short and long-term goals.

The infrastructure in rural areas is based on the complex of community health centres, primary health centres and their subcentres. They provide preventive and promotive health care services. Since deliveries by trained health personnels are crucial in reducing maternal and infant mortality in rural areas, the government of India undertook a scheme to train local dais to conduct safe deliveries. These dais are now available in most villages. Mention must be made of ICDS (Integrated Child Development Services) projects which are functioning all over the country providing a package of basic health services (eg. supplementary nutrition, immunization, health check-up, referral, nutrition and health education, and non-formal education services) to mother and children.

Maternal health care was a part of family welfare programme from its inception. Interventions were introduced on vertical schemes, but family planning remained a separate intervention. In 1992, the Child Survival and Safe Motherhood Programme integrated all the schemes for better compliance. More recently, Reproductive and Child Health Programme was launched in 1997, which integrated family planning, Child Survival and Safe Motherhood Programme, Preventive management of STD/ RTI, AIDS, and a client approach to health care. This programme has entered into phase II, with reorientation to make it consistant with the requirement of the National Rural Health Mission.

In urban areas, the general trend is towards institutional delivery. In larger cities, almost 90 per cent of deliveries take place in maternity hospitals and maternity homes. Some of the institutions are under the auspices of the Municipal Corporations and voluntary organizations. The services of obstetricians are available at district hospitals, which are the apical hospitals for MCH care at the district level. For specialized care of children, paediatric units have been established in several district hospitals.

Table 12 shows the evolution of maternal and child health programmes in India.

TABLE 12

Evolution of maternal and child health programmes in India

Year	Milestones
1952	Family Planning programme adopted by Government of India (GOI)
1961	Department of Family Planning created in Ministry of Health
1971	Medical Termination of Pregnancy Act (MTP Act), 1971
1977	Renaming of Family Planning to Family Welfare
1978	Expanded Programme on Immunization (EPI)
1985	Universal Immunization Programme (UIP) + National Oral Rehydration Therapy (ORT) Programme

INDICATORS OF MCH CARE

Maternal and child health status is assessed through measurements of mortality, morbidity and, growth and development. In many countries, mortality rates are still the only source of information. Morbidity data are scarce and poorly standardized. In recent years, attention has been paid to systematizing the collection, interpretation and dissemination of data on growth and development. The commonly used mortality indicators of MCH care are :

1. Maternal mortality ratio
2. Mortality in infancy and childhood
   a. Perinatal mortality rate
   b. Neonatal mortality rate
   c. Post-neonatal mortality rate
   d. Infant mortality rate
   e. 1–4 year mortality rate
   f. Under-5 mortality rate
   g. Child survival rate.

MATERNAL MORTALITY RATIO

According to WHO, a maternal death is defined as "the death of a woman while pregnant or within 42 days of termination of pregnancy, irrespective of the duration and site of pregnancy, from any cause related to or aggravated by the pregnancy or its management but not from accidental or incidental causes" *(68)*.

Maternal mortality ratio measures women dying from "puerperal causes" and is defined as :

$$= \frac{\text{Total no. of female deaths due to complications of pregnancy, childbirth or within 42 days of delivery from "puerperal causes" in an area during a given year}}{\text{Total no. of live births in the same area and year}} \times 1000 \text{ (or } 100{,}000\text{)}$$

Late maternal death : Complications of pregnancy or childbirth can also lead to death beyond the six-weeks postpartum period. In addition, increasingly available modern life-sustaining procedures and technologies enable more women to survive adverse outcomes of pregnancy and delivery, and to delay death beyond 42 days postpartum. Despite being caused by pregnancy-related events, these deaths do not count as maternal deaths in routine civil registration system. An alternative concept of late maternal death was included in ICD-10, in order to capture these delayed deaths that occur between six weeks and one year postpartum. It is defined as "the death of a women from direct or indirect causes, more than 42 days but less than one year after termination of pregnancy" *(69)*.

Pregnancy–related death : A pregnancy–related death is the death of a woman while pregnant or within 42 days of termination of pregnancy, irrespective of the cause of death *(33)*.

Statistical measures of maternal mortality *(69, 70)*

(a) *Maternal mortality ratio* : Number of maternal deaths during a given time period per 100,000 live births during the same time-period.

(b) *Maternal mortality rate* : Number of maternal deaths in a given period per 100,000 women of reproductive age during the same time-period.

(c) *Adult lifetime risk of maternal death* : The probability

of dying from a maternal cause during a woman's reproductive lifespan.

(d) *The proportion of maternal deaths of women of reproductive age (PM) :* The number of maternal deaths in a given time period divided by the total deaths, among women aged 15–49 years.

The International Classification of Diseases (ICD) has recommended that maternal deaths may be disaggregated into two groups :

(1) *Direct obstetric deaths :* those resulting from obstetric complications of the pregnant state (pregnancy, labour and puerperium), from interventions, omissions, incorrect treatment, or from a chain of events resulting from any of the above.

(2) *Indirect obstetric deaths :* those resulting from previous existing disease or disease that developed during pregnancy and which was not due to direct obstetric causes, but which was aggravated by physiological effects of pregnancy.

The maternal mortality rate, the direct obstetric rate and the indirect obstetric rate are fine measures of the quality of maternity services.

The 43rd World Assembly in 1990 adopted the recommendation that countries consider the inclusion on death certificates of questions regarding current pregnancy and pregnancy within one year preceding death in order to improve the quality of maternal mortality data and provide alternative methods of collecting data on deaths during pregnancy or related to it, as well as to encourage the recording of deaths from obstetric causes occurring more than 42 days following termination of pregnancy.

Approaches for measuring maternal mortality

In the absence of complete and accurate civil registration systems, MMR estimates are based upon a variety of methods :

(1) Civil registration systems : This approach involves routine registration of births and deaths. Ideally, maternal mortality statistics should be obtained through civil registration data.

(2) Household survey : Where civil registration data are not available, household survey provides an alternative.

(3) Sisterhood methods : Sisterhood methods obtain information by interviewing a representative sample of respondents about the survival of all their adult sisters (to determine the number of ever marrried sisters, how many are alive, how many are dead, and how many died during pregnancy, delivery, or within six weeks of pregnancy.

(4) Reproductive-age mortality studies (RAMOS) : This approach involves identifying and investigating the causes of all deaths of women of reproductive age in a defined area/population by using multiple sources of data.

(5) Verbal autopsy : This approach is used to assign cause of death through interview with family or community members, where medical certification of cause of death is not available. Records of births and deaths are collected periodically among small populations, under demographic surveillance systems maintained by the research institutions in developing countries.

(6) Census : A national census, with the addition of a limited number of questions, could produce estimates of maternal mortality; this approach eliminates sampling errors and hence allows a more detailed breakdown of the results, including time trends, geographic subdivisions and social strata.

Incidence

WORLD SCENARIO

Globally, an estimated 289,000 maternal deaths occurred in 2013, a decline of 47 per cent from levels in 1990. Sub-Saharan Africa (62 per cent) and Southern Asia (24 per cent) accounted for 86 per cent (249,000 maternal deaths) of the global burden in 2013. At the country level, two countries account for a third of global maternal deaths; India at 17 per cent (50,000) and Nigeria at 14 per cent (40,000). The global MMR in 2013 was 210 maternal deaths per lac live births. The MMR in developing regions (250) was 15 times higher than in developed regions. Sub-Saharan Africa had the highest MMR at 510 maternal deaths per lac live births, while Eastern Asia had the lowest among developing regions at 33 maternal deaths per lac live births *(1)*.

A woman is most vulnearble at the post-partum period. About 50–70 per cent maternal deaths occur in the postpartum period of which 45 per cent deaths occur in the first 24 hours after delivery and more than two-thirds during the first week. Between 11–17 per cent of maternal deaths occur during child birth itself *(69)*.

Maternal mortality ratios strongly reflect the overall effectiveness of health systems, which in many low-income developing countries suffer from weak administrative, technical and logistical capacity, inadequate financial invesment and a lack of skilled health personnel. Scaling up key interventions – for example, increasing the number of births attended by skilled health personnel, providing access to emergency obstetric care when necessary and providing post-natal care for mothers and babies – could sharply reduce both maternal and neonatal deaths. Enhancing women's access to family planning, adequate nutrition, improved water and sanitation facilities and affordable basic health care protection from abuse, violene, discrimination, empowerment of women, greater involvement of men in maternal and child care, would lower mortality rates further still. These are not impossible, impractical actions, but proven, cost-effective provisions that women of reproductive age have a right to expect.

The low status of women in the society coupled with their low literacy levels prevent the women from taking antenatal care even if services are available. Most deliveries take place at home without the services of the trained midwifery personnel. There is an inverse relationship between lifetime risk of maternal death and the availability of the trained health worker during pregnancy and at the time of delivery. The lifetime chances of maternal death in the world in 2010 as a whole is about 1 in 80. It varies from region to region and from country to country. In the least developed countries the chances are about 1 in 37, in the developing countries about 1 in 150 and in the industrialized countries about 1 in 3,800. In Sub-Saharan Region the chances are very high – about 1 in 39 pregnancies *(70)*.

It is a tragic situation as these deaths are not caused by disease but occurred during or after a natural process. It is one of the leading cause of death for women of reproductive age in many parts of the world. Most maternal deaths and pregnancy complications can be prevented if pregnant women have access to good-quality antenatal, natal and postnatal care, and if certain harmful birth practices are avoided. Estimates of antenatal care coverage, deliveries conducted by skilled personnel, lifetime risk of maternal death and maternal mortality ratio in some developing and developed countries are shown in Table 13.

TABLE 13

Maternal mortality ratio, deliveries conducted by skilled personnel, antenatal care coverage and lifetime risk of maternal deaths in some developing and developed countries.

Country	Antenatal care coverage (%) (2008–2012)		Deliveries conducted by skilled personnel (%) (2008–2012)	Lifetime risk maternal death (one in) (2013)	Maternal mortality ratio (per 100,000 live births) (2013)

Source : *(1, 7)*

Maternal health, however, goes beyond the survival of pregnant women and mothers. For every woman who dies from causes related to pregnancy or childbirth, it is estimated that there are 20 others who suffer pregnancy-related illness or experience other severe consequences. The number is striking: An estimated 10 million women annually who survive their pregnancies experience such adverse outcomes.

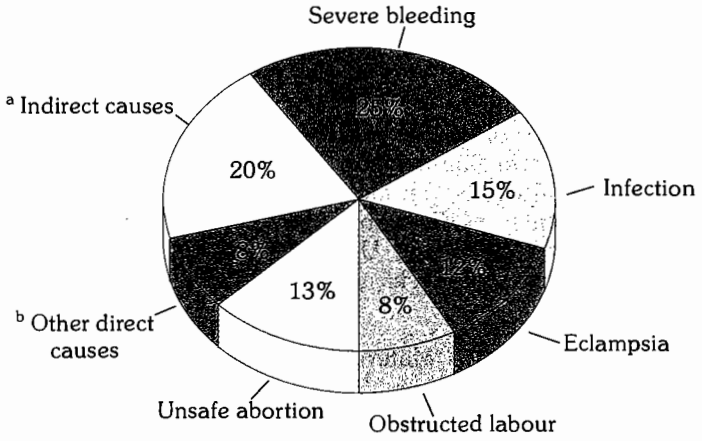
Causes

Maternal deaths mostly occur from the third trimester to the first week after birth (with the exception of deaths due to complications of abortion). Studies show that mortality risks for mothers are particularly elevated within the first two days after birth. Most maternal deaths are related to obstetric complications – including postpartum haemorrhage, infections, eclampsia and prolonged or obstructed labour - and complications of abortion. Most of these direct causes of maternal mortality can be readily addressed if skilled health personnel are on hand and key drugs, equipment and referral facilities are available.

About 80 per cent of maternal deaths are due to direct causes i.e. obstetric complications of pregnancy, labour and puerperium to interventions or incorrect treatment. As shown in Fig. 10 the single most common cause-accounting for a quarter of all maternal deaths – is obstetric haemorrhage, generally occurring postpartum which can lead to death very rapidly in the absence of prompt life-saving care.

Puerperal infections, often the consequence of poor hygiene during delivery, or untreated reproductive tract infections account for about 15% of maternal mortality. Such infections can be easily prevented. Hypertensive disorders of pregnancy, particularly eclampsia (convulsions), result in about 13% of all maternal deaths. They can be prevented through careful monitoring during pregnancy and treatment with relatively simple anticonvulsant drugs in cases of eclampsia.

Of the estimated 210 million pregnancies that occur every year, about 42 million end in induced abortion, of which only approximately 60 per cent are carried out under safe conditions. More than 20 million induced abortions each year are performed by people lacking the necessary skills or in an environment lacking the minimal medical standards, or both.



[a] Indirect causes including for example: anaemia, malaria, heart diseases

[b] Other direct causes including, for example : ectopic pregnancy, embolism, anaesthesia-related

FIG. 10
Causes of maternal deaths worldwide

Around 8% of maternal deaths occur as a result of prolonged or obstructed labour. Other direct causes include ectopic pregnancies, embolism and deaths related to interventions. Around 20 per cent of maternal deaths are due to indirect causes, that is, the result of pre-existing diseases or disease that developed during pregnancy, which are not due to direct obstetric cause but are aggravated by the physiological effect of pregnancy. One of the most significant is anaemia, which can cause death. Maternal anaemia affects about half of all pregnant women. Pregnant adolescents are more prone to anaemia than older women, and they often receive less care. Infectious diseases such as malaria, and intestinal parasites can exacerbate anaemia, as can poor quality diet – all of which heighten vulnerability to maternal death. Severe anaemia contributes to the risk of death in cases of haemorrhage. Other important causes of indirect death are hepatitis, cardiovascular diseases,

diseases of the endocrine and metabolic system and infections such as tuberculosis, malaria and increasingly HIV/AIDS *(71)*. Each year, approximately 50 million women living in malaria-endemic countries throughout the world become pregnant. Around 10,000 of these women die as a result of malaria *(72)*.

Social correlates

A number of social factors influence maternal mortality. The important ones are : (a) *Women's age* : The optimal child-bearing years are between the ages of 20 and 30 years. The further away from this age range, the greater the risks of a woman dying from pregnancy and childbirth. (b) *Birth interval* : Short birth intervals are associated with an increased risk of maternal mortality. (c) *Parity*: High parity contributes to high maternal mortality.

Not only are these three variables interrelated, but there are also other factors which are involved, e.g., economic circumstances, cultural practices and beliefs, nutritional status, environmental conditions and violence against women. The social factors often precede the medical causes and make pregnancy and child-birth a risky venture.

INDIA

India is among those countries which have a very high maternal mortality ratio. According to the estimates the MMR has reduced from 212 per lac live births in 2007–09 to 178 per lac live births in 2010–12, a reduction of 34 points over a period of three years period. States of Kerala, Maharashtra and Tamil Nadu have already achieved the goal of a MMR of 100 per lac live births. In EAG and Assam category of states, MMR is about 257 per lac live births, with Assam on top (328) and Uttar Pradesh (292), Rajasthan (255), Madhya Pradesh (250), Odisha (235) closely following. Assam, Madhya Pradesh and Rajasthan have shown an acceleration in reduction in last three years *(73)*.

During the year 2012, about 47,000 women died of pregnancy related causes *(74)*. It is mainly due to large number of deliveries conducted at home by untrained persons. In addition, lack of adequate referral facilities to provide emergency obstetric care for complicated cases also contribute to high maternal morbidity and mortality.

From year 2000 onwards, SRS (Central registration system) included a new method called the "RHIME" or Representative, Re-sampled, Routine Household Interview of Mortality with Medical Evaluation. This is an enhanced form of *"verbal autopsy"* which is the key feature of a prospective study of 1 million deaths within the SRS. RHIME include random re-sampling of field-work by an independent team for maintaining quality of data. For comparability with WHO estimates for India and for other countries, the WHO's "Global Burden of Disease" categorizaton of maternal deaths have been used, which includes various categories with their ICD-10 codes such as : haemorrhage, sepsis, hypertensive disorder, obstructed labour, abortion, and other conditions.

The SRS report has been grouped into three categories; (a) EAG states of Bihar and Jharkhand, Madhya Pradesh and Chhattisgarh, Orissa, Rajasthan, Uttar Pradesh and Uttaranchal and Assam. These states have high mortality indicators; (b) This category includes southern states of Andhra Pradesh, Karnataka, Kerala and Tamil Nadu. These states have comparatively better health indicators; (c) The remaining states have been classified as others *(73)*.

Table 14 shows live births, maternal deaths, maternal mortality ratio in India by states from 2010–2012, special survey of deaths using RHIME. During this period the life time

risk of maternal death of women in the age group 15–49 has been reported to be 0.6 per cent. This is substantially higher for women in the category EAG states and Assam (1.0 per cent) compared to women in the category southern (0.3 per cent) or in the "other" states (0.4 per cent).

The age distribution of maternal and non-maternal deaths from the 2010–2012 Special Survey of Deaths are given in Table 15. It shows that more than two-thirds of the maternal deaths are of women in age group 20–34 years. In contrast, non-maternal deaths are more evenly distributed over the reproductive age span of 15–49 years.

TABLE 15

Age distribution of maternal and non-maternal deaths, India, 2010–12

Age groups	Maternal deaths		Non-maternal deaths	
	Proportion	95% CI	Proportion	95% CI
15–19	7%	(5–8)	12%	(11–13)
20–24	39%	(35–42)	16%	(15–16)
25–29	28%	(25–32)	13%	(12–14)
30–34	17%	(14–19)	12%	(12–13)

Causes

The major causes of maternal mortality according to the 2001–2003 SRS survey are haemorrhage (38 per cent), sepsis (11 per cent), hypertension (5 per cent), obstructed labour (5 per cent), abortion (8 per cent) and other conditions (34 per cent). Anaemia (19 per cent) is not only the leading cause of death but also an aggravating factor in haemorrhage, sepsis and toxaemia. Illegal abortions are also one of the leading causes of maternal death. That this should continue despite MTP facilities points to the need for wider dissemination of information about these facilities. Induced abortions also point to a large unmet need for contraceptives, as with each pregnancy the woman faces increased risk of death. The percentage distribution of causes of maternal deaths during the year 2001–2003 are as shown in Fig. 11.

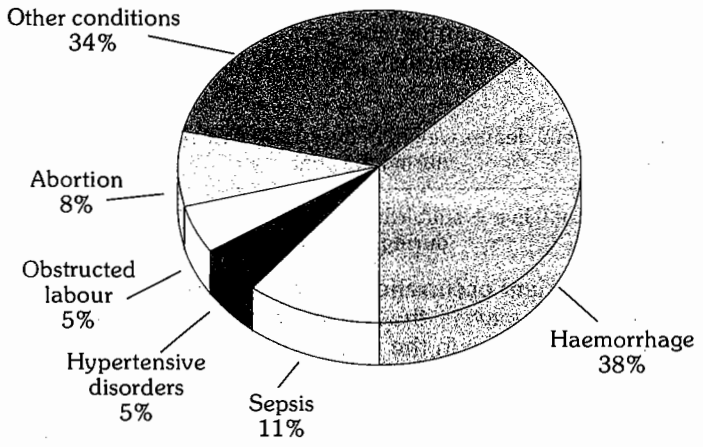

FIG. 11

Major causes of maternal deaths in India (2003)

Source : *(75)*

The determinants of maternal mortality in India are as listed in Table 16.

TABLE 16

Determinants of maternal mortality in India

Medical causes	Social factors
Obstetric causes:	
Toxaemias of pregnancy	Age at child birth
Haemorrhage	Parity
Infection	Too close pregnancies
Obstructed labour	Family size
Unsafe abortion	Malnutrition
	Poverty
	Illiteracy
	Ignorance and prejudices
	Lack of maternity services
Non-obstetric causes:	Shortage of health manpower
Anaemia	Delivery by untrained dais
Associated diseases, e.g., cardiac, renal, hepatic metabolic and infectious	Poor environmental sanitation
	Poor communications and transport facilities
Malignancy	Social customs, etc.
Accidents	

Newer approaches such as "risk approach" and primary health care are steps in the right direction to reduce maternal mortality and morbidity. Despite best antenatal care, some women may develop complications without warning signs and require emergency care. Essential obstetric care and establishment of first referral units (FRUs) for emergency obstetric care is, therefore, a high priority under the safe motherhood component of Reproductive and Child Health Programme. Equally important is an attack on social and cultural factors (e.g., ignorance, low levels of female literacy, prejudices inherent in the socio-cultural milieu, low levels of nutrition and poor environmental sanitation). It calls for socio-economic development of the community through active community involvement.

National maternal health care indicators

The estimates of maternal mortality can only be used as a rough indicator of maternal health situation in any given country. Hence indicators such as antenatal check-up, institutional delivery and delivery by trained personnel etc. are used to assess the maternal health status. These indicators also reflect the status of the ongoing programme interventions and the situation of maternal health *(76)*. Table 17 shows the national average of key indicators as per different surveys conducted in India *(76)*.

TABLE 17

National average of key indicators (per cent) in India

Indicators	NFHS-III (2005–06)	DLHS-III (2007–08)
1. Ante-natal care :		
Any visit	77.0	75.2
Three or more ANC	50.7	51.1
2. Deliveries		
Institutional	41.0	47.0
Safe delivery[a]	48.2	52.7
3. IFA tablet consumption for 100 days	22.3	46.6
4. Postnatal check-up within 2 days	36.4	47.9

NFHS : National Family Health Survey
DLHS : District level household survey
[a] Safe delivery is defined as institutional deliveries plus deliveries conducted at home by skilled staff and do not include deliveries by trained birth attendants (dais).

Preventive and social measures

High maternal mortality reflects not only in inadequacy of health care services for mothers, but also a low standard of living and socio-economic status of the community. In the world as a whole, the problem of maternal mortality is principally one of applying existing obstetric knowledge through antenatal, intranatal and postnatal services rather than developing new skills. Any attempt to lower MMR must take into consideration the following measures :

1. Early registration of pregnancy.
2. At least four antenatal check-ups.
3. Dietary supplementation, including correction of anaemia.
4. Prevention of infection and haemorrhage during puerperium.
5. Prevention of complications, e.g., eclampsia, malpresentations, ruptured uterus.
6. Treatment of medical conditions, e.g., hypertension, diabetes, tuberculosis, etc.
7. Anti-malaria and tetanus prophylaxis.
8. Clean delivery practice.
9. In India, a large number of maternal deaths could be prevented with the help of trained local dais and female health workers.
10. Institutional deliveries for women with bad obstetric history and risk factors.
11. Promotion of family planning – to control the number of children to not more than two, and spacing of births.
12. Identification of every maternal death, and searching for its cause, and
13. Safe abortion services.

MORTALITY IN INFANCY AND CHILDHOOD

Mortality rates are good indicators to measure the level of health and health care in different countries. They also help in assessing the overall socio-economic development of a country and correlate well with certain economic variables such as GNP. Medical and social progress have substantially reduced mortality in childhood.

It has become customary to consider mortality in and around infancy in a number of time periods convenient from both the analytical and programmatic point of view as under :

a. perinatal period
b. early neonatal period
c. late neonatal period
d. neonatal period
e. post neonatal period

These are as illustrated in Fig. 12.

FOETAL DEATH : Foetal death is death prior to the complete expulsion or extraction from its mother of a product of conception, irrespective of the duration of pregnancy; the death is indicated by the fact that after such separation the foetus does not breathe or show any other evidence of life, such as beating of the heart, pulsation of the umbilical cord, or definite movement of voluntary muscles *(77)*. Defined variously as death after the 20th or 28th week of gestation (the definition of length of gestation varies between countries).

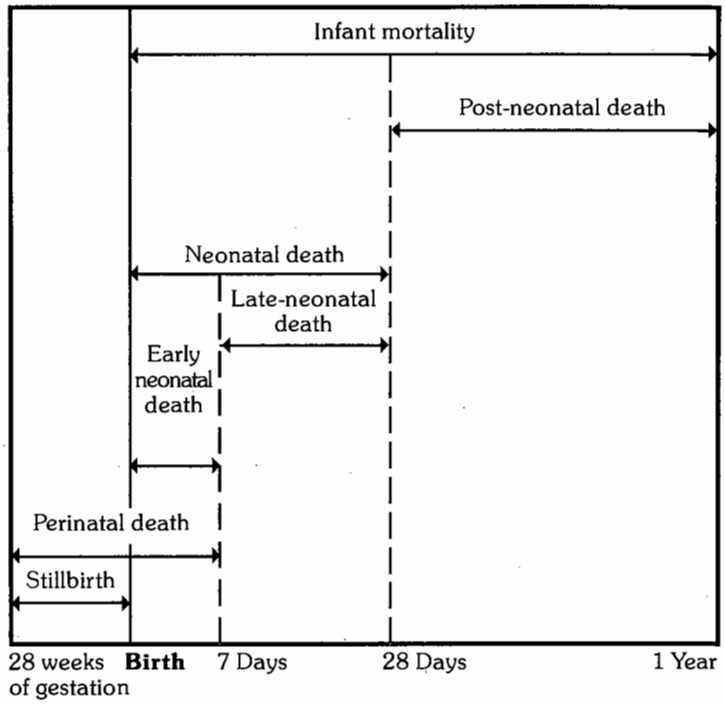

FIG. 12
Mortality in and around infancy

Some observers have expressed the view that vital statistical reports are less reliable on foetal deaths occurring at 20–27 weeks than on those occurring after 28 completed weeks, and have preferred to analyze the data separately for the two intervals. Stillbirths are seldom reported in developing countries.

Because of the above difficulties WHO has recommended that within any country the term "stillbirth" be applied to a foetus born dead, and weighing over 500 g – the birth weight most frequently associated with a gestation period of 22 weeks. But for international comparison, however, they suggested a boundary of 1000 g or more, which is more frequently associated with a gestation period of 28 weeks.

STILLBIRTH RATE

The most widespread use of the term is, "death of a foetus weighing 1000 g (this is equivalent to 28 weeks of gestation) or more" occurring during one year in every 1000 total births (live births plus stillbirths). Stillbirth rate is given by the formula :

$$\text{Stillbirth rate} = \frac{\text{Foetal deaths weighing over 1000 g at birth during the year}}{\text{Total live + stillbirths weighing over 1000 g at birth during the year}} \times 1000$$

It is a frequent occurrence in the developing countries. Its prevention involves the detection and treatment of infectious pathology in the course of pregnancy as well as of high blood pressure and its complications, Rh incompatibility, diabetes and premature rupture of the membrane. Some causes are difficult or impossible to eliminate, such as multiple pregnancies, cord anomalies, foetal malformations, placenta anomalies.

Approximately 3.3 million babies are stillborn each year worldwide *(72)*. In India, the SRS estimates for the year 2012 for the whole country is about 5 per 1000 total births (5 for the rural and 5 for the urban areas). Among the bigger

states, the highest level of stillbirths has been estimated for Karnataka (14) and the lowest for Bihar (1) and Jharkhand (1). Table 18 shows the statewise break-up of stillbirth rate.

TABLE 18

Perinatal mortality rates and stillbirth rates by residence, India and bigger states, 2012

India and bigger states	Perinatal mortality rate			Stillbirth rate

The estimates provided by Lancet Stillbirth Series for India is 22 per 1000 live births for the year 2009. This estimate is being used as a target-setting excercise by India Newborn Action Plan (launched in June 2014). With the current level of average annual rate of reduction, which is less than 1 per cent, India is expected to reach SBR of 19 per 1000 live births by 2030 *(81)*.

PERINATAL MORTALITY RATE

As currently defined, the term "perinatal mortality" includes both late foetal deaths (stillbirths) and early neonatal deaths. The Eighth Revision of the International Classification of Diseases (ICD) defined the "perinatal period" as lasting from the 28th week of gestation to the seventh day after birth. The Ninth Revision (1975) of ICD added that :

i) Babies chosen for inclusion in perinatal statistics (this means late foetal deaths, live births and early neonatal deaths) should be those above a minimum birth weight, i.e., 1000 g at birth (A birth weight of 1000 g is considered equivalent to gestational age of 28 weeks)

ii) if the birth weight is not available, a gestation period of at least 28 weeks should be used, and

iii) where (i) and (ii) are not available, body length (crown to heel) of at least 35 cm should be used. But the preferred criterion is birth weight.

The Conference for the Tenth Revision (ICD–10) made no changes to these definitions.

DEFINITIONS *(79)*

The WHO's definition, more appropriate in nations with well established vital records of stillbirths is as follows :

$$PMR = \frac{\text{Late foetal deaths (28 weeks gestation and more) + early neonatal deaths (first week) in one year}}{\text{Live births + late foetal deaths (28 weeks gestation and more) in the same year}} \times 1000$$

The WHO's definition, more appropriate in nations with less well established vital records, is :

$$\text{Perinatal mortality rate} = \frac{\text{Late foetal deaths (28 weeks + of gestation) + postnatal deaths (first week) in a year}}{\text{Live births in a year}} \times 1000$$

There is a difference in denominator of the perinatal mortality rate defined by the WHO and industrially developed nations. This makes international comparisons difficult.

International comparisons

For international comparisons, the WHO Expert Committee on the Prevention of Perinatal Mortality and Morbidity (1970) recommended a more precise formulation : "Late foetal and early neonatal deaths weighing over 1000 g at birth, expressed as a ratio per 1000 live births weighing over 1000 g at birth". It is calculated as :

$$\text{Perinatal mortality rate} = \frac{\text{Late foetal and early neonatal deaths weighing over 1000 g at birth}}{\text{Total live births weighing over 1000 g at birth}} \times 1000$$

Why perinatal mortality rate ?

With the decline of infant mortality rate to low levels in many developed countries, perinatal mortality rate has assumed greater significance as a yardstick of obstetric and paediatric care before and around the time of birth.

First, two types of death rate i.e., stillbirths and deaths under the first week of life are combined in perinatal mortality rate because the factors responsible for these two types of deaths are often similar, being those operating before and around the time of birth. *Secondly,* a proportion of deaths which occur after birth are incorrectly registered as stillbirths, thereby inflating the stillbirth rate and lowering the neonatal death rate. The perinatal mortality rate, being a combination of stillbirths and early neonatal deaths, is not influenced by this error, by removing from consideration the dividing line between a stillbirth and a live birth with death shortly after birth.

Although perinatal period occupies less than 0.5 per cent (less than 168 hours) of the average life span, there are more deaths within this period than during the next 30–40 years of life in many developing countries *(80)*. The value of perinatal mortality rate is that it gives a good indication of the extent of pregnancy wastage as well as the quality and quantity of health care available to the mother and the newborn. It reflects the results of maternity care more clearly than the neonatal death rate.

Incidence

Perinatal mortality is a problem of serious dimensions in all countries. It now accounts for about 90 per cent of all

foetal and infant mortality in the developed countries. In India, stillbirths are seldom registered. Consequently, most studies on perinatal mortality in this country are hospital–based. The SRS estimates for perinatal mortality rate in India for the year 2010 was about 32 per 1000 live births and stillbirths, with about 35 for rural areas and 22 for the urban areas. The statewise perinatal mortality rate is shown in Table 18.

In developed countries, perinatal mortality rates have gradually declined during the past decades due to improved obstetric and perinatal technologies.

Social and biological variables

A number of social and biological factors are known to be associated with perinatal mortality. The degree to which these factors influence perinatal mortality varies from country to country. Many of these factors also endanger the life of the mother, causing high maternal mortality. An appreciation of these factors (at-risk factors) will certainly make the greatest impact on reducing perinatal mortality. The overall risk is increased in the following categories : (1) Low socio-economic status; (2) High maternal age (35 years or more); (3) Low maternal age (under 16 years); (4) High parity (fifth and subsequent pregnancies, especially with short intervals between pregnancies); (5) Heavy smoking (10 or more cigarettes daily); (6) Maternal height – short stature (as compared with average for locality); (7) Poor past obstetric history (one or more previous stillbirths and neonatal deaths, one or more premature live–born infants); (8) Malnutrition and severe anaemia; and (9) Multiple pregnancy.

For further details see page 569 under factors affecting infant mortality.

Causes of perinatal mortality

About two-thirds of all perinatal deaths occur among infants with less than 2500 g birth weight. The causes involve one or more complications in the mother during pregnancy or labour, in the placenta or in the foetus or neonate.

Main causes : The main causes of death are intrauterine and birth asphyxia, low birth weight, birth trauma, and intrauterine or neonatal infections. The various causes of perinatal mortality may be grouped as below :

(a) Antenatal causes

(1) Maternal diseases : hypertension, cardiovascular diseases, diabetes, tuberculosis, anaemia
(2) Pelvic diseases : uterine myomas, endometriosis, ovarian tumours
(3) Anatomical defects : uterine anomalies, incompetent cervix
(4) Endocrine imbalance and inadequate uterine preparation
(5) Blood incompatibilities
(6) Malnutrition
(7) Toxaemias of pregnancy
(8) Antepartum haemorrhages
(9) Congenital defects
(10) Advanced maternal age

(b) Intranatal causes

(1) Birth injuries
(2) Asphyxia
(3) Prolonged effort time
(4) Obstetric complications

(c) Postnatal causes

(1) Prematurity
(2) Respiratory distress syndrome
(3) Respiratory and alimentary infections
(4) Congenital anomalies

(d) Unknown causes

In some cases; the causes are not clinically ascertainable.

Interventions for the reduction of perinatal mortality

Measures to reduce perinatal mortality rates are essential to accelerate the declining trend in neonatal and infant mortality rates. For further details, refer to Table 21.

International certificate of perinatal death

For international comparability, the 9th (1975) Revision of International Classification of Diseases (ICD–9) recommended a special certificate of cause of perinatal death. The ICD has also a list of 100 causes (the "P" list) for tabulation of perinatal morbidity and mortality *(32)*.

Prevention of perinatal mortality

See page 571 under Preventive & Social Measures.

NEONATAL MORTALITY RATE

Neonatal deaths are deaths occurring during the neonatal period, commencing at birth and ending 28 completed days after birth. Neonatal mortality rate is the number of neonatal deaths in a given year per 1000 live births in that year.

The neonatal mortality rate is tabulated as :

$$= \frac{\text{Number of deaths of children under 28 days of age in a year}}{\text{Total live births in the same year}} \times 1000$$

Causes of neonatal mortality

The main causes of neonatal death globally are as shown in Fig 13.

No woman should die giving life. Nor should any mother endure pregnancy and childbirth, only to go through the agony of having her child born dead or watching the baby die minutes after birth. Yet for countless women around the

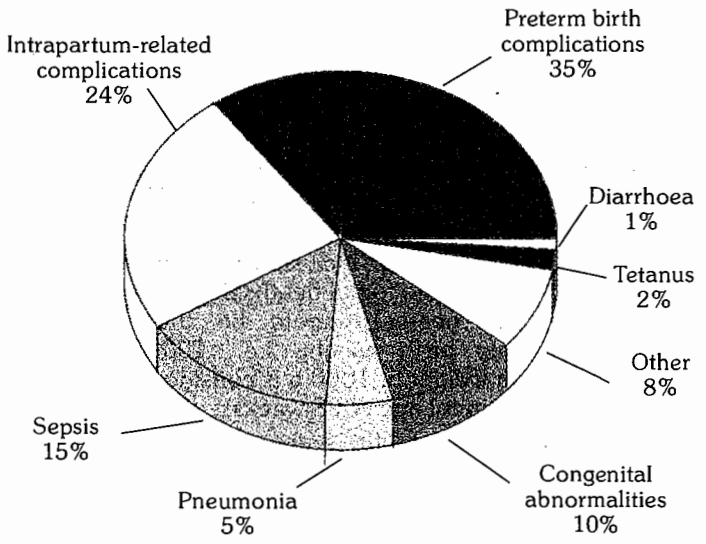

FIG. 13

Global distribution of neonatal deaths by cause, 2013

Source : *(82)*

world this scenario remains a tragic reality. The first 28 days of life – the neonatal period, is the most vulnerable time for a child's survival. In order to continue to accelerate progress in under-five mortality, focussing on newborns is critical.

Neonatal mortality is a measure of intensity with which "endogenous factors" (e.g., low birth weight, birth injuries) affect infant life. The neonatal mortality is directly related to the birth weight and gestational age. Intrapartum related complications, low birth weight and preterm birth is a causal factor in 60 per cent of neonate deaths.

Prematurity and congenital anomalies account for about 60 per cent of newborn deaths, and these often occur in the first week of life. A further quarter of neonatal deaths are attributable to asphyxia – also mainly in the first week of life. In the late neonatal period, that is, after the first week, deaths attributable to infection (including diarrhoea and tetanus) predominate. The importance of tetanus as a cause of neonatal death, however, has diminished sharply due to intensified immunization efforts.

Neonatal mortality rates of babies born to mothers with no education are nearly twice as high as those of babies born to mothers with secondary education or higher. The family's wealth and rural/urban residence also remain powerful determinant of inequities in neonatal mortality. Ending child marriage, reducing adolescent pregnancy and extending birth intervals are crucial to reducing the risk of newborn mortality.

Direct causes of newborn death vary from region to region. In general, the proportions of deaths attributed to prematurity and congenital disorders increase as the neonatal mortality rate decreases, while the proportions caused by infections, asphyxia, diarrhoea and tetanus decline as care improves. Patterns of low birth weight vary considerably between countries. Babies with a low birth weight are especially vulnerable to the hazards of the first hours and days of life, particularly if they are premature. Majority of low-birth-weight babies are not actually premature but have suffered from in utero growth restriction, usually because of the mother's poor health. These babies too are at increased risk of death.

The main causes of neonatal mortality are intrinsically linked to the health of the mother and the care she receives before, during and immediately after giving birth. Asphyxia and birth injuries usually result from poorly managed labour and delivery, and lack of access to obstetric services. Many neonatal infections, such as tetanus and congenital syphilis, can be prevented by care during pregnancy and childbirth. Inadequate calorie or micronutrient intake also results in poorer pregnancy outcomes. It has been argued that nearly three quarters of all neonatal deaths could be prevented if women were adequately nourished and received appropriate care during pregnancy, childbirth and in the postnatal period.

However, neonatal mortality is the most difficult part of infant mortality to alter, because of the endogenous factors which are not sensitive to improvements in environmental conditions. Neonatal mortality is greater in boys throughout the world, because newborn boys are biologically more fragile than girls.

Incidence

Each year, about 2.8 million newborns die before they are 4 weeks old and half of them die in their first 24 hours. 98 per cent of these deaths occur in developing countries. Newborn deaths now contribute to about 44 per cent of all deaths in children under five years of age globally, and more than half of infant mortality. About 1 million babies die every year on the day of their birth and close to 2 million die in the first week of their life. Rates are highest in sub-Saharan Africa and Asia. Two-thirds of newborn deaths occur in WHO Region of Africa (31 per cent) and South East Asia (30 per cent). The gap between rich and poor countries is widening – neonatal mortality is now 6.5 times lower in high income countries than in other countries. The lifetime risk for a woman to lose a newborn baby is now 1 in 5 in Africa, compared to 1 in 125 in more developed countries *(82)*.

India

In India the SRS estimates for the year 2012 is about 23 per 1000 live births in early-neonatal period (0–7 days), with about 25 for rural areas and 12 for urban areas. Table 19 shows the early neonatal mortality rate and percentage share of early neonatal mortality to infant deaths in the country and the major states. Among the bigger states, Kerala (4) and Madhya Pradesh and Odisha (29) are the two extremes. The percentage of early neonatal deaths to the total infant deaths during the year 2012, at the national level, has been 33.3, and it varied from 55 in rural areas to 42.9 in urban areas. In most of the states rural proportion is relatively higher than the urban proportion. Among the bigger states, the percentage for total varied from 38.0 in Kerala to 62.5 in Karnataka.

Table 20 shows the neonatal mortality rate in the country and the percentage of neonatal deaths to infant deaths for the year 2012, both at the national and state levels. At the national level, the neonatal mortality rate was 29 and ranged from 16 in urban areas to 33 in rural areas. Among the bigger states neonatal mortality ranges from 39 each in Madhya Pradesh and Odisha to 7 in Kerala. The percentage of neonatal deaths to total infant deaths was 68.5 per cent at the national level and varied from 56.8 per cent in urban areas to 70.4 per cent in rural areas. Among the bigger states Jammu & Kashmir (77.2) registered the highest percentage of neonatal deaths to infant deaths, and the lowest was in Assam (52.1).

CAUSES OF NEONATAL DEATHS IN INDIA

The major causes of neonatal deaths are shown in Fig. 14.

It is estimated that 40 per cent of all stillbirths and neonatal deaths take place during labour and the day of birth, and about 75 per cent of total neonatal deaths occur within the first week of life. Notably half of all the maternal deaths also take place in this period *(81)*.

India accounts for 40 per cent of the global burden of low birth weight babies with 7.5 million babies (or about 30 per cent of the country's total annual live births) being born with a birth weight less than 2500 grams. Of these 7.5 million babies, about 60 per cent are born at term after foetal growth retardation, while the remaining 40 per cent are born preterm, constituting one fourth of global burden of preterm births. Preterm babies in addition to being at a higher risk of neonatal mortality, are at an increased risk of post-neonatal mortality, stunting, and long-term neurodevelopmental impairment during childhood *(81)*.

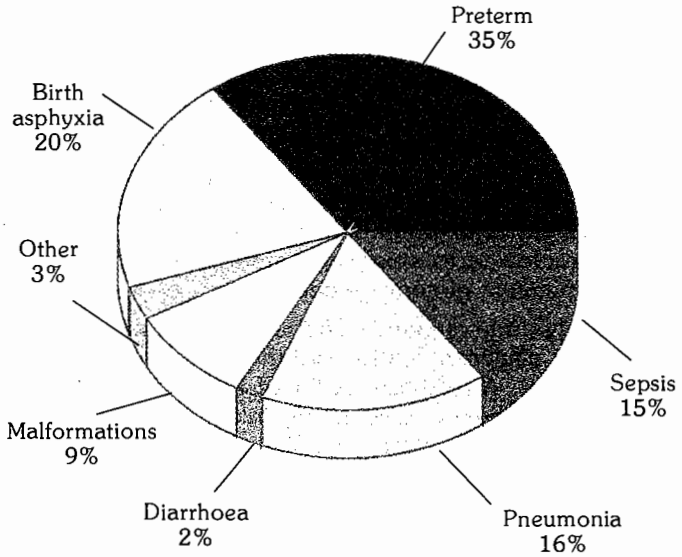

FIG. 14

Causes of neonatal deaths in India, 2012

Source : *(81)*

Interventions for the reduction of neonatal mortality

Measures to reduce neonatal mortality rates and to improve newborn health are enumerated in Table 21.

POST-NEONATAL MORTALITY RATE

Deaths occurring from 28 days of life to under one year are called "post-neonatal deaths". The post-neonatal death rate is defined as : "the ratio of post-neonatal deaths in a given year to the total number of live births in the same year; usually expressed as a rate per 1000" *(84)*.

The post-neonatal mortality rate is tabulated as :

$$= \frac{\text{Number of deaths of children between 28 days and one year of age in a given year}}{\text{Total live births in the same year}} \times 1000$$

Whereas neonatal mortality is dominated by endogenous factors, post-neonatal mortality is dominated by exogenous (e.g., environmental and social) factors. Diarrhoea and respiratory infections are the main causes of death during the post-neonatal period. Malnutrition is an additional factor, reinforcing the adverse effects of the infections. In the developed countries, the main cause of post-neonatal mortality is congenital anomalies. Studies show that post-neonatal mortality increases steadily with birth order, and that infants born into already large families run a higher risk of death from infectious diseases.

In some areas of South East Asia (including India), during the post-neonatal period girls die more frequently than boys. This is attributed to neglect of the female children in terms of nutrition and health care *(85)*.

TABLE 21

Priority areas to improve newborn health

Before and during pregnancy	• Delayed child-bearing. • Well-timed, well-spaced and wanted pregnancies • Well-nourished and healthy mother • Pregnancy free of drug abuse, tobacco and alcohol • Tetanus and rubella immunization • Prevention of mother-to-child transmission of HIV • Female education
During preganancy	• Early contact with health systems including : – Birth and emergency preparedness – Early detection and treatment of maternal complications – Monitoring of foetal well-being and timely interventions for foetal complications – Tetanus immunization – Prevention and treatment of anaemia – Prevention and treatment of infections (malaria, hookworm, syphilis and other STIs) – Voluntary HIV counselling and testing, and prevention of mother-to-child transmission of HIV • Good diet • Prevention of violence against women
During and soon after delivery	• Safe and clean delivery by skilled attendant • Early detection and prompt management of delivery and foetal complications • Emergency obstetric care for maternal and foetal conditions • Newborn resuscitation • Newborn care ensuring warmth and cleanliness • Newborn cord, eye and skin care • Early initiation of exclusive breast-feeding • Early detection and treatment of complications of the newborn • Special care for infants born too early or too small and/or complications • Prevention and control of infections • Prevention of mother-to-child transmission of HIV • Information and counselling on home care, danger signs and care seeking
During the first month of life	• Early post-natal contact • Protection, promotion and support of exclusive breast feeding • Prompt detection and management of diseases in newborn infant • Immunization • Protection of girl child

Source : *(83)*

The SRS estimates for post-neonatal mortality rate in India for the year 2012 is about 13 per 1000 live births for the whole country, and 14 for rural areas and 12 for the urban areas. The state-wise break-up is shown in Table 22.

INFANT MORTALITY RATE

Infant mortality rate (IMR) is defined as "the ratio of infant deaths registered in a given year to the total number of live births registered in the same year; usually expressed as a rate per 1000 live births" *(86)*. It is given by the formula :

$$IMR = \frac{\text{Number of deaths of children less than 1 year of age in a year}}{\text{Number of live births in the same year}} \times 1000$$

IMR is universally regarded not only as a most important indicator of the health status of a community but also of the level of living of people in general, and effectiveness of MCH services in particular. Infant mortality is given a separate treatment by demographers because : (a) infant mortality is the largest single age–category of mortality; (b) deaths at this age are due to a peculiar set of diseases and conditions to which the adult population is less exposed or less vulnerable; (c) infant mortality is affected rather quickly and directly by specific health programmes and hence may change more rapidly than the general death rate.

International comparisons

During the past decades, there has been a steady decline in infant mortality (Table 23)

TABLE 23

Infant mortality rate in selected countries (1990–2013)

Source : *(82)*

There are wide variations between countries or regions in the levels of infant mortality. The world average of IMR for 2013 has been estimated at about 34 per 1000 live births. However, IMR varies from 5 per 1000 live births in the developed countries to 61 per 1000 live births in the sub–saharan countries. The average in the south asian countries was 43 per 1000 live births. Although infant mortality declined significantly, the drop was greatest for the developed countries and lowest for least developed countries. The developed world had a much greater reduction in infant mortality compared to child mortality, while in the developing world the situation was reverse *(82)*.

The IMRs in industrialized countries were around 200 or even more some 150 years ago. Even at the beginning of the 20th century. USA, UK, Japan, France, etc, had rates above 140 per 1000 live births. Within 50 years (1950) a spectacular fall in the rate was observed in all developed countries. By 1980s, most developed countries achieved IMR rates below 10 per 1000 live births. Demographers opine that in most developed countries, further decline in IMRs would be difficult to achieve without some revolutionary advances in perinatology. Any further reduction in infant mortality in developed countries will depend upon preventing one of its principal causes, namely, congenital abnormalities.

In general, the infant mortality rates reflect the socio–economic development of a country. Deaths during the first four weeks are largely preventable by good health care. Much of the variations between developed and developing world in death among newborn can be explained by differences in antenatal care – about half of all pregnant women in the least developed countries have no antenatal care, and 7 out of 10 babies are born without the help of a trained birth attendant. The other major factors being malnutrition and high parity of the mother, low birth weight of the baby, and congenital anomalies.

The decline in infant mortality has been attributed to : (a) improved obstetric and perinatal care, e.g., availability of oxygen, foetal monitoring during labour, improved techniques for the induction of labour (b) improvement in the quality of life, that is, economic and social progress (c) better control of communicable diseases, e.g., immunization and oral rehydration (d) advances in chemotherapy, antibiotics and insecticides (e) better nutrition, e.g., emphasis on breast feeding, and (f) family planning, e.g., birth spacing.

In the industrial world, the dominant factor in the decline of infant mortality was economic and social progress (i.e., quality of life), with medical services playing secondary role. On the other hand, in most of the developing countries, this pattern has been almost turned upside down. That is, medical services (e.g., mass control of disease, immunization, antibiotics and insecticides) have made the major impact, with social and economic progress taking the supporting role. Therefore, infant mortality rates are reluctant to fall below 100 per 1000 live births in many developing countries. It is now conceded that only socio-economic development can re–accelerate the progress and lead to further significant fall in infant deaths.

Infant mortality in India

India is still among high infant mortality rate countries (41 in the year 2012). IMR has declined slowly from 204 during 1911–15, to 129 per 1000 live births in 1970 and remained static at around 127 for many years, and then declined a bit once again to 114 in 1980 and coming down to 41 in the year 2012. Despite this significant decline, the rates are very high as compared to developed countries (Table 23) which are now mostly in the range of 3–7 per 1000 live births.

India is a vast country with widely differing populations. The all-India rate masks variations that exist among sub–groups of the population. An examination of state-wise IMR shows a vast regional variation, with Madhya Pradesh having IMR of 56 and Kerala as low as 12 per thousand live births during the year 2012. Among the larger States Kerala, Maharashtra, Punjab, Tamil Nadu, West Bengal, Andhra Pradesh, Haryana, Karnataka, Gujarat, Himachal pradesh, and Jharkhand have achieved IMR below the national average of 42. Within each state there is rural urban variation. A critical infant mortality belt runs through Odisha, Madhya Pradesh, Assam, Uttar Pradesh, and Rajasthan; all these states have infant mortality rates above the national average.

Table 24 shows infant mortality rate in major states of India.

There is plenty of evidence to show that better control of infant mortality is related to a wider spread of literacy (particularly female literacy) and primary health care. Also, the states with the highest infant mortality are also the states with the highest fertility. Table 25 illustrates the impact of the above variables on infant mortality.

TABLE 25

IMR, female literacy rate and birth rate in major Indian States

Source : *(78, 87)*

Table 25 shows that Kerala has managed to surpass all the Indian states in certain important measures of social development. It has the lowest infant mortality rate, the lowest birth rate and the highest literacy rate.

Mortality pattern

(a) *Age* : Deaths in the age–group 0–1 year account for 13.0 per cent of the total deaths in the country. About 68.5 per cent of infant deaths occur within the first month (neonatal period) of life. Of these, 51.6 per cent may die during the first week of birth *(78)*. The risk of death is the greatest during the first 24–48 hours after birth. The problem is more acute in rural areas where expert obstetric care is scarce. (b) *Sex* : Whereas in all developed countries, male death rates are higher than female deaths, in India, after the age of one month (post-neonatal period) female deaths are invariably higher than male deaths. Social scientists have attributed this phenomenon to social factors unfavourable to females in India *(88)*.

Medical causes of infant mortality

The causes of infant mortality are multifactorial. The medical causes are shown in Table 26 under two subdivisions – neonatal and post-neonatal mortality.

TABLE 26

Causes of infant mortality

Neonatal mortality (0–4 weeks)	Post-neonatal mortality (1–12 months)
1. Low birth weight and prematurity	1. Diarrhoeal diseases
2. Birth injury and difficult labour	2. Acute respiratory infections
3. Sepsis	3. Other communicable diseases
4. Congenital anomalies	
5. Haemolytic diseases of newborn	4. Malnutrition
6. Conditions of placenta and cord	5. Congenital anomalies
7. Diarrhoeal diseases	6. Accidents
8. Acute respiratory infections	
9. Tetanus	

The principal causes of infant mortality in India are low birth weight (57%), respiratory infections (17%), diarrhoeal diseases (4%), congenital malformations (5%) and cord infection (2%), birth injury (3%) and unclassified about (18%) *(68)*. Neonatal deaths make a major contribution to infant mortality. Whereas in developing countries, the high infant mortality is mainly due to low birth weight, and the combined effects of infection (e.g., diarrhoea, respiratory infections) and malnutrition, in developed countries, it is mainly due to congenital anomalies, anoxia and hypoxia.

Factors affecting infant mortality

Infant mortality is due to the interaction of several factors in combination. They may be classified as biological, economic and social factors.

1. BIOLOGICAL FACTORS

(a) *Birth weight*

Birth weight is a major determinant of infant and perinatal mortality and morbidity. Babies of low birth weight (under 2.5 kg) and high birth weight (over 4 kg) are at special risk. Virtually, all infants weighing less than 1000 g at birth succumb. One major cause of low birth weight is poor maternal nutrition – not only during pregnancy, but even before that. It has been observed that the mother who was adequately nourished during her own growing–up years has an excellent chance of delivering a normal size baby even if she has taken an inadequate diet during her pregnancy. An increase in birth weight would lower the perinatal and neonatal mortality.

(b) *Age of the mother*

There is a definite relationship between the age of the mother and the fate of the child. Infant mortality rates are greater when the mother is either very young (below the age of 19 years) or relatively older (over 30 years). Very young mothers also tend to be poorer and less educated *(89)*.

(c) *Birth order*

The live births are classified according to their order of rank. The highest mortality is found among first born, and the lowest among those born second. The risk of infant mortality escalates after the third birth. The fate of the 5th and later children is always worse than the fate of the 3rd child. Infant mortality from nutritional deficiencies are 3–4 times higher for infants born with fifth or higher birth order compared to the first three. These deaths occur mostly in post-neonatal period.

(d) *Birth spacing*

Repeated pregnancies exert a great influence on infant mortality. They cause malnutrition and anaemia in the mother, again predispose to low birth weight, which results in higher infant death. The mother who becomes pregnant again too early and whose youngest baby is displaced from the breast, and prematurely weaned – that baby is more prone to develop (a) protein energy malnutrition (b) diarrhoea and dehydration, both of which cause an increased mortality in infants and young children. The Khanna Study in India showed that IMR was highest for infants born after an interval of one year, lower for those born after an interval of 2–3 years, and lowest for those born after an interval of 4 years *(90)*. A WHO study in rural India also showed similar findings *(91)*. Evidence from the World Fertility Survey – the largest survey into human behaviour ever undertaken – suggests that the risks to life for babies born within a year of each other is 2–4 times higher than for babies born more than 2 years apart. Wider spacing of births curtails infant mortality, and is considered as important part of health care as immunization *(92)*.

(e) *Multiple births*

Infants born in multiple births face a greater risk of death than do those in single births due in large part to the greater frequency of low birth weight among the former.

(f) *Family size*

Studies show the infant mortality increases with family size. The number of episodes of infectious diarrhoea, prevalence of malnutrition, and severe respiratory infections have been found to increase with family size. Besides the frequency of disease, the duration of illness is also affected by the family size. It was found that the duration of illness is much longer in families with 3 or more children. Deprivation of maternal care is also found in large families. Fewer children would mean better maternal care, a better share of family resources, less morbidity and greatly decreased infant mortality.

(g) *High fertility*

Fertility is one of the most important factors that influence infant mortality. High fertility and high infant mortality go together.

(2) ECONOMIC FACTORS

One of the most important variables affecting infant mortality rates, both directly and indirectly, is socio-economic status. The availability and quality of health care and the nature of the child's environment are closely related to socio-economic status. Statistics reveal that infant mortality rates are highest in the slums and lowest in the richer residential localities. Major improvements in health status and a decrease in infant mortality require continuing socio-economic development, including provision of health services.

(3) CULTURAL AND SOCIAL FACTORS

(a) *Breast-feeding*

Infant health is related to breast feeding because of the nutritional content and natural immunizing agents contained in breast milk, at least for fully breast-fed infants. Early weaning and bottle-fed infants living under poor hygienic conditions are more prone to die than the breast-fed infants living under similar conditions.

(b) *Religion and caste*

The differences are attributed to socio-cultural patterns of living, involving age-old habits, customs, traditions affecting cleanliness, eating, clothing, child care and almost every detail of daily living.

(c) *Early marriages*

The baby of teen-age mother has the highest risk for neonatal and post-neonatal mortality.

(d) *Sex of the child*

In most parts of India, female infants receive far less attention than males. This is especially the case, where there are already several female children. In many families, the birth of a female child is unwelcome. Statistics show that female infant mortality is higher than the male infant mortality. But when the total infant mortality is split into neonatal and postneonatal deaths, the picture gets reversed, i.e., neonatal death rate is higher for males than for female infants; post–neonatal death rate is higher for female infants than male infants *(88)*.

(e) *Quality of mothering*

The art of child care has to be learnt. Even in conditions of extreme poverty, children could reasonably survive if they had an efficient mother. It is the "quality of mothering" that helps to reduce infant mortality.

(f) *Maternal education*

Illiteracy is the greatest barrier to any improvement in the health conditions. Mother's education level, even within the same socio-economic class is a key determinant of their children's health. There is extensive evidence (e.g. Kerala experience) that maternal education plays a major role in the decline of infant and child mortality, presumably reflecting personal health behaviour, care and access to and use of health services. Women with schooling tend to marry later, delay child-bearing and are more likely to practice family planning. They generally have fewer children with wider spacing between births.

(g) *Quality of health care*

Another likely factor affecting infant mortality in contemporary India is inadequate prenatal care and infrequent attendance at delivery.

The percentage of deliveries attended by untrained persons or relatives is very high in rural India. Shortage of trained personnel like dais, midwives and health visitors is another determinant of high infant mortality in India. According to estimates only 47 per cent of the deliveries are attended by trained birth attendants.

(h) *Broken families*

Infant mortality tends to be high where the mother or father has died or separated.

(i) *Illegitimacy*

Illegitimacy is also an important factor contributing to high infant mortality rate. A child born out of wedlock is generally unwanted both by the mother as well as society. Consequently such a child does not receive the care in terms of nutrition and medical care that it needs.

(j) *Brutal habits and customs*

Certain age-old customs and beliefs greatly influence infant mortality rate. These include depriving the baby of the first milk or colostrum, frequent purgation, branding the skin, application of cowdung to the cut end of umbilical cord, faulty feeding practices and early weaning.

(k) *The indigenous dai*

The untrained midwife is greatly responsible for the high infant mortality in India. She is usually an illiterate person devoid of all knowledge of rules of hygiene. Her unhygienic delivery practice is an important cause of high infant mortality.

(l) *Bad environmental sanitation*

Infants are highly susceptible to bad environmental sanitation. Lack of safe water supply, poor housing conditions, bad drainage, overcrowding, and insect breeding, all increase the risk of infant mortality.

The third National Family Health Survey conducted in India during 2005–06 provides vast information on factors associated with mortality in infancy and childhood.

Preventive and social measures

There is no single specific health programme or a single set of action that can reduce IMR. Since the aetiology of infant and perinatal mortality is multifactorial, nothing less than a multipronged approach will reduce infant and perinatal mortality. Under ideal conditions of Social Welfare, no baby should die, except possibly the few who are born with serious handicaps such as congenital abnormalities or disorders originating in uterine life. The measures needed to achieve reduction of infant mortality comprise the following :

1. *Prenatal nutrition*

The risk of death begins to appear even before birth, if the mother is malnourished. Therefore, the very first need is to improve the state of maternal nutrition. There is mounting evidence that the addition of even a small amount of extra food by way of supplementation to the mother's basic diet goes a long way in improving the birth weight of babies. In a controlled study in India, poor women were fed an additional 500 kcals and 10 g of protein during the last 4 weeks of pregnancy. Their infants' birth weights were on an average 300 g above those infants born to the control group *(93, 94)*. This points to the need for food supplementation programmes during pregnancy. ICDS (Integrated Child Development Services) in India is active in this field.

2. *Prevention of infection*

The major causes of sickness and death of children in India are infectious diseases, many of which are preventable by immunization, as for example, neonatal tetanus. A large number of cases of EPI targeted diseases are reported each year. The Universal Immunization Programme launched in 1985 aims at providing protection to all the expectant mothers and children against 6 vaccine preventable diseases, and thereby ensure greater child survival.

3. *Breast-feeding*

The most effective measure for lowering infant mortality is to promote breast-feeding, which is a safeguard against gastrointestinal and respiratory infections and PEM.

4. *Growth monitoring*

It is a low cost technology available for reducing infant mortality. All infants should be weighed periodically (at least once a month) and their growth charts maintained. These charts help to identify children at risk of malnutrition early. Babies who do not thrive or show growth failure are given special health care to pull them on to the road–to–health. Thus systematic use of growth chart will help to promote health in children.

5. *Family planning*

Family limitation and spacing of births contribute substantially to lowering of infant mortality rate. The risk of death is greatly enhanced if the last child was born less than 2 years ago, and if the mother already has four or more children. Smaller sibship and longer spacing between pregnancies are associated in all societies with improved infant and child survival.

6. *Sanitation*

For infants and young children, the risk of dying is very closely related to the environment in which they live. Exposure to infections through contaminated food and polluted water, lack of elementary hygiene, flies and poor housing pose hazards which the young cannot escape. This is why infant mortality rate is universally recognized not only as a most important indicator of the health status of the children, but also of the level of social environment.

7. *Provision of primary health care*

(a) All those involved in maternity care, from the obstetrician down to the local dai should collaborate and work together as a team, (b) Prenatal care must be improved with a view to detecting mothers with "high-risk factors", and those with prenatal conditions associated with high-risk (e.g., toxaemia of pregnancy, antipartum haemorrhage, diabetes mellitus) are hospitalized and treated. (c) "Special care baby units" must be provided for all babies weighing less than 2000 g. (d) Proper referral services.

8. *Socio-economic development*

Since the causes of infant and perinatal mortality are also social, there is no getting away from the fact that the ultimate solution for lowering IMR and PMR lies in socio-economic development. This must include spread of education (especially female literacy), improvement of nutritional standards, provision of safe water and basic sanitation, improvement of housing conditions, the growth of agriculture and industry and the availability of commerce and communication; in short, it implies allround health and social development of the community.

9. *Education*

Education of females as a driving force for better health has been extensively studied and documented. Educated women generally do not have early pregnancies, are able to space their pregnancies, have better access to information related to personal hygiene and care of their children, and make better use of health care services. Higher literacy rate

among women is associated with low fertility and low maternal mortality, as well as low infant mortality. A study during 1991 in the Indian State of Tamil Nadu, with a population of more than 60 million, showed that a mid-day meal programme for school children together with improvement of health care for women and their babies raised retention levels in school, reduced child mortality, increased immunization rates and led to dramatic fall in infant deaths from 90 per 1000 live births in 1984 to 57 in 1991. This in turn seems to have reduced the fertility level to 2.5 children per women in 1991 *(42)*, and Tamil Nadu has now achieved zero population growth.

1–4 YEAR MORTALITY RATE
(Child death rate)

Child death rate is the number of deaths of children aged 1–4 years per 1000 children in the same age group in a given year. It thus excludes infant mortality. The rate is computed by the formula :

$$= \frac{\text{No. of deaths of children aged 1–4 years during a year}}{\text{Total no. of children aged 1–4 years at the middle of the year}} \times 1000$$

The child death rate is a more refined indicator of the social situation in a country than infant mortality rate. It reflects the adverse environmental health hazards (e.g., malnutrition, poor hygiene, infections and accidents), including economic, educational and cultural characteristics of the family. Mortality in this age group no longer depends on perinatal hazards and other endogenous factors, which often cause loss of life during the first year of life.

In the age group 1–4 years, the second year is the period when the young child runs the highest risk of dying. In the developing countries, death in the second year of life commonly accounts for 50 per cent of all deaths between 1–4 years of age. After the second year, death rates decline progressively. The infectious diseases of childhood such as measles, whooping cough, diphtheria, diarrhoea and acute respiratory infections affect mostly this age group, and can lead to high case–fatality rate in malnourished children.

Mortality rate at ages 1–4 years is about 30 in some developing countries whereas it is less than one in developed countries. The contrast is glaring. While on an average, the IMR is 10–20 times higher in developing countries than in the developed countries, the average mortality rate between the age 1–4 years is 30–50 times higher.

In India, for the year 2012, 1–4 years age mortality was estimated to be 2.8 per cent of total deaths. Like infant mortality, 1–4 year age mortality also shows wide state-wise variations as shown in Table 27. The states reporting rates higher than the national average are Madhya Pradesh 4.6, Uttar Pradesh 4.4, Jharkhand 4.0, Bihar 5.3, and Assam with 5.2 per cent of total deaths *(78)*. Kerala recorded the lowest with 0.2 per cent followed by Andhra Pradesh with 0.4 per cent.

TABLE 27

SRS estimates for child death (1-4 years) and under-five mortality in major states of India, 2012

State	Child death (1–4 years) (% of total deaths)	Under-five mortality rate (per 1000 live births)

Source : *(78)*

Leading causes of death

The leading causes of death in the 1–4 years age group are as shown in Table 28.

TABLE 28

Leading causes of death in 1–4 years age group

Developing countries	Developed countries
Diarrhoeal diseases	Accidents
Respiratory infections	Congenital anomalies
Malnutrition	Malignant neoplasms
Infectious diseases (e.g., measles, whooping cough)	Influenza
Other febrile diseases	Pneumonia
Accidents and injuries	

The leading causes of death in 1–4 years age group in developing countries are diarrhoeal diseases and respiratory infections, closely followed by other communicable diseases such as whooping cough and measles. When combined with malnutrition these diseases have high case fatality rates. In the developed countries deaths from infectious diseases are quite rare, while accidents are the leading cause of death from the age of one year. Four groups of home accidents have been identified – (a) falls from unprotected stairs, and balconies (b) suffocation (c) burns and scalds (d) poisoning. Almost all accidents are preventable. The factors such as congenital anomalies and neoplasms are not easy to prevent or to cure. These conditions also affect children in developing countries, but their relative importance is overshadowed by infections.

UNDER-5 MORTALITY RATE
(Child mortality rate)

UNICEF defines this as the "annual number of deaths of children age under 5 years, expressed as a rate per 1000 live births." More specifically, it measures the probability of dying between birth and exactly 5 years of age. UNICEF considers this as the best single indicator of social

development and well-being rather than GNP per capita, as the former reflects income, nutrition, health care and basic education etc *(95)*. The rate is calculated by the formula :

$$\text{Child mortality rate} = \frac{\text{Number of deaths of children less than 5 years of age in a given year}}{\text{Number of live births in the same year}} \times 1000$$

The dramatic decline in preventable child deaths over the past quarter of a century is one of the most significant achievements in human history. Since 1990, the global under-five mortality rate has declined by nearly half (49 per cent), from 90 deaths per 1,000 live births to 46 deaths in 2013. Over the same period, the neonatal mortality rate (the probability of dying in the first 28 days after birth) has been reduced by 40 per cent, from 33 deaths per 1,000 live births to 20. The progress is especially dramatic when viewed in terms of the decline in the number of under-five deaths. In 1990, 12.7 million children under age 5 died. In 2013, by contrast, that number fell to 6.3 million, a reduction of 50 per cent. In other words, about 17,000 children under-5 died everyday in 2013 – 17,000 fewer than in 1990 *(82)*.

The global progress in reducing newborn deaths is almost as striking. Between 1990 and 2013, the number of newborn babies who died within the first 28 days of life declined from 4.7 million to 2.8 million. The world saved almost 100 million children – among them, 24 million newborns – who would have died had mortality remained at 1990 rate. The bulk of progress has taken place since Millennium Development Goals were set in the year 2000.

Not surprisingly the burden of under-five mortality is concentrated in the world's poorest regions and countries. The latest data from 2013 show that sub-Saharan Africa shoulders the world's highest under-five mortality rates. All 12 countries with an under-five mortality rate of 100 or more deaths per 1,000 live births are in sub-Saharan Africa, and 10 of these are in West and Central Africa. On an average, 1 out of every 11 children born in Sub-Saharan Africa dies before age 5. This is nearly 15 times the average rate (1 in 159) in high-income countries. Sub-Saharan Africa and South Asia remain the regions with the greatest numbers of child deaths. In 2013, about half of global under-five deaths occurred in sub-Saharan Africa and 32 per cent in South Asia.

Table 29 shows child mortality rate in some selected developed and developing countries.

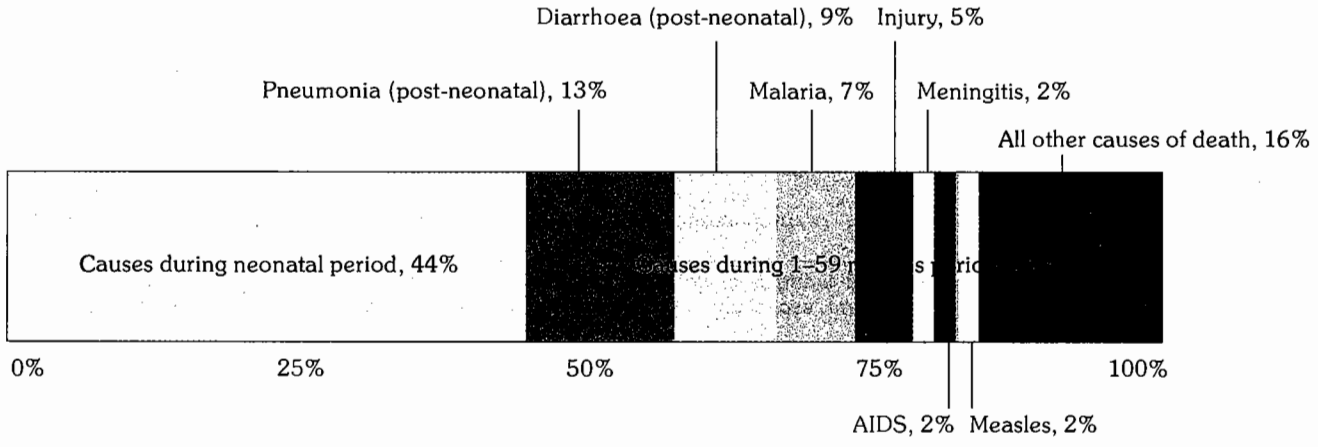
Causes of under five deaths

Understanding the causes of child mortality provides important public health insights. Of the 6.2 million deaths in children under-5, that occurred in 2013, almost one-thirds (38%) were caused by infectious diseases and conditions such as pneumonia, diarrhoea, malaria, meningitis, tetanus, HIV and measles. Around 44% of all under-five deaths occurred in the neonatal period (within the first 28 days of life), the majority from preterm birth complications and intrapartum-related complications (complications during delivery). Globally, more than half of the under-five deaths are attributable to undernutrition *(82)*.

Worldwide, the leading causes of death among children under-5 (1–59 months) include pneumonia (13% of all under-five deaths), preterm birth complications (13%), diarrhoea (9%), intrapartum-related complications (9%), malaria (7%), and neonatal sepsis, meningitis and tetanus (6%). Cross-country comparisons show a wide variation among countries in the proportions of under-five deaths attributable to specific causes. Such variations indicate that optimal programmatic approaches for child survival will differ from country to country. Fig. 15 shows the causes of death of children under-five in 2013.

Summarizing data across regions and countries masks



Globally, nearly half of all deaths among children under-5 are attributable to undernutrition

FIG. 15

Global distribution of deaths among children under-5 by cause, 2013

substantial differences in the distribution of causes of death. Approximately 90% of all malaria and HIV/AIDS deaths in children, more than 50% of measles deaths and about 40% of pneumonia and diarrhoeal deaths are in the African Region. On the other hand, deaths from injuries and non-communicable diseases other than congenital anomalies, account for 20–30% of under-five deaths in the region of the Americas and in the European and Western Pacific Regions *(96)*.

The steady improvement in under-five survival is explained by a combination of advances. They include developments in science and techonology (for example, oral rehydration salts that treat diarrhoeal dehydration and insecticide-treated mosquito nets for malaria prevention), improved health-seeking behaviours (such as women's increasing use of antenatal care and skilled providers for care around the time of birth), improved sanitation and improved coverage of effective interventions to prevent or treat the most important causes of child mortality. Each one of these advances is due to the political will of committed governments and the expansion of innovative partnerships involving civil society and the public and private sectors. Taken together, these efforts are reducing the number of young lives claimed by the leading causes of under-five mortality: pneumonia, diarrhoea, malaria, measles and AIDS. As a result 2.2 million fewer children died from these five diseases in 2013.

The Expanded Programme on Immunization started in 1974 and widened range of vaccines routinely provided, from smallpox, BCG and DPT to include polio and measles and more recently hepatitis B. It set-out to increase coverage in line with the international commitment to achieve the universal child immunization goal of 80 per cent coverage in every country.

As mortality from diarrhoeal diseases and vaccine preventable diseases decreased, pneumonia came to the forefront as a cause of death, and in the 1980s programmes were developed around simplified diagnostic and treatment techniques. In the meantime, promotion of breast-feeding continued, backed by international initiative and countries widely implemented the Baby-Friendly Hospitals initiative.

The Integrated Management of Childhood Illness (IMCI) strategy addresses the principal causes of child mortality i.e. diarrhoeal disease, acute respiratory infection, measles, malaria and underlying malnutrition. Several countries like India have added neonatal care in the national adaptations. It combines effective interventions for preventing death and for improving healthy growth and development, e.g., oral rehydration therapy for diarrhoea; antibiotics for sepsis, pneumonia and ear infection, antimalarials and insecticide-treated bed-nets; vitamin A, treatment of anaemia, promotion of breast-feeding and complementary feeding for healthy nutrition and for recovery from illness; and immunization. Some countries have included guidelines to treat children with HIV/AIDS, others for dengue fever, wheezing or sore throat, or for the follow-up of healthy children.

More recently, Every Newborn Action Plan proposes five strategic objectives for achieving two clear and measurable targets : (1) Ending preventable newborn deaths – By 2035, all countries reach a national target of 10 or fewer newborn deaths per 1000 live births and continue to reduce death and disability; and (2) Ending preventable stillbirths – By 2035, all countries reach the target of 10 or fewer stillbirths per 1000 total births and continue to narrow gaps in equity. Developed under WHO and UNICEF, the ENAP recommends the integrated delivery of high-impact interventions across the full continuum of maternal and newborn care, including care during labour, newborn care during the first week of life and care of small and sick newborns. Fig. 16 shows the package of interventions.

Focus of the Every Newborn Action Plan

The time around birth results in the majority of maternal and newborn deaths and stillbirths as well as human capital loss. These packages have the highest impact yet some of the lowest coverage of equitable and quality care across the continuum.

Referral and tertiary level facility	Reproductive health, including family planning	Management of pregnancy complications	Skilled care at birth	Essential newborn care Emergency care of small and sick newborns	Hospital care of childhood illness
First and secondary level facility	Reproductive health, including family planning	Pregnancy care	Skilled care at birth Basic emergency obstetric and newborn care	Essential newborn care Postnatal visits Care of small and sick newborns	Prevention and management of childhood illness
Community	Adolescent and pre-conception health care and nutrition Gender violence prevention	Counselling and birth preparedness	Home birth with skilled care and clean practices	Essential newborn care Postnatal home visits for mothers and newborns	Ongoing care for the child at home
Intersectoral : Improved living and working conditions, including housing, water and sanitation, and nutrition, education and empowerment, especially of girls, folic acid fortification; safe and healthy work environments for women and pregnant women					
	Adolescence and Before pregnancy	**Pregnancy**	**Labour, Birth and First Week** **Labour and Birth**	**Postnatal**	**Child**

FIG. 16

Packages of interventions in the continuum of care

Child mortality rate in India

In India, the deaths among young children are monitored by the Registrar General's Office. The SRS estimates of child mortality rate is calculated as "the annual number of deaths in children < 5 years of age per 1000 < 5 years children (the international agencies calculate this rate as per 1000 live births). That is why, while reviewing reports and analyzing data, these differences should be kept in mind *(52)*.

Each year 27 million children are born in India. Around 10 per cent of them do not survive to 5 years of age. In absolute figures, India contributes to 25 per cent of the over 6.9 million under-five deaths occurring worldwide every year. Nearly half of the under-five deaths occur in neonatal period. The mortality rates for children below age 5 years for the year 2012, by residence are shown in Table 27. At the national level the mortality rate was estimated at 56 per 1000 live births, and the rate varies from 15 in Kerala to 83 in Assam. The rate for rural areas is about 66 and for urban areas 38. The mortality rate in female children is higher than the male children *(97)*.

Among children who die before their fifth birthday, almost one-third die of infectious causes nearly all of which are preventable. The estimates of the cause of death for the year 2013 are shown in Fig. 17.

Preterm birth has emerged as the leading cause of neonatal death, underlying the need for rapid scale-up of maternal health interventions in order to improve neonatal health outcomes.

Social determinants for maternal and child mortality include marriage and childbirth at a very young age, less spacing between births and low literacy level among women, in particular those belonging to the urban poor and rural settings, and socially-disadvantaged groups (such as scheduled caste and tribes). Access to and use of contraceptives, particularly modern, non-permanent contraceptives, and access to safe abortion services are also factors that influence maternal health and child survival. It has been reported in SRS 2010 that TFR for those women who have no education is 3.4 compared to 2.2 for those who are literate. Furthermore, there is a gradual decline of TFR with the increase in the level of education. Low level of education is itself linked to the low status of women, and associated risks such as violence against women, emotional and physical abuse and malnutrition *(98)*.

A large number of maternal and child deaths are attributable to the 'three delays' : (1) the delay in deciding to seek care, (2) the delay in reaching the appropriate health facility, and (3) the delay in receiving quality care once inside an institution. The delay in deciding to seek care can occur due to inadequate resources, poor access to high-quality health care and lack of awareness of the importance of maternal and newborn health care at the household level. The unavailability of basic reproductive health services, including contraceptives, pre and postnatal care and emergency obstetric and neonatal care, as well as delays in seeking institutional care and the poor quality of care provided in the health facility can potentially contribute to child deaths *(98)*.

The interventions included in the RMNCH+A approach essentially look to address the major causes of death as well as the three delays in accessing and utilising healthcare services. These interventions are described in the later sections of this document.

The reproductive, maternal, neonatal and child health packages that are currently being implemented under the NRHM address the most common causes of maternal and child deaths. However, the coverage of key interventions, such as antenatal care, deliveries by skilled birth attendants, and use of oral rehydration solution (ORS) for the

Causes of death among children under 5 years, India, 2013

Source : *(82)*

management of childhood diarrhoea during the NRHM period has been slow and of variable quality across states *(98)*.

To pursue the goals of NPP, the Government of India constituted a National Technical Committee on Child Health in June 2000. New initiatives taken on the basis of this are *(68)* :

- Launch of Immunization Strengthening Project;
- Organization of RCH camps, health "melas" and RCH outreach scheme to reach disadvantageous segments of the population;
- Launch of Hepatitis B vaccine in the immunization programme;
- Operationalization of newborn care facilities in identified weak districts;
- Operations research by ICMR for provision of home–based neonatal care through community–level providers;
- Policy for exclusive breast-feeding upto 6 months of age;
- Preparation and approval of concept note on development of community based mid-wives;
- Implementation of Dai training to provide key messages for newborn health in 166 districts; and
- Adaptation of IMCI to incorporte newborn issues and development of IMNCI.

The Government of India established an IMCI Adaptation Committee that has led the development of Integrated Management of Newborn and Childhood Illnesses (IMNCI). Separate tools and guidelines have been produced that focus on newborn issues; these are used to train field staff and for supervision and monitoring purposes.

CHILD SURVIVAL INDEX

The basic measure of infant and child survival is the Under-5 mortality (number of deaths under the age of 5 years, per 1000 live births). A child survival rate per 1000 births can be simply calculated by subtracting the Under-5 mortality rate from 1000. Dividing this figure by ten shows the percentage of those who survive to the age of 5 years *(99)*.

$$\text{Child survival rate} = \frac{1000 - \text{under-5 mortality rate}}{10}$$

The following table (Table 30) shows the child survival rates of some countries.

TABLE 30

Child survival rates of some countries during 1990 and 2013

Country	1990	2013
India	87.4	94.7
Sri Lanka	97.9	99.0
Bangladesh	85.6	95.9
Nepal	85.8	96.0
Pakistan	86.1	91.4
China	94.6	98.7
UK	99.1	99.5
USA	98.4	99.3
Japan	99.4	99.7
Singapore	99.2	99.7

The difference in the survival rates of children in developed and developing countries is a grim pointer to the Third World's need for preventive services. Through breast-feeding, adequate nutrition, clean water, immunization programmes, oral rehydration therapy and birth spacing, a virtual revolution in child survival could be achieved. The impact would be dramatic in humanitarian and fertility terms.

INTEGRATED MANAGEMENT OF CHILDHOOD ILLNESS (IMCI)

The notion of integration has a long history. Integration is supposed to tackle the need for complementarity of different independent services and administrative structures, so as to better achieve common goals. In 1950s, the goals were defined in terms of outcome, in 1960s of process and in the 1990s of economic impact. Integration has different meanings at different levels. At the patient level it means case management. At the point of delivery it means that multiple interventions are provided through one delivery channel, e.g., where vaccination is used as an opportunity to provide vitamin A to the child, boosting efficiency and coverage. At the system level integration means bringing together management and support function of different sub-programmes and ensuring complimentarity between different levels of care. IMCI is now the only child health strategy that aims for improved integration at these three levels simultaneously. More than just adding more programmes to a single delivery channel, it has sought to transform the way the health system looks at the child care.

Most sick children present with signs and symptoms related to more than one conditions. This overlap means that a single diagnosis may not be possible or appropriate, and that treatment may be complicated by the need to combine therapy for several conditions. Surveys of the management of sick children at these facilities reveal that many children are not properly assessed and treated and that their parents are poorly advised. Providing quality care to sick children in these conditions is a serious challenge. In response to these challenge, WHO and UNICEF developed a strategy known as IMCI. The strategy combines improved management of childhood illness with aspects of nutrition, immunization, and other important disease prevention and health promotion elements. The objectives are to reduce deaths and the frequency and severity of illness and disability and to contribute to improved growth and development.

The strategy includes three main components :

- Improvements in the case-management skills of health staff through the provision of locally adapted guidelines on IMCI and through activities to promote their use.
- Improvements in the health system required for effective management of childhood illness.
- Improvements in family and community practices.

The core of the IMCI strategy is integrated case management of the most common childhood problems, with a focus on the most important causes of death i.e. diarrhoea, ARI, malaria, measles and malnutrition. A guided process of adaptation ensures that the guidelines, and the learning materials that go with them, reflect the epidemiology within a country and are tailored to fit the needs, resources and capacity of a country's health system.

The clinical guidelines, which are based on expert clinical opinion and research results, are designed for the management of sick children aged 1 week up to 5 years. They promote evidence-based assessment and management, using a syndromic approach that supports the rational, effective and affordable use of drugs. They include methods for assessing signs that indicate severe disease; assessing a child's nutrition, immunization, and feeding; teaching parents how to care for a child at home; counselling parents to solve feeding problems; and advising parents about when to return to a health facility.The guidelines also include recommendations for checking the parent's understanding of the advice given and for showing them how to administer the first dose of treatment.

When assessing a sick child, a combination of individual signs leads to one or more classifications, rather than to a diagnosis. IMCI classifications are action oriented and allow a health care provider to determine if a child should be urgently referred to another health facility, if the child can be treated at the first-level facility (e.g. with oral antibiotic, antimalarial, ORS, etc.) or if the child can be safely managed at home.

The complete IMCI case management process involves the following elements *(100)* :

a. Assess a child by checking first for danger signs (or possible bacterial infection in a young infant), asking questions about common conditions, examining the child, and checking nutrition and immunization status. Assessment includes checking the child for other health problems.

b. Classify a child's illnesses using a colour-coded triage system. Because many children have more than one condition, each illness is classified according to whether it requires :

- urgent pre-referral treatment and referral (pink), or
- specific medical treatment and advice (yellow), or
- simple advice on home management (green).

c. After classifying all conditions, **identify** specific treatments for the child. If a child requires urgent referral, give essential treatment before the patient is transferred. If a child needs treatment at home, develop an integrated treatment plan for the child and give the first dose of drugs in the clinic. If a child should be immunized, give immunization.

d. Provide practical **treatment** instructions, including teaching the caretaker how to give oral drugs, how to feed and give fluids during illness, and how to treat local infections at home. Ask the caretaker to return for follow-up on a specific date, and teach her how to recognize signs that indicate the child should return immediately to the health facility.

e. Assess feeding, including assessment of breast-feeding practices, and **counsel** to solve any feeding problems found. Then counsel the mother about her own health.

f. When a child is brought back to the clinic as requested, **give follow-up care and,** if necessary, reassess the child for new problems.

The IMCI guidelines address most, but not all, of the major reasons a sick child is brought to a clinic. A child returning with chronic problems or less common illnesses may require special care. The guidelines do not describe the management of trauma or other acute emergenceis due to accidents or injuries.

Although AIDS is not addressed specifically, the case management guidelines address the most common reasons children with HIV seek care : diarrhoea and respiratory infections. When a child, who is believed to have HIV, presents with any of these common illnesses, he or she can be treated the same way as any child presenting with an illness. If a child's illness does not respond to the standard treatments described or if a child becomes severely malnourished, or returns to the clinic repeatedly, the child is referred to a hospital for special care.

Case management can only be effective to the extent that families bring their sick children to a trained health worker for care in a timely way. If a family waits to bring a child to a clinic until the child is extremely sick, or takes the child to an untrained provider, the child is more likely to die from the illness. Therefore, teaching families when to seek care for a sick child is an important part of the case management process.

The case management process is presented on two different sets of charts : one for children age 2 months up to five years, and one for children age 1 week up to 2 months. Annexure 'A' at the end of this chapter shows the flowchart about the IMNCI guidelines for the management of various conditions of childhood.

The Indian version of IMCI is known as IMNCI (Integrated Management of Neonatal and Childhood Illness) as it includes the first 7 days of age in the programme. Please refer to page 459 chapter 7 for further details.

CONGENITAL MALFORMATIONS

Definitions

Congenital disorders are defined as "those diseases that are substantially determined before or during birth and which are in principle recognizable in early life" *(85)*. Some are obvious at birth like, cleft palate; some are obvious in early life like congenital dislocation of hip which may escape detection until walking should commence; and some may not become apparent until much later in life, like patent ductus arteriosus which may escape diagnosis until school age or even later. Internal defects, when they are not lethal, may go unrecognized. In addition to the list of late diagnoses are a host of inborn errors of metabolism like PKU, Tay–Sachs disease, galactosaemia, and mental retardation. Some defects are classified as major which may require surgical intervention, and some are classified as minor that have no functional implications like skin tags in front of the ear. Thus a broad definition of **congenital malformation** includes not only anatomical defects but also molecular and cellular abnormalities present at birth *(101)*. A WHO document in 1972, however, held that the term **congenital malformation** should be confined to structural defects at birth, and the term **congenital anomaly** being used to include all biochemical, structural and functional disorders present at birth *(84)*. Thus the basic difficulty in the study of congenital defects is the actual definition of the term without which comparisons between studies are difficult to make.

Incidence

Congenital anomalies (also referred as birth defects) affect approximately 1 in 33 infants and result in approximately 3.2 million birth defect-related disabilities every year. An estimated 270,000 newborns die during the first 28 days of life every year from congenital anomalies. Congenital anomalies may result in long-term disability,

which may have significant impacts on individuals, families, health-care systems and societies. The most common serious congenital disorders are heart defect, neural tube defects and Down syndrome. Congenital anomalies may have a genetic, infectious or environmental origin; although in most of the cases it is difficult identify their cause *(102)*.

Causes

The aetiology of most congenital anomalies is poorly understood; both genetic and environmental factors have been implicated. They include :

1. GENETIC FACTORS : The congenital disorders with genetic aetiology are : (a) *Chromosomal abnormalities :* The chromosome is either missing or in excess. The examples include Down's syndrome, Klinefelter's syndrome and Turner's syndrome. (b) *Inborn errors of metabolism :* These include PKU, Tay–Sachs disease and galactosaemia (c) *Others :* Other genetically inherited disorders, presumably due to single gene defects, are much more common than conditions with demonstrable chromosomal abnormalities. Single gene disorders may be dominant (e.g., Huntington's chorea), recessive (e.g., thalassaemia, sickle cell disease) or sex–linked disorders (e.g., haemophilia) (d) *Those with probable or possible genetic aetiology :* This applies to congenital dislocation of hip, club foot and neural tube defects.

2. ENVIRONMENTAL FACTORS : These include intra–uterine Infections (e.g., rubella, cytomegalovirus, toxoplasmosis, syphilis), Drugs (e.g., thalidomide, stilboestrol, anti-convulsants, tobacco, high dose of vitamin A during early pregnancy, alcohol, anaesthetics, etc.), Maternal diseases complicated by pregnancy (e.g., diabetes, cardiac failure), Irradiation, and Dietary factors (e.g., folic acid deficiency).

Risk factors

The factors significantly associated with the occurrence of congenital malformations are : (a) *Maternal age :* Advanced maternal age at conception is a recognized risk factor. The overall risk of giving birth to an infant with Down's syndrome is 1 : 800. The risk rises sharply with age; it is 1 : 67 for those aged 40–45. (b) *Consanguinity :* In consanguinous marriages (e.g., first–cousin and uncle–niece marriages), there is a relatively high incidence of mental retardation and congenital malformations.

Prenatal diagnosis

It is now possible to detect certain congenital anomalies in utero using the following techniques : (a) **Alpha fetoprotein** : Neural tube defects can be detected by measurement of a specific protein of foetal origin, called alpha fetoprotein in maternal blood and in amniotic fluid during pregnancy. (b) **Ultrasound** : This can be used to visualize the foetus and detect many abnormalities of the foetus. (c) **Amniocentesis :** This test is possible only in the second trimester (i.e., after the completion of 12 weeks). It can detect many abnormalities (e.g., Down's syndrome, Neural tube defects). (d) **Chorionic villi sampling** : This new technique allows prenatal diagnosis at 9 to 11 weeks of pregnancy. By this test, the chromosome status can be easily determined. Prenatal diagnosis of congenital abnormalities offers the parents the option of therapeutic abortion.

PREVENTION OF CONGENITAL DEFORMITIES

There are 3 main approaches to the reduction of congenital abnormalities: *(103)*. (1) By discouraging further reproduction after the birth of a malformed child; after such a birth, the frequency of malformations in subsequent pregnancies is increased by about 10 times; (2) The avoidance of pregnancy in circumstances where malformations are likely to occur, e.g., advanced maternal age and Down's syndrome; (3) the identification and removal of teratogens such as certain drugs (e.g., thalidomide, steroid hormones, folate antagonists, anti-convulsants); infective agents (e.g., rubella, cytomegalovirus, herpes simplex virus, varicella zoster virus, Toxoplasma gondii); and physical agents such as X-rays and irradiation. Immunization against rubella is now routine in some countries which is bound to lead to some reduction in congenital abnormalities. A largely untapped preventive measure is the avoidance of drugs in pregnancy except where they are absolutely necessary *(104)*.

Congenital malformations may be regarded as one form of reproductive failure. The most unfavourable environmental and genetic factors result in sterility, and the favourable factors lead to normal reproduction. Between these extremes there may be abortions, stillbirths, premature births or neonatal deaths. Malformation represent a relative reproductive "success" when compared with sterility or early abortion *(105)*. Penrose (1961) stressed that major advances in the prevention of malformations must be achieved by attention to environmental factors rather than by attempting to improve heredity. It is more within reach than genetic control *(106)*.

SCHOOL HEALTH SERVICE

School health is an important branch of community health. According to modern concepts, school health service is an economical and powerful means of raising community health, and more important, in future generations. The school health service is a personal health service. It has developed during the past 70 years from the narrower concept of medical examination of children to the present–day broader concept of comprehensive care of the health and well-being of children throughout the school years.

Historical development

The beginning of School Health Service in India dates back to 1909, when for the first time medical examination of school children was carried out in Baroda city. The Bhore Committee (1946) *(107)* reported that School Health Services were practically non-existent in India, and where they existed, they were in an under-developed state. In 1953, the Secondary Education Committee emphasized the need for medical examination of pupils and school feeding programmes. In 1960, the Government of India constituted a School Health Committee to assess the standards of health and nutrition of school children and suggest ways and means to improve them. The Committee submitted its report in 1961, which contains many useful recommendations *(108)*. During the Five Year Plans, many State Governments have provided for school health, and school feeding programmes. Inspite of these efforts to improve school health, it must be stated that in India, as in other developing countries, the school health services provided are hardly more than a token service because of shortage of resources and insufficient facilities.

HEALTH PROBLEMS OF THE SCHOOL CHILD

Any discussion of a school health service must be based

on the local health problems of the school child, the culture of the community and the available resources in terms of money, material and manpower. While the health problems of school children vary from one place to another, surveys carried out in India indicate that the main emphasis will fall in the following categories : (1) malnutrition (2) infectious diseases (3) intestinal parasites (4) diseases of skin, eye and ear; and (5) dental caries.

OBJECTIVES OF SCHOOL HEALTH SERVICE

The objectives of the programme of a school health service are as follows *(109, 110)* :

1. the promotion of positive health
2. the prevention of diseases
3. early diagnosis, treatment and follow-up of defects
4. awakening health consciousness in children
5. the provision of healthful environment.

Aspects of School Health Service

The tasks of a school health service are manifold, and vary according to local priorities. Where resources are plentiful, special school health services may be developed. Some aspects of a school health service are as follows :

1. Health appraisal of school children and school personnel
2. Remedial measures and follow-up
3. Prevention of communicable diseases
4. Healthful school environment
5. Nutritional services
6. First-aid and emergency care
7. Mental health
8. Dental health
9. Eye health
10. Health education
11. Education of handicapped children
12. Proper maintenance and use of school health records.

1. Health appraisal

The health appraisal should cover not only the students but also the teachers and other school personnel. Health appraisal consists of periodic medical examinations and observation of children by the class teacher. (a) *Periodic Medical Examination* : The school health committee (1961) in India recommended medical examination of children at the time of entry and thereafter every 4 years *(108)*. In big cities, where facilities for medical examination are available, this could be more frequent. The initial examination should be thorough and unhastened and should include a careful history and physical examination of the child, with tests for vision, hearing and speech. A routine examination of blood and urine should be carried out. Clinical examination for nutritional deficiency, and examination of faeces for intestinal parasitosis are particularly important in India. Tuberculin testing or mass screening should not be withheld. The parents should be persuaded to be present at these examinations. The teacher should help in the medical inspection by recording the medical history, regular (quarterly) recording of height and weight, annual testing of vision, and preparing children for the medical examination by helping them understand the "how" and "why" of health appraisal. (b) *School Personnel* : Medical examination should be given to teachers and other school personnel as they form part of the environment to which the child is exposed. (c) *Daily Morning Inspection* : The teacher is in a unique position to carry out the "daily inspection", as he is familiar with the children and can detect changes in the child's appearance or behaviour that suggest illness or improper growth and development. The following clues will help the school teacher in suspecting children who need medical attention : (1) unusually flushed face (2) any rash or spots (3) symptoms of acute cold (4) coughing and sneezing (5) sore throat (6) rigid neck (7) nausea and vomiting (8) red or watery eyes (9) headache (10) chills or fever (11) listlessness or sleepiness (12) disinclination to play (13) diarrhoea (14) pains in the body (15) skin conditions like scabies and ringworm (16) pediculosis *(111)*. Children showing any such signs or symptoms should be referred to the school medical officer. Teacher observation of school children is of particular importance in India because of the limited number of trained personnel for school health work. For this work, the teachers should be adequately trained during Teacher Training Courses and subsequently by short In–service Training Courses.

2. Remedial measures and follow-up

Medical examinations are not an end in themselves; they should be followed by appropriate treatment and follow-up. Special clinics should be conducted exclusively for school children at the primary health centres in the rural areas, and in one of the selected schools or dispensaries for a group of about 5,000 children in the urban areas *(110)*. The clinic days and time should be intimated to all the concerned schools. Considering the high prevalence of dental, eye, ear, nose and throat defects in the school children in India, special clinics should be secured or provided for the exclusive use of school children for examination and treatment of such defects. In the big cities, the required number of specialists should be employed in the School Health Service. There should be provision for beds in the existing referral hospitals for the children to be admitted for investigation and treatment as and when required.

3. Prevention of communicable diseases

Communicable diseases control through immunization is the most emphasized school health service function. A well planned immunization programme should be drawn up against the common communicable diseases.

A record of all immunizations should be maintained as part of the school health records. When the child leaves school, the health record should accompany him.

4. Healthful school environment

The school building, site and equipment are part of the environment in which the child grows and develops. A healthful school environment therefore is necessary for the best emotional, social and personal health of the pupils. Schools should also serve as demonstration centres of good sanitation to the community. The following minimum standards for sanitation of the school and its environs have been suggested in India *(109, 110, 112)*.

(1) *Location* : The school should normally be centrally situated with proper approach roads and at a fair distance from busy places and roads, cinema houses, factories, railway tracks and market places. The school premises should be properly fenced and kept free from all hazards.

(2) *Site* : The site should be on suitable high land, and not subject to inundation or dampness and can be properly drained. The School Health Committee (1961) had recommended that 10 acres of land be provided for higher elementary schools and 5 acres for primary schools with an additional one acre of land per 100 students. In congested areas, the nearest public park or playground should be made available to the students. (3) *Structure* : Nursery and secondary schools, as far as possible, be single storied. Exterior walls should have a minimum thickness of 10 inches and should be heat resistant. (4) *Classroom* : Verandhas should be attached to classrooms. No classroom should accommodate more than 40 students. Per capita space for students in a classroom should not be less than 10 sq. ft. (5) *Furniture* : Furniture should suit the age group of students. It is desirable to provide single desks and chairs. Desks should be of "minus" type. Chairs should be provided with proper back-rests, with facilities for desk-work. (6) *Doors and windows*: The windows should be broad with the bottom sill, at a height of 2'–6" from the floor level; combined door and window area should be at least 25 per cent of the floor space; windows should be placed on different walls for cross-ventilation; the ventilators should not be less than 2 per cent of the floor area. (7) *Colour* : Inside colour of the classroom should be white and should be periodically white–washed. (8) *Lighting* : Classrooms should have sufficient natural light, preferably from the left, and should not be from the front. (9) *Water supply* : There should be an independent source of safe and potable water supply, which should be continuous, and distributed from the taps. (10) *Eating facilities* : Vendors other than those approved by the school authorities should not be allowed inside school premises; there should be a separate room provided for mid-day meals. (11) *Lavatory* : Privies and urinals should be provided – one urinal for 60 students and one latrine for 100 students. Arrangements should be separately made for boys and girls.

5. Nutritional services

A child who is physically weak will be mentally weak, and cannot be expected to take full advantage of schooling. The diet of the school child should, therefore receive first attention. The diet should contain all the nutrients in proper proportion, adequate for the maintenance of optimum health. Studies in India have shown that nutritional disorders are widely prevalent among school children, particularly deficiencies relating to proteins; vitamins A, C, thiamine and riboflavin, calcium and iron.

Mid-day School Meal : In order to combat malnutrition and improve the health of school children, it is now an accepted procedure in all advanced countries to provide a good nourishing meal to school children. The School Health Committee (1961) recommended that school children should be assured of at least one nourishing meal *(113)*. Those who can afford it may bring their lunch packets from home, and during lunch hours take their meals in school. Otherwise, schools should have some arrangement for providing mid-day meals through their own cafeteria on a 'no profit no loss' basis. In view of the limited finances in India, it is recommended that the school meal should provide at least one-third of the daily calorie requirement and about half of daily protein requirement of the child.

Applied Nutrition Programme : UNICEF is assisting in the implementation of the Applied Nutrition Programme in the form of implements, seeds, manure and water supply equipment. Wherever land is available, the facilities provided by the UNICEF should be utilized in developing school gardens. The produce may be utilized in the school feeding programmes as well as for nutrition education.

Specific Nutrients : Advances in the knowledge of nutrition have revealed that specific nutrients may be necessary for the prevention of some nutrient disorders. Dental caries, endemic goitre, nightblindness, protein malnutrition, anaemias and a host of other nutrient disorders are eminently preventable. Use of specific nutrients is indicated where such nutrient disorders are problems in a community.

6. First-aid and emergency care

The responsibility of giving first-aid and emergency care to pupils who become sick or injured on school premises rests with the teacher and therefore all teachers should receive adequate training during "Teacher Training Programmes" or "In–service Training programmes" to prepare them to carry out this obligation. The emergencies commonly met within schools are (a) accidents leading to minor or serious injuries, and (b) medical emergencies such as gastroenteritis, colic, epileptic fits, fainting, etc. In every school a fully equipped First-Aid-Post should be provided as per regulations of St. John Ambulance Association of India.

7. Mental health

The mental health of the child affects his physical health and the learning process. Juvenile delinquency, maladjustment and drug addiction are becoming problems among school children. The school is the most strategic place for shaping the child's behaviour and promoting mental health. The school teacher has both a positive and preventive role – he should be concerned with helping all children attain mental health, so that they may develop into mature, responsible and well adjusted adults. The school routine should be so planned that there is enough relaxation between periods of intense work, and every effort should be made to relieve the tedium of the class room. No distinction should be made between race, religion, caste or community; between the rich and poor; and between the clever and the dull. It is now increasingly realized that there is a great need for vocational counsellors and psychologists in schools for guiding the children into careers for which they are suited.

8. Dental health

Children frequently suffer from dental diseases and defects. Dental caries and periodontal disease are the two common dental diseases in India. A school health programme should have provision for dental examination, at least once a year. In the developed countries, dental hygienists are employed in schools to assist the school dentist with the examination of the teeth. They make preliminary inspection of the teeth and do prophylactic cleansing which is of great value in preventing gum troubles and in improving personal appearance. They take part in the teaching of dental hygiene as they work with the children.

9. Eye health services

Schools should be responsible for the early detection of refractive errors, treatment of squint and amblyopia, and detection and treatment of eye infections such as trachoma. Administration of vitamin A to children at risk, has shown gratifying results. In other words, basic eye health services should be provided in schools.

10. Health education

The most important element of the school health programme is health education. The goal of health education should be to bring about desirable changes in health knowledge, in attitudes and in practice, and not merely to teach the children a set of rules of hygiene.

Health education in schools should cover the following areas: (1) *Personal hygiene* : Health education programme in schools should be lively, practical and based on everyday needs and interests of children. The need for hygiene of skin, hair, teeth and clothing should be impressed upon them. Attention to posture is also important. Children often adopt bad postures while sitting and standing. Such tendencies, should be observed and corrected. It is increasingly recognized that the major degenerative diseases of adults have their origin in poor health habits formed early in life. Cigarette smoking is an example of a public health problem that should be tackled in schools. (2) *Environmental Health* : Encouraging young people to take part in health activities and keep their environment clean is an important function of school health services. Visits to observe community health programmes, and even better participation in community action programmes (e.g., vaccination, fly control campaigns, construction of sanitary wells and latrines) are excellent opportunities for health education. (3) *Family life* : Family life education is being increasingly recognized as a priority in both developed and developing countries. The school health service is concerned not only with the development of healthy lives but also with healthy attitudes towards human reproduction.

Health education in schools is a function of the school teacher. The health officer and the public health nurse/health worker/health assistant may furnish teaching materials and advice, but the teacher is the key person in the presentation of the material to the children. To do this important work, the teacher should be well versed in health education techniques, and sincerely interested in the welfare of the pupils. Children take back to their parents the health instructions they receive in schools, and even more important, when they become adults they apply this knowledge to their own families. In developing countries, where ill-health is a major problem, "every school child is a health worker".

11. Education of handicapped children

The ultimate goal is to assist the handicapped child and his family so that the child will be able to reach his maximum potential, to lead as normal a life as possible, to become as independent as possible, and to become a productive and self–supporting member of society. The resources for managing handicapped child vary from country to country. It requires the cooperation of health, welfare, social and educational agencies.

12. School health records

A cumulative health record of each student should be maintained. Such records should contain (a) Identifying data – name, date of birth, parent's name and address, etc. (b) past health history (c) record of findings of physical examination and screening tests and record of services provided. The purpose of maintaining school health records is to have cumulative information on the health aspects of school children in order to give continuing intelligent health supervision. These records will also be useful in analysing and evaluating school health programmes and providing a useful link between the home, school and the community.

School health administration

The health of the school child is the responsibility of the parents, teachers, health administrators and the community. The success or efficiency of school health service depends largely on effective coordination between the participating agencies. There is no uniform pattern of school health administration, both here and abroad. In England, school health service is part of the Education service of the country. In India, school health service is administered by different departments in different States – these are usually the departments of Health and Education. The School Health Committee set up by the Government of India in 1960 recommended that school health service should be an integral part of the general health services. The general health services in India are administered largely through the primary health centres in the rural areas, where the bulk of India's population lives. School health service is therefore an important function of the primary health centres.

(a) Primary health centres

The primary health centres are charged with the responsibility of administering school health service within their jurisdiction. It requires a whole-time, medical officer to cover 5,000 to 6,000 children a year. The School Health Committee (1961) has therefore recommended that the staff of the primary health centres should be augmented by additional staff to carry out effectively the school health programme.

(b) School Health Committees

The School Health Committee (1961) in India recommended the formation of school health committees at the village level, block level, district level, state level and national level. These Committees should mobilize community resources and make the school health programme continuous and self–supporting. The National School Health Council will be an advisory and coordinating body.

HANDICAPPED CHILDREN

Definitions

"Handicap" may be defined as "reduction in a person's capacity to fulfil a social role as a consequence of an impairment, inadequate training for the role, or other circumstances. Applied to children, the term usually refers to the presence of an impairment or other circumstances that are likely to interfere with normal growth and development or with the capacity to learn" *(114)*.

International Classification of Impairments, Disabilities and Handicaps (ICIDH) : First published by WHO in 1980, this is an attempt to produce a systematic taxonomy of the consequences of injury and disease.

An *impairment* is defined as "any loss or abnormality of psychological, physiological, or anatomical structure or function". Impairments are disturbances at the level of the organ and include defects, loss of limb, organ or other body structure and defects or loss of mental function.

A *disability* is defined as "any restriction or lack (resulting from an impairment) of ability to perform an activity in a manner or within the range considered normal for a human being". The term disability reflects the consequences of impairment in terms of functional performance and activity by the individual; disability thus represents disturbances at the level of the person.

A *handicap* is defined as a disadvantage for a given individual, resulting from an impairment or a disability, that limits or prevents the fulfilment of a role that is normal (depending on age, sex, and social and cultural practice) for that individual. The term handicap thus reflects interaction with and adaptation to the individual's surroundings.

Handicap may be intrinsic or extrinsic. For example, blindness is an intrinsic handicap, and loss of parents is an extrinsic handicap. One handicap can give rise to further handicaps and the terms "primary" and "secondary" are used to denote this relationship. Blindness is a primary handicap; it can lead to poverty, which will be secondary handicap.

Extent of the problem

Nearly 83 million of the world's population are estimated to be mentally retarded, with 41 million having long-term or permanent disability. It ranks fourth in the list of leading causes of disability. Hearing loss (41 decibels and above) over the age of 3 is estimated to affect 42 million people, ranking 3rd in the list. Disability resulting from poliomyelitis has affected about 10 million people *(42)*. It is difficult to state how many people are mentally retarded in India as the census estimates do not cover mental handicap. About 16.15 million persons (1.9 per cent of the population) suffer from some or the other physical disability in the country. About 3 per cent child population in 1–14 years age group is affected by developmental delays *(115)*.

Classification

It is usual to classify handicapped children into the following groups :

1. Physically handicapped
2. Mentally handicapped
3. Socially handicapped.

1. Physically handicapped children

This category includes children who are blind, deaf and mute; those with hare–lip, cleft palate, talipes; and the "crippled" – e.g., resulting from polio, cerebral palsy, congenital heart disease, road accidents, burns, injuries, etc. These conditions fall into three broad causative groups : (a) birth defects (b) infections, and (c) accidents. These are all preventable to a large extent through adequate prenatal, natal, postnatal services, and genetic counselling.

2. Mentally handicapped children

Mental handicap is the present term used for mental retardation. It is a condition of sub-average intellectual function combined with deficits in adaptive behaviour. Terms which were previously used such as idiot, moron and imbecile are now discarded. At least 2 per cent of India's population is said to be suffering from some kind of mental disability *(116)*.

Causes

Mental handicap has many causes. These may be genetic, or environmental and include prenatal as well as postnatal causes. The possible and earliest time to recognize the problem of mental retardation is to look for any delayed milestones and development.

The known causative factors include the following : (a) *Genetic conditions* : Down's syndrome, Klinefelter syndrome, PKU, Tay–Sach disease, galactosaemia, microcephaly, congenital hypothyroidism involving both single and multiple gene action and chromosomal abnormalities. (b) *Antenatal factors* : These comprise neural tube defects, Rh incompatibility, certain infections (e.g., rubella, cytomegalovirus, toxoplasmosis, syphilis), drugs and irradiation. (c) Perinatal *factors* : These include birth injuries, hypoxia and cerebral palsy. (d) *Postnatal factors* : Head injuries, accidents, encephalitis, physical and chemical agents such as lead and mercury poisoning may result in mental retardation. (e) *Miscellaneous* : Maternal malnutrition, protein-energy malnutrition, iodine deficiency (endemic goitre), consanguineous marriages, pregnancy after the age of 40 (late marriages) are all known to be associated with mental retardation.

Categories of mental retardation

Psychologists have used the concept of IQ to classify the degree of mental retardation. The IQ scores rest on the assumption that intelligence distribution in the general public follow the normal or Gaussian curve, with a mean of 100. The half of the general population achieve scores above 100, and one half below. The lower 3 per cent or so of the population achieve scores of 70 or less. They are usually considered to be mentally retarded. The WHO gave the following classification of mental retardation :

Mild mental retardation	....	IQ	50–70
Moderate mental retardation	....	IQ	35–49
Severe mental retardation	....	IQ	20–34
Profound mental retardation	....	IQ	under 20

Children scoring above 70 are no longer described as mentally handicapped. The number of mild cases far exceed the severe and profound cases. English statistics which have been widely quoted suggest that, among 100 mentally handicapped persons, the following proportion will be found : 70 mild, 20 moderate and 5 severe cases. In other words, a very great majority of cases of mental handicap are of the mild type and potentially capable of being taught to make a fairly adequate social adaptation in appropriate circumstances *(117)*.

Severe mental retardation is uncommon. The great majority of severely handicapped children remain more or less dependant throughout life. Mental retardation often involves psychiatric disturbances. It has been stressed that the IQ range suggested must not be applied too rigidly. IQ level is not necessarily constant during the individual's life span.

3. Socially handicapped children

A "socially handicapped child" may be defined as a child whose opportunities for a healthy personality development and a full unfolding of potentialities are hampered by certain elements in his social environment such as parental inadequacy, environmental deprivation (i.e. lack of stimulation of learning process), and emotional disturbances. Such children would include children who are orphaned either due to death or loss of parents; neglected and destitute children; those who are exploited or victimized; and, delinquent children. It may be pointed out that a child who is physically or mentally handicapped also meets with social handicaps to the extent to which he is subject to social rejection or misunderstanding and cannot make use of the normal value of social fulfilment.

Approaches to prevention

One of the objectives of Mother and Child Health Services is the prevention of handicapping conditions, and the early management of illness to prevent crippling sequelae.

1. Primary prevention

The ideal is to prevent the handicap from occurring through the application of preventive measures during preconceptional, prenatal and intranatal periods and during infancy, childhood and adolescence. The approaches in primary prevention include (a) *Genetic counselling* : The optimum maternal age for producing normal babies is between 20 and 30 years. After the age of 30 or 35 years, there is a greater chance of producing a genetically abnormal child, especially one with Down's syndrome. The mother should be advised accordingly. In some communities consanguineous marriages are common. The incidence of such marriage should be reduced through educational efforts. (b) *At-risk approach* : People "at-risk" of transmitting inherited diseases (e.g., chromosomal or sex–linked diseases) should be identified. They should be offered all the investigations currently available and should have competent advice about future risks. (c) *Immunization* : In India, the main cause of disability is poliomyelitis which is preventable by immunization *(118)*. Immunization against other diseases such as rubella should also be considered. (d) *Nutrition* : Proper nutrition of the expectant mother is important for the welfare of the unborn child, especially to reduce the incidence of prematurity which is associated with mental handicaps. (e) *Others* : These include health care of mothers and children through prenatal, natal and postnatal periods; avoidance of infectious diseases, potentially teratogenic drugs, X-rays and smoking; special care of high risk women especially during labour, and accident prevention. The Medical Termination of Pregnancy Act of 1971 allows abortion of the foetus which may be seriously handicapped. In short, the obstetrician has a major role to play in reducing the frequency of handicaps in the population.

2. Secondary prevention

The broad objective for all children whatever their condition or problem is to bring them as close to normality as possible – physically, mentally and socially. This will involve : (a) *Early diagnosis of handicap* : Parents themselves have the responsibility to bring the child to paediatrician and seek advice. Investigation of the child requires full history, assessment of the degree of handicap and perhaps special investigations including the natural potentialities of the child. This should be done through MCH and School Health Services and such other agencies. (b) *Treatment* : Handicapped children need specialized treatment facilities such as physiotherapy, (the deformities are corrected, the weakened muscles are given exercise as in polio, infrared rays, diathermy etc.); occupational therapy (the child is taught, according to his ability and taste, things like music, painting, weaving, woodwork, pottery, basket making etc.); speech therapy (the child is trained to talk normally); and prosthetics (provision of artificial limbs, hearing aids and other equipment). The modern term for this branch of medicine is "Physical Medicine and Rehabilitation". The purpose of treatment is to improve the physical condition of the patient. (c) *Training and education* : the handicapped child is trained for an independent living. This is called "vocational guidance". He is trained to "work with what is left", so that he is not a burden on others. In India, there are over 150 schools and institutions for the handicapped. The following are some of the important ones : (1) Occupational Therapy School, Mumbai. (2) Physical Therapy School, Mumbai. (3) Occupational Therapy School, Nagpur. (4) All India Institute of Physical Medicine and Rehabilitation, Mumbai. (5) Institute of Physical Medicine and Rehabilitation, Christian Medical College, Vellore. (6) Occupational Therapy College, New Delhi. Beside these, there are schools for the blind, deaf, and special hospitals and wards for crippled children. Institutional care of the handicapped children is being replaced by various social support measures and services, enabling families to assume a larger share of rehabilitation within the family cycle *(36)*.

The mentally handicapped children can be helped to reach their optimal capacity through attention to the following : (a) they should get love and warmth, patience and tolerance, besides discipline (b) their natural potentials should be identified, and the child must be helped to develop in that direction in all possible manner.

The mentally handicapped require attention from diverse disciplines such as medicine, psychology, education, rehabilitation and social welfare. Taking into account the gravity of the problem, the Ministry of Social Welfare, Govt. of India, has set-up the National Institute for Mentally Handicapped (NIMH) in 1984 at Secunderabad. It has Regional Branches at Mumbai, New Delhi and Kolkata. The NIMH serves as an apex organization for developing appropriate models for care for the mentally handicapped *(116)*.

Apart from NIMH, 3 other premier National Institutes are working in specific disabilities : (a) Ali Yavar Jung National Institute for the Hearing Handicapped, Mumbai with Regional branches at New Delhi, Kolkata and Secunderabad; (b) National Institute for the visually Handicapped, Dehradun with Regional branch at Chennai; (c) National Institute for the Orthopaedically Handicapped, Kolkata. Apart from developing models for care and services, these institutions conduct research, promote human resource development, crises management, education, placement and employment, development and supply of appropriate aids and appliances, and documentation and dissemination of information *(115)*.

In India the Ministry of Social Welfare operates through five major schemes of assistance to voluntary organizations providing services to disabled persons. These are : (a) Assistance to voluntary organizations for the disabled : Assistance upto 90 per cent in urban and 95 per cent in rural areas is given to NGOs for education, training and rehabilitation of the disabled; for rehabilitation of people recovering from mental illness; emphasis on vocational guidance and training; liaison with nearest psychiatrist centre or hospital; provision for Half–way Homes. (b) Assistance for aids and appliances : Aids and appliances upto Rs 3,600 are provided to people with disabilities free, if the monthly income is up to Rs 1,200, and at 50 per cent cost if the monthly income is between Rs 1,201 to 2,500. (c) Assistance to voluntary organizations for rehabilitation of leprosy–cured persons : Assistance to voluntary organizations working for leprosy–cured persons is given upto 90 per cent for public education and awareness, early intervention, educational and vocational training, economic rehabilitation and social integration. (d) Development in the field of cerebral palsy and mental retardation : For manpower training of professionals and also

for developing organizational infrastructure such as class room/library/hostel in the field of cerebral palsy and mental retardation. (e) Assistance to voluntary organization for establishment of special schools : For setting up special schools NGOs receive grants upto 90 per cent. Preference is given for opening schools in new districts and upgradation of existing schools.

On 26th August 1995, Ministry of Social Welfare, Govt. of India has introduced a comprehensive Bill in the Parliament known as "Persons with disabilities (equal opportunities, protection of right and full participation) Bill 1995. It deals with preventive and promotional aspects of rehabilitation.

In considering the management of the socially handicapped child, we must remember that such children are normal in their needs and development. Their needs should be identified and met. The children Act, 1960 provides for the "care, protection, maintenance, welfare, training, education and rehabilitation" of the socially handicapped children.

Lastly, we need to strengthen the family. The family is the most effective bulwark to prevent children from becoming socially handicapped. There were times when the handicapped child was considered a liability to the parents and to the society. All over the world, there is an awakening that handicapped children can and must be helped to make their lives as happy and useful as possible.

BEHAVIOUR PROBLEMS

The behaviour problems in children may be classified as below :

(a) *Problems antisocial in nature* : Stealing, lying, gambling, cruelty, sexual offences, destructiveness.

(b) *Habit disorders* : Thumb sucking, nail-biting, bed-wetting, masturbation.

(c) *Personality disorders* : Jealousy, temper-tantrums, timidity, shyness, day-dreaming, fears and anxieties, unsociability, hysterical manifestations.

(d) *Psychosomatic complaints* : Tremors, headache, asthma, depression, delusion, hallucinations.

(e) *Educational difficulties* : Backwardness in studies, school phobia, school failures, etc.

Some of the behaviour disorders are due to mental deficiency; some are due to organic disease and some due to failure in adjustment to external environment. The answer to these problems lies in improvement of living conditions, better social environment and education.

JUVENILE DELINQUENCY

The Children Act, 1960 in India defines delinquent as "a child who has committed an offence". Juvenile means a boy who has not attained the age of 16 years and a girl who has not attained the age of 18 years. In a broad sense, delinquency is not merely "juvenile crime". It embraces all deviations from normal youthful behaviour and includes the incorrigible, ungovernable, habitually disobedient and those who desert their homes and mix with immoral people, those with behaviour problems and indulge in antisocial practices.

INCIDENCE : In the United States it is reported that 2 per cent of children between 7 and 17 years attend juvenile courts. Comparable statistics are not available in India to denote the size of the problem, but it is agreed that juvenile delinquency is on the increase in India during the past few decades, due to changes in the cultural pattern of the people, urbanization and industrialization. The highest incidence is found in children aged 15 and above. The incidence among boys is 4 to 5 times more than among girls.

CAUSES : (1) *Biological causes* : Certain biological causes such as hereditary defects, feeble-mindedness, physical defects and glandular imbalance may be at the bottom of juvenile delinquency. Recent studies indicate that chromosome anomaly might be associated with a tendency for delinquency and crime. A survey of criminal patients in Scotland and elsewhere demonstrated such a link – some of the patients showing an extra Y chromosome. The XYY men suffer from severe disturbance of the whole personality *(119)*. (2) *Social causes* : Among the social causes may be mentioned broken homes, e.g., death of parents, separation of parents, step mothers and disturbed home conditions, e.g., poverty, alcoholism, parental neglect, ignorance about child care, too many children, etc. (3) *Other causes* : Absence of recreation facilities, cheap recreation, sex–thrillers, urbanization and industrialization, cinemas and television, slum-dwelling, etc.

PREVENTIVE MEASURES : (1) *Improvement of family life* : A well adjusted family can stem the tide of delinquency. Parents should be prepared for parenthood. The needs of children should be appreciated and met. (2) *Schooling* : The school comes next to home in the community in ordering the behaviour of children. There should be a healthy teacher–pupil relationship. The school teacher can play an important part by detecting early signs of maladjustment. (3) *Social welfare services* : These comprise recreation facilities, parent–counselling, child guidance, educational facilities and adequate general health services.

Children in difficult circumstances *(64)*

In a globalized economy, the increased vulnerability of some children due to their identity, and/or their socio-economic and geo-political circumstances calls for more focused attention as well as coordination of social and economic policies and monitoring of child impact. Besides being victims of globalization, these children may be barred from benefits meant for all children simply because they belong to a group or community with difficulties of access. These barriers must be overcome.

Over the years, some children have been categorized as children in difficult circumstances and these categorizations include :

- Homeless children (pavement dwellers, displaced/ evicted, etc.)
- Orphaned or abandoned children
- Children whose parents cannot or are not able to take care of them
- Children separated from parents
- Migrant and refugee children
- Street children
- Working children
- Trafficked children
- Children in bondage

- Children in prostitution
- Children of sex workers / prostitutes / sexual minorities
- Children of prisoners
- Children affected by conflict
- Children affected by natural disasters
- Children affected by HIV/AIDS
- Children suffering from terminal diseases
- The girl child
- Children with disabilities and related special needs
- Children belonging to the ethnic and religious minorities, and other minority communities, and those belonging to the Scheduled Castes and Scheduled Tribes
- Children in institutional care, be it in state-run institutions or religious and other charitable institutions
- Children in conflict with law (those who commit crimes)
- Children who are victims of crime

For the first time in the history of planning for children, India has adopted a clear understanding and definition of the child in the NPAC 2005. The NPAC definition of the child as a person upto the age of 18 years and its clear declaration that 'all rights apply to all age-groups, including before birth' reiterates the 1974 National Policy mandate that the State takes responsibility for children 'both before and after birth,' and the child's interests are to receive paramount attention. This national reaffirmation must set the frame for future planning and intervention to secure the well-being of all children of the country and provide them a caring and protective environment.

Battered baby syndrome

It has been defined as "a clinical condition in young children, usually under 3 years of age who have received non-accidental wholly inexcusable violence or injury, on one or more occasions, including minimal as well as severe fatal trauma, for what is often the most trivial provocation, by the hand of an adult in a position of trust, generally a parent, guardian or foster parent. In addition to physical injury, there may be deprivation of nutrition, care and affection in circumstances which indicate that such deprivation is not accidental".

Battered baby syndrome has been found in all strata of society. Its incidence is not known. So far as sequelae are concerned, the most worrying is the risk of mental and neurological complications. Thus it has been tentatively suggested that 10–15 per cent of cases of cerebral palsy and almost double that proportion of the new mentally retarded children each year may be the result of the battered baby syndrome.

Girl child and gender bias *(64)*

Gender biases pose a specific threat to girl children across the social and economic strata. For a girl child, life is a constant fight for survival, growth and development from the time she is conceived till she attains 18 years. The life chart of a girl child and the many life threatening problems she faces are as follows :

Years	Problems faced
Before birth to 1 year	– Being unwanted, risk of prenatal detection – Foeticide and infanticide – Infant mortality – Discrimination in breast-feeding and infant food – Neglect of health (immunization)
1 to 5 years	– Discrimination in access to food – Poorer health attention and poorer access to health care; high risk of nutritional anaemia – Discrimination in overall treatment, parental care; expression of value and worth – Vitamin and micro-nutrient deficiencies – Early definition and imposition of 'suitable' roles; limits on permitted learning and play activities – Child marriages in some areas of country – Household/near-home sexual abuse – If enrolled in school, less time for learning. – Assignment of domestic duties, minor small domestic chores
6 to 11 years	– Malnutrition and anaemia – Health problems like diarrhoea – Iodine and Vitamin A deficiency – Low school enrolment, school drop outs – Vulnerable to trafficking, child labour, child marriage – Abuse, exploitation and violence – Increasing domestic duties/workload – Looking after siblings – Restrictions on mobility, play
12 to 18 years	– Poor health, poor health attention – High risk/high levels of anaemia – Frequent illness due to malnutrition and micro-nutrient deficiency – Child marriage – High-risk/incidence of early child-bearing related morbidity/mortality – Becoming a 'child-mother', health risks and burden of childcare – Denied information, mobility, access to services – Low literacy/learning level – Early and frequent pregnancy coupled with abortions – Marital and domestic violence – Dowry harassment, desertion, polygamy, divorce – Child labour, trafficking – STDs and HIV/AIDS – Unpaid and unrecognized work, and drudgery – No voice either in home or society.

It is evident from the text above that age-specific and setting-specific interventions have to be put in place for appropriate and effective response to the above problems, highlighting the inter-sectoral nature of actions required.

Protecting girl children in India will not be easy. The nation cannot any longer afford the cost of hoping that society will change its mindset on its own, in a situation where pervasive negative attitudes towards women are being reflected on girl children, to the extent of denying them life itself.

The well-being of daughters in the community must become the subject of government monitoring (with NGO assistance if appropriate), covering every age and stage of childhood. Such vigilance must apply to all stages of a girl child's childhood. Panchayats, gram sabhas and local self-government bodies should be brought into this benevolent surveillance.

The specific goals for girls in the National Plan of Action for Children 2005

- Assurance of equality of status for girl child as an individual and a citizen in her own right through promotion of special opportunities for her growth and development.
- To ensure survival, development and protection of the girl child and to create an environment wherein she lives a life of dignity with full opportunity for choice and development.
- To stop sex selection, female foeticide and infanticide.
- To eliminate child marriages.
- To ensure the girl child's security and protect her from abuse, exploitation, victimization and all other forms of violence.
- To protect the girl child from deprivation and neglect and to ensure to the girl child an equal share of care and resources in the home and community, and equal access to services.
- To take measures to protect girl children from any treatment which undermines their self esteem, and causes their exclusion from social mainstream and also to break down persistent gender stereotype.
- To eliminate all obstacles that prevent girls from full enjoyment of human rights and fundamental freedom including equal rights in succesion and inheritance.
- To ensure equal opportunity for free and compulsory elementary education to all girls.
- Health and nutrition.

Child abuse

In ancient times, general opinion accepted that children could be beaten and abused. The industrial exploitation of children after the Middle Ages was commonplace, with no widespread protest. The prevention of cruelty to children, as to animal, was beginning to be a matter of public concern in the 18th century, but birch and cane lingered on and were brandished righteously at home and at school, well into the present century.

The broader concept of child abuse (which includes battering) is of recent origin. Its recognition by the caring professions have brought a spate of conferences, symposia and publications. The concept itself has been broadened to include not only physical violence, but sexual abuse, mental and emotional maltreatment, neglect, deprivation and lack of opportunity. The consequences of physical battering – death, blindness, mental and emotional retardation, stunting of growth – is only one part of the whole picture of child abuse. Some contributory factors of child abuse are poverty, alcohol and other drug abuse, loneliness, immaturity and a host of other factors. Many causes are embedded in the family and in its function of child rearing.

During the year 1991, there were one million cases of child abuse and neglect in the USA, i.e., an incidence of about 2 per cent children being subjected to physical and/or sexual abuse. Countries around the world report comparable figures *(120)*.

Studies carried out throughout the past two decades have shown that the provision of supportive home visitors, either public health nurse or trained lay people, to families who are at risk of using violence against children can prevent the abuse from happening. However, we have not yet reached a similar level of confidence about our ability to prevent the sexual abuse of children, which is also a worldwide phenomenon.

Suggested remedial measures include increased legal help, more case workers, educating young people to postpone having children until they are sufficiently mature to be adequate parents. Attempt to strengthen the individual and his family may prove helpful. The problem is complex and reflects merely one facet of the larger issue of violence in the home and in society at large *(121)*.

Street children

A large number of children live and work on the streets, a high proportion without any family support, particularly in the megacities of the developing world. They are at high-risk of malnutrition, tuberculosis, STDs including HIV, parasite and worm infestation and skin diseases. Both sexes are highly vulnerable to drug abuse, prostitution and criminal exploitation.

Most street children describe major losses in their lives. Many have lost family members through diseases, natural or manmade disasters, or may be by-product of war and riots.

Although poverty and rapid urbanization are major contributing factors to the problem, many claim that physical and sexual abuse were the reason for their leaving home.

Recent global estimates place their number at as many as 100 million. There may be 40 million in Latin America, 25 million in Asia and 10 million in Africa, with about 25 million in other areas including the developed world. In 1993 WHO launched an innovative project to study links between street children and substance abuse. The study noted regular use of alcohol and other drugs by a major proportion of street children. Often the lives of street children are intimately entwined with the illicit drug industry. Street children are used in the production and marketing of cocain and the trafficking of cannabis and heroin *(42)*.

There are particular problems in the provision of health and welfare services to street children with regard not only to health care but also to housing, educational opportunities and employment. The rehabilitation of these children should be taken up by the government and non-government voluntary agencies.

The "Integrated Programme for Street Children" without homes and families was launched to prevent destitution of children and provide facilities for their withdrawal from life on the streets. During 2008–09 the scheme was merged to Integrated Child Protection Scheme. Under the scheme NGOs are given financial support to run 24 hour shelters and

provide food, clothing, non-formal education, recreation, counselling, guidance and referral services for children. The other components of the scheme include enrolment in schools, vocational training, occupational placement, mobilizing preventive health services and reducing incidence of drug substance abuse, HIV/AIDS etc. *(65)*.

Refugee and displaced children *(122)*

At the end of 2004, roughly 48 per cent of all refugees worldwide were children.

During the same year, the total number of people displaced within their own countries by conflict or human rights violations amounted to roughly 25 million.

Refugee and internally displaced children face many risks, given the violence and uncertainty surrounding both their flight and their lives in the country and/or place of asylum. They may become separated from their families, lose their homes and find themselves living in poor conditions that jeopardize their health and education.

Displacement complicates birth registration and the issuance of travel documents, thereby compromising displaced persons' right to an identity. Both refugees and internally displaced people may have been forced to leave their homes without proper documentation, making it difficult to establish their identities. They may, therefore, be unable to prove their right to receive basic social services, such as education or health care, or to work in a different part of the country.

The loss of family protection, and inadequate resources to address the needs and challenges that refugee and internally displaced children face, can leave them at significant risk of recruitment by armed groups and forces, abuse and sexual exploitation. Girls are especially at risk of abduction, trafficking and sexual violence, including rape used as a weapon of war.

Orphaned children are much more vulnerable to protection violations. The death of a parent, in situations where no adequate alternative care systems are in place, opens up a protection gap. Children living on their own are at much greater risk of abuse and exploitation. Assessments by the International Labour Organization (ILO) have found that orphaned children are much more likely than non-orphans to be working in commercial agriculture, as street vendors, in domestic service and in the sex trade.

Primary responsibility for both refugee and displaced children lies with national governments. However, the Office of the United Nations High Commissioner for Refugees (UNHCR) has a mandate to assist and protect refugees, while the International Committee of the Red Cross (ICRC) has a mandate to assist internally displaced people if displacement is a result of armed conflict and internal violence.

Child labour and child exploitation

A sizeable number of growing children of poor socio-economic class especially in rural areas are known to be inducted as child labour. Studies have shown that labour at very young ages can have dire consequences on the child's development, both physical and mental. Child labourers always had lower growth and health status compared to their non-working counterparts, besides exposure to occupational hazards at a very young stage in their lives. The Declaration of the Rights of the Child and our own Constitution has laid down that childhood and youth should be protected against exploitation. In 1973, the ILO passed a convention establishing 15 as the minimum work age for most sectors while permitting light work from age 13, provided that such work was unlikely to harm child's health, morals and safety or prejudice his school attendance *(123)*.

Surveys by International Labour Organization (ILO) in 1990 found that over 79 million children under the age of 15 years were obliged to work. In some cases children as young as 5 years have been reported to be in paid employment. Africa and Asia dominate the data on child labour. The scenario has not changed much to the present time.

According to ILO, forced child labour is present in all regions and kinds of economy. For the most part, there is neither official data on the incidence of forced labour nor a widespread awareness among society at large that forced labour is a problem. Children in domestic service are the most invisible child labourers. Their work is performed within individual homes, removed from public scrutiny and their conditions of life and labour are entirely dependant on the whims of their employers. The number of children involved in domestic service around the world is unquantifiable because of the hidden nature of the work, but it certainly runs into millions. Many of these children are girls, and in many countries domestic service is seen as the only avenue of employment for a young girl, though in some places, such as Nepal and South Africa, boys are more likely to be domestic workers than girls. Children exploited in domestic service are generally paid little or nothing over and above food and lodging. In addition, children in domestic service are especially susceptible to physical and psychological harm. Many are forced to undertake tasks that are completely inappropriate for their age and physical strength. Another form of forced labour is debt bondage, whatever the origin of the debt, it leaves children under complete control of a money lender in a state little distinguishable from slavery.

India fosters the largest number of child labour in the world. Child labour contributes about 20 per cent of India's GNP. Child workers work for 12 hours at an average every day *(124)*. Jammu and Kashmir has the highest percentage of child labour, where children are mainly engaged in carpet weaving industry *(125)*. The other fields where child labour is used is in agriculture, plantations, mining, building construction, beedi-making, garbage picking, cashew descalding and processing, cloth printing, dyeing and weaving etc.

In India, various items of health and social legislation have been enacted to protect the health, safety and welfare of working children below the age of 15 years.

The Child Labour (Prohibition and Regulation) Act, 1986

Except in the process of family–based work or recognized school-based activities, children are not permitted to work in occupations concerned with :

- Passenger, goods mail transport by railways
- Carpet weaving
- Cinder picking, cleaning of ash-pits
- Cement manufacturing
- Building construction operations

- Cloth printing
- Dyeing, weaving
- Manufacturing of matches, explosives, fire-works
- Beedi making
- Mica cutting, splitting
- Abattoirs
- Wool cleaning
- Printing
- Cashew descalding and processing
- Soldering process in electronic industries.

Child labour is rooted in poverty, unemployment and lack of education. A great deal of effort is needed to eliminate these basic causes. It is felt that instead of proliferating the laws relating to children, all the statutory provisions of the various Acts relating to children should be grouped in one comprehensive code of children. It is not feasible to abolish child labour entirely in the present context, but it is expedient to protect such children against abuse, exploitation and health hazards, and regulate the conditions of work in occupations where child labour is permitted.

Child trafficking *(122)*

Trafficking of children takes many different forms. Some children are forcibly abducted, others are tricked and still others opt to let themselves be trafficked by promise of earnings, but not suspecting the level of exploitation they will suffer at the other end of the recruiting chain. Trafficking always involves journey, whether within the country or across the international border. The relocation takes children away from their families, communities and support net-work, leaving them isolated and utterly vulnerable to exploitation. Collecting data about these children is very difficult. It is estimated that trafficking affects about 1.2 million children each year. Fig. 18 shows children in worst forms of child labour and exploitation.

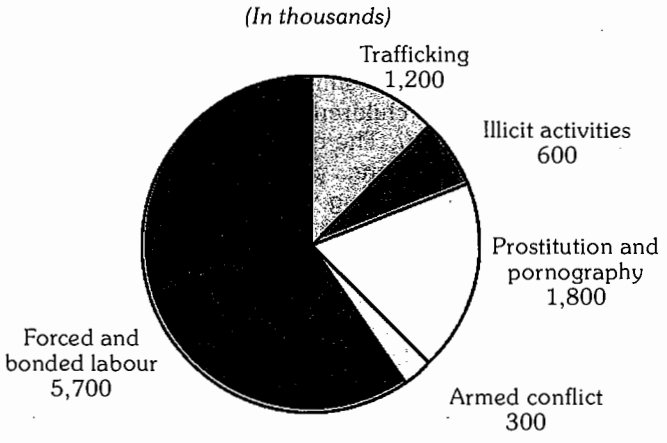

FIG. 18

Children in unconditional worst forms*
of child labour and exploitation

* Unconditional worst forms of child labour : These forms of labour correspond to those outlined in Article 3, of the International Labour Organization Convention No.182

Source : International Labour Organization, Every Child Counts : New global estimates on child labour, ILO, International Programme on the Elimination of Child Labour, Statistical Informational and Monitoring Programme on Child Labour, April 2002.

Though the trafficking of children is a shadowy practice, some dominant regional patterns are identifiable. In West and Central Africa, children are "placed" in a marginal position within other families. This practice is being used to exploit children both within and outside home. Children are also trafficked into plantations and mines, and in those countries affected by conflict, they are directly abducted by militias. In East Asia and Pacific, most trafficking is into child prostitution, though some children are also recruited for industrial and agricultural work. In South Asia, trafficking forms most of immense child labour problem in the sub-continent, often related to debt bondage. In addition, significant number of children are trafficked for other purposes, including into prostitution, carpet and garment factories, construction projects and begging. In Europe, children are mainly trafficked from east to west, reflecting the demand for cheap labour and child prostitution in richer countries of the continent. Children are also used as unskilled labour and in the entertainment sector.

An estimated 8.4 million children work under terrible circumstances and are forced into bondage or other forms of slavery (Fig. 18).

Making children safe requires creating a protective environment for them. The key elements of a protective environment include :

- Strengthening the capacity of families and communities to care for and protect children.
- Government commitment to child protection by providing budgetary support and social welfare policies targeted at the most excluded and invisible children.
- Ratification and implementation of legislation, both national and international, concerning children's rights and protection.
- Prosecution of perpetrators of crimes against children, and avoidance of criminalizing child victims.
- An open discussion by civil society and the media of attitudes, prejudices, beliefs and practices that facilitate or lead to abuses.
- Ensuring that children know their rights, are encouraged to express them and are given vital life skills and information to protect themselves from abuse and exploitation.
- Availability of basic social services to all children without discrimination.
- Monitoring, transparent reporting and oversight of abuses and exploitation.

The key to building the protective environment is the responsibility of members of the society, by ensuring that children are not exploited. While families and the State have the primary responsibility for protecting children, ongoing and sustained efforts by individuals and organizations at all levels, are essential to break patterns of abuse.

UJJAWALA : "Ujjawala", a comprehensive scheme to combat trafficking was launched in India by the Ministry of Women and Child Development on 4th December, 2007 and is being implemented mainly through NGOs. The scheme has five components of prevention, rescue, rehabilitation, reintegration and repatriation of victims

trafficked for commercial sexual exploitation. Some of the provisions under the scheme are *(65)* :

(1) Formation of community vigilance groups, adolescents groups, awareness creation and preparation of IEC material, organizing workshops;

(2) Safe withdrawal of victims from the place of exploitation;

(3) Rehabilitation of victims by providing them safe shelter, basic amenities, medical care, legal aid, vocational training and employment.

(4) Re-integration of victims into society; and

(5) Provide support to cross-border victims for their safe repatriation to the country of origin.

Child marriage

Early marriage is a long–established custom in India. As early as 1929, the Sharda Act was enacted forbidding the practice of child marriages. Inspite of the spread of literacy and legislations prohibiting early marriages, child marriages are still in vogue in the countryside particularly in Rajasthan, Madhya Pradesh and Uttar Pradesh, where substantial proportion of marriages take place when the girl is around 15 years of age *(126)*. The census data reveal that prior to 1951, the average age at marriage for girls in India was 13 years. There is however a gradual rise in the age at marriage in the country. The Child Marriage Restraint Act of 1978 raises the legal age of marriage from 15 to 18 years for girls; and from 18 to 21 years for boys. Studies indicate that in many states, the mean age at marriage for girls has already moved into 19 years and 24 years for the boys. The Prohibition of Child Marriage Act, 2006 (PCMA) was enacted repealing the Child Marriage Restraint Act of 1929 in order to prohibit child marriage rather than only restraining them. PCMA has been enforced with effect from 1st November, 2007. It makes child marriage an offence and makes provision for punishment for those conducting / abetting /promoting / permitting the marriage *(65)*.

The age at which the girl marries and enters the reproduction period of life has a great impact on her fertility. Girls who marry before the age of 18 give birth to larger number of children than those who married late. It is estimated that if the marriages were postponed from the age of 16 to 20–21, the number of births would decrease by 20–30 per cent.

Child guidance clinic

The first child guidance clinic was started in Chicago in 1909 and ever since, they have grown in number and complexity throughout the world. Originally intended to deal with problems of juvenile delinquency, child guidance clinics deal with all children or adolescents who for one reason or other, are not fully adjusted to their environment. The object of child guidance is to prevent children from the possibility of becoming neurotics and psychotics in later life.

Team work : Child guidance is a team work job – the team comprising of a psychiatrist, clinical psychologist, educational, psychologist, psychiatric social workers, public health nurses, paediatrician, speech therapist, occupational therapist and a neurologist. The psychiatrist is the central figure and is helped by the others in arriving at a correct diagnosis and formulating the line of treatment.

Services : The paediatrician takes care of the physical health of the child. The core of therapy is psychotherapy in order to restore positive feelings of security in the child. To achieve this, many methods are employed, e.g., play therapy, counselling, suggestions, change in the physical environment, easing of parental tensions, reconstruction of parental attitudes, etc. The child guidance clinics operate on the premise that if sound foundations of mental health are laid in childhood and adolescence, the same will continue into adulthood.

Child placement

(1) ORPHANAGES : Children who have no home or who for some reason could not be cared for by their parents are placed in orphanages. Scientific studies of human behaviour have revealed that mass care of infants and children in large institutions is undesirable. In such institutions, there is little opportunity for the child to experience the warmth and intimacy of family life, to develop emotional security and to participate in activities that would help him to become an adequate citizen. (2) FOSTER HOMES : Fostering is an arrangement whereby a child lives, usually on a temporary basis, with an extended or unrelated family member. Such an arrangement ensures that the birth parents do not lose any of their parental rights or responsibilities. This arrangement cater to children who are not legally free for adoption, and whose parents are unable to care for them due to illness, death or desertion by one parent, or any other crisis. The aim is to eventually re-unite the child with his/her own family, when the family circumstances improve *(65)*. (3) ADOPTION : In addition to the more or less temporary placement of children in foster or boarding homes, children are legally adopted. Legal adoption confers upon the child and adoptive parents, rights and responsibilities similar to that of natural parents. The laws of adoption vary from country to country; the relevant law in India is the "Hindu Adoptions and Maintenance Act, 1956". (4) BORSTALS : Boys over 16 years who are too difficult to be handled in a certified school or have misbehaved there, are sent to a Borstal. This institution falls in a category between a certified school and an adult prison. A Borstal sentence which is usually for three years, is regarded as a method of training and reformation. There are about six Borstals for boys in India but none for girls. Borstals do not come under the Children Act but are governed by the State Inspector General of Prisons *(125)*. (5) REMAND HOMES : In the remand home, the child is placed under the care of doctors, psychiatrists and other trained personnel. Every effort is made to improve the mental and physical well–being of the child. Elementary schooling is given, various arts and crafts are taught, games are played and other recreational activities are arranged.

THE CHILDREN ACT, 1960

The Children Act, 1960 in India (amended in 1977) provides for the care, maintenance, welfare, training, education and rehabilitation of the delinquent child. It covers the neglected and destitute, socially handicapped, uncontrollable, victimized and delinquent children. In Article 39 (f) the Constitution of India provides that "the state shall in particular direct its policy towards securing that childhood and youth are protected against moral and material abandonment."

JUVENILE JUSTICE ACT 1986

With the implementation of the Juvenile Justice Act, 1986, all Children's Acts applicable in different parts of the country have been repealed. The new Act, apart from rectifying the inadequacies of Children's Act, provides a comprehensive scheme for care, protection, treatment, development and rehabilitation of delinquent juveniles. The new Act has come into force from 2nd Oct 1987. Some of the special features of the Act are :

a. It provides a uniform legal framework for juvenile justice in the country so as to ensure that no child under any circumstances is put in jail or police lock–up;

b. It envisages specialized approach towards prevention and treatment of juvenile delinquency in keeping with the developmental needs of children;

c. It establishes norms and standards for administration of juvenile justice in terms of investigation, care, treatment and rehabilitation;

d. It lays down appropriate linkages and coordination between the formal system of juvenile justice and voluntary organizations. It specifically defines the roles and responsibilities of both.

Juvenile Justice Act 2000 *(64)*

Juvenile Justice (Care and Protection of Children) Act, 2000 (now Amendment Act 2006) is an Act to consolidate and amend the law relating to juveniles in conflict with law and children in need of care and protection, by providing for proper care, protection and treatment by catering to their development needs, and by adopting a child-friendly approach in the adjudication and disposition of matters in the best interest of children and for their ultimate rehabilitation. The Act defines a juvenile/child as a person who has not completed the age of 18 years. It has two separate chapters – one for juveniles in conflict with law and the other for children in need of care and protection. It also contains an exclusive chapter concerning rehabilitation and social reintegration of children. The Act defines Juvenile in conflict with law as a child who is alleged to have committed an offence and Children in need of care and protection broadly as children who are neglected, abused, abandoned, victim of any armed conflict or natural calamity amongst others. Offences committed against a child as listed in the Act, are cognizable and punishable under the provisions of this Act.

In order to implement its provisions and procedure, the Act provides for :

- Juvenile Justice Boards
- Child Welfare Committees
- Institutional care through children's homes, observation homes, shelter homes, special homes and aftercare organizations
- Non-institutional care through Adoption, Foster Care, Sponsorship Act and After Care
- Special Juvenile Police Units
- Juvenile Justice Fund
- Central/State/District Advisory Boards
- Selection Committee
- Inspection Committee.

SOCIAL WELFARE PROGRAMMES

The various social welfare programmes for women and children in India may be broadly categorized under six heads : (1) programmes for the welfare of women (2) programmes for the welfare of children (3) composite programmes (both for women and children) (4)schemes for the maladjusted groups (5) schemes for the physically handicapped persons; and (6) programmes for the welfare of backward classes.

CHILD WELFARE

Child welfare covers the entire spectrum of needs of children who by reason of handicap – social, economic, physical or mental – are unable to avail of services provided by the community *(128)*. Child welfare programmes thus seek to provide supportive services to the families of these children because one of the important responsibility of the society and state is to assist the family in its natural obligations for the welfare of the children.

Child welfare services in their various facets are preventive, promotive, developmental and rehabilitative in nature. The problem is gigantic, and the resources available are only supplementary in nature and are designed to meet certain needs of the most deprived and vulnerable among country's child population. Attention is generally focussed on 3 categories of children in the poverty groups : children of working mothers; destitute children, and handicapped children *(128)*.

CHILD WELFARE AGENCIES

The important child welfare agencies in India are : (1) Indian Council for Child Welfare (ICCW), (2) Central Social Welfare Board, (3) Kasturba Gandhi Memorial Trust, and (4) the Indian Red Cross Society. These agencies have got branches all over the country. They get financial aid from the government to organize child welfare services in the country. The following are some of their activities. (a) DAY CARE SERVICES : This is for children of working mothers. Nursery schools, BALWADIS and creches are set up to help the children of working mothers. Day care centres are mainly for infants and toddlers. (b) HOLIDAY HOMES : These are organized for children in the age group 12 to 16 years at hill stations and sea-side resorts. The children spend their holidays in a useful manner. (c) RECREATION FACILITIES : These comprise organization of play centres, public parks, children's libraries, BAL BHAVANS, children's films, national museums, hobby classes, etc. Besides the national agencies, the following international agencies are interested in child welfare : UNICEF, WHO, International Union for Child Welfare, CARE and FAO of the United Nations.

INTEGRATED CHILD DEVELOPMENT SERVICES (ICDS)

Currently, the most important scheme in the field of child welfare is the ICDS scheme. The blue print for the scheme was prepared by the Department of Social Welfare in 1975. Considering the magnitude of the task, it was decided to take up on an experimental basis 33 projects in the year 1975–76 in 4 urban, 19 rural and 10 tribal areas spread over 22 states and the Union Territory of Delhi. The projects were

sanctioned in October 1975. The Government of India decided to expand the project to cover 100 areas by 1978-79. Two major evaluations were conducted in 1978 and 1982. The positive results of these evaluations formed the basis for the governments decision to accelerate the expansion of ICDS in 1982.

Prior to 2005–06, providing supplementary nutrition was the responsibility of the states and administrative cost was provided by the central government. Government of India has modified the cost sharing pattern under ICDS by giving aid of 50 per cent of the financial expenditure to the states/UTs.

The population norms for setting up of Angan Wadi Centres (AWC) and Mini–AWC have been revised to cover all habitations by SC/ST/minorities. The revised norms are as follows *(65)* :

For AWCs in rural/urban projects

1 AWC for 400–800 population

2 AWCs for 800–1600 population

3 AWCs for 1600–2400 population

Thereafter one AWC for multiples of 800 population. For Mini–AWC, the norm is one mini–AWC for 150 to 400 population.

For tribal/reverine/desert/hilly and other difficult areas

1 AWC for 300–800 population

1 Mini – AWC for 150–300 population.

The ICDS seeks to lay a solid foundation for the development of the nation's human resource by providing an integrated package of early childhood services. These consist of (1) supplementary nutrition (2) immunization (3) health check-up (4) medical referral services (5) nutrition and health education for women and (6) non-formal education of children up to the age of 6 years, and pregnant and nursing mothers in rural, urban, slums and tribal areas. ICDS scheme is designed both as a preventive and development effort. The services of immunization, health check-up and referral services are provided through public health infrastructure i.e., sub-centres, PHC and CHC. The services are provided concurrently.

Objectives *(127)*

The objectives of the ICDS scheme are :

(a) to improve the nutritional and health status of children in the age group 0–6 years;

(b) to lay the foundations for proper psychological, physical and social development of the child ;

(c) to reduce mortality and, morbidity, malnutrition and school drop-out;

(d) to achieve an effective coordination of policy and implementation among the various departments working for the promotion of child development; and

(e) to enhance the capability of the mother and nutritional needs of the child through proper nutrition and health education.

To achieve the above objective the ICDS aims at providing the following package of services.

Beneficiary	Services
Pregnant women	Heath check-up Immunization against tetanus Supplementary nutrition Nutrition and health education
Nursing mothers	Health check-up Supplementary nutrition Nutrition and health education
Other women 15–45 years	Nutrition and Health education
Children less than 3 years	Supplementary nutrition Immunization Health check-up Referral services
Children in age group 3–6 years	Supplementary nutrition Immunization, Health check-up Referral services Non-formal education
Adolescent girls 11–18 years	Supplementary nutrition Nutrition and health education

Source : *(127)*

The strategy adopted in ICDS is one of simultaneous delivery of early childhood services. While the health component forms a major component, ICDS is much more than a mere health programme for delivery of social services input for development.

Delivery of services

1. Supplementary nutrition

Supplementary nutrition is given to children below 6 years, and nursing and expectant mothers from low income group. The type of food depends upon local availability, type of beneficiary, location of the project etc. The aim is to supplement nutritional intake as follows *(65)* :

a. each child 6–72 months of age to get 500 calories and 12–15 grams of protein (financial norm of Rs 4.00 per child per day);

b. Severely malnourished child 6–72 months to get 800 calories and 20–25 grams protein (financial norm of Rs 6.00 per child per day); and

c. Each pregnant and nursing woman to get 600 calories and 18–20 grams of protein (financial norm of Rs 5.00 per beneficiary per day.

Under the revised nutritional and feeding norms for supplementary nutrition, state governments/UTs have been mandated to provide more than one meal to the children who come to AWCs, which include providing a morning snack in the form of milk/banana/egg/seasonal fruit/micro-nutrient fortified food followed by a hot cooked meal. For children below 3 years of age, and pregnant and lactating mothers, "take home ration" is to be provided. All are eligible for availing of the services of ICDS, below poverty line is not a criteria for registration of beneficiaries. The scheme is universal.

Supplementary nutrition is given 300 days in a year *(127)*. Adequate funds for supplementary nutrition is provided in the State Plan under Minimum Needs Programme. Children are weighed every month. Nutrition education and health education is given to mothers of children suffering from 1st degree of malnutrition.

Supplementary nutrition (therapeutic food) is given to children suffering from 2nd and 3rd degree malnutrition. Children suffering from 4th degree malnutrition are recommended hospitalization.

2. Nutrition and health education

Nutrition education and health education is given to all women in the age group 15–45 years, giving priority to nursing and expectant mothers. It is imparted by specially organized courses in village during home visits by anganwadi workers.

3. Immunization

Immunization of children against 6 vaccine preventable diseases is being done, while for expectant mothers, immunization against tetanus is recommended.

4. Health check-up

This includes (a) antenatal care of expectant mothers; (b) postnatal care of nursing mother and care of newborn infants; (c) care of children under 6 years of age. Besides immunization, expectant mothers are given iron and folic acid tablets along with protein supplements. A minimum of 3 physical examinations are done. High risk mothers are referred to appropriate institutions for special care.

The health care of children under 6 years of age consists of :

1. Record of weight and height of children at periodical intervals
2. Watch over milestones
3. Immunization
4. General check-up every 3-6 months to detect disease, malnutrition etc.
5. Treatment for disease like diarrhoea, dysentery, respiratory tract infections etc. which are widely prevalent.
6. Deworming
7. Prophylaxis against vitamin A deficiency and anaemia.
8. Referral of serious cases to hospital has also been provided for.

Health records : Health records of the children, antenatal care and delivery card etc. are maintained. A card containing the health record of the child is given to the mother.

5. Non-formal pre-school education

Children between the ages 3–6 years are imparted non-formal pre-school education in an anganwadi in each village with about 1000 population. The objective is to provide opportunities to develop desirable attitude, values and behaviour pattern among children. Locally produced inexpensive toys and material are used in organizing play and creative activity.

Schemes for adolescent girls (65)

At present, there are two schemes for adolescent girls viz. "Kishori Shakti Yojana" and "Nutrition Programme for adolescent girls".

Kishori Shakti Yojana is being implemented using the infrastructure of ICDS. The scheme targets adolescent girls in the age group of 11 to 18 years and addresses their needs of self development, nutrition and health status, literacy and numerical skills, vocational skills etc.

Nutrition Programme for Adolescent Girls was approved in the year 2009–10, on a pilot project basis. The project is being implemented in 51 identified districts from the major states. Undernourished adolescent girls in the age group of 11 to 19 years (with body weight less than 30 kg in the age group of 11 to 15 years and 35 kg in the age group of 15 to 19 years) are covered under the scheme. 6 kg of free food grain is provided to each beneficiary per month. The programme is being implemented through the administrative set-up of ICDS scheme at the state, district, block and Anganwadi Centre level.

Two more schemes are being implemented at the ICDS level. They are (a) Rajiv Gandhi Scheme for Empowerment of Adolescent Girls – "SABLA" for the age group 11 to 18 years to improve their nutritional and health status; and (b) Indira Gandhi Matrutva Sahyog Yojana (IGMSY), under which conditional cash transfer will be made to pregnant and lactating mothers in order to improve their nutritional and health status *(65)*.

At the end of 2012, about 6,908 ICDS projects and 13.04 lakh Anganwadi Centres/Mini-Anganwadi Centres are functional in the country. About 751.03 lakh children and 167.62 lakh pregnant and lactating mothers (total 918.65 lakh) are getting the benefit of the scheme.

The administrative unit of an ICDS project is the "community development block" in rural areas, the "tribal development block" in tribal areas and a group of slums in urban areas. In selection of project areas preference was given to areas predominantly inhabited by backward tribes, backward areas, draught prone areas and areas in which nutritional deficiencies are rampant. The rural/urban project has a population of 100,000 and a tribal project about 35,000 population. The number of villages in the rural project may be 100 while in tribal areas, it may be only about 50, taking into account the difficult terrain in which the tribal projects are located. The focal point for the delivery of integrated early childhood services under the ICDS scheme is the trained local woman known as Anganwadi worker (AWW). Other functionaries in the ICDS are the Child Development Project Officer (CDPO), who is in charge of 4 Supervisors (Mukhya Sevika) and 100 AWWs. Each Supervisor is responsible for 20–25 anganwadis and acts as mentor to AWWs; assists in record keeping, visits of health personnel and organizing community visits; and provides on–the–job training to AWWs. Anganwadi worker is the multipurpose agent, selected from the community. AWW provides direct link to children and mother; assists CDPO in survey of community and beneficiaries; organizes non-formal education sessions; provides health and nutrition education to mothers; assists PHC staff in providing health services; maintains records of immunization, feeding and pre-school attendance; liaises with block administrator, local school, health staff and community, and works for other community based activities, e.g., family planning.

The Government of India is committed to child development as a policy priority and is steadily expanding ICDS programme with the ultimate aim of reaching every child. The impact of the programme on the lives of children is evident in several crucial indicators : increased birth

weight, reduced incidence of malnutrition, increased immunization coverage, and a reduced infant and child mortality rate in areas covered by the ICDS *(113)*.

Health of adolescents

The term "adolescence" has been defined as including those aged between 10 and 19, and "youth" as those between 15 and 24; "young people" is a term that covers both age groups, i.e. those between the ages of 10 and 24. True adolescence, however, being the period of physical, psychological and social maturing from childhood to adulthood, may fall within either age range. The development that takes place in adolescence is generally uneven, in that physical maturity may well be achieved in advance of psychological or social maturity; in most societies, in fact, reproductive capability is now established at an earlier age than in the past.

The importance of the health of adolescents has started to receive increasing recognition, particularly in developing countries where four out of five of the world's young people live, and where more than half the population is under the age of 25. These young men and women are, or will become, the parents of the next generation. They must be given every opportunity to develop to their full potential as healthy individuals.

Because adolescents are less vulnerable to disease than the very young and the very old, health problems specific to their age group have been given little prominence until now. Moreover, in societies where girls in particular have traditionally married at an early age, adolescence has been regarded merely as a brief interlude between puberty and marriage. As the average age of menarche has fallen, and with an increasing trend towards late marriage, however, this period has been extended and traditional attitude has begun to change. At the same time, the influence of the family has declined, urbanization and migration have become more common, and young people have been increasingly exposed to the mass media – all factors that contribute to major changes in social and sexual behaviour.

High rate of mortality and morbidity has always been associated with pregnancy and childbirth in pubertal and adolescent girls. This problem is now compounded by the dramatic rise in the number of pregnancies, both wanted and unwanted, among adolescents, who are also having more abortions and contracting sexually transmitted diseases more often. There appears also to be an increase in the number of abandoned and abused children born to adolescent mothers. As long as these problems are allowed to persist, much of the energy, creativity and idealism of youth will be lost to society. However, the problems are preventable, and efforts to eliminate them must involve the young people themselves, contributing in ways appropriate to their particular cultures.

Society today demands more of young people than ever before. With the decline of the extended family greater autonomy is expected of them, especially in the raising of children; increasing urbanization and industrialization means that economic independence is achieved only through more education and training. Early parenthood, particularly for girls, may limit or preclude social and educational development and the ability to achieve full status in society and is associated with greater morbidity and mortality. The World Fertility Survey observed an inverse relationship between fertility and the education of women: women with no education have, on average, twice as many children as those with seven or more years of schooling. Corollaries of this finding are the increased earning power of educated women, their improved status within the family, and the greater control they are able to exercise over their own lives.

A more universal consequence of early and more frequent childbearing is the increase in population size and growth rate. Where girls marry at 15, the age gap between successive generations may be less than 20 years; this gap may widen to as much as 30 years where the age at marriage is 25. The sexual behaviour and reproductive patterns of young people are highly susceptible to social influences and related to their own sense of psychological well-being.

Although an adolescent girl is likely to give birth and rear her children within the context of an extended family, the risks she and her children run of illness, injury and death are far greater than those for a mature woman in her twenties. The chances of anaemia, developing during pregnancy, and of retarded fetal growth; premature birth and complications during labour are all significantly higher for the adolescent mother, as are the risks of her own death during pregnancy or child-birth.

Formal education of girls generally ends with marriage, and from then on their social status may well depend on fecundity. An adolescent girl who proves to be infertile (or whose husband is infertile) runs the risk of being rejected by both husband and family and thus of losing what little status she has. The second major set of problems of reproductive health in adolescence results from the profound socio-economic changes taking place in most developing countries. The average age of menarche has fallen, there is a trend towards later marriage, and young people are often less directly supervised than was the case in the past – all of which have the effect of increasing the opportunities for sexual encounter. Since the subject of adolescent sexuality remains taboo in most societies, there is widespread ignorance among young people of the risks associated with unprotected sexual activity. Sources of information and contraceptive advice are rarely available or accessible to them. In addition, impulsive sexual behaviour and non-use of contraceptives are sometimes exacerbated by alcohol and drug abuse.

A number of major approaches to reducing problems by modification of the contributing factors will serve to promote good health among the young and thus to improve health and social development of their communities. These approaches include the following :

1. Informing, educating and sensitizing key groups in society to individual health and social development needs.
2. Advocating appropriate policy, legislation and programmes for promoting adolescent reproductive health.
3. Using appropriate and innovative research to improve knowledge of, and disseminate information about, the factors that influence and determine young people's sexual, contraceptive and reproductive decisions and behaviour.
4. Modifying, extending and evaluating services specially designed to meet young people's needs.

5. Mobilizing the energy, creativity and idealism of young people in promoting health and developing appropriate activities in their communities.
6. Facilitating action to extend education opportunities for girls.

PREVENTIVE MEDICINE AND GERIATRICS

Ageing is a natural process. In the words of Seneca; "Old age is an incurable disease", but more recently, Sir James Sterling Ross commented : "You do not heal old age. You protect it; you promote it; you extend it" *(129)*. These are in fact the basic principles of preventive medicine. Old age should be regarded as a normal, inevitable biological phenomenon. The study of the physical and psychological changes which are incident to old age is called gerontology. The care of the aged is called clinical gerontology or geriatrics. Another aspect of gerontology is social gerontology which was born on the one hand out of the instincts of humanitarian and social attitudes and on the other out of the problems set by the increasing number of old people *(130)*. Experimental gerontology is concerned with research into the basic biological problems of ageing, into its physiology, biochemistry, pathology and psychology. The fields of studies range from studies of populations through individuals, organs, systems, tissues and cells, down to the molecular level. GERIATRIC GYNAECOLOGY : With the lengthening span of life a new chapter in gynaecology – geriatric gynaecology – is fast opening up. More patients are coming for repair of prolapse of varying degrees, non-specific vaginitis, ovarian tumours, psychic aberrations and sexual problems. There is ample scope for research into the degenerative and other diseases of old age; their treatment in hospital and general practice; and finally into preventive geriatrics and the epidemiology of conditions affecting the aged.

Size of the problem

Discoveries in medical science and improved social conditions during past few decades have increased the life span of man. The expectation of life at birth in developed countries is over 70 years. The age structure of the population in the developed countries has so evolved that the numbers of old people is continually on the increase. These trends are appearing in all countries where medical and social services are well developed and the standard of living is high.

In the year 2002, there were an estimated 605 million old persons in the world, of which 400 million were living in low-income countries *(131)*. Italy and Japan have the highest proportion of older persons (about 16.7 per cent and 16 per cent respectively in the year 2003). By 2025, the number of elderly people is expected to rise more than 1.2 billion with about 840 million of these in low-income countries *(131)*. In India, although the percentage of aged persons to the total population is low in comparison to the developed countries, nevertheless, the absolute size of aged population is considerable. For the year 2010 the estimates are 8 per cent of total population were above the age of 60 years, and is likely to rise to 19% by 2050. This profound shift in the share of older Indians, brings with it a variety of social, economic and healthcare policy challenges *(132)*.

Health problems of the aged

(1) PROBLEMS DUE TO THE AGEING PROCESS

No one knows when old age begins. The "biological age" of a person is not identical with his "chronological age". It is said that nobody grows old merely by living a certain number of years. Years wrinkle the skin, but worry, doubt, fear, anxiety and self-distrust wrinkle the soul. While ageing merely stands for growing old, senescence is an expression used for the deterioration in the vitality or the lowering of the biological efficiency that accompanies ageing. With the passage of time, certain changes take place in an organism. These changes are, for the most part deleterious and eventually lead to the death of the organism. Our knowledge about the ageing process is incomplete. We do not know much about the disabilities incident to the ageing process. However the following are some of the disabilities considered as incident to it; (a) senile cataract, (b) glaucoma, (c) nerve deafness, (d) osteoporosis affecting mobility, (e) emphysema, (f) failure of special senses, (g) changes in mental outlook. This list is not exhaustive; we need to know a lot more about the disabilities incident to the ageing process.

(2) PROBLEMS ASSOCIATED WITH LONG-TERM ILLNESS

Certain chronic diseases are more frequent among the older people than in the younger people. These are : (a) DEGENERATIVE DISEASES OF HEART AND BLOOD VESSELS : Of particular importance after the age of 40, are the degenerative diseases of the heart and blood vessels. The inner walls of arteries break down, and a lipoid material is deposited. This in time is replaced by calcium which leads to narrowing of blood vessels or atherosclerosis. This leads to diminished blood supply, thrombus formation, rupture of blood vessels and high blood pressure. No single factor has been identified as the cause of atherosclerosis. Diet, heredity, overweight, nervous and emotional strain have all been implicated. Cardiovascular diseases are the major causes of death in the developed countries. A reduction of body weight and modification of the habits of life are needed to decrease the strain on heart and blood vessels. By these, it is possible to lead a longer and more useful life. (b) CANCER : The danger of cancer looms large past middle life. In the developed countries, cancer is a leading cause of death. The incidence of cancer rises rapidly after the age of 40. Cancer of the prostate is common after the age of 65. (c) ACCIDENTS : Accidents are a health problem in the elderly. The bones become fragile due to a certain amount of decalcification as a result of which they break easily. Accidents are more common in the home than outside. Fracture neck of femur is a very common geriatric problem. (d) DIABETES : Diabetes is a long-term illness due to faulty carbohydrate metabolism. It is a leading cause of death as the population grows older. About 75 per cent of the diabetics are over 50 years of age. (e) DISEASES OF LOCOMOTOR SYSTEM : A wide range of articular and non-articular disorders affect the aged – fibrositis, myositis, neuritis, gout, rheumatoid arthritis, osteoarthritis, spondylitis of spine, etc. These conditions cause more discomfort and disability than any other chronic disease in the elderly. (f) RESPIRATORY ILLNESSES : In the upper decades of life, respiratory diseases such as chronic bronchitis, asthma, emphysema are of major importance. (g) GENITOURINARY SYSTEM : Enlargement of the prostate, dysuria, nocturia, frequent and urgency of micturition are the common complaints.

(3) PSYCHOLOGICAL PROBLEMS

(1) MENTAL CHANGES : Impaired memory, rigidity of

outlook and dislike of change are some of the mental changes in the aged. Reduced income leads to a fall in the living standards of the elderly; it does have mental and social consequences. (2) SEXUAL ADJUSTMENT : Between 40 and 50, there is cessation of reproduction by women and diminution of sexual activity on the part of men. During this phase, physical and emotional disturbances may occur. Irritability, jealousy and despondency are very frequent. (3) EMOTIONAL DISORDERS : Emotional disorders result from social maladjustment. The degree of adaptation to the fact of ageing is crucial to a man's happiness in this phase of life. Failure to adapt can result in bitterness, inner withdrawal, depression, weariness of life, and even suicide.

Lifestyle and healthy ageing

People can do a great deal to influence their individual risk of developing many of the diseases of later life by paying careful attention to lifestyle factors. By adopting a healthier lifestyle, the risk of a whole range of diseases can be reduced. These factors are : (a) DIET AND NUTRITION : A good diet reduces the chances of developing the diseases of old age. As countries rapidly develop economically, diets and lifestyles change considerably and overnutrition replaces undernutrition. One of the problem is excessive fat intake. Saturated fats and trans-fatty acids, have been linked to raised cholesterol levels in the blood, leading to increased risk of cardiovascular diseaes. People should eat healthy diet since very early age to avoid or delay diseases. The diet should be balanced with less saturated fats and oils; should contain lots of fruits and vegetables; salt and sugar should be less; include plenty of calcium rich food; eat high fibre diet; (b) EXERCISE : Exercise helps maintain good health, as it helps to control weight, improves emotional well-being and relieves stress, improves blood circulation, increases flexibility, lowers blood pressure, increases energy levels, improves balance and thus reduces the dangers of falls, lowers blood sugar levels thus helps in diabetes, improves bone density and thus helps prevent osteoporosis. (c) WEIGHT : Overweight and obesity have become major problem worldwide and it contributes to many diseases of later life. Obesity is an important factor in heart disease, stroke, hypertension, diabetes, arthritis (especially in the knees), and breast cancer. (d) SMOKING : It is estimated that 22 per cent of men and 18 per cent of women aged 65 to 74 years in developed countries are smokers *(131)*. Though this figure is lower than among younger adults, older people have usually smoked for longer, have been and continue to be heavy smokers, and are likely to have chronic diseases, with smoking causing further deterioration. Former smokers live longer than continuing smokers; smoking cessation at the age of 50 years reduces the risk of dying within the next 15 years by 50 per cent. For some, but not for all former smokers, the risk of developing smoking–related diseases reverts to that of lifelong non-smokers *(131)*. (e) ALCOHOL : Drinking beyond a specified amount contributes to a number of later life diseases. Research suggests that sensitivity to the effect of alcohol increases with age. Older people achieve a higher blood alcohol concentration, than younger people after consuming an equal amount of alcohol. This is largely as a result of the age-related decrease in the amount of body water which dilutes alcohol. While younger people are likely to develop tolerance to increasing amount of alcohol, older people have a decreased ability to develop this tolerance *(131)*. Drinking is linked to liver diseases, stomach ulcers, gout, depression, osteoporosis, heart disease, breast cancer, diabetes and hypertension *(132)*. (f) SOCIAL ACTIVITIES : People who become socially isolated – who rarely go out, do not join in the community activities, have few friends or do not see much of their family – are less healthy. Getting out and keeping involved with others creates a sense of belonging. Mixing with other people of similar age, at similar stage of life or perhaps with similar health concerns, can help people realize that they are not alone. The support gained from others can be important in recovering from illness. Simply knowing that others care, helps *(132)*.

Health status of the aged in India

A few hospital based studies have been made in India on the health status of the aged persons, but such studies provide only a partial view of the spectrum of illness in the aged. The overall data on aged are scarce. The main causes of illness are arthritis, cataract, bronchitis, avitaminosis, ear diseases, hypertension, diabetes, rheumatism, helminthic infestations, accidents, etc. The findings of an ICMR survey conducted in 1984–85 of elderly persons over 60 years of age attending geriatric clinics in rural areas is as shown in Table 31.

TABLE 31

Percentage of elderly reporting various ailments

Ailment	Reported percentage
Visual impairment/complaint	88.0
Locomotive disorder, joints, muscles	40.0
Neurological complaints	18.7
Cardiovascular disease	17.4
Respiratory disorder	16.1
Skin conditions	13.3
Gastro-intestinal/abdominal disorder	9.0
Psychiatric problem	8.5
Hearing loss	8.2
Genitourinary disorder	3.5

Source : *(133)*

The government of India announced a *National Policy on older persons* in January 1999. This policy identifies principal areas of intervention as financial security, health care, nutrition, shelter, education, welfare, protection of life and property of older citizens. The policy provides for a broad framework for collaboration and cooperation, both within as well as between governmental and non-governmental agencies. An important thrust in the policy is on active and productive involvement of older persons, and not just their care. A national council for older persons (NCOP) was constituted to operationalize the policy. An integrated programme for older persons has been formulated by revising the earlier scheme of assistance to voluntary organizations for programmes relating to the welfare of the aged. The objective is to promote a society for all ages, to empower and improve the quality of life of older persons.

The programme for the first time recognizes formation of self-help groups, association of older persons for advancement of their rights and utilization of their

experience and services. 234 Old age homes, 398 day care centres and 40 mobile medical units are operational. Scheme of assistance to Panchayat Raj Institutions / Voluntary Organizations / Self Help Groups, for construction of old age homes has also been revised to encourage Multi Service Centres for older persons.

As a part of National Social Assistance Programme, old age pension is being provided to more than 4 million destitute elderly all over the country. The amount of pension varies from state to state – from Rs 75 per month in Assam to Rs 300 per month in West Bengal and Rajasthan *(131)*. An Old Age Social and Income Security (OASIS) project was launched to comprehensively examine policy questions, connected with Old Age Income Security. Travel related concessions / facilities are provided to the older people by Indian Railways, Indian Airlines and State Transport Corporations. Health care is being provided to the older persons through Bhavishya Arogya Mediclaim, and Rural Group Life Insurance Schemes. Income Tax Concessions are also available to the elderly citizens.

On 19th Nov. 2007, the Indira Gandhi National Old Age Pension Scheme was launched to provide monthly pension to people over 65 years and living below poverty line. The scheme is to cover about 1.57 crore people, the central government is to provide a monthly pension of Rs. 200 to each beneficiary and the state governments are expected to contribute an equal amount.

In India, *HelpAge India* is the largest voluntary organization working for the cause and care of the disadvantaged older people. In the 26 years since its inception, it has made an impact on the lives of nearly 6 million senior citizens, through 3,084 projects. HelpAge India supports the following programmes to make life easier for older people : (a) Free cataract operations; (b) Mobile medicare units; (c) Income generation and micro-credit; (d) Old-age homes and day-care centres; (e) Adopt-a-Gran (grand parent); and (f) Disaster mitigation.

Implication of the ageing population in terms of preventive and social medicine

The ageing population is both a medical and sociological problem. It makes a greater demand on the health services of a community. In rapidly greying world, healthy ageing is vital for countries. It is a prerequisite for economic growth. The predicted explosion of non-communicable diseases like cardiovascular diseases, cancer, and depression in the ever increasing number of older persons globally, will result in enormous human and social costs unless preventive action is taken.

The alteration of the age pyramid, however, poses significant new challenges for governments, societies, and families in the 21st century. Ageing developing countries are slated to face a heavy double burden of infectious and non-communicable diseases, yet they often lack significant resources, including comprehensive ageing policies, to cope. Industrialized countries, on the otherhand, were fortunate enough to become affluent before they became old *(131)*.

The modern philosophy is that the old must continue to take their share in the responsibilities and in the enjoyment of the privileges, which are an essential feature of remaining an active member of the community. The community must assist the aged to fight the triple evils of poverty, loneliness and ill–health.

Potential for disease prevention in the elderly

For older individuals, a great proportion of the disease burden derives from existing conditions, whether this burden is measured by prevalence rates, indicators of morbidity, disability, mortality, or by health and long term care utilization. In addition, older people with disability, resulting from chronic diseases, appear at high risk of acute illness and injuries. The evidence arrayed of the role of existing and often immutable disease argues for the importance of secondary and tertiary prevention, in combination with primary screening or prevention for this population *(134)*.

Among older individuals, categories of conditions, occurrences, and illnesses exist in a variety of combinations, and risk factors as well as disease sequelae often overlap. Examples of conditions potentially amenable to prevention in older persons are outlined in Table 32.

Many factors that contribute to decrements of ageing and the burden of illness are potentially responsive to preventive interventions. In view of this evidence, the design of preventive strategies appropriate to this population becomes crucial for the utility of preventive care, both in reducing risk and maintaining functional independence.

Much care is bestowed upon the old people in Western societies by providing Social Welfare measures such as national assistance, supplementary pensions, home services, home care services, meals on wheels services, old folk's homes, sitters-up service and provision of services of health visitors. By providing these services, the State ensures that the years of retirement of those who have worked hard in its service shall be free from anxiety, want and boredom.

TABLE 32

Areas potentially amenable to preventive health care in the elderly

Primary	Secondary	Tertiary
Health habits –smoking –alcohol abuse –obesity –nutrition –physical activity –sleep	Screening for – hypertension – diabetes – periodontal disease – dental caries – sensory impairment – medication side-effects	Rehabilitation – physical deficits – cognitive deficits – functional deficits Caretaker support
Coronary heart disease risk factors	– colo-rectal cancer breast cancer, cervical cancer prostatic cancer	Introduction of support necessary to prevent loss of autonomy
Immunization –influenza –pneumovax –tetanus	– nutritionally-induced anaemias – depression, stress – urinary incontinence – podiatric problems	
Injury prevention Iatrogenesis prevention	– fall risk – tuberculosis (high-risk)	
Osteoporosis prevention	– syphilis (high-risk) – stroke prevention – myocardial infarction

ANNEXURE A *(135)*

ASSESS AND CLASSIFY THE SICK YOUNG INFANT AGE UPTO 2 MONTHS

The steps to assess and classify a sick young infant during an initial visit are :

- Check for signs of possible bacterial infection. Then classify the young infant based on the clinical signs found.
- Ask about diarrhoea. If the infant has diarrhoea, assess for related signs. Classify the young infant for dehydration. Also classify for persistent diarrhoea and dysentery if present.
- Check for feeding problem or low weight. This may include assessing breast-feeding. Then classify feeding.
- Check the young infant's immunization status.
- Assess any other problems.

If you find a reason that a young infant needs urgent referral, you should continue the assessment.

ASSESS | **CLASSIFY** | **IDENTIFY** | **TREATMENT**

ASK THE MOTHER WHAT THE YOUNG INFANT'S PROBLEMS ARE

- Determine if this is an initial or follow-up visit for this problem.
  - If follow-up visit, use the follow-up instructions on the bottom of this chart.

USE ALL BOXES THAT MATCH INFANT'S SYMPTOMS

A child with a pink classification needs urgent attention, complete the assessment and pre-referral treatment immediately so referral is not delayed.

CHECK FOR POSSIBLE BACTERIAL INFECTION / JAUNDICE

ASK :

- Has the infant had convulsions ?

LOOK, LISTEN, FEEL :

- Count the breaths in one minute. Repeat the count if elevated.
- Look for severe chest indrawing.
- Look for nasal flaring.
- Look and listen for grunting.
- Look and feel for bulging fontanelle.

YOUNG INFANT MUST BE CALM

- Look for pus draining from the ear.
- Look at the umbilicus. Is it red or draining pus ?
- Look for skin pustules. Are there 10 or more skin pustules or a big boil ?
- Measure auxillary temperature (if not possible, feel for fever or low body temperature).
- See if the young infant is lethargic or unconscious.
- Look at the young infant's movements. Are they less than normal ?
- Look for jaundice. Are the palms and soles yellow ?

SIGNS	CLASSIFY AS	IDENTIFY TREATMENT (Urgent pre-referral treatments are in bold print.)
Classify ALL YOUNG INFANTS		
• Convulsions, or • Fast breathing (60 breaths per minute or more), or • Severe chest indrawing, or • Nasal flaring, or • Grunting, or • Bulging fontanelle, or • 10 or more skin pustules or a big boil, or • If axilliary temperature 37.5°C or above (or feels hot to touch) or temperature less than 35.5°C (or feels cold to touch), or • Lethargic or unconscious, or • Less than normal movements.	POSSIBLE SERIOUS BACTERIAL INFECTION	➢ **Give first dose of intramuscular ampicillin and gentamicin.** ➢ **Treat to prevent low blood sugar.** ➢ **Warm the young infant by skin to skin contact, if temperature less than 36.5°C (or feels cold to touch) while arranging referral.** ➢ **Advise mother how to keep the young infant warm on the way to the hospital.** ➢ **Refer *URGENTLY* to hospital**
• Umbilicus red or draining pus, or • Pus discharge from ear or • <10 skin pustules.	LOCAL BACTERIAL INFECTION	➢ Give oral cotrimoxazole or amoxycillin for 5 days. ➢ Teach mother to treat local infections at home. ➢ Follow-up in 2 days.
If the infant has jaundice		
• Palms and soles yellow, or • Age <24 hours, or • Age 14 days or more	SEVERE JAUNDICE	➢ **Treat to prevent low blood sugar.** ➢ **Warm the young infant by skin to skin contact, if temperature less than 36.5°C (or feels cold to touch) while arranging referral.** ➢ **Advise mother how to keep the young infant warm on the way to the hospital.** ➢ **Refer URGENTLY to hospital.**
• Palms and soles not yellow	JAUNDICE	➢ Advise mother to give home care for the young infant. ➢ Advise mother when to return immediately. ➢ Follow-up in 2 days.
If the temp. is between 35.5-36.4 °C		
• Temperature between 35.5-36.4°C	LOW BODY TEMPE-RATURE	➢ Warm the young infant using skin to skin contact for one hour and RE-ASSESS. ➢ Treat to prevent low blood sugar.

THEN ASK:

Does the young infant have diarrhoea ? *

IF YES ASK :

- For how long ?

LOOK AND FEEL :

- Look at the young infant's general condition. Is the infant :
  - Lethargic or unconscious ?
  - Restless and irritable ?
- Look for sunken eyes.
- Pinch the skin of the abdomen. Does it go back:
  - Very slowly (longer than 2 seconds) ?
  - Slowly ?

Classify DIARRHOEA

If the stools have changed from usual pattern and are many and watery (more water than faecal matter). The normally frequent or loose stools of a breast-fed baby are not diarrhoea.

	SIGNS	CLASSIFY AS	TREATMENT (Urgent pre-referral treatments are in bold print.)
For DEHDYRATION	Two of the following signs : • Lethargic or unconscious. • Sunken eyes. • Skin pinch goes back very slowly.	SEVERE DEHYDRATION	➢ **Give first dose of intramuscular ampicillin and gentamicin.** ➢ **If infant also has low weight or another severe classification.** – **Refer Urgently to hospital with mother giving frequent sips of ORS on the way.** – **Advise mother to continue breast-feeding.** – **Advise mother how to keep the young infant warm on the way to the hospital.** ***OR*** ➢ If infant does not have low weight or any other severe classification. – Give fluid for severe dehydration (Plan C) and then refer to hospital after rehydration.
	Two of the following signs : • Restless, irritable. • Sunken eyes. • Skin pinch goes back slowly.	SOME DEHYDRATION	➢ **If infant also has low weight or another severe classification.** – **Give first dose of intramuscular ampicillin and gentamicin.** – **Refer urgently to hospital with mother giving frequent sips of ORS on the way.** – **Advise mother to continue breast-feeding.** – **Advise mother how to keep the young infant warm on the way to the hospital.** ➢ If infant does not have low weight or another severe classification: – Give fluids for some dehydration (Plan B). – Advise mother when to return immediately. – Follow-up in 2 days.
	• Not enough signs to classify as some or severe dehydration.	NO DEHYDRATION	➢ Give fluids to treat diarrhoea at home (Plan A). ➢ Advise mother when to return immediately. ➢ Follow-up in 5 days if not improving.
If diarrhoea for 14 days or more	• Diarrhoea lasting 14 days or more.	SEVERE PERSISTENT DIARRHOEA	➢ **Give first dose of intramuscular ampicillin and gentamicin if the young infant has low weight, dehydration or another severe classification.** ➢ **Treat to prevent low blood sugar.** ➢ **Advise how to keep infant warm on the way to the hospital.** ➢ **Refer to hospital.**
If blood in stool	• Blood in the stool.	SEVERE DYSENTERY	➢ **Give first dose of intramuscular ampicillin and gentamicin if the young infant has low weight, dehydration or another severe classification.** ➢ **Treat to prevent low blood sugar.** ➢ **Advise how to keep infant warm on the way to the hospital.** ➢ **Refer to hospital.**

THEN CHECK FOR FEEDING PROBLEM & MALNUTRITION :

ASK :

- Is there any difficulty in feeding ?
- Is the infant breastfed ? If yes, how many times in 24 hours ?
- Does the infant usually receive any other foods or drinks ? If yes, how often ?
- What do you use to feed the infant ?

LOOK, FEEL :

- Determine weight for age.

Classify FEEDING

If an infant : Has any difficulty in feeding, or
Is breastfeeding less than 8 times in 24 hours, or
Is taking any other foods or drinks, or
Is low weight for age,
AND
Has no indications to refer urgently to hospital :

ASSESS BREAST-FEEDING :

- Has the infant breastfed in the previous hour ?

If the infant has not fed in the previous hour, ask the mother to put her infant to the breast. Observe the breastfeed for 4 minutes.
(If the infant was fed during the last hour, ask the mother if she can wait and tell you when the infant is willing to feed again.)

- Is the infant able to attach ?

no attachment at all	not well attached	good attachment

TO CHECK ATTACHMENT, LOOK FOR :
- Chin touching breast
- Mouth wide open
- Lower lip turned outward
- More areola visible above than below the mouth.

(All of these signs should be present if the attachment is good)

- Is the infant suckling effectively (that is, slow deep sucks, sometimes pausing) ?

not suckling at all	not suckling effectively	suckling effectively

Clear a blocked nose if it interferes with breastfeeding.

- Look for ulcers or white patches in the mouth (thrush).
- Does the mother have pain while breastfeeding ?

If yes, look and feel for :
- Flat or inverted nipples, or sore nipples
- Engorged breasts or breast abscess.

SIGNS	CLASSIFY AS	TREATMENT (Urgent pre-referral treatments are in bold print.)
• Not able to feed or • No attachment at all or • Not suckling at all or • Very low weight for age.	NOT ABLE TO FEED POSSIBLE SERIOUS BACTERIAL INFECTION OR SEVERE MALNUTRITION	➢ **Give first dose of intramuscular ampicillin and gentamicin.** ➢ **Treat to prevent low blood sugar.** ➢ **Warm the young infant by skin to skin contact if temperature less than 36.5°C (or feels cold to touch) while arranging referral.** ➢ **Advise mother how to keep the young infant warm on the way to the hospital.** ➢ **Refer URGENTLY to hospital.**
• Not well attached to breast or • Not suckling effectively or • Less than 8 breastfeeds in 24 hours or • Receives other foods or drinks or • Thrush (ulcers or white patches in mouth) or • Low weight for age OR • Breast or nipple problems	FEEDING PROBLEM OR LOW WEIGHT	➢ If not well attached or not suckling effectively, teach correct positioning and attachment. ➢ If breastfeeding less than 8 times in 24 hours, advise to increase frequency of feeding. ➢ If receiving other foods or drinks, counsel mother about breastfeeding more, reducing other foods or drinks, and using a cup and spoon. ➢ If not breastfeeding at all, advise mother about giving locally appropriate animal milk and teach the mother to feed with a cup and spoon. ➢ If thrush, teach the mother to treat thrush at home. ➢ If low weight for age, teach the mother how to keep the young infant with low weight warm at home. ➢ If breast or nipple problem, teach the mother to treat breast or nipple problems. ➢ Advise mother to give home care for the young infant. ➢ Advise mother when to return immediately. ➢ Follow-up any feeding problem or thrush in 2 days. ➢ Follow-up low weight for age in 14 days.
• Not low weight for age and no other signs of inadequate feeding.	NO FEEDING PROBLEM	➢ Advise mother to give home care for the young infant. ➢ Advise mother when to return immediately. ➢ Praise the mother for feeding the infant well.

ASSESS AND CLASSIFY THE SICK CHILD AGE 2 MONTHS UP TO 5 YEARS

ASK THE MOTHER WHAT THE CHILD'S PROBLEMS ARE

- Determine if this is an initial or follow-up visit for this problem.
  - If follow-up visit, use the follow-up instructions on *TREAT THE CHILD* chart.
  - if initial visit, assess the child as follows :

CHECK FOR GENERAL DANGER SIGNS

ASK :	*LOOK :*
• Is the child able to drink or breastfeed ? • Does the child vomit everything ? • Has the child had convulsions ?	• See if the child is lethargic or unconscious.

A child with any general danger sign needs urgent attention; complete the assessment and any pre-referral treatment immediately so referral is not delayed.

USE ALL BOXES THAT MATCH THE CHILD'S SYMPTOMS AND PROBLEMS TO CLASSIFY THE ILLNESS.

THEN ASK ABOUT MAIN SYMPTOMS :

Does the child have cough or difficult breathing ?

IF YES ASK :
- For how long ?

LOOK, LISTEN :
- Count the breaths in one minute
- Look for chest indrawing.
- Look and listen for stridor.

CHILD MUST BE CALM

→ Classify COUGH or DIFFICULT BREATHING

If the child is :	Fast breathing is :
2 months up to 12 months	50 breaths per minute or more
12 months up to 5 years	40 breaths per minute or more

SIGNS	CLASSIFY AS	IDENTIFY TREATMENT (Urgent pre-referral treatments are in bold print.)
• Any general danger sign or • Chest indrawing or • Stridor in calm child.	SEVERE PNEUMONIA OR VERY SEVERE DISEASE	➢ **Give first dose of injectable chloramphenicol (If not possible give oral amoxycillin).** ➢ **Refer URGENTLY to hospital.**
• Fast breathing.	PNEUMONIA	➢ **Give Cotrimoxazole for 5 days.** ➢ Soothe the throat and relieve the cough with a safe remedy if child is 6 months or older. ➢ Advise mother when to return immediately. ➢ Follow-up in 2 days.
• No signs of pneumonia or very severe disesase.	NO PNEUMONIA : COUGH OR COLD	➢ If coughing more than 30 days, refer for assessment. ➢ Soothe the throat and relieve the cough with a safe home remedy if child is 6 months or older. ➢ Advise mother when to return immediately. ➢ Follow-up in 5 days if not improving.

Does the child have diarrhoea ?

IF YES ASK :
- For how long ?
- Is there blood in the stool ?

LOOK AND FEEL:
- Look at the child's general condition. Is the child :
  - Lethargic or unconscious ?
  - Restless and irritable ?
- Look for sunken eyes.
- Offer the child fluid. Is the child :
  - Not able to drink or drinking poorly ?
  - Drinking eagerly, thirsty ?
- Pinch the skin of the abdomen. Does it go back:
  - Very slowly (longer than 2 seconds) ?
  - Slowly ?

Classify DIARRHOEA

	SIGNS	CLASSIFY AS	TREATMENT (Urgent pre-referral treatments are in bold print.)
For DEHYDRATION	Two of the following signs : • Lethargic or unconscious. • Sunken eyes. • Not able to drink or drinking poorly. • Skin pinch goes back very slowly.	SEVERE DEHYDRATION	➢ If child has no other severe classification : – Give fluid for severe dehydration (Plan C). ➢ **If child also has another severe classification : Refer URGENTLY to hospital. With mother giving frequent sips of ORS on the way. Advise the mother to continue breastfeeding.** ➢ **If child is 2 years or older and there is cholera in your area, give doxycycline for cholera.**
	Two of the following signs : • Restless, irritable. • Sunken eyes. • Drinks eagerly, thirsty. • Skin pinch goes back	SOME DEHYDRATION	➢ Give fluid and food for some dehydration (Plan B). ➢ **If child also has a severe classification : Refer URGENTLY to hospital with mother giving frequent sips of ORS on the way. Advise the mother to continue breastfeeding.** ➢ Advise mother when to return immediately. ➢ Follow-up in 5 days if not improving.
	Not enough signs to classify as some or severe dehydration.	NO DEHYDRATION	➢ Give fluid and food to treat diarrhoea at home (Plan A). ➢ Advise mother when to return immediately. ➢ Follow-up in 5 days if not improving.
If diarrhoea 14 days or more	• Dehydration present.	SEVERE PERSISTENT DEHYDRATION	➢ **Treat dehydration before referral unless the child has another severe classification.** ➢ **Refer to hospital.**
	• No Dehydration.	PERSISTENT DEHYDRATION	➢ Advise the mother on feeding a child who has persistent diarrhoea. ➢ Give single dose of vitamin A. ➢ Give zinc sulphate 20 mg daily for 14 days. ➢ Follow-up in 5 days.
If blood in stool	• Blood in the stool.	DYSENTERY	➢ **Treat for 5 days with cotrimoxazole.** ➢ Follow-up in 2 days.

Does the child have fever ?
(by history or feels hot or temperature 37.5°C* or above)

IF YES:
- Decide Malaria Risk : High/Low

THEN ASK:
- Fever for how long ?
- If more than 7 days, has fever been present every day ?
- Has the child had measles within the last 3 months ?

If the child has measles now or within the last 3 months :

LOOK AND FEEL :
- Look or feel for stiff neck.
- Look and feel for bulging fontanelle.
- Look for runny nose.

Look for signs of Measles
- Generalized rash and
- One of these : cough, runny nose, or red eyes.
- Look for mouth ulcers. Are they deep and extensive ?
- Look for pus draining from the eye.
- Look for clouding of the cornea.

Classify FEVER

High Malaria Risk

Low Malaria Risk

If MEASLES Now or within last 3 months, Classify

SIGNS	CLASSIFY AS	TREATMENT (Urgent pre-referral treatments are in bold print.)
HIGH MALARIA RISK		
• Any general danger sign or • Stiff neck or • Bulging fontanelle.	VERY SEVERE FEBRILE DISEASE	➢ **Give first dose of IM quinine after making a blood smear.** ➢ **Give first dose of IV or IM chloramphenicol (if not possible, give oral amoxycillin).** ➢ **Treat the child to prevent low blood sugar.** ➢ **Give one dose of paracetamol in clinic for high fever (temp. 38.5°C or above).** ➢ **Refer URGENTLY to hospital.**
• Fever (by history or feels hot or temperature 37.5°C or above).	MALARIA	➢ **Give oral antimalarials for HIGH malaria risk area after making a blood smear.** ➢ **Give one dose of paracetamol in clinic for high fever (temp. 38.5°C or above).** ➢ Advise mother when to return immediately. ➢ Follow-up in 2 days if fever persists. ➢ If fever is present every day for more than 7 days, refer for assessment.
LOW MALARIA RISK		
• Any general danger sign or • Stiff neck or • Bulging fontanelle.	VERY SEVERE FEBRILE DISEASE	➢ **Give first dose of IM quinine after making a blood smear.** ➢ **Give first dose of IV or IM chloramphenicol (if not possible, give oral amoxycillin).** ➢ **Treat the child to prevent low blood sugar.** ➢ **Give one dose of paracetamol in clinic for high fever (temp. 38.5°C or above).** ➢ **Refer URGENTLY to hospital.**
• No runny nose and No measles and No other cause of fever.	MALARIA	➢ **Give oral antimalarials for LOW malaria risk area, after making a blood smear.** ➢ **Give one dose of paracetamol in clinic for high fever (temp. 38.5°C or above).** ➢ Advise mother when to return immediately. ➢ Follow-up in 2 days if fever persists. ➢ If fever is present every day for more than 7 days, refer for assessment.
• Runny nose Present or • Other cause of fever Present **	FEVER MALARIA UNLIKELY	➢ **Give one dose of paracetamol in clinic for high fever (temp. 38.5°C or above).** ➢ Advise mother when to return immediately. ➢ Follow-up in 2 days if fever persists. ➢ If fever is present every day for more than 7 days, refer for assessment.
• Any general danger sign or • Clouding of cornea or • Deep or extensive mouth ulcers.	SEVERE COMPLICATED MEASLES#	➢ **Give first dose of Vitamin A.** ➢ **Give first dose of injectable chloramphenicol (if not possible give oral amoxycillin).** ➢ **If clouding of the cornea or pus draining from the eye, apply tetracycline eye ointment.** ➢ **Refer URGENTLY to hospital.**
• Pus draining from the eye or • Mouth ulcers.	MEASLES WITH EYE OR MOUTH COMPLI-CATIONS	➢ **Give first dose of Vitamin A.** ➢ **If pus draining from the eye, treat eye infection with tetracycline eye ointment.** ➢ If mouth ulcers, treat with gentian violet. ➢ Follow-up in 2 days.
• Measles now or within the last 3 months.	MEASLES	➢ **Give first dose of Vitamin A.**

* This cut-off is for auxillary temperatures; rectal temperature cut-off is approximately 0.5°C higher.
** Other causes of fever include cough or cold, pneumonia, diarrhoea, dysentery and skin infections.

Other important complications of measles - pneumonia, stridor, diarrhoea, ear infection, and malnutrition - are classified in other tables.

Does the child have an ear problem ?

IF YES, ASK :
- Is there ear pain ?
- Is there ear discharge ? If yes, for how long ?

LOOK, FEEL :
- Look for pus draining from the ear.
- Feel for tender swelling behind the ear.

Classify EAR PROBLEM

SIGNS	CLASSIFY AS	TREATMENT (Urgent pre-referral treatments are in bold print.)
• Tender swelling behind the ear.	MASTOIDITIS	➢ **Give first dose of injectable chloramphenicol (If not possible give oral amoxycillin).** ➢ **Give first dose of paracetamol for pain.** ➢ **Refer URGENTLY to hospital.**
• Pus is seen draining from the ear and discharge is reported for less than 14 days, or • Ear pain.	ACUTE EAR INFECTION	➢ Give cotrimoxazole for 5 days. ➢ Give paracetamol for pain. ➢ Dry the ear by wicking. ➢ Follow-up in 5 days.
• Pus is seen draining from the ear and discharge is reported for 14 days or more.	CHRONIC EAR INFECTION	➢ Dry the ear by wicking. ➢ Follow-up in 5 days.
• No ear pain, and • No pus seen draining from the ear.	NO EAR INFECTION	No additional treatment.

THEN CHECK FOR MALNUTRITION

LOOK AND FEEL :

- Look for visible severe wasting.
- Look for oedema of both feet.
- Determine weight for age.

Classify NUTRITIONAL STATUS

SIGNS	CLASSIFY AS	TREATMENT (Urgent pre-referral treatments are in bold print.)
• Visible severe wasting or • Oedema of both feet.	SEVERE MALNUTRITION	➢ **Give single dose of Vitamin A.** ➢ **Prevent low blood sugar.** ➢ **Refer URGENTLY to hospital.** ➢ **While referral is being organized, warm the child.** ➢ **Keep the child warm on the way to hospital.**
• Very low weight for age.	VERY LOW WEIGHT	➢ Assess and counsel for feeding. ➢ Advise mother when to return immediately. ➢ Follow-up in 30 days.
• Not very low weight for age and no other signs of malnutrition.	NOT VERY LOW WEIGHT	➢ If child is less than 2 years old, assess the child's feeding and counsel the mother on feeding. – If feeding problem, follow-up in 5 days. ➢ Advise mother when to return immediately.

THEN CHECK FOR ANAEMIA

LOOK:

- Look for palmar pallor. Is it :
  - Severe palmar pallor ?
  - Some palmar pallor ?

Classify ANAEMIA

• Severe palmar pallor	SEVERE ANAEMIA	➢ **Refer URGENTLY to hospital.**
• Some palmar pallor	ANAEMIA	➢ **Give iron folic acid therapy for 14 days.** ➢ Assess the child's feeding and counsel the mother on feeding. – If feeding problem, follow-up in 5 days. ➢ Advise mother when to return immediately. ➢ Follow-up in 14 days.
• No palmar pallor	NO ANAEMIA	➢ **Give prophylactic iron folic acid if child 6 months or older.**

THEN CHECK THE CHILD'S IMMUNIZATION,* PROPHYLACTIC VITAMIN A & IRON-FOLIC ACID SUPPLEMENTATION STATUS

IMMUNIZATION SCHEDULE :

AGE	VACCINE
Birth	BCG + OPV-0
6 weeks	DPT-1 + OPV-1 (+ Hep B-1**)
10 weeks	DPT-2 + OPV-2 (+ HepB-2**)
14 weeks	DPT-3 + OPV-3 (+ HepB-3**)
9 months	Measles + Vitamin A
16-18 months	DPT Booster + OPV + Vitamin A
60 months	DT

PROPHYLACTIC VITAMIN A

Give a single dose of vitamin A :
100,000 IU at 9 months with measles immunization
200,000 IU at 16-18 months with DPT Booster
200,000 IU at 24 months
200,000 IU at 30 months
200,000 IU at 36 months

PROPHYLACTIC IFA

Give 20 mg elemental iron + 100 mcg folic acid (one tablet of Paediatric IFA or 5 ml of IFA syrup or 1 ml of IFA drops) for a total of 100 days in a year after the child has recovered from acute illness if :

- ➢ The child 6 months of age or older, and
- ➢ Has not received Paediatric IFA tablet syrup/drops for 100 days in last one year.

* A child who needs to be immunized should be advised to go for immunization the day vaccines are available at AW/SC/PHC
** Hepatitis B to be given wherever included in the immunization schedule.

ASSESS OTHER PROBLEMS

MAKE SURE CHILD WITH ANY GENERAL DANGER SIGN IS REFERRED after first dose of an appropriate antibiotic and other urgent treatments.
Exception : Rehydration of the child according to Plan C may resolve danger signs so that referral is no longer needed.

Treatment in the out-patient health facility of the sick child from age 2 months upto 5 years

NO DEHYDRATION

WHO Treatment Plan A

Plan A focuses on the three rules of home treatment: give extra fluids, continue feeding, and advise the caretaker when to return to the doctor (if the child develops blood in the stool, drinks poorly, becomes sicker, or is not better in three days).

Fluids should be given as soon as diarrhoea starts; the child should take as much as s/he wants. Correct home therapy can prevent dehydration in many cases. ORS may be used at home to prevent dehydration. However, other fluids that are commonly available in the home may be less costly, more convenient and almost as effective. Most fluids that a child normally takes can also be used for home therapy especially when given with food.

Recommended home fluid should be :

- Safe when given in large volumes. Very sweet tea, soft drinks, and sweetened fruit drinks should be avoided. These are often hyperosmolar owing to their high sugar content (less than 300 mOsm/L). They can cause osmotic diarrhoea, worsening dehydration and hypernatraemia. Also to be avoided are fluids with purgative action and stimulants (e.g., coffee, some medicinal teas or infusions).
- Easy to prepare. The recipe should be familiar and its preparation should not require much effort or time. The required ingredients and measuring utensils should be readily available and inexpensive.
- Acceptable. The fluid should be one that the mother is willing to give freely to a child with diarrhoea and that the child will readily accept.
- Effective. Fluids that are safe are also effective. Most effective are fluids that contain carbohydrates and protein and some salt. However, nearly the same result is obtained when fluids are given freely along with weaning foods that contain salt.

SOME DEHYDRATION

WHO Treatment Plan B

Give initial treatment with ORS over a period of four hours. The approximate amount of ORS required (in ml) can be calculated by multiplying the child's weight (in kg) times 75; during these four hours, the mother slowly gives the recommended amount of ORS by spoonfuls or sips.

Note : If the child is breastfed, breast-feeding should continue.

After four hours, the child is re-assessed and re-classified for dehydration, and feeding should begin; resuming feeding early is important to provide required amounts of potassium and glucose. When there are no signs of dehydration, the child is put on Plan A. If there is still some dehydration, Plan B should be repeated. If the child now has severe dehydration, the child should be put on Plan C.

SEVERE DEHYDRATION

Plan C – Treat Severe Dehydration Quickly

If you can give intravenous (IV) treatment and you have acceptable solutions such as Ringer's Lactate or Normal Saline at the clinic, give the solution intravenously to the severely dehydrated child.

The sections of Plan C below describe the steps to rehydrate a child intravenously. It includes the amounts of IV fluid that should be given according to the age and weight of the child.

- Start IV fluid immediately. If the child can drink, give ORS by mouth while the drip is set up. Give 100 ml/kg Ringer's Lactate Solution (or, if not available, normal saline), divided as follows :

Age	First give 30 ml/kg in :	Then give 70 ml/kg in :
Infants (under 12 months)	1 hour *	5 hours
Children (12 months upto 5 years)	30 minutes *	2½ hours

** Repeat once if radial pulse is still very weak or not detectable.*

- Re-assess the child every 1–2 hours. If hydration status is not improving, give the IV drip more rapidly.
- Also give ORS (about 5 ml/kg/hour) as soon as the child can drink : usually after 3–4 hours (infants) or 1–2 hours (children).
- Re-assess an infant after 6 hours and a child after 3 hours. Classify dehydration. Then choose the appropriate plan (A, B or C) to continue treatment.

Note :

- If possible, observe the child at least 6 hours after rehydration to be sure the mother can maintain hydration giving the child ORS solution by mouth.

10 Nutrition and Health

"What people eat is not calories but food, and consideration of fads, flavours and variations of appetite can make nonsense of the dietician's theories"

Nutrition may be defined as the science of food and its relationship to health. It is concerned primarily with the part played by nutrients in body growth, development and maintenance *(1)*. The word *Nutrient* or "food factor" is used for specific dietary constituents such as proteins, vitamins and minerals. *Dietetics* is the practical application of the principles of nutrition; it includes the planning of meals for the well and the sick. Good nutrition means "maintaining a nutritional status that enables us to grow well and enjoy good health" *(2)*. The subject of nutrition is very extensive. Since our concern is with community aspects of nutrition, the subject will be dealt with in five sections : dietary constituents, nutritional requirements, assessment of nutritional status, nutritional problems in public health and nutritional programmes in India.

Changing concepts

Through centuries, food has been recognized as important for human beings, in health and disease. The history of man to a large extent has been a struggle to obtain food. Until the turn of the nineteenth century the science of nutrition had a limited range. Protein, carbohydrate and fat had been recognized early in the 19th century as energy-yielding foods and much attention was paid to their metabolism and contribution to energy requirements *(3)*. The discovery of vitamins "rediscovered" the science of nutrition. Between the two World Wars, research on protein gained momentum. By about 1950, all the presently known vitamins and essential amino acids had been discovered. Nutrition gained recognition as a scientific discipline, with roots in physiology and biochemistry. In fact nutrition was regarded as a branch of physiology and taught as such to medical students.

Great advances have been made during the past 50 years in knowledge of nutrition and in the practical application of that knowledge. Specific nutritional diseases were identified and technologies developed to control them, as for example, protein energy malnutrition, endemic goitre, nutritional anaemia, nutritional blindness and diarrhoeal diseases.

While attention was concentrated on nutritional deficiency diseases during the first decades of the century, the science of nutrition was extending its influence into other fields – agriculture, animal husbandry, economics and sociology. This led to "green revolution" and "white revolution" in India and increased food production. However, studies of the diets and state of nutrition of people in India showed that poorer sections of the population continued to suffer from malnutrition despite increased food production. One result was that for the first time the problem of nutrition began to attract international attention *(3)* as a cause of social problems. International activities in the field of nutrition initiated by the League of Nations, later continued by FAO, WHO and UNICEF form a striking part of the story.

Significant advances have been made during the past two decades. The association of nutrition with infection, immunity, fertility, maternal and child health and family health have engaged scientific attention. More recently, a great deal of interest has been focussed on the role of dietary factors in the pathogenesis of non-communicable diseases such as coronary heart disease, diabetes and cancer.

It has been said that most nutrition scientists are far more familiar with rats than with humans. Of greater significance during recent years is that the science of nutrition has moved out of the laboratory and linked itself to epidemiology. This association has given birth to newer concepts in nutrition such as epidemiological assessment of nutritional status of communities, nutritional and dietary surveys, nutritional surveillance, nutritional and growth monitoring, nutritional rehabilitation, nutritional indicators and nutritional interventions – all parts of what is broadly known as **nutritional epidemiology.** Epidemiological methods are now increasingly used not only in the elucidation of disease aetiology and identification of risk factors of disease, but also in the planning and evaluation of nutritional programmes. With these newer concepts and newer approaches, nutritional science has become more dynamic.

Another concept that has emerged in recent years is that nutrition is the cornerstone of socio-economic development, and that nutritional problems are not just medical problems but are "multifactorial" with roots in many other sectors of development such as education, demography, agriculture and rural development. It has become apparent that lasting improvement in the health and nutritional status of people can be brought about only through a successful attack on the basic problems of poverty and injustice. The old concept that the health sector alone is responsible for all nutritional ills of the community has faded away. It is now realized that a broad intersectoral and integrated approach of sectors of development is needed to tackle today's nutritional problems.

In the global campaign of Health for All, promotion of proper nutrition is one of the eight elements of primary health care *(4)*. Nutritional indicators *(5)* have been developed to monitor "Health for All". Greater emphasis is now placed on integrating nutrition into primary health care systems whenever possible, and formulation of **national dietary goals** to promote health and nutritional status of families and communities.

CLASSIFICATION OF FOODS

There are many ways of classifying foods

1. *Classification by origin*
   1) Foods of animal origin
   2) Foods of vegetable origin.
2. *Classification by chemical composition*
   1) Proteins 2) Fats
   3) Carbohydrates 4) Vitamins
   5) Minerals.
3. *Classification by predominant function*
   1) *Body-building foods,* e.g., milk, meat, poultry, fish, eggs, pulses, groundnuts, etc.
   2) *Energy-giving foods*, e.g., cereals, sugars, roots and tubers, fats and oils.
   3) *Protective foods,* e.g., vegetables, fruits, milk.
4. *Classification by nutritive value*
   1) Cereals and millets
   2) Pulses (legumes)
   3) Vegetables
   4) Nuts and oilseeds
   5) Fruits
   6) Animal foods
   7) Fats and oils
   8) Sugar and jaggery
   9) Condiments and spices
   10) Miscellaneous foods.

NUTRIENTS

Nutrients are organic and inorganic complexes contained in food. There are about 50 different nutrients which are normally supplied through the foods we eat. Each nutrient has specific functions in the body. Most natural foods contain more than one nutrient. These may be divided into :

(i) Macronutrients : These are proteins, fats and carbohydrates which are often called "proximate principles" because they form the main bulk of food. In the Indian dietary, they contribute to the total energy intake in the following proportions.

Proteins	....	7 to 15 per cent
Fats	....	10 to 30 per cent
Carbohydrates	....	65 to 80 per cent

(ii) Micronutrients : These are vitamins and minerals. They are called micronutrients because they are required in small amounts which may vary from a fraction of a milligram to several grams. A short review of basic facts about these nutrients is given below.

PROTEINS

The word "protein" by derivation means that which is of first importance. Indeed they are of the greatest importance in human nutrition. Proteins are complex organic nitrogenous compounds. They are composed of carbon, hydrogen, oxygen, nitrogen and sulphur in varying amounts. Some proteins also contain phosphorus and iron and occasionally other elements. Proteins differ from carbohydrates and fats in that they contain nitrogen, this usually amounts to about 16 per cent. Proteins constitute about 20 per cent of the body weight in an adult.

Essential amino acids

Proteins are made up of smaller units, called amino acids. Some 20 amino acids are stated to be needed by the human body, of which 9 are called "essential" because the body cannot synthesize them in amounts corresponding to its needs, and therefore, they must be obtained from dietary proteins. They are : leucine, isoleucine, lysine, methionine, phenylalanine, threonine, valine, tryptophan and histidine. Evidence is now accumulating that histidine is essential even for adults *(6)*. Non-essential amino acids include arginine, asparaginic acid, serine, glutamic acid, proline and glycine. Both essential and non-essential amino acids are needed for synthesis of tissue proteins, the former must be supplied through diet, whereas the latter can be synthesized by the body provided other building blocks are present.

Some of the essential amino acids have important biological functions, e.g., formation of niacin from tryptophan; the action of methionine as a donor of methyl groups for the synthesis of choline, folates and nucleic acids. There is evidence that cystine and tyrosine are essential for premature babies *(7)*. New tissues cannot be formed unless all the essential amino acids (EAA) are present in the diet.

A protein is said to be "biologically complete" if it contains all the EAA in amounts corresponding to human needs. When one or more of the EAA are lacking, the protein is said to be "biologically incomplete". The quality of dietary protein is closely related to its pattern of amino acids. From the nutritional standpoint, animal proteins are rated superior to vegetable proteins because they are "biologically complete". For example milk and egg proteins have a pattern of amino acids considered most suitable for humans.

Functions

Proteins are needed by the body for (a) body building, – this component is small compared with the maintenance component, except in the very young child and infant; (b) repair and maintenance of body tissues; (c) maintenance of osmotic pressure; and (d) synthesis of certain substances like antibodies, plasma proteins, haemoglobin, enzymes, hormones and coagulation factors. Proteins are connected with the immune mechanism of the body. The cell mediated immune response and the bactericidal activity of leucocyte have been found to be lowered in severe forms of protein energy malnutrition. Proteins can also supply energy (4 kcal per one gram) when the calorie intake is inadequate, but this is not their primary function. It is considered wasteful if proteins were used for such a purpose.

Sources

Humans obtain protein from two main dietary sources; *(a) ANIMAL SOURCES* : Proteins of animal origin are found in milk, meat, eggs, cheese, fish and fowl. These proteins contain all the essential amino acids (EAA) in adequate amounts. Egg proteins are considered to be the best among food proteins because of their high biological value and digestibility. They are used in nutrition studies as a "reference protein". *(b) VEGETABLE SOURCES* : Vegetable proteins are found in pulses (legumes), cereals, beans, nuts, oil-seed cakes, etc. They are poor in EAA. In developing countries such as India, cereals and pulses are the main sources of dietary protein because they are cheap, easily available and consumed in bulk. Protein content of some foods are as given in Table 1.

TABLE 1
Protein contents of some foods

Food	Protein (g. per 100 g. of food)
Antimal foods :	
Milk	3.2-4.3
Meat	18.0-26.0
Egg	13.0
Fish	15.0-23.0
Plant foods :	
Cereals	6.0-13.0
Pulses	21.0-28.0
Vegetables	1-4
Fruits	1-3
Nuts	4.5-29.0
Soyabean	43.2
Others :	
Oils and fats	nil
Sugar and jaggery	nil

Supplementary action of proteins

Man derives protein not from a single source, but from a variety of food sources, animal and vegetable. Cereal proteins are deficient in lysine and threonine; and pulse proteins in methionine. These are known as "limiting" amino acids. When two or more of vegetarian foods are eaten together (as for example, rice–dhal combination in India) their proteins supplement one another and provide a protein comparable to animal protein in respect of EAA. Thus with proper planning, it is possible for a vegetarian to obtain a high grade protein, at low cost, from mixed diets of cereals, pulses and vegetables. This is known as supplementary action of proteins, and is the basis of counselling people to eat mixed diets.

Protein metabolism

There are three features of protein metabolism : (a) since proteins are not stored in the human body in the way that energy is stored in adipose tissue, they have to be replaced every day; (b) the body proteins are constantly being broken down into their constituent amino acids and then reused for protein synthesis. The rates of turnover vary from tissue to tissue. The reutilization of amino acids is a major contributory factor to the economy of protein metabolism *(6)*. The overall rate of turnover in adult man is equivalent to replacement between 1–2 per cent of body protein each day *(7)*; (c) it is not only the amount of protein that is maintained constant, but also the pattern of specific protein in body. For maximum utilization of dietary proteins, the calorie intake should be adequate.

Evaluation of proteins

A knowledge of the amino acid content of protein is not sufficient for the evaluation of protein quality. Information is also required about the digestibility and suitability to meet the protein needs of the body. The parameters used for such an evaluation include the estimation of the biological value, digestibility coefficient, protein efficiency ratio and net protein utilization *(8)*. The net protein utilization (NPU) is considered of more practical value because it is the product of biological value and digestibility coefficient divided by 100. In exact terms, it is the "proportion of ingested protein that is retained in the body under specified conditions for the maintenance and/or growth of the tissues". In other words, growth is an important yardstick for ascertaining the essentiality of a nutrient.

Assessment of protein nutrition status

A battery of tests have been suggested to assess the state of protein nutrition. These include : arm muscle circumference, the creatinine – height index, serum albumin and transferrin, total body nitrogen, etc.

At the present time the best measure of the state of protein nutrition is probably serum albumin concentration. It should be more than 3.5 g/dl, a level of 3.5 g/dl is considered mild degree of malnutrition; a level of 3.0 g/dl severe malnutrition. Serum albumin and transferrin assess the ability of the liver to synthesize proteins.

Protein requirements

It is customary to express protein requirements in terms of body weight. The Indian Council of Medical Research in 2010 *(9)* recommended 1.0 g protein/kg body weight for an Indian adult, assuming a NPU of 65 for the dietary proteins. Daily allowances recommended by the ICMR for various population groups are as given in Table 27.

FATS

Fats are solid at 20 deg. C; they are called "oils" if they are liquid at that temperature. Fats and oils are concentrated sources of energy. They are classified as :

(a) *Simple lipids,* e.g., triglycerides
(b) *Compound lipids,* e.g., phospholipids
(c) *Derived lipids,* e.g., cholesterol

The human body can synthesize triglycerides and cholesterol endogenously. Most of the body fat (99 per cent) in the adipose tissue is in the form of triglycerides. In normal human subjects, adipose tissue constitutes between 10 to 15 per cent of body weight. The accumulation of one kilogram of adipose tissue corresponds to 7,700 kcal of energy *(10)*.

Fatty acids

Fats yield fatty acids and glycerol on hydrolysis. Fatty acids are divided into **saturated** fatty acids such as lauric, palmitic and stearic acids, and **unsaturated** fatty acids which are further divided into monounsaturated (MUFA) (e.g., oleic acid) and poly-unsaturated fatty acids (PUFA) (e.g., linoleic acid and α–linolenic acid). Table 2 shows the fatty acid content of different fats.

The poly-unsaturated fatty acids are mostly found in vegetable oils, and the saturated fatty acids mainly in animal fats. However, there are exceptions, as for example, coconut and palm oils, although vegetable oils, have an extremely high percentage of saturated fatty acids. On the other hand, fish oils, although they are not vegetable oils, contain poly and mono-unsaturated fatty acids.

Essential fatty acids

Essential fatty acids are those that cannot be synthesized by humans. They can be derived only from food. The most important essential fatty acid (EFA) is ***linoleic acid,*** which serves as a basis for the production of other essential fatty acids (e.g., linolenic and arachidonic acids). Not all polyunsaturated fatty acids are essential fatty acids.

TABLE 2

Approximate fatty acid composition of dietary fats and oils consumed in India (% of total fatty acids)

Fats/oils	SFAs	MUFAs	LA	ALA
High (medium chain) SFAs				
Coconut	92	6	2	–
Palm kernel	83	15	2	–
Butter/Ghee	68	29	2	1
High SFAs & MUFAs				
Palmolein	39	46	11	<0.5
High MUFAs & Moderate LA				
Groundnut	19	41	32	<0.5
Rice bran	17	43	38	1
Sesame	16	41	42	<0.5
High LA				
Cottonseed	24	29	48	1
Corn	12	35	50	1
Safflower	9	13	75	–
Sunflower	12	22	62	–
LA & ALA				
Soyabean	14	24	53	7
Canola	6	60	22	10
Mustard/rapeseed	4	65	15	14
Flax-seed	10	21	16	53
High TFAs				
Vanaspati	46	49	4	–

SFA – Saturated fatty acids; MUFA – Mono-unsaturated fatty acids; LA – Linoleic acid; ALA – alpha-linolenic acid; TFA – trans-fatty acids.

Source : *(9)*

Linoleic acid is abundantly found in vegetable oils. The dietary sources of EFA are as shown in Table 3.

TABLE 3

Dietary sources of EFA

Essential fatty acids	Dietary source	Per cent content
Linoleic acid	Safflower oil	73
	Corn oil	57
	Sunflower oil	56
	Soyabean oil	51
	Sesame oil	40
	Groundnut oil	39
	Mustard oil	15
	Palm oil	9
	Coconut oil	2
Arachidonic acid	Meat, eggs	0.5–0.3
	Milk (fat)	0.4–0.6
Linolenic acid	Soyabean oil	7
	Leafy greens	Varied
Eichosapentaenoic acid	Fish oil	10

Source : *(11)*

Sources

The dietary sources of fats may be classified as :

(a) ANIMAL FATS : The major sources of animal fats are ghee, butter, milk, cheese, eggs, and fat of meat and fish. Animal fats with few exceptions like cod liver oil and sardine oil are mostly saturated fats.

(b) VEGETABLE FATS : Some plants store fat in their seeds, e.g., groundnut, mustard, sesame, coconut, etc. They are sources of vegetable oils.

(c) OTHER SOURCES : Small quantities of fat (invisible fat) are found in most other foods such as cereals, pulses, nuts and vegetables. For example, rice carries 3 per cent of fat, wheat 3 per cent, jowar 4 per cent and bajra 6.5 per cent. Large cereal consumption, as in India, provides considerable amounts of "invisible fat". Moreover, the body can convert carbohydrate into fat.

Visible and invisible fats

"Visible" fats are those that are separated from their natural source, e.g., ghee (butter) from milk, cooking oils from oil–bearing seeds and nuts. It is easy to estimate their intake in the daily diet. "Invisible" fats are those which are not visible to the naked eye. They are present in almost every article of food, e.g., cereals, pulses, nuts, milk, eggs, etc. It is difficult to estimate their intake. In fact, the major contribution to total fat intake is from invisible sources rather than visible sources as cereals and pulses constitute the bulk of Indian diet.

Edible plant foods have a low content of fat and saturated fatty acids but they are good source of mono-unsaturated fatty acids and poly-unsaturated fatty acids. In most cereals, millets, pulses and legumes, fat content ranges between 1.5 to 3 per cent. In cereals, millets and most oil seeds, linoleic acid is the major fatty acid whereas pulses, legumes, green leafy vegetables and some oil seeds (e.g. soyabean, rapeseed/mustard and flaxseed) and fenugreek are good sources of both linoleic acid and alpha-linolenic acid. Animal foods like butter, ghee, whole milk cream, fatty cheese and fatty meats provide cholesterol and high amount of saturated fatty acids, and are natural source of trans-fatty acids. Lean meats have a fairly high content of long chain poly-unsaturated fatty acids (PUFA). Poultry meat contains less fat and cholesterol and have high amount of PUFA including long chain PUFA. Egg has high cholesterol but are good source of linoleic acid, alpha-linolenic acid and docosahexaenoic acid (DHA). Fish has less fat, saturated fatty acids and cholesterol but are good source of PUFAs. The total quantity of invisible fat and its fatty acid composition depends on the kind of diet consumed *(9)*.

Vegetable oil used in cooking is the major type of visible fat consumed; vanaspati and ghee are the other sources. India has a wide range of edible vegetable oils (groundnut, rapeseed/mustard, soyabean, sunflower, sesame, safflower, ricebran, cottonseed and linseed). In India, the type of vegetable oil consumed varies from one part of the country to the other. Vanaspati (PHVO) promoted as vegetable ghee is used as a substitute for ghee and is used in preparing commercially fried, processed, ready to eat, packaged, frozen, pre-mixed foods and street foods. In recent years, there is change in choice of cooking oils in the urban population. The daily intake of visible fat in rural India is about the same as reported about 25 years back *(9)*.

Functions

Fats have always been equated with calories. They are high energy foods, providing as much as 9 kcal for every gram. By supplying energy, fats spare proteins from being used for energy. Besides providing energy, fats serve as

vehicles for fat-soluble vitamins. Fats in the body support viscera such as heart, kidney and intestine; and fat beneath the skin provides insulation against cold. Without fat, food is limited in palatability.

It is only recently that the "non-calorie" roles of fats have been discovered. For example vegetable fats are rich sources of essential fatty acids which are needed by the body for growth, for structural integrity of the cell membrane and decreased platelet adhesiveness. Diets rich in EFA have been reported to reduce serum cholesterol and low–density lipoproteins *(12)*. Poly-unsaturated fatty acids are precursors of prostaglandin – a group of compounds, now recognized as "local hormones"; they play a major role in controlling many of the physiological functions of the body such as vascular haemostasis, kidney function, acid secretion in stomach, gastro-intestinal motility, lung physiology and reproduction. Cholesterol is essential as a component of membranes and nervous tissue and is a precursor for the synthesis of steroid hormones and bile acids. Thus fats and oils are useful to the body in several ways.

Hydrogenation

When vegetable oils are hydrogenated under conditions of optimum temperature and pressure in the presence of a catalyst, the liquid oils are converted into semi-solid and solid fat. The resulting hydrogenated fat is known as "vanaspati" or vegetable ghee, which is a popular cooking medium in India.

During the process of hydrogenation, unsaturated fatty acids are converted into saturated acids and the EFA content is drastically reduced. The main advantage of vanaspati is its ghee-like consistency and its keeping quality even in hot humid climates. Since vanaspati is lacking in fat-soluble vitamins, it is fortified with vitamins A and D by government regulation to the extent of 2500 IU of vitamin A and 175 IU of vitamin D per 100 grams.

Trans-fatty acids

Trans-fatty acids are geometrical isomers of Cis-unsaturated fatty acids that adapt a saturated fatty acid like configuration. Partial hydrogenation, the process used to increase shelf-life of poly-unsaturated fatty acids (PUFAs) create trans fatty acids and also removes the critical double bonds in essential fatty acids. Metabolic studies have demonstrated that trans-fatty acids render the plasma lipid profile even more atherogenic than saturated fatty acids, by not only elevating LDL cholesterol but also by decreasing HDL cholesterol. Several large cohort studies have found that intake of trans-fatty acids increases the risk of coronary heart disease *(13)*. It takes years for trans fatty acids to be flushed from the body. Deep fried fast foods, cake mixes, cereals and energy bars, chips and crackers and whipped toppings, packaged cookies and candy, packaged doughnuts, pies and cakes are major sources of trans-fatty acids. It is better to look for "partially hydrogenated oil" on the label of any packaged food.

Refined oils

Refining is usually done by treatment with steam, alkali, etc. Refining and deodourization of raw oils is done mainly to remove the free fatty acids and rancid materials which may be present in them. Refining does not bring about any change in the unsaturated fatty acid content of the oil. It only improves the quality and taste of oils. Refined oils are costly.

Fats and disease

(a) OBESITY : A diet, rich in fat, can pose a threat to human health by encouraging obesity. In fat people, adipose tissue may increase upto 30 per cent. *(b) PHRENODERMA :* Deficiency of essential fatty acids in the diet is associated with rough and dry skin, a condition known as phrenoderma or "toad skin". This condition is reported in Kerala, Karnataka and Gujarat *(14)*. It is characterized by horny papular eruptions on the posterior and lateral aspects of limbs and on the back and buttocks. Phrenoderma can be cured rapidly by the administration of linseed or safflower oil which are rich in EFA, along with vitamins of the B-complex group. *(c) CORONARY HEART DISEASE :* High fat intake (i.e., dietary fat representing 40 per cent or over of the energy supply and containing a high proportion of saturated fats) has been identified as a major risk factor for CHD *(15)*. Epidemiological studies indicate that LDL and VLDL fractions are atherogenic and HDL exerts a protective effect against the development of artherosclerosis. There is evidence indicating an inverse relationship between EFA intake and CHD mortality. *(d) CANCER :* In recent years, there has been some evidence that diets high in fat increase the risk of colon cancer and breast cancer *(16)*. *(e) OTHERS :* The skin lesions of kwashiorkor and those induced by EFA deficiency are similar. The possible association between the skin lesions of kwashiorkor and EFA deficiency has attracted attention *(18)*.

The WHO/FAO Expert Group on diet, nutrition and prevention of chronic diseases endorse that qualitative composition of fats in the diet has a significant role to play in modifying risk factors of CVD and set the following ranges for population nutrient goals (% of Energy) : total fat, 15–30 (at least 20%E (energy) is consistent with good health); Saturated fatty acids less than 10 per cent; PUFAs 6–10 per cent; n-6 about 5–8 per cent; n-3 about 1–2 per cent; Trans-fatty acids less than 1 per cent; MUFAs by difference, and cholesterol less than 300 mg a day *(9)*.

The FAO/WHO expert consultation on fats and fatty acids in human nutrition held in November 2008 in Geneva, Switzerland, reviewed the scientific evidence on nutrient intake values for total fat and fatty acids for different life stages. It also assessed the risks to adequate growth, development and maintenance of health and provided recommendations for infants, children, adults and for women during pregnancy and lactation. Some of their conclusions and recommendations are as follows :

(a) There is convincing evidence on the following :

Energy balance is critical to maintain healthy body weight and ensure optimal nutrient intakes, regardless of macronutrient distribution of energy as % total fat and % total carbohydrates.

Saturated fatty acids (SFAs)

(1) Replacing SFAs with PUFAs decreases LDL cholesterol concentration and the total/HDL cholesterol ratio. A similar but lesser effect is achieved by replacing these SFAs with MUFAs.

(2) Replacing SFAs with carbohydrates decreases both LDL and HDL cholesterol concentration but does not change the total/HDL cholesterol ratio.

(3) Replacing SFAs with trans-fatty acids (TFAs) decreases HDL cholesterol and increases the total/HDL cholesterol ratio.

(4) Considering the data from epidemiological studies on

morbidity and mortality due to coronary heart disease (CHD) and controlled clinical trials (using CHD events and death), it was also agreed that replacing SFAs with PUFAs decrease the risk of CHD.

MUFAs (Monounsaturated fatty acids)

(1) Replacing carbohydrates with MUFAs increases HDL cholesterol concentrations.

(2) Replacing SFA with MUFA reduces LDL cholesterol concentration and total/HDL cholesterol ratio.

PUFAs (Polyunsaturated fatty acids)

Linoleic acid (LA) and alpha-linolenic acid (ALA) are indispensable since they cannot be synthesized by humans. Minimum intake levels for essential fatty acids to prevent deficiency symptoms are estimated to be 2.5% E LA plus 0.5% E ALA.

Trans-fatty acids (TFAs)

TFAs from commercial partially hydrogenated vegetable oils (PHVO) increase CHD risk factors and CHD events to a greater extent than what was thought earlier.

(b) Based on epidemiologic studies and randomized controlled trials of CHD events, 6% has been fixed as the minimum recommended consumption level of total PUFAs for lowering LDL and total cholesterol concentrations, increasing HDL cholesterol concentrations and decreasing the risk of CHD events.

(c) Whilst ALA may have individual properties in their own right, there is evidence that the n-3 long chain PUFAs may contribute to the prevention of CHD and possibly other degenerative diseases of ageing.

(d) Based on both the scientific evidence and conceptual limitations, there is no compelling scientific rationale for recommending a specific ratio of n-6 to n-3 fatty acids or LA to ALA, especially if intakes of n-6 and n-3 fats lie within the recommendations established.

(e) In promoting the removal of TFA, which are predominantly a by-product of industrial processing (partial hydrogenation) usually in the form of PHVO, particular attention must be given to what would be their replacement; this is a challenge for the food industry.

Choice of cooking oils *(9)*

Taking into account the contribution of various fatty acids from all foods (visible fats and invisible fats), the complete dependence on just one vegetable oil does not ensure the recommended intake of fatty acids for optimal health. To achieve intake of individual fatty acids, the type of visible fats and correct combination of vegetable oils to be used are as follows :

1. Use correct combination/blend of 2 or more vegetable oils (1:1)

   (a) Oil containing LA + oil containing both LA and ALA

   Groundnut/Sesame/Rice bran/Cottonseed + Mustard/ Rapeseed

   Groundnut/Sesame/Rice bran/Cottonseed + Canola

   Groundnut/Sesame/Rice bran/Cottonseed + Soyabean

   Palmolein + Soyabean

   Safflower/Sunflower + Palm oil/Palmolein + Mustard/ Rapeseed

   (b) Oil containing high LA + oil containing moderate or low LA

   Sunflower/Safflower + Palmolein/Palm oil/Olive

   Safflower/Sunflower + Groundnut/Sesame/Ricebran/ Cottonseed

2. Limit use of butter/ghee

3. Avoid use of PHVO as medium for cooking/frying.

4. Replacements for PHVO

Frying : oils which have higher thermal stability – palm oil/palmolein, sesame, ricebran, cottonseed – single/blends (home/commercial)

Fat requirements

Recommendations for dietary fats for Indians have been revised taking into account the recent FAO and WHO recommendations for : (1) total fat, individual fatty acids and health promoting non-glyceride components; (2) source of dietary fats in Indians; and (3) availability of fat. The recommendations are directed towards meeting the requirements of optimal foetal and infant growth and development, maternal health and for combating chronic energy deficiency in children and adults, and diet related non-communicable diseases in adults.

Taking into account the unfavourable effect of low fat-high carbohydrate diets and the energy requirement set on the basis of age, physiological status and physical activity, the minimum intakes of visible fat for Indian adults range between 20–40 g/day. The minimum level of total fat should be 20 per cent of energy. To furnish 20 per cent of total energy, diet of pregnant and lactating mothers should contain at least 30 grams of visible fat *(9)*. For further details see Table 28.

CARBOHYDRATES

The third major component of food is carbohydrate, which is the main source of energy, providing 4 kcals per gram. Carbohydrate is also essential for the oxidation of fats and for the synthesis of certain non-essential amino acids. There are three main sources of carbohydrates, viz., starches, sugar and cellulose. ***Starch*** is basic to the human diet. It is found in abundance in cereals, roots and tubers. ***Sugars*** comprise monosaccharides (glucose, fructose and galactose) and disaccharides (sucrose, lactose and maltose). These free sugars are highly water soluble and easily assimilated. Free sugars along with starches constitute a key source of energy. ***Cellulose*** which is the indigestible component of carbohydrate with scarcely any nutritive value, contributes to dietary fibre.

The carbohydrate reserve (glycogen) of a human adult is about 500 g. This reserve is rapidly exhausted when a man is fasting. If the dietary carbohydrates do not meet the energy needs of the body, protein and glycerol from dietary and endogenous sources are used by the body to maintain glucose haemostasis.

Glycaemic index *(9)*

Glycaemic index of a food is defined by the area under the two-hour blood glucose response curve (AUC) following the ingestion of a fixed portion of test carbohydrate (usually 50 g) as a proportion (%) of the AUC of the standard (either glucose or white bread).

Some foods containing different fractions of soluble and

insoluble fibres favour slow release of sugar into small intestine and its absorption into blood (reduced peak and prolonged rate). They are therefore termed low glycaemic index foods as compared to high glycaemic foods with readily digestible and absorbable sugar. The concept has practical utility in management of diabetes and control of obesity.The classification of foods according to GI is as follows :

Classification	GI range	Examples
Low GI	55 or less	most fruit and vegetables (except potatoes, watermelon and sweet corn), whole grains, pasta foods, beans, lentils
Medium GI	56-69	sucrose, basmati rice, brown rice
High GI	70 or more	corn flakes, baked potato, some white rice varieties (e.g. jasmine), white bread, candy bar and syrupy foods.

GI - Glycaemic index

DIETARY FIBRE

By definition "Dietary fibre is the remnants of the edible part of plants and analogous carbohydrates that are resistant to digestion and absorption in the human small intestine with complete or partial fermentation in the human large intestine". It includes polysaccharides, oligosaccharides, lignin and associated plant substances. Dietary fibre exhibits one or more of either laxation (faecal bulking and softening; increased frequency; and or regularity), blood cholesterol attenuation, and or blood glucose attenuation. Organic acids (butyric acid) and polyols (sorbitol) are also considered as part of fibre. Animal foods do not contain any fibre.

Type and sources

Dietary fibres have been characterized by its source, e.g., cereal, vegetable and fruits or its solubility in water – soluble (partly or fully) or insoluble. Both characters of solubility are essential for health promotion. Digestibility of fibre is determined by physiochemical and structural properties of the dietary component and the process used. When exposed to longer duration of degradative conditions in large intestine, more fibre is digested. It forms the substance for fermentation by intestinal microbes. It is through this mechanism that part of energy from resistant starch is rendered available. Apart from the energy yielding reactions during digestion, at different pH, the action of enzymes on dietary fibres promotes interaction between nutrients. It also changes the pattern of microbes colonizing the colon and thus the metabolic products of such fermentation over the time. Vegetarians may have different digestion pattern than that of the non-vegetarians and thus derive different health benefits. This knowledge of probiotics characterized by helpful microbes and prebiotics (substrates promoting the colonization of probiotic strains) has opened up new areas for research *(9)*.

Original estimates of fibre covered all that was insoluble in boiling water or in dilute acid and alkali conditions. It was reported as 'crude fibre', which may include all structural fibre, cellulose, lignin and haemicellulose. It is related to digestibility and has the property of holding water and swelling properties of the diet. It adds to the bulk of the food, favours satiety, increases transit time of the food in the gut and is an active substrate in the large intestine for release of important functional components like organic acids and nutraceuticals. Mostly complex carbohydrates, such as polysaccharides i.e. cellulose, haemicellulose, pectin and a variety of gums, mucilages form the fibre.

Dietary fibre is known to be associated with reduced incidence of coronary heart disease. The mechanism of its action is attributed to its binding to bile salts and preventing its reabsorption and thus reducing cholesterol level in circulation. The fibre, particularly the gum and pectin, when ingested with a diet, are reported to reduce post-prandial glucose level in blood. Recent studies have shown that gum present in fenugreek seeds, which contains 40 per cent gum, is most effective in reducing blood glucose and cholesterol levels as compared to other gums.

Fibre have no metabolic effects. However, too much of fibre can decrease the absorption of valuable micronutrients. There is conflicting evidence as to whether fibre tends to bind some vitamins and minerals like calcium, magnesium, iron and zinc, and reduce their bio-availability. People who eat well-balanced diet obtain enough roughage. Considering the qualitative and quantitative decrease in fibre content of diet over the past many decades, an increase in dietary fibre, particularly from cereals emerge as a recommendation. Intake in excess of 60 g of fibre over a day can reduce the nutrient absorption and cause bowel irritation *(9)*. A daily intake of about 40 grams of dietary fibre per 2000 kcal is desirable. The actual quantity of fibre intake depends upon the nature of cereals, pulses, whole grain, vegetables and millets used. The total fibre content of common foods are as shown in Table 4.

TABLE 4

Different dietary fibre fractions in selected Indian foods

Food Group	Food Item	Fibre content g/100 g edible portion			Soluble (%
		Crude fibre	TDF *	Soluble	TDF *)
Cereals	Rice	0.2	4.11	0.92	22.4
	Wheat	0.3	12.48	2.84	22.7
	Bajra	1.2	11.33	2.19	19.3
	Maize	2.7	11.54	1.65	14.2
	Jowar	1.6	9.67	1.64	17.0
	Ragi	3.6	11.85	0.89	7.50
Pulses, dhals	Lentil	0.7	10.31	2.04	19.8
	Chick pea	1.2	15.30	2.56	16.7
	Pigeon pea	0.9	9.14	2.33	25.4

Source : *(9)*

VITAMINS

Vitamins are a class of organic compounds categorized as essential nutrients. They are required by the body in very small amounts. They fall in the category of micronutrients. Vitamins do not yield energy but enable the body to use other nutrients. Since the body is generally unable to synthesize them (at least in sufficient amounts) they must be provided by food. A well balanced diet supplies in most instances the vitamin needs of a healthy person.

Vitamins are divided into two groups : (a) fat soluble vitamins, viz., vitamins A, D, E and K; and (b) water soluble vitamins, viz., vitamins of the B–group and vitamin C. Each vitamin has a specific function to perform and deficiency of any particular vitamin may lead to specific deficiency diseases. For some vitamins (e.g., vitamin E), no deficiency disease is yet known. The minimum intake for the maintenance of health in respect of many of the vitamins has been determined, but the optimum intake remains somewhat speculative.

VITAMIN A

"Vitamin A" covers both a pre-formed vitamin, retinol, and a pro-vitamin, beta carotene, some of which is converted to retinol in the intestinal mucosa *(17)*. The international units (IU) originally established for vitamin A and provitamin were discarded in 1954 and 1956 respectively *(18)*. In 1960, the term "retinol" was introduced for vitamin A – 1 alcohol (which is available in crystalline form), but most workers prefer the older term vitamin A and the international unit. The international unit (IU) of vitamin A is equivalent to 0.3 microgram of retinol (or 0.55 microgram of retinol palmitate).

Some food composition tables give separate values for retinol and beta-carotene. To convert these into a single value, the term "retinol equivalent" (RE) has been conventionally adopted. The conversion can be done in the following way.

1 mcg of retinol = 1 RE
1 mcg of β–carotene = 0.167 mcg of RE
1 mcg of other carotenoids = 0.084 mcg of RE
1 RE = 3.333 IU of Vitamin A

Functions

Vitamin A participates in many bodily functions : (a) it is indispensable for normal vision. It contributes to the production of retinal pigments which are needed for vision in dim light. (b) it is necessary for maintaining the integrity and the normal functioning of glandular and epithelial tissue which lines intestinal, respiratory and urinary tracts as well as the skin and eyes. (c) it supports growth especially skeletal growth. (d) it is anti-infective; there is increased susceptibility to infection and lowered immune response in vitamin A deficiency, and (e) it may protect against some epithelial cancers such as bronchial cancers, but the data are not fully consistent *(19)*. However, the role of vitamin A at the molecular level is not yet known.

Sources

Vitamin A is widely distributed in animal and plant foods – in animal foods as preformed vitamin A (retinol), and in plant foods as provitamins (carotenes).

(a) ANIMAL FOODS : Foods rich in retinol are liver, eggs, butter, cheese, whole milk, fish and meat. Fish liver oils are the richest natural sources of retinol (Table 5), but they are generally used as nutritional supplements rather than as food sources.

(b) PLANT FOODS : The cheapest source of vitamin A is green leafy vegetables such as spinach and amaranth which are found in great abundance in nature throughout the year. The darker the green leaves, the higher its carotene content. Vitamin A also occurs in most green and yellow fruits and vegetables (e.g., papaya, mango, pumpkin) and in some roots (e.g., carrots). The most important carotenoid is beta–carotene which has the highest vitamin A activity. Carotenes are converted to vitamin A in the small intestine. This action is poorly accomplished in malnourished children and those suffering from diarrhoea.

(c) FORTIFIED FOODS : Foods fortified with vitamin A (e.g., vanaspati, margarine, milk) can be an important source. Vitamin A content of selected foods is as given in Table 5.

TABLE 5
Retinol content of selected foods

	Retinol equivalents (RE) (mcg/100 g)		
Halibut liver oil	900,000	Carrot	1,167
Cod liver oil	18,000	Spinach	607
Liver, Ox	16,500	Amaranth	515
Butter	825	Green leaves	300
Margarine	900	Mango, ripe	313
Cheese	350	Papaya	118
Egg	140	Orange	25
Milk, Cow	38	Tomato	84
Fish	40		

Source : *(20)*

The liver has an enormous capacity for storing vitamin A, mostly in the form of retinol palmitate. Under normal conditions, a well-fed person has sufficient vitamin A reserves to meet his needs for 6 to 9 months or more. Free retinol is highly active but toxic and is therefore transported in the blood stream in combination with retinol-binding protein, which is produced by the liver. In severe protein deficiency, decreased production of retinol-binding protein prevents mobilization of liver retinol reserves.

Deficiency

The signs of vitamin A deficiency are predominantly ocular. They include nightblindness, conjunctival xerosis, Bitot's spots, corneal xerosis and keratomalacia. The term "xerophthalmia" (dry eye) comprises all the ocular manifestations of vitamin A deficiency ranging from nightblindness to keratomalacia, Given below is a short description of the ocular manifestations.

(a) Nightblindness

Lack of vitamin A, first causes nightblindness or inability to see in dim light. The mother herself can detect this condition when her child cannot see in late evenings or find her in a darkened room. Nightblindness is due to impairment in dark adaptation. Unless vitamin A intake is increased, the condition may get worse, especially when children also suffer from diarrhoea and other infections.

(b) Conjunctival xerosis

This is the first clinical sign of vitamin A deficiency. The

conjuctiva becomes dry and non-wettable. Instead of looking smooth and shiny, it appears muddy and wrinkled. It has been well described as "emerging like sand banks at receding tide" when the child ceases to cry *(21)*.

(c) Bitot's spots

Bitot's spots are triangular, pearly-white or yellowish, foamy spots on the bulbar conjunctiva on either side of the cornea. They are frequently bilateral. Bitot's spots in young children usually indicate vitamin A deficiency. In older individuals, these spots are often inactive sequelae of earlier disease.

(d) Corneal xerosis

This stage is particularly serious. The cornea appears dull, dry and non-wettable and eventually opaque. It does not have a moist appearance. In more severe deficiency there may be corneal ulceration. The ulcer may heal leaving a corneal scar which can affect vision.

(e) Keratomalacia

Keratomalacia or liquefaction of the cornea is a grave medical emergency. The cornea (a part or the whole) may become soft and may burst open. The process is a rapid one. If the eye collapses, vision is lost.

EXTRA-OCULAR MANIFESTATIONS

These comprise follicular hyperkeratosis, anorexia and growth retardation which have long been recognized. They are non-specific and difficult to quantify. Recent studies seem to indicate that even mild vitamin A deficiency causes an increase in morbidity and mortality due to respiratory and intestinal infection *(22)*. Deficiency of vitamin A has recently been linked to child mortality *(23)*.

Treatment

Vitamin A deficiency should be treated urgently. Nearly all of the early stages of xerophthalmia can be reversed by administration of a massive dose (200,000 IU or 110 mg of retinol palmitate) orally on two successive days *(24)*. All children with corneal ulcers should receive vitamin A whether or not a deficiency is suspected.

Prevention

Prevention and/or control takes two forms – (a) improvement of people's diet so as to ensure a regular and adequate intake of foods rich in vitamin A, and (b) reducing the frequency and severity of contributory factors, e.g., PEM, respiratory tract infections, diarrhoea and measles. Both are long term measures involving intensive nutrition education of the public and community participation.

Since vitamin A can be stored in the body for 6 to 9 months and liberated slowly, a short term, simple technology had been evolved by the National Institute of Nutrition at Hyderabad (India) for community based intervention against nutritional blindness, which has subsequently been adopted by other countries *(25)*. The strategy is to administer a single massive dose of 200,000 IU of vitamin A in oil (retinol palmitate) orally every 6 months to preschool children (1 year to 6 years), and half that dose (100,000 IU) to children between 6 months and one year of age *(24)*. In this way, the child would be, as it were "immunized" against xerophthalmia. The protection afforded by six–monthly dosing seems very adequate as measured by clinical signs of deficiency *(26)*.

Assessment of vitamin A deficiency

The formulation of an effective intervention programme for prevention of vitamin A deficiency (VAD) begins with the characterization of the problem. This is done by population surveys employing both clinical and biochemical criteria. These surveys (prevalence surveys) are done on preschool children (6 months to 6 years) who are at special risk. The criteria recommended by WHO *(18)* are as given in Table 6. The presence of any one of the criteria should be considered as evidence of a xerophthalmia problem in the community.

TABLE 6

Prevalence criteria for determining the xerophthalmia problem

Criteria	Prevalence in population at risk (6 months to 6 years)
Nightblindness	more than 1 per cent
Bitot's spots	more than 0.5 per cent
Corneal xerosis/corneal ulceration/keratomalacia	more than 0.01 per cent
Corneal ulcer	more than 0.05 per cent
Serum retinol (less than 10 mcg/dl)	more than 5 per cent

Source : *(18)*

Recommended allowances

The recommended daily intake of vitamin A is 600 micrograms for adults. The present expert committee has modified the extent of conversion efficiency of 1:4 to 1:8 and has retained the previous recommendation on retinol requirements for all age groups except pregnancy. The committee recommends that a minimum of 50 per cent retinol be drawn from animal sources *(9)*. The detailed recommendations are as given in Table 7.

TABLE 7

Daily intake of vitamin A recommended by ICMR (2010)

Group		Retinol (mcg)	OR β–carotene (mcg)*
Adults			
	Man	600	4,800
	Woman	600	4,800
	Pregnancy	800	6,400
	Lactation	950	7,600
Infants	0 to 6 months	350	–
	6 to 12 months	350	2800
Children			
	1 to 6 years	400	3,200
	7 to 9 years	600	4,800
Adolescents			
	10 to 17 years	600	4,800

* A conversion ratio of 1 : 8 is used

Source : *(9)*

Toxicity

An excess intake of retinol causes nausea, vomiting, anorexia and sleep disorders followed by skin desquamation and then an enlarged liver and papillar oedema. High

intakes of carotene may colour plasma and skin, but do not appear to be dangerous *(19, 27)*. The teratogenic effects of massive doses of vitamin A is the most recent focus of interest *(28)*.

VITAMIN D

The nutritionally important forms of Vitamin D in man are Calciferol (Vitamin D_2) and Cholecalciferol (Vitamin D_3). Calciferol may be derived by irradiation of the plant sterol, ergosterol. Cholecalciferol is the naturally occurring (preformed) vitamin D which is found in animal fats and fish liver oils. It is also derived from exposure to UV rays of the sunlight which convert the cholesterol in the skin to vitamin D. Vitamin D is stored largely in the fat depots.

Vitamin D : Kidney hormone

Major advances have been made in recent years in our understanding of the metabolism of vitamin D in the body *(29)*. It is now known that vitamin D, by itself, is metabolically inactive unless it undergoes endogenous transformation into several active metabolites (e.g., 25 HCC; 1 : 25 DHCC) first in the liver and later in the kidney. These metabolites are bound to specific transport proteins and are carried to the target tissues – bone and intestine. It has been proposed that vitamin D should be regarded as a kidney hormone *(30)* because it does not meet the classic definition of a vitamin, that is, a substance which must be obtained by dietary means because of a lack of capacity in the human body to synthesize it. In fact, vitamin D_3 is not a dietary requirement at all in conditions of adequate sunlight. It can be synthesized in the body in adequate amounts by simple exposure to sunlight even for 5 minutes per day.

Functions

The functions of vitamin D are as summarized in Table 8.

TABLE 8

Functions of vitamin D and its metabolites

Intestine	Promotes intestinal absorption of calcium and phosphorus
Bone	Stimulates normal mineralization, enhances bone reabsorption, affects collagen maturation.
Kidney	Increases tubular reabsorption of phosphate, Variable effect on reabsorption of calcium
Other	Permits normal growth.

Source : *(31)*

Sources

Vitamin D is unique because it is derived both from sunlight and foods. (a) **Sunlight :** Vitamin D is synthesized by the body by the action of UV rays of sunlight on 7–dehydrocholesterol, which is stored in large abundance in the skin. Exposure to UV rays is critical; these can be filtered off by air pollution. Dark-skinned races such as Negros, also suffer from this disadvantage because black skin can filter off up to 95 per cent of UV rays. (b) **Foods :** Vitamin D occurs only in foods of animal origin. Liver, egg yolk, butter and cheese, and some species of fish contain useful amounts. Fish liver oils, although not considered to be a food, are the richest source of vitamin D. Human milk has been shown to contain considerable amounts of water–soluble vitamin D sulphate *(31)*. Other sources of vitamin D are foods artificially fortified with vitamin D, such as milk, margarine, vanaspati and infant foods. Dietary sources of vitamin D are as given in Table 9.

TABLE 9

Dietary sources of vitamin D

	µg/per 100g		µg/per 100g
Butter	0.5–1.5	Shark liver oil	30–100
Eggs	1.25–1.5	Cod liver oil	200–750
Milk, whole	0.1	Halibut liver oil	500–10,000
Fish fat	5–30		

Deficiency

(1) *Rickets :* Vitamin D deficiency leads to *rickets,* which is usually observed in young children between the age of six months and two years. There is reduced calcification of growing bones. The disease is characterized by growth failure, bone deformity, muscular hypotonia, tetany and convulsions due to hypocalcaemia. There is an elevated concentration of alkaline phosphate in the serum. The bony deformities include curved legs, deformed pelvis, pigeon chest, Harrison's sulcus, rickety rosary, kyphoscoliosis, etc. The milestones of development such as walking and teething are delayed. (2) *Osteomalacia :* In adults, vitamin D deficiency may result in osteomalacia which occurs mainly in women, especially during pregnancy and lactation when requirements of vitamin D are increased.

Both rickets and osteomalacia are frequently reported in India, although they do not appear to be a problem of public health importance. In the world as a whole, their prevalence has declined as a result of changes in social customs (e.g., purdah system), and the expansion of mother and child health services leading to better care and feeding of infants and children *(3)*. In the developing countries today, rickets as a menace to child health is overshadowed by the prevalence of protein-energy-malnutrition.

Prevention

Prevention measures include (a) educating parents to expose their children regularly to sunshine; (b) periodic dosing (prophylaxis) of young children with vitamin D; and (c) vitamin D fortification of foods, especially milk. Some industrialized countries still carry out the last measure. Periodic dosing and education appear to be the most practical approaches in developing countries.

Fraser *(32)* urges caution concerning oral supplementation, because orally administered vitamin D appears to bypass the protective mechanism that prevent excessive 25(OH)D_3 formation. The margin of safety with oral vitamin D between the nutrient requirement and toxic intake is narrow.

Vitamin D is stored in the body in fatty tissues and in the liver. An excessive intake is harmful and may result in anorexia, nausea, vomiting, thirst, and drowsiness. The patient may lapse into coma, while cardiac arrhythmias and renal failure may occur. The effects are due to hypercalcaemia induced by increased intestinal absorption and mobilization of calcium from bone. Recent literature contains warning against the administration of amounts of vitamin D that greatly exceed accepted requirement levels. This warning applies to pregnant women also since manifestations of hypercalcaemia may develop *in utero (4)*.

Daily requirements

The expert committee of ICMR emphasizes importance of outdoor physical activities as a means of achieving adequate vitamin D status in a tropical country like India. However,

under minimal exposure to sunlight, particularly in certain urban groups, like 1–2 year old children, a specific recommendation of a daily supplement of 400 IU (10 mcg) is suggested *(9)*.

VITAMIN E (Tocopherol)

Vitamin E is the generic name for a group of closely related and naturally occurring fat soluble compounds, the **tocopherols**. Of these alpha-tocopherol is biologically the most potent. Vitamin E is widely distributed in foods. By far the richest sources are vegetable oils, cotton-seed, sunflower seed, egg yolk and butter. Foods rich in polyunsaturated fatty acids are also rich in vitamin E. The usual plasma level of vitamin E in adults is between 0.8 and 1.4 mg per 100 ml *(31)*. While there is no doubt that man requires tocopherol in his diet, there is no clear indication of dietary deficiency. The role of vitamin E at the molecular level is little understood. The current estimate of vitamin E requirement is about 0.8 mg/g of essential fatty acids. This roughly works out to 8–10 mg tocopherol per day depending on the edible oil used *(9)*.

Recently the cytotoxic effect of vitamin E on human lymphocytes *in vitro* at high concentrations has been reported. This being so, caution should be exercised against the mega-dose consumption of vitamin E in clinical practice.

VITAMIN K

Vitamin K occurs in at least two major forms – vitamin K_1 and vitamin K_2. Vitamin K_1 is found mainly in fresh green vegetables particularly dark green ones, and in some fruits. Cow's milk is a richer source (60 mcg/L) of vitamin K than human milk (15 mcg/L). Vitamin K_2 is synthesized by the intestinal bacteria, which usually provides an adequate supply in man. Long-term administration of antibiotic doses for more than a week may temporarily suppress the normal intestinal flora, (a source of vitamin K_2) and may cause a deficiency of vitamin K. Vitamin K is stored in the liver.

The role of vitamin K is to stimulate the production and/or the release of certain coagulation factors. In vitamin K deficiency, the prothrombin content of blood is markedly decreased and the blood clotting time is considerably prolonged.

The vitamin K requirement of man is met by a combination of dietary intake and microbial synthesis in the gut. The daily requirement for man appears to be about 0.03 mg/kg for the adult. Newborn infants tend to be deficient in vitamin K due to minimal stores of prothrombin at birth and lack of an established intestinal flora. Soon after birth, all infants or those at increased risk should receive a single intramuscular dose of a vitamin K preparation (0.1–0.2 mg of menadione sodium bisulphite or 0.5 mg of vitamin K_1) by way of prophylaxis *(33)*.

B GROUP OF VITAMINS
THIAMINE (B_1)

Thiamine (vitamin B_1) is a water-soluble vitamin. It is essential for the utilization of carbohydrates. Thiamine pyrophosphate (TPP), the coenzyme of cocarboxylase plays a part in activating transketolase, an enzyme involved in the direct oxidative pathway for glucose. In thiamine deficiency, there is accumulation of pyruvic and lactic acids in the tissues and body fluids.

Sources

Thiamine occurs in all natural foods, although in small amounts. Important sources are : whole grain cereals, wheat, gram, yeast, pulses, oilseeds and nuts, especially groundnut. Meat, fish, eggs, vegetables and fruits contain smaller amounts. Milk is an important source of thiamine for infants, provided the thiamine status of their mothers is satisfactory. The main source of thiamine in the diet of Indian people is cereals (rice and wheat) which contribute from 60–85 per cent of the total supply. The thiamine content of selected food stuff is given in Table 10.

TABLE 10

Dietary sources of thiamine

Foods of vegetable origin	mg/100 g	Foods of animal origin	mg/100 g
Wheat (whole)	0.45	Milk, cow's	0.05
Rice, raw homepounded	0.21	Egg hen's	0.10
Rice, milled	0.06	Mutton	0.18
Bengal gram dhal	0.48	Liver, sheep	0.36
Almonds	0.24		
Gingelly seeds	1.01		
Groundnut	0.90		

Source : *(34)*

Thiamine losses

Thiamine is readily lost from rice during the process of milling. Being a water-soluble vitamin, further losses take place during washing and cooking of rice. This is the basis for advising people to eschew highly polished rice and eat parboiled or under-milled rice (see page 627). Much of thiamine in fruits and vegetables is generally lost during prolonged storage *(35)*. Thiamine is also destroyed in toast and in cereals cooked with baking soda. The occurrence or absence of beriberi is determined by the local customs and cultural practices concerning the processing and cooking of rice and other foodstuffs.

Deficiency

The two principal deficiency diseases are beriberi and Wernick's encephalopathy. Beriberi may occur in three main forms : (a) the **dry** form characterized by nerve involvement (peripheral neuritis); (b) the **wet** form characterized by heart involvement (cardiac beriberi); and (c) **infantile** beriberi, seen in infants between 2 and 4 months of age. The affected baby is usually breast-fed by a thiamine-deficient mother who commonly shows signs of peripheral neuropathy. Wernick's encephalopathy (seen often in alcoholics) is characterized by ophthalmoplegia, polyneuritis, ataxia and mental deterioration. It occurs occasionally in people who fast.

A few short decades ago, frank cases of beriberi used to be frequently seen in the coastal districts of Andhra Pradesh where people eat highly polished rice. Investigations by the ICMR showed that such cases are now rarely encountered because of improved socio-economic conditions and diversification in the diet consumed now *(36)*.

Prevention

Beriberi can be eliminated by educating people to eat well-balanced, mixed diets containing thiamine-rich foods (e.g., parboiled and undermilled rice) and to stop all

alcohol. Direct supplementation of high-risk groups (e.g., lactating mothers) is another approach. Beriberi tends to disappear as economic conditions improve and diets become more varied *(10)*. The disease, as has been shown, is not completely vanquished but the knowledge and resources needed to bring about its disappearance are available *(3)*.

Recommended allowances

The body content of thiamine is placed at 30 mg, and if more than this is given it is merely lost in the urine *(19)*. Patients on regular haemodialysis should routinely be given supplements of thiamine. Thiamine should also be given prophylactically to people with persistent vomiting or prolonged gastric aspiration and those who go on long fasts. For further details see Table 30.

RIBOFLAVIN (B_2)

Riboflavin (Vitamin B_2) is a member of the B–group vitamins. It has a fundamental role in cellular oxidation. It plays an important role in maintaining the integrity of mucocutaneous structure. It is a co-factor in a number of enzymes involved with energy metabolism. It is also involved in antioxidant activity, being a co-factor for the enzymes like glutathione reductace and is required for the metabolism of other vitamins like vitamin B6, niacin and vitamin K *(9)*.

Sources

Its richest natural sources are milk, eggs, liver, kidney and green leafy vegetables. Meat and fish contain small amounts. Cereals (whether whole or milled) and pulses are relatively poor sources but because of the bulk in which they are consumed, they contribute much of the riboflavin to Indian diets. Germination increases the riboflavin content of pulses and cereals. The riboflavin content of some common foods is given in Table 11.

TABLE 11

Dietary sources of riboflavin

Foods of animal origin	mg/100 g	Foods of vegetable origin	mg/100 g
Liver, sheep	1.70	Whole cereals	0.10–0.16
Milk, cow's	0.19	Milled cereals	0.03–0.08
Egg, hen	0.40	Pulses	0.21–0.32
Meat	0.14	Leafy vegetables	0.15–0.30

Source : *(34)*

Deficiency

The most common lesion associated with riboflavin deficiency is angular stomatitis, which occurs frequently in malnourished children and its prevalence is used as an index of the state of nutrition of groups of children *(3)*. Other clinical signs suggestive (but not specific) include cheilosis, glossitis, nasolabial dyssebacia, etc. Hypo-riboflavinosis, even when severe, seldom incapacitates the individual, but it may have subtle functional effects such as impaired neuromotor function, wound healing and perhaps increased susceptibility to cataract *(37)*. Riboflavin deficiency almost always occurs in association with deficiencies of other B-complex vitamins such as pyridoxine; it is usually a part of a multiple deficiency syndrome.

Requirement

There are no real body stores of riboflavin. Daily requirement is 0.6 mg per 1000 kcal of energy intake *(9)*. For further details see Table 30.

NIACIN (B_3)

Niacin or nicotinic acid (B_3) is essential for the metabolism of carbohydrate, fat and protein. It is also essential for the normal functioning of the skin, intestinal and nervous systems. This vitamin differs from the other vitamins of the B-complex group in that an essential amino acid, tryptophan serves as its precursor. Another characteristic of niacin is that it is not excreted in urine as such, but is metabolized to at least 2 major methylated derivatives : N-methyl-nicotinamide and N-methyl pyridones.

Sources

Foods rich in niacin and/or tryptophan are liver, kidney meat, poultry, fish, legumes and groundnut. Milk is a poor source of niacin but its proteins are rich in tryptophan which is converted in the body into niacin (about 60 mg of tryptophan is required to result in 1 mg of niacin). In many cereals, especially maize, niacin occurs in "bound" form unavailable to the consumer.

Deficiency

Niacin deficiency results in pellagra. The disease is characterized by three D's – diarrhoea, dermatitis and dementia. In addition glossitis and stomatitis usually occur. The dermatitis is bilaterally symmetrical and is found only on those surfaces of the body exposed to sunlight, such as back of the hands, lower legs, face and neck. Mental changes may also occur which include depression, irritability and delirium.

Once a formidable and widespread deficiency disease among malnourished population subsisting mainly on maize diets, pellagra has declined in all parts of the world. It is still prevalent in some parts of Western Asia and Southern Africa where people subsist on maize and little else *(38)*. While pellagra is historically a disease of the maize–eating population, it was reported in India in the Telangana area of Andhra Pradesh in some segments of the population eating another cereal – that is jowar (Sorghum vulgare), these people consuming very little of milk or other foods of animal origin. Studies by Gopalan and others *(39)* have shown that amino- acid imbalance caused by an excess of leucine is the cause of pellagra in both jowar and maize eaters. Excess of leucine appears to interfere in the conversion of tryptophan to niacin.

Prevention

Pellagra is a preventable disease. A good mixed diet containing milk and/or meat is universally regarded as an essential part of prevention and treatment. Avoidance of total dependence on maize or sorghum is an important preventive measure. Pellagra is a disease of poverty. Given modern knowledge and opportunities for economic, agricultural and social development, there is every reason to hope that this disease could be eliminated *(3)*.

Requirement

The recommended daily allowance is 6.0 mg/1000 kcal of energy intake *(9)*. For further details see Table 30.

PYRIDOXINE (B_6)

Pyridoxine (vitamin B_6) exists in three forms : pyridoxine, pyridoxal and pyridoxamine. It plays an important role in the metabolism of amino-acids, fats and carbohydrate. It is widely distributed in foods, e.g., milk, liver, meat, egg yolk, fish, whole grain cereals, legumes and vegetables. Pyridoxine deficiency is associated with peripheral neuritis. Riboflavin deficiency impairs the optimal utilization of pyridoxine. INH, an antituberculosis drug is a recognized antagonist, and patients receiving INH are provided with a supplement of pyridoxine (10 mg/day).

The requirements of adults vary directly with protein intake. Adults may need 2 mg/day; during pregnancy and lactation, 2.5 mg/day. Balanced diets usually contain pyridoxine, therefore deficiency is rare. For further details see Table 30.

PANTOTHENIC ACID (B_5)

There is a long standing evidence for a relation between pantothenic acid and adrenal cortical function. Work indicates a more specific role for pantothenic acid in the biosynthesis of corticosteroids *(7)*. Human blood normally contains 18 to 35 mg of pantothenic acid per 100 ml, mostly present in the cells as coenzyme A. The daily requirement is set at 10 mg *(31)*. All foods contribute to dietary intake. About 3 mg are excreted daily in urine.

FOLATE

The recommended name is folate, alternative name is folacin and the usual pharmaceutical preparation is folic acid *(19)*.

Folic acid occurs in food in two forms : free folates and bound folates. The total folates represent both the groups. In man, free folate is rapidly absorbed, primarily from the proximal part of small intestine. The availability of bound folate is uncertain. Folic acid plays a role in the synthesis of the nucleic acids (which constitute the chromosomes). It is also needed for the normal development of blood cells in the marrow.

Sources

The name comes from the latin folia (= leaf) but foods such as liver, meat, dairy products, eggs, milk, fruits and cereals are as good dietary sources as leafy vegetables. Overcooking destroys much of folic acid and thus contributes to folate deficiency in man. Folate deficiency has been reported in babies given milk foods subjected to heat sterilization.

Deficiency

Folate deficiency may occur simply from a poor diet. It is commonly found in pregnancy and lactation *(40)* where requirements are increased. It results in megaloblastic anaemia, glossitis, cheilosis and gastrointestinal disturbances such as diarrhoea, distension and flatulence. Severe folate deficiency may cause infertility or even sterility. There is also evidence that the administration of folic acid antagonists (e.g., alcohol, pyrimethamine, and cotrimoxazole) in early pregnancy may produce abortions or congenital malformations.

The laboratory diagnosis of folate deficiency is based on measurement of serum and red cell folate concentrations, usually by microbiological assay *(41)*.

Requirement

Body stores of folate are not large, about 5–10 mg, and therefore, folate deficiency can develop quickly. Folic acid requirements are greatest in conditions where there is rapid cell multiplication, such as during growth in young children and during pregnancy *(41)*. Folic acid supplementation during pregnancy has been found to increase the birth weight of infants and decrease the incidence of low birth weight babies. Intake values recommended by ICMR (2010) are given below:

		Per day
a) Healthy adults	....	200 mcg
b) Pregnancy	....	500 mcg
c) Lactation	....	300 mcg
d) Children	....	80–120 mcg

VITAMIN B_{12}

Vitamin B_{12} is complex organo-metallic compound with a cobalt atom. The preparation which is therapeutically used is cyanocobalmin, which is relatively cheap. Vitamin B_{12} cooperates with folate in the synthesis of DNA, so deficiency of either leads to megaloblastosis. Vitamin B_{12} has a separate biochemical role, unrelated to folate, in synthesis of fatty acids in myelin *(19)*. The physiological mechanism for its absorption requires intrinsic factor from the stomach, and the complex is absorbed only at a special site in the terminal ileum.

Sources

Good sources are liver, kidney, meat, fish, eggs, milk and cheese. Vitamin B_{12} is not found in foods of vegetable origin. It is also synthesized by bacteria in colon. Unlike folic acid, vitamin B_{12} is relatively heat stable. Liver is the main storage site of vitamin B_{12}. About 2 mg are stored in liver, and another 2 mg elsewhere in the body. These stores are sufficient to tide over any deficiency for one to three years. Because of these reserves, deficiency of vitamin B_{12} appears to be rare.

Deficiency

Vitamin B_{12} deficiency is associated with megaloblastic anaemia (pernicious anaemia), demyelinating neurological lesions in the spinal cord and infertility (in animal species); which is rarely seen in India. While clinical deficiency of B_{12} is not manifested, sub-clinical deficiency is reported to exist in India. Reports indicate that there exist more than 30 per cent deficiency in adults and children in the country. It is not surprising that blood levels of vitamin B_{12} are low, since a large proportion of population depends on plant food for nutrients *(9)*.

Requirement

Intake values recommended by ICMR (2010) are as below *(9)*:

		Per day
a) Normal adults	....	1 mcg
b) Pregnancy	....	1.2 mcg
c) Lactation	....	1.5 mcg
d) Infants & children	....	0.2 mcg

VITAMIN C

Vitamin C (ascorbic acid) is a water-soluble vitamin. It is the most sensitive of all vitamins to heat. Man, monkey and guinea pig are perhaps the only species known to require vitamin C in their diet.

Functions

Vitamin C is a potent antioxidant and has an important role to play in tissue oxidation. It is needed for the formation of collagen, which accounts for 25 per cent of total body protein *(7)*. Collagen provides a supporting matrix for the blood vessels and connective tissue, and for bones and cartilage. That explains why in vitamin C deficiency this support fails, with the result that local haemorrhages occur and the bones fracture easily. Vitamin C, by reducing ferric iron to ferrous iron, facilitates the absorption of iron from vegetable foods. It inhibits nitrosamine formation by the intestinal mucosa. Other claims such as prevention of common cold and protection against infections are not substantiated.

Sources

The main dietary sources of vitamin C are fresh fruits and green leafy vegetables. Traces of vitamin C occur in fresh meat and fish but scarcely in cereals. Germinating pulses contain good amounts. Roots and tubers contain small amounts. Amla or the Indian gooseberry is one of the richest sources of vitamin C both in the fresh as well as in the dry condition. Guavas are another cheap but rich source of this vitamin. The dietary sources of vitamin C are as given in Table 12.

TABLE 12

Dietary sources of vitamin C

	mg/100 g		mg/100 g
Fruits		Vegetables	
Amla ..	600	Cabbage ..	124
Guava ..	212	Amaranth ..	99
Lime ..	63	Cauliflower ..	56
Orange ..	30	Spinach ..	28
Tomato ..	27	Brinjal ..	12
Germinated pulses		Potatoes ..	17
Bengal gram ..	16	Raddish ..	15

Source : *(34)*

Deficiency

Deficiency of vitamin C results in scurvy, the signs of which are swollen and bleeding gums, subcutaneous bruising or bleeding into the skin or joints, delayed wound healing, anaemia and weakness. Scurvy which was once an important deficiency disease is no longer a disease of world importance *(3)*.

Requirement

The estimated requirement for vitamin C is 40 mg per day for adults. The normal body when fully saturated contains about 5 g of vitamin C. Daily intakes recommended by the ICMR *(9)* are as given in Table 30.

MINERALS

More than 50 chemical elements are found in the human body, which are required for growth, repair and regulation of vital body functions. These can be divided into three major groups : (a) MAJOR MINERALS : These include calcium, phosphorus, sodium, potassium and magnesium. (b) TRACE ELEMENTS : These are elements required by the body in quantities of less than a few milligrams per day, e.g. iron, iodine, fluorine, zinc, copper cobalt, chromium, manganese, molybdenum, selenium, nickel, tin, silicon and vanadium *(41)*. Many more have been added to the list in the last few years. (c) TRACE CONTAMINANTS WITH NO KNOWN FUNCTION : These include lead, mercury, barium, boron, and aluminium.

Only a few mineral elements (e.g., calcium, phosphorus, sodium, iron, fluorine, iodine) are associated with clearly recognizable clinical situations in man. For none of the other elements do we know with any certainty for their metabolic roles, and much less the clinical effects of dietary insufficiency *(42)*. The bio-availability of minerals such as iron and zinc may be low in a total vegetarian diet because of the presence of substances such as phytic acid. Besides, large amounts of dietary fibre may interfere with proper absorption. Man is not likely to suffer from trace element deficiencies as long as he is omnivorous. Surveys have shown that mineral deficiencies are no greater among vegetarians than among non-vegetarians. In fact, man's need for trace elements has not yet been precisely determined. Trace elements should not be used as dietary supplements, since excessive amounts can have injurious effects.

CALCIUM

Calcium is a major mineral element of the body. It constitutes 1.5–2 per cent of the body weight of an adult human. An average adult body contains about 1200 g of calcium of which over 98 per cent is found in the bones. The amount of calcium in the blood is usually about 10 mg/dl. The developing foetus requires about 30 g of calcium. There is a dynamic equilibrium between the calcium in the blood and that in the skeleton; this equilibrium is maintained by the interaction of vitamin D, parathyroid hormone, and probably calcitonin.

Functions

Ionized calcium in the plasma has many vital functions including formation of bones and teeth, coagulation of blood, contraction of muscles, cardiac action, milk production, relay of electrical and chemical messages that arrive at a cell's surface membrane to the biochemical machinery within the cell, keeping the membranes of cells intact and in the metabolism of enzymes and hormones. It also plays a crucial role in the transformation of light to electrical impulses in the retina. In short, the calcium ion controls many life processes ranging from muscle contraction to cell division.

Sources

Calcium is readily available from many sources. By far the best natural sources are milk and milk products, (e.g., cheese, curd, skimmed milk and butter milk), eggs and fish. A litre of cow's milk provides about 1200 mg of calcium, and human milk about 300 mg. Calcium occurs in milk as

calcium caseinogenate which is readily assimilated by the body. The cheapest dietary sources are green leafy vegetables, cereals and millets. The limiting factor in the complete absorption of calcium from green leafy vegetables (e.g., spinach, amaranth) is the presence of oxalic acid with which calcium forms an insoluble compound, calcium oxalate which interferes with the absorption of calcium. Most cereals are generous providers of calcium, and the millet "ragi" is particularly rich in calcium. Rice is very deficient in calcium *(43)*. The bioavailability of calcium from cereals is poor because of the presence of phytic acid which forms an insoluble compound with calcium, calcium phytate. An additional source of calcium is drinking water which may provide up to 200 mg/day. Some fruits (e.g. Sitaphal) contain good amounts of calcium.

Absorption

Overall, about 20–30 per cent of dietary calcium is normally absorbed. Absorption of calcium is enhanced by vitamin D and decreased by the presence of phytates, oxalates and fatty acids in the diet. Calcium absorption is regulated to some extent by the body's needs.

Deficiency

No clear-cut disease due to calcium deficiency has ever been observed, even under conditions of low intake *(44)*. It has been established that if the intake of vitamin D is adequate, the problems of rickets and osteomalacia do not arise even with low calcium intake. On the other hand, no deleterious effects have been observed in man as a result of prolonged intakes of large amounts of dietary calcium, neither have any benefits been demonstrated.

Requirement

A daily intake of 600 mg of calcium has been suggested for adults *(9)*. The physiological requirements are higher in children, expectant and nursing mothers. Intake values recommended by ICMR *(9)* are as given in Table 29.

PHOSPHORUS

Phosphorus is essential for the formation of bones and teeth. It plays an important part in all metabolisms. An adult human body contains about 400–700 g of phosphorus as phosphates, most of this occurs in bones and teeth. Phosphorus is widely distributed in foodstuffs; its deficiency rarely occurs. A large part of phosphorus present in vegetable foods occurs in combination with phytin and is available to the body only to the extent of 40–60 per cent. Phosphorus requirements have not been specifically considered by FAO/WHO Committees, but other groups of experts have suggested that phosphorus intake should be at least equal to calcium intakes in most age groups, except in infancy where the ratio suggested is 1:1.5 *(9)*.

SODIUM

Sodium is found in all body fluids. The adult human body contains about 100 g of sodium ion. Sodium occurs in many foods, and is also added to food during cooking in the form of sodium chloride. Sodium is lost from the body through urine and sweat; that which is passed out in urine is regulated by the kidney but that which is lost by sweating is not controlled. Depletion of sodium chloride causes muscular cramps. The requirement of sodium chloride depends upon climate, occupation and physical activity. Adult requirement is about 5 g per day. A strong relationship between hypertension and dietary salt intake has been observed and intake of more than 10 g of salt per day is considered to have definitive tendency to raise blood pressure *(9)*.

POTASSIUM

The adult human body contains about 250 g of potassium. Potassium occurs widely in foodstuffs, so there is little likelihood of its deficiency. Potassium is vasoactive, increases blood flow and sustains metabolic needs of the tissue. Potassium is released by endothelial cells. Potassium supplements lower blood pressure, although the response is slow. Much of the information regarding potassium and blood pressure is in relation to dietary sodium. High dietary sodium, low dietary potassium have been implicated in the aetiology of hypertension as evidenced by epidemiological clinical studies *(9)*.

The ideal desirable sodium : potassium ratio in the diet is 1:1 (in mmol).

MAGNESIUM

Magnesium is a constituent of bones, and is present in all body cells. Human adult body contains about 25 g of magnesium of which about half is found in the skeleton. It appears that magnesium is essential for the normal metabolism of calcium and potassium *(45)*. Magnesium deficiency may occur in chronic alcoholics, cirrhosis of liver, toxemias of pregnancy, protein-energy malnutrition and malabsorption syndrome *(46)*. The principal clinical features attributed to magnesium deficiency are irritability, tetany, hyper-reflexia and occasionally hypo-reflexia. Requirements are estimated to be about 340 mg/day for adults *(9)*. For details see Table 29.

IRON

Iron is of great importance in human nutrition. The adult human body contains between 3–4 g of iron, of which about 60–70 per cent is present in the blood (Hb iron) as circulating iron, and the rest (1 to 1.5 g) as storage iron. Each gram of haemoglobin contains about 3.34 mg of iron.

Functions

Iron is necessary for many functions in the body including formation of haemoglobin, brain development and function, regulation of body temperature, muscle activity, and catecholamine metabolism. Lack of iron directly affects the immune system; it diminishes the number of T-cells and the production of antibodies. Besides haemoglobin, iron is a component of myoglobin, the cytochromes, catalase and certain enzyme systems. Iron is essential for binding oxygen to the blood cells. The central function of iron is "oxygen transport", and cell respiration.

Sources

There are two forms of iron, haem-iron and non-haem iron. Haem-iron is better absorbed than non-haem iron. Foods rich in **haem-iron** are liver, meat, poultry and fish.

They are not only important sources of readily available iron but they also promote the absorption of non-haem iron in plant foods eaten at the same time *(47)*. The iron content of milk is low in all mammalian species. Iron content of breast milk averages less than 0.2 mg/dl, and it is well utilized. Foods containing **non-haem** iron are those of vegetable origin, e.g., cereals, green leafy vegetables, legumes, nuts, oilseeds, jaggery and dried fruits. They are important sources of iron in the diets of a large majority of Indian people. The bioavailability of non-haem iron is poor owing to the presence of phytates, oxalates, carbonates, phosphates and dietary fibre which interfere with iron absorption. Other foods which inhibit iron absorption are milk, eggs and tea *(48)*. The Indian diet which is predominantly vegetarian contains large amounts of these inhibitors, e.g., phytates in bran, phosphates in egg yolk, tannin in tea and oxalates in vegetables. In some areas, significant amounts of iron may be derived from cooking in iron vessels.

Absorption

Iron is mostly absorbed from duodenum and upper small intestine in the ferrous state, according to body needs. The rate of iron absorption is influenced by a great many factors like iron reserves of the subjects, the presence of inhibitors (e.g., phosphates), and promoters (e.g., ascorbic acid and ascorbic acid-rich foods) of iron absorption, and disorders of duodenum and jejunum (e.g., coeliac disease, tropical sprue). Iron absorption is greater when there is an increased demand for iron, as for example during pregnancy. Iron absorption from habitual Indian diets is less than 5 per cent *(17)*, the bioavailability being poor.

The absorbed iron is transported as plasma ferritin and stored in liver, spleen, bone marrow and kidney. The characteristic feature of iron metabolism is conservation. When red cells are broken down, the liberated iron is reutilized in the formation of new red cells.

Iron losses

The total daily iron loss of an adult is probably 1 mg, and about 12.5 mg per 28 days cycle in menstruating women. Major routes of iron loss are : (a) through **haemorrhage**, that is, wherever blood is lost, iron is lost, the causes of which may be physiological (e.g., menstruation, childbirth) or pathological (e.g., hookworms, malaria, haemorrhoids, peptic ulcer); (b) **basal losses**, such as excretion through urine, sweat and bile, and desquamated surface cells. The widespread use of IUDs in the family planning programme is an additional cause of iron loss. IUDs have been shown to increase the average monthly blood loss by between 35 and 146 per cent depending upon the type of the device *(49, 50)*. Hormonal contraceptives, on the other hand, decrease menstrual blood loss by about 50 per cent *(51)*.

Iron deficiency

Three stages of iron deficiency have been described : (a) First stage characterized by decreased storage of iron without any other detectable abnormalities. (b) An intermediate stage of "latent iron deficiency", that is, iron stores are exhausted, but anaemia has not occurred as yet. Its recognition depends upon measurement of serum ferritin levels. The percentage saturation of transferrin falls from a normal value of 30 per cent to less than 15 per cent. This stage is the most widely prevalent stage in India. (c) The third stage is that of overt iron deficiency when there is a decrease in the concentration of circulating haemoglobin due to impaired haemoglobin synthesis *(49)*.

The end result of iron deficiency is nutritional anaemia which is not a disease entity. It is rather a syndrome caused by malnutrition in its widest sense *(51)*. Besides anaemia, there may be other functional disturbances such as impaired cell-mediated immunity, reduced resistance to infection, increased morbidity and mortality and diminished work performance.

Diagnosis of anaemia

A WHO Expert Group *(52)* proposed that "anaemia or deficiency should be considered to exist" when haemoglobin is below the following levels (see Table 13).

TABLE 13

Cut-off points for the diagnosis of anaemia

	g/dl (Venous blood)	MCHC (per cent)
Adult males	13	34
Adult females, non-pregnant	12	34
Adult females, pregnant	11	34
Children, 6 months to 6 years	11	34
Children, 6 to 14 years	12	34

At all ages the normal MCHC should be 34; values below that indicate that red cells are hypochromic, which occurs in iron deficiency anaemia. A haemoglobin level of 10 to 11 g/dl has been defined as early anaemia; a level below 10 g/dl as marked anaemia *(53)*.

EVALUATION OF IRON STATUS

Evaluation of iron status is based on the following parameters :

(a) *Haemoglobin concentration :* Values below those given in Table 14 indicate anaemia. Haemoglobin concentration is a relatively insensitive index of nutrient depletion. Its value is less in population groups in which anaemia is not severe. This is because anaemia is a late manifestation of iron deficiency which can frequently occur without the manifestation of anaemia *(52)*.

(b) *Serum iron concentration :* This is a more useful index than haemoglobin concentration. The normal range is 0.80 to 1.80 mg/L; values below 0.50 mg/L indicate probable iron deficiency *(54)*.

(c) *Serum ferritin :* The single most sensitive tool for evaluating the iron status is by measurement of serum ferritin. It reflects the size of iron stores in the body. It is the most useful indicator of iron status in a population where the prevalence of iron deficiency is not high. Values below 10 mcg/L probably indicate an absence of stored iron *(19)*.

(d) *Serum transferrin saturation :* This should be above 16 per cent. Normal value is 30 per cent.

Iron requirements

Because of the recycling of iron, only a small amount of iron is needed by the body. In general, iron requirements are greater when there is rapid expansion of tissue and red cell mass, as for example during pregnancy, childhood & adolescence. Table 14 shows the recommended daily intakes.

TABLE 14

Requirement of iron for different age groups

Group			Body weight (kg)	Iron in mg that should be absorbed (daily needs)
Adult man			60	0.84
Adult woman (NPNL)			55	1.65
Pregnant woman			55*	2.80
Lactating woman (0-6 months)			55	1.65
Infants	0-6 months		5.4	46 µg/kg/d
	6-12 months		8.4	87 µg/kg/d
Children		1-3 years	12.9	0.45
		4-6 years	18.0	0.63
		7-9 years	25.1	0.77
Adolescents				
	Boys	10-12 years	34.3	1.05
	Girls	10-12 years	35.0	1.33
	Boys	13-15 years	47.6	1.60
	Girls	13-15 years	46.6	1.36
	Boys	16-17 years	55.4	1.37
	Girls	16-17 years	52.1	1.30

* Pre-pregnancy weight ; NPNL – non-pregnant non-lactating

Source : *(9)*

The recommended dietary intakes of iron are as given in Table 29.

IODINE

Iodine is an essential micronutrient. It is required for the synthesis of the thyroid hormones, thyroxine (T_4) and triiodothyronine (T_3) containing respectively 4 and 3 atoms of iodine. Iodine is essential in minute amounts for the normal growth and development and well-being of all humans. The adult human body contains about 50 mg of iodine, and the blood level is about 8–12 micrograms/dl *(31)*.

Sources

The best sources of iodine are sea foods (e.g., sea fish, sea salt) and cod liver oil. Smaller amounts occur in other foods, e.g., milk, meat, vegetables, cereals, etc. The iodine content of fresh water is small and very variable, about 1–50 micrograms/L *(31)*.

About 90 per cent of iodine comes from foods eaten; the remainder from drinking water. The iodine content of the soil determines its presence in both water and locally grown foods. The deficiency is geochemical in nature.

Goitrogens

"Goitrogens", are chemical substances leading to the development of goitre. They interfere with iodine utilization by the thyroid gland. They may occur in food and water. The brassica group of vegetables (e.g., cabbage, cauliflower) may contain goitrogens. Most important among the dietary goitrogens are probably cyanoglycosides and the thiocyanates.

Deficiency

The most obvious consequence of iodine deficiency is goitre but recent studies have indicated that there is a much wider spectrum of disorders, some of them so severe as to be disabling. They include : (a) hypothyroidism (b) retarded physical development and impaired mental function (c) increased rate of spontaneous abortion and stillbirth (d) neurological cretinism, including deaf-mutism; and (e) myxoedematous cretinism, including dwarfism and severe mental retardation. To express this state of affairs more accurately, the term "endemic goitre", is now replaced by the term **Iodine Deficiency Disorders** (IDD) to refer to all the effects of iodine deficiency on human growth and development which can be prevented by correction of iodine deficiency *(55, 56, 57)*. The spectrum of IDD is as shown in Table 15.

TABLE 15

The spectrum of iodine-deficiency disorders in approximate order of increasing severity

Disorders	Levels of severity
Goitre	– Grade I
	– Grade II
	– Grade III
	– Multinodular
Hypothyroidism	– Varying combinations of clinical signs (depending on age of onset, duration and severity)
Subnormal intelligence Delayed motor milestones Mental deficiency Hearing defects Speech defects	Variable severity
Strabismus (squint)	– Unilateral
	– Bilateral
Nystagmus	
Spasticity (extrapyramidal) Neuromuscular weakness	– Muscle weakness in legs, arms, trunk
	– Spastic diplegia
	– Spastic quadriplegia
Endemic cretinism	– Hypothyroid cretinism
	– Neurological cretinism
Intrauterine death (spontaneous abortion, miscarriage)	

It can be seen from Table 15 that the problem of IDD is of far greater magnitude than one of goitre and cretinism. It is a national problem with grave socio-economic consequences. Adequate technology exists for the successful prevention of iodine deficiency disorders (see page 643).

Requirement

The daily requirement of iodine for adults is placed at 150 micrograms. The recommendations of WHO of 250 mcg per day for iodine during pregnancy have also been adopted. This amount is normally supplied by well-balanced diet and drinking water except in regions where food and water are deficient in iodine.

Epidemiological assessment of iodine deficiency

This is necessary before initiating an iodization programme, and for surveillance of goitre control

programmes. The following indicators are useful in this regard *(58)* :

- prevalence of goitre
- prevalence of cretinism
- urinary iodine excretion
- measurement of thyroid function by determination of serum levels of thyroxine (T_4) and pituitary thyrotropic hormone (TSH), and
- prevalence of neonatal hypothyroidism.

Since the objective of goitre control programme is to increase iodine intake, indices of urinary excretion are particularly recommended for use in surveillance. Neonatal hypothyroidism has been found to be a sensitive indicator of environmental iodine deficiency. Serum T_4 level is a more sensitive indicator of thyroid insufficiency than T_3.

FLUORINE

Fluorine is the most abundant element in nature. Being so highly reactive, it is never found in its elemental gaseous form, but only in combined form. About 96 per cent of the fluoride in the body is found in bones and teeth. Fluorine is essential for the normal mineralization of bones and formation of dental enamel.

Sources

The principal sources of fluorine available to man are : (a) **Drinking water** : The major source of fluorine to man is drinking water. In most parts of India, the fluoride content of drinking water is about 0.5 mg/L, but in fluorosis-endemic areas, it may be as high as 3 to 12 mg/L *(59)*. (b) **Foods** : Fluorides occur in traces in many foods, but some foods such as sea fish,, cheese and tea are reported to be rich in fluorides *(38)*.

Deficiency/excess

Fluorine is often called a two-edged sword. Prolonged ingestion of fluorides through drinking water in excess of the daily requirement is associated with dental and skeletal fluorosis; and inadequate intake with dental caries. The use of fluoride is recognized as the most effective means available for the prevention of dental caries.

Requirements

The recommended level of fluorides in drinking water in India is accepted as 0.5 to 0.8 mg per litre *(60, 61)*. In temperate countries where the water intake is low, the optimum level of fluorides in drinking water is accepted as 1 to 2 mg per litre *(62)*.

OTHER TRACE ELEMENTS

Zinc

Zinc is a component of more than 300 enzymes. It is active in the metabolism of glucides and proteins, and is required for the synthesis of insulin by the pancreas and for the immunity function. Zinc is present in small amounts in all tissues. Zinc–plasma level is about 96µg per 100 ml for healthy adults, and 89 µg per 100 ml for healthy children *(63)*. The average adult body contains 1.4 to 2.3 g of zinc *(64)*. Zinc deficiency has been reported to result in growth failure and sexual infantilism in adolescents, and in loss of taste and delayed wound healing *(10)*. There are also reports of low circulating zinc levels in clinical disorders such as liver disease, pernicious anaemia, thalassaemia and myocardial infarction. Zinc deficiency is common in children from developing countries due to lack of intake of animal food, high dietary phytate content, inadequate food intake and increased faecal losses during diarrhoea. Zinc supplementation in combination with oral rehydration therapy has been shown to significantly reduce the duration and severity of acute and persistent diarrhoea and to increase survival in a number of randomized control trials. Adequate zinc intake is essential for maintaining the integrity of immune system. Zinc affects multiple aspects of the immune system, from the barrier of the skin to gene regulation within lymphocytes. Severe maternal zinc deficiency has been associated with spontaneous abortion and congenital malformations like anencephaly. Milder forms of zinc deficiency has been associated with low birth weight, intrauterine growth retardation and preterm delivery. Several studies have indicated that zinc supplementation may reduce the incidence of clinical attacks of malaria in children. Zinc plays an important role as antioxidant agent *(65)*. These reports suggest that zinc deficiency may not be uncommon in man *(63)*. Zinc is widely distributed in foodstuffs, both animal and vegetable – but the bioavailability of zinc in vegetable foods is low. Animal foods such as meat, milk and fish are dependable sources. Suggested daily intake for adults is 12 mg per day for men, 10 mg per day for women, 10 mg per day for children and 5 mg for infants. Refer to Table 29 for details. Growing children and pregnant and lactating women need more. Most human diets provide these amounts.

Copper

The amount of copper in an adult body is estimated to be between 100–150 mg. Copper is widely distributed in nature. Even poor diets provide enough copper for human needs. Deficiency or excess of this element is very rare. Hypocupremia occurs in patients with nephrosis, Wilson's disease and protein-energy malnutrition and in infants fed for long periods exclusively on cow's milk. Neutropenia is the best documented abnormality of copper deficiency. Hypercupremia may reflect excessive intake which may result from eating food prepared in copper cooking vessels, or it may be associated with several acute and chronic infections (leukaemia, Hodgkin's disease, severe anaemia, haemochromatosis, myocardial infarction and hyperthyroidism *(66)*. Estimated copper requirement for adults is about 2.0 mg per day.

Cobalt

The only established function of cobalt in the human is as a part of the vitamin B_{12} molecule, which must be ingested preformed. There is no evidence as yet of cobalt deficiency in man *(10)*. Recently cobalt deficiency and cobalt iodine ratio in the soil have shown to produce goitre in humans. It is suggested that cobalt may be necessary for the first stage of hormone production. i.e., capture of iodine by the gland *(67)*. Cobalt may interact with iodine and affect its utilization *(10)*.

Chromium

Total body content of chromium is small, less then 6 mg. Current interest in chromium is based on the occurrence of unusual glucose tolerance curves that are responsive to chromium *(41)*. Thus there is suggestive evidence that chromium plays a role in relation to carbohydrate and insulin function *(10)*.

Selenium

Little attention had been given earlier to selenium in human nutrition. The first report that selenium deficiency may occur in man appeared in 1961, and a similar report in 1967. Selenium administration to children with kwashiorkor resulted in significant weight increase. Studies indicate that human selenium deficiency may occur in protein-energy malnutrition *(66)*. Selenium deficiency especially when combined with vitamin E deficiency, reduces antibody production *(68)*.

Molybdenum

Excess absorption of molybdenum has been shown to produce bony deformities. On the other hand, deficiency of molybdenum is associated with mouth and oesophageal cancer *(67)*.

Dietary antioxidants *(9)*

Antioxidants are substances which are both nutrients, viz. vitamins E, C, β-carotene, selenium, and non-nutrients, viz. plant phenols, flavonoids, coumarins, benzyl isothiocyanates, caffeic, ferrulic, gallic and ellagic acids, some enzymes like superoxide dismutase and catalase superoxides mutase. These antioxidants reduce the adverse effects of reactive oxygen species (ROS) and nitrogen species which are generated during physiological or pathological conditions and result in oxidant damage. Literature is replete with evidence that ageing and several diet/nutrient related chronic disorders are due to chronic exposure to ROS. It is well established that vegetables, fruits, legumes, spices, beverages such as tea and wine, and cereals are excellent sources of AO, however scientific evidence for their protective role is available only for vegetables and fruits in several chronic disorders. None of the randomized clinical trials conducted so far with nutrient AO supplements has demonstrated a significant benefit in community trials barring one or two major trials in high-risk populations.

Experimental studies have amply indicated that both pro-oxidant and AO have a fundamental role in pathogenesis of diseases. Reactive oxygen species (ROS) damage the bio-molecules such as DNA, protein, carbohydrates and lipids, and affect the enzyme processes and genetic machinery. The oxidation products of bio-molecules accumulate with age. ROS can be derived from an enviornmental source also. There are several endogenous and exogenous sources of ROS, which play an important role in diseases such as cardiovascular, cancer, cataract, diabetes, neuro-degenerative disorders and age-related masculopathy. Chronic infections aggravate the damage. Further, research in this field has highlighted the mechanistic details about the role of antioxidants in mitigating the damage.

Free radicals produced during tissue metabolism and their consequent damage are reduced by nutrient antioxidants. The antioxidants, particularly vitamin E, C, co-enzyme Q and glutathione seem to work in concert by recycling each other.

In healthy subjects, the dietary antioxidants from a balanced diet with adequate fruits and vegetables ranging from 500–600 gm/d will probably be enough to take care of oxidant damage and repair cellular and tissue defects. However, certain groups of populations like pre-mature infants, smokers, alcoholics, and those exposed to environmental pollutants including carcinogens, individuals with chronic infections as well as those engaged in strenous physical activity and geriatric population, are at high-risk of oxidant damage.

At present the amount of antioxidants to be consumed daily to protect against risk factors cannot be quantitatively fixed *(9)*.

NUTRITIONAL PROFILES OF PRINCIPAL FOODS

When planning balanced diets, it is important to know what foods are available according to origin, approximate chemical composition, predominant function and how to combine them to increase nutritive value. Since each food has a different nutritional profile, an intake of different types of foods is desired to achieve optimum health.

1. Cereals and millets

CEREALS

Cereals (e.g., rice, wheat) constitute the bulk of the daily diet. Rice is the staple food of more than half the human race. Next to rice, wheat is the most important cereal. Maize ranks next to rice and wheat in world consumption. Maize is also used as food for cattle and poultry because it is rich in fat, besides being cheaper than rice or wheat.

Cereals are the main sources of energy (carbohydrates). They also contribute significant quantities of proteins (6 to 12 per cent), minerals and B-group vitamins. The yellow variety of maize contains significant amounts of carotene. In terms of energy, cereals provide about 350 kcal per 100 grams. Considering the large amounts in which they are consumed, cereals contribute 70 to 80 per cent of the total energy intake, and more than 50 per cent of protein intake in typical Indian diets.

Cereal proteins are poor in nutritive quality, being deficient in the essential amino acid, lysine. The proteins of maize are still poorer, being deficient in lysine and tryptophan (a precursor of niacin). However, if cereals are eaten with pulses, as is common in the traditional Indian diets, cereal and pulse proteins complement each other and provide a more balanced and "complete" protein intake. Some strains of maize contain an excess of leucine which interferes with the conversion of tryptophan into niacin; this aggravates the pellagragenic action of maize.

Table 16 gives the nutritive value of some common cereals.

TABLE 16

Nutritive value of cereals (values per 100 g.)

		Raw rice milled	Wheat whole	Maize dry
Protein	(g)	6.8	11.81	11.1
Fat	(g)	0.5	1.5	3.6
Carbohydrate	(g)	78.2	71.2	66.2
Thiamine	(mg)	0.06	0.45	0.42
Niacin	(mg)	1.9	5.0	1.8
Riboflavin	(mg)	0.06	0.17	0.1
Minerals	(g)	0.6	1.5	1.5
Energy	(kcal)	345	346	342

Source : *(34)*

Rice

Rice is the staple food of more than half the human race. The rice grain consists of 3 parts – the germ (embryo), the inner endosperm, and the outer pericarp and aleurone grain layer. The endosperm is composed mostly of starch; the outer pericarp aleurone layer and germ contain most of the essential nutrients. The protein content of rice varies from 6–9 per cent. Rice proteins are richer in lysine than the other cereal proteins, and for this reason, rice protein is considered to be of better quality. Rice is a good source of B group vitamins, especially thiamine. It is devoid of vitamins A, D and C. In regard to minerals rice is a poor source of calcium and iron (Table17).

TABLE 17

Effect of milling on rice

	Protein (g)%	Calcium (g)%	Phosphorus (g)%	Iron (mg)%	Vit.B (mg)%	Niacin (mg)%
Raw, husked rice	7.7	0.015	0.368	4.0	0.40	3.5
Raw, undermilled or home pounded rice (about 7% polishings removed)	7.2	0.013	0.146	2.2	0.22	2.2
Raw milled rice (about 14% polishings removed)	7.0	0.010	0.110	2.0	0.11	1.0

Effect of milling

The milling process deprives the rice grain of its valuable nutritive elements (thiamine, riboflavin, protein). The losses may be upto 15 per cent of protein, 75 per cent of thiamine and 60 per cent of riboflavin and niacin *(69)*. The resulting white or polished rice, although attractive in appearance, is poor in nutritive value. People subsisting mainly on white or polished rice are prone to beriberi, the best known deficiency disease of rice eaters. Nutrition workers therefore advocate under-milled or "parboiled" rice in place of white rice.

Washing and cooking

The rice grain is subjected to further loss of essential nutrients during the process of washing and cooking. Washing in large quantities of water would remove upto 60 per cent of the water-soluble vitamins and minerals. The practice of cooking rice in large quantities of water and draining away the excess of water at the end of cooking leads to further loss of B-group vitamins. Thus the combined effect of washing and cooking may affect seriously the nutritive value of rice. It is therefore best to cook rice in just enough water (about 2 measure of water for 1 measure of rice).

Parboiling

Parboiling (partial cooking in steam) is ancient Indian technique of preserving the nutritive quality of rice. There are many techniques of parboiling. The technique recommended by the Central Food Technological Research Institute, Mysore *(8)* is known as the **hot soaking process**.

The process starts with soaking the paddy (unhusked rice) in hot water at 65 to 70 deg. C for 3 to 4 hours, which swells the grain. This is followed by draining of water and steaming the soaked paddy in the same container for 5 to 10 minutes. The paddy is then dried and later homepounded or milled.

During the steaming process, a greater part of the vitamins and minerals present in the outer aleurone layer of the rice grain are driven into the inner endosperm. With subsequent milling, even to a high degree, the nutrients are not removed. During the drying process, the germ gets attached more firmly to the grain. In addition, the heat used in drying hardens the rice grain. It results in the grain becoming more resistant to insect invasion and more suitable for storage than raw rice. The starch also gets gelatinized which improves the keeping quality of rice *(8)*. The serious disadvantage of parboiling is the development of a peculiar smell or "off flavour" which some consumers do not relish. Modern methods of parboiling rice have been developed by which the finished product does not give any bad odour.

Wheat

Next to rice, wheat is the most important cereal. The nutritive composition of wheat is given in Table 16. The protein content of wheat varies from 9 to 16 per cent, the limiting amino-acids are lysine and threonine. The wheat grain is much less subjected to loss of essential nutrients during processing than rice. In India, the bulk of wheat is consumed as whole grain wheat flour or atta. Maida or white flour which represents 70 per cent extraction of wheat is poorer from the nutrition standpoint. The whiter the flour the greater the loss of vitamins and minerals. Thus whole grain wheat flour is richer source of vitamin B than refined white flour.

Maize

Maize (Corn, *bhutta*) ranks next to rice and wheat in world consumption, and in certain areas it is the principal source of proteins and energy both. It is also used as a food for cattle and poultry. The yellow variety of maize contains significant amount of carotenoid pigments. Maize is fairly rich in fat (Table 16). The proteins of maize are deficient in tryptophan and lysine; and some strains contain an excess of leucine. Studies indicate that excess of leucine interferes in the conversion of tryptophan into niacin, and thus aggravates the pellagragenic action of maize. Maize is also used in the manufacture of breakfast foods such as cornflakes. Maize flour or corn flour is widely used in the preparation of custards and table desserts. The incorporation of opaque–2 gene into maize has greatly improved the quality of its protein.

MILLETS

The term "millet" is used for smaller grains which are ground and eaten without having the outer layer removed; they are jowar (sorghum), bajra (pearl millet), ragi, kodo and a few others known as "minor millets" or pseudocereals *(70)*. The nutritive value of millets is as shown in Table 18.

TABLE 18
Nutritive value of millets (values per 100 g)

		Jowar	Bajra	Ragi
Protein	(g)	10.4	11.6	7.3
Fat	(g)	1.9	5.0	1.3
Carbohydrate	(g)	72.6	67.5	72.0
Minerals	(g)	1.6	2.3	2.7
Calcium	(mg)	25.0	42.0	344.0
Iron	(mg)	4.1	8	3.9
Thiamine	(mg)	0.3	0.3	0.2
Riboflavin	(mg)	1.3	0.25	0.18
Niacin	(mg)	3.1	2.3	2.3
Energy	(kcal)	349	361	328

Source : *(34)*

Jowar (sorghum)

Jowar is also known as kaffir corn or Milo. It is a major crop grown in India next only to wheat and rice. For several population groups, it is a staple diet. The protein content of jowar varies from 9 to 14 per cent, and the proteins are limiting in lysine and threonine. Certain varieties of jowar have a high leucine content and consumption of these varieties is associated with pellagra. This disorder is often seen in the Telengana and Marathwada regions where jowar is predominantly consumed.

Bajra (pearl millet)

Bajra is grown extensively in the dry belts of northern and peninsular India, viz. Rajasthan, Gujarat and Maharashtra, where it forms the staple food of large sections of the population. The protein content varies from 10 to 14 per cent; the proteins are deficient in lysine and threonine. Bajra contains significant amounts of B-group vitamins and minerals such as calcium and iron.

Ragi

Ragi is a popular millet in Andhra and Karnataka. It is the cheapest among millets. Ragi flour is cooked and eaten as porridge. Ragi is rich in calcium (see Table 18).

2. Pulses (legumes)

Pulses comprise a variety of grams, also known as dhals. Most commonly eaten pulses are bengal gram (chana), red gram (tuvar or arhar), green gram (mung) and black gram (urd). Others include lentils (masur), peas and beans including soyabean. Khesari dhal *(lathyrus sativus),* is consumed in parts of Madhya Pradesh, Uttar Pradesh and Bihar, excessive consumption of which is associated with lathyrism.

Pulses contain 20 to 25 per cent of proteins, which is double that found in wheat and three times that found in rice. In fact, pulses contain more protein than eggs, fish or flesh foods. But in regard to quality, pulse proteins are inferior to animal proteins. Pulse proteins are poor in methionine and to a lesser extent in cysteine. On the other hand they are rich in lysine. Soyabean is exceptionally rich in protein, containing up to 40 per cent. In addition, pulses are rich in minerals and B-group vitamins such as riboflavin and thiamine. In the dry state, pulses do not contain vitamin C. Germinating pulses, however, contain higher concentration of vitamins, especially vitamin C and B vitamins. Fermentation also modifies the nutritive value of pulses in that the vitamin content particularly that of riboflavin, thiamine and niacin is enhanced.

Although pulses are called "poor man's meat", they are eaten by the rich and poor alike in India. They give variety to the diet and make the food more palatable. Table 19 gives the nutritive value of some common pulses.

TABLE 19
Nutritive value of pulses (values per 100 g)

Pulses	Ene-rgy (kcal)	Prot-eins g	Fat g	Calc-ium mg	Iron mg	Thia-mine mg	Ribo-flavin mg	Nia-cin mg	Vit-C mg
Bengal gram	360	17.1	5.3	202	4.6	0.30	0.15	2.9	3
Black gram	347	24.0	1.4	154	3.8	0.42	0.20	2.0	0
Red gram	335	22.3	1.7	73	2.7	0.45	0.19	2.9	0
Soyabean	432	43.2	19.5	240	10.4	0.73	0.39	3.2	0
Green gram	348	24.5	1.2	75	3.9	0.47	0.21	2.4	0
Peas dry	315	19.7	1.1	75	7.05	0.47	0.19	3.4	0
Horse gram	321	22.0	0.5	287	6.77	0.42	0.2	1.5	1

Source : *(34)*

Anti-nutritional factors : In the raw state, pulses have some anti-nutritional factors such as phytates and tannins which adversely affect the availability of some nutrients to the body. However, most of the anti-nutritional factors are destroyed by heat. Presence of high amounts of certain sugars known as oligosaccharides is known to be associated with flatulence *(71)*.

Soyabean

Soyabean is the richest among pulses. It contains about 40 per cent of protein, 20 per cent of fat and 4 per cent of minerals. The proteins of soyabean are of relatively high nutritive value. The limiting amino-acid is methionine. Soyabean can be cooked and eaten as dhal. It can be tried in other forms like mixing its powder with atta for chappatis, soyabean milk and curd and in baby foods. Soyabean is yet to become popular in India despite many years of publicity.

3. Vegetables

Vegetables are classed as "protective foods"; their value resides in their high vitamin and mineral content. Some vegetables (e.g., green peas, beans) are also good sources of protein. Vegetables usually have a large water content, low energy and protein content and varying amounts of "dietary fibre". Vegetables are divided into three groups "green leaves", "roots and tubers", and "others".

a. Green leaves

The term "green leaves" designates a number of indigenous leafy vegetables consumed by the people. They include palak (spinach), amaranth, cabbage, fenugreek (methi) etc. The darker the green leaves, the greater their nutritive value. With the possible exception of vitamin B_{12}, green leaves are rich sources of carotenes, calcium, iron and vitamin C. They are also fairly good sources of riboflavin, folic acid and many other micronutrients. In addition, leaf proteins (2 to 4 per cent) are good sources of lysine, although deficient in sulphur – containing amino acids. The bioavailability of calcium and iron from greens is rather poor because of the presence of high amounts of oxalates. Leafy vegetables are high in water content and dietary fibre. Because of their low calorific value (25 to 50 kcal per 100 g)

and large bulk, they have an important place in the dietaries of obese people who wish to cut down their calorie intake. The recommended daily intake of green leafy vegetables is about 40 g for an adult.

b. Roots and tubers

Included in this group are potato, sweet potato, tapioca, yam, carrots, onion, radish and colocasia. They vary widely in composition, some are good sources of carbohydrates such as potatoes and tapioca. In general roots and tubers are poor in protein, minerals and vitamins. Carrots are exceptionally high in betacarotene. In times of cereal shortage, potatoes, sweet potatoes, and tapioca can serve as subsidiary foods for limited periods. But bulk and low protein make them unsuitable as staple foods for longer periods, unless supplemented by foods richer in protein. The recommended daily intake of roots and tubers is 50 to 60 g for an adult.

c. Other vegetables

There is a wide range of "other" vegetables such as brinjal, tomatoes, cauliflower, etc. They bring variety to the diet. Many of them are fairly good sources of minerals and vitamins. Some vegetables like cluster beans, drumsticks and green mango contain fair amounts of iron. The daily recommended intake is 60 to 70 grams.

4. Nuts and oilseeds

Included in this group are groundnut (Peanut), cashewnut, coconut, walnut, almonds, pistachio, mustard seeds, sesame seeds, cotton seeds, sunflower seeds, maize germ and many others from which cooking oils are extracted.

Nuts and oilseeds contain good amount of fat and good quality protein in a relatively small bulk. Regarding the fat content, walnuts contain 64.5 per cent, almonds 58.7 per cent, cashewnuts 46.9 per cent and groundnut 40 per cent. Peanut (groundnut) butter is a very valued article of the diet. Regarding protein content, groundnut tops the list with 26.7 per cent. Being of vegetable origin, their protein is not equal to that of meat or eggs in quality. Nuts are good sources of vitamins of the B-group. They contribute minerals such as calcium, phosphorus, and iron. Among the commonly used nuts, cashewnuts and almonds are good sources of iron, but pistachio is the richest containing 14 mg of iron per 100 g.

Most of the vegetable oils are rich in essential fatty acids. After oil extraction in the case of some, the residue (oilseed cake) can be formulated into acceptable foods rich in protein. For example, groundnut flour is used in the manufacture of Indian Multipurpose Food, balahar and balanced malt food. Due partly to their high fat content and partly to their high cellulose content, nuts are not easily digestible. However nuts eaten in a mixed diet are an extremely valuable source of protein. Peanuts for human consumption should be thoroughly dried and properly stored to avoid the growth of *Aspergillus flavus* which produces "aflatoxin".

5. Fruits

Fruits are protective foods. They are invaluable in human nutrition because they are good sources of vitamins and minerals. One special feature which distinguishes fruits from other foods is that they can be eaten raw and fresh. This makes the vitamins and minerals present in fruit easily available.

Nutritive value

(1) *Vitamins :* Fruits are prized for their vitamins. Most fruits contain significant amounts of ascorbic acid. The orange, guava and the Indian gooseberry (amla) are particularly rich in ascorbic acid. One medium sized orange can provide enough juice to meet the daily requirement of ascorbic acid of an adult. Apart from ascorbic acid, several fruits contain good amounts of carotene. The papaya and mango are excellent sources of carotene. (2) *Minerals :* Fruits are good sources of minerals especially sodium and potassium. Some fruits like sitaphal (custard apple) are rich in calcium. Dried fruits like raisins, dates and apricots are good sources of calcium and iron. Fruits also contain a great variety of organic acids which are responsible for the sources of unripe fruits. The intake of fruits leads to an alkaline urine. (3) *Carbohydrates :* Fruits in general have a low energy value but some fruits like banana and mango contain good amounts of carbohydrate and can act as good source of energy. Pectin, a kind of sugar, present in fruits like guavas is helpful in the preparation of fruit jellies. The fruit sugars are easily digestible and completely absorbed. The more ripe a fruit is, the higher its sugar content. (4) *Cellulose :* Fruits contain cellulose which assists in normal bowel movements.

Nutrition experts recommend a daily intake of 85 grams or more of fresh fruit for maintenance of good health. Fruits are costly and it may not be within the reach of all to afford them daily. If green leafy vegetables are included in the daily diet, the need for fruit as an essential item in the diet is much reduced. The aim in nutrition education should be to promote the intake of seasonal fruits which are cheaper and easily available. The costly fruits are not necessarily the best in respect of nutrients. The food values of some common fruits are as given in Table 20.

TABLE 20

Nutritive value of some common fruits (per 100 g of edible portion)

Name	Calories	Calcium (mg)	Iron (mg)	Carotene (µg)	Vit. C (mg)
Fresh fruits :					
Banana	104	10	0.5	124	7
Grapes	71	20	1.5	0	1
Guava	51	10	0.27	0	212
Mango	74	14	1.3	2,210	16
Orange	48	26	0.32	2,240	68
Papaya	32	17	0.5	2,740	57
Sitaphal	104	17	4.31	0	37
Amla	58	50	1.2	9	600
Dry fruits :					
Dates	317	120	7.3	44	3

Cashew nut	596	50	5.81	0	0
Ground nut	567	90	2.5	37	0

Source : *(34)*

6. Animal foods

Foods of animal origin include meat, poultry, fish, eggs, milk and dairy products. They provide high quality protein (containing all the essential amino acids) and good amounts of fat, besides some vitamins and minerals. Vitamin B_{12} is one of the rare nutrients found only in animal foods. Since they are expensive, animal foods are consumed in small

amounts in most developing countries. Even small amounts of animal foods add considerably to the nutritive value of the diet. Among animal foods, cow's milk and hen's egg are perhaps nature's two most "nearly perfect" foods.

Milk

Milk is the best and most complete of all foods. It is secreted by the animals to serve as the sole and wholesome food for their suckling young ones. It is a fine blend of all the nutrients necessary for growth and development of the young ones. Thus milk is a good source of proteins, fats, sugars, vitamins and minerals.

(i) *Proteins* : The chief protein of milk is casein; it occurs in combination with calcium as calcium caseinogenate. The other proteins are lactalbumin and lactoglobulin. Animal milks contain nearly three times as much protein as human milk. Milk proteins contain all the essential amino acids. Human milk proteins contain greater amounts of tryptophan and sulphur–containing amino-acids (especially cystein) than the animal milk proteins. (ii) *Fat* : The fat content of milk varies from 3.4 per cent in human milk to 8.8 per cent in buffalo milk. Human milk contains a higher percentage of linoleic acid and oleic acid than animal milks. Milk fat is a good source of retinol and vitamin D. (iii) *Sugar* : The carbohydrate in all milks is lactose or milk sugar. It is found nowhere else in nature. It is less sweet than cane sugar and is readily fermented by lactic acid bacilli. Human milk contains more sugar than animal milks. (iv) *Minerals* : Milk contains almost all known minerals needed by the body such as calcium, phosphorus, sodium, potassium, magnesium, cobalt, copper, iodine, etc. Milk is particularly rich in calcium; it is however a poor source of iron. (v) *Vitamins* : Milk is a good source of all vitamins except vitamin C.

Human and animal milks are as compared in Table 21, which illustrates that milk is to a great extent species-specific.

TABLE 21
Nutritive value of milks compared
(value per 100 grams)

		Buffalo	Cow	Goat	Human
Fat	(g)	6.5	4.1	4.5	3.4
Protein	(g)	4.3	3.2	3.3	1.1

Calcium	(mg)	210	120	170	28
Iron	(mg)	0.2	0.2	0.3	
Vitamin C	(mg)	1	2	1	3
Minerals	(g)	0.8	0.8	0.8	0.1
Water	(g)	81.0	87	86.8	88
Energy	(kcal)	117	67	72	65

Source : *(34)*

Milk products

Milk is consumed in a variety of forms – as whole milk, butter, ghee, cheese, dried and condensed milk, khoa, ice cream, etc. Milk from which fat has been removed, is known as "skimmed milk". It is devoid of fat and fat soluble vitamins, but a good source of milk protein (35 per cent) and calcium.

Toned milk

The term "toned" is an Indian coinage. It is a blend of natural milk and "made-up" milk. It contains 1 part of water, 1 part of natural milk and 1/8 part of skim milk powder. The mixture is stirred, pasteurized and supplied in bottles. Toned milk has a composition nearly equivalent to cow's milk. It is cheaper and yet a wholesome product.

Vegetable milk

Milk prepared from certain vegetable foods (viz. groundnut, soyabean) is termed "vegetable milk". It may be used as a substitute for animal milk. The Central Food Technological Research Institute, Mysore has perfected techniques for the preparation of vegetable milk *(72)*.

Egg

Egg contains all the nutrients except carbohydrate and vitamin C. About 12 per cent of egg is made of shell, 58 per cent of egg white, and 30 per cent of egg yolk. An egg weighing 60 grams contains 6 g of protein, 6 g of fat, 30 mg of calcium and 1.5 mg of iron, and supplies about 70 kcal of energy. Egg proteins have all the nine essential amino acids needed by the body in right proportions. Nutritionists consider egg protein as the best among food proteins. In fact, egg protein is the standard against which the quality of other proteins is compared. Except for vitamin C, egg contains all the fat-soluble and water-soluble vitamins in appreciable amounts. Important minerals such as calcium, phosphorus, iron, zinc and other trace elements are present in the egg. Barring milk, no other food can supply such a diverse range of nutrients. Net protein utilization (NPU) which combines in a single value the biological value and digestibility, is 100 for egg compared to 80 for meat and 75 for milk. Raw egg white is not assimilated by the intestinal mucosa, therefore it must be cooked before consumption. Boiling destroys 'avidin', a substance which prevents the body from obtaining biotin, one of the B-complex vitamins. Boiled egg is therefore nutritionally superior to raw egg. In recent years the cholesterol content of egg (250 mg/egg) has generated a sense of fear because of the risk of CHD. A reduction in intake of eggs is advised for those at risk of CHD. This should not distract others from eating eggs. Eggs or no eggs, cholesterol is formed in the body endogenously and is controlled by what is known as feedback mechanism.

Fish

Fish is nutritious food rich in proteins (15 to 25 per cent) with a good biological value and a satisfactory amino acid balance. The fat of fish is rich in unsaturated fatty acids and A and D vitamins. Fish liver oils are the richest source of vitamins A and D. Fish bones when eaten are an excellent source of calcium, phosphorus and fluorides. Fish are less rich in iron (0.7 to 3 mg per 100 g) than meat. Fresh water fish do not contain iodine, but sea fish do. Of all the sea foods, oysters and lobsters are the richest in iodine. There is practically no carbohydrate in fish. The fish proteins are easily digested. The nutritive value of diet is greatly enhanced by inclusion of fish.

Meat

The term "meat" is applied to the flesh of cattle, sheep and goats. Meats contain 15 to 20 per cent of protein, which is less than that found in pulses, but meat proteins are a good source of essential amino acids. Iron contained in meat (2 to 4 mg per 100 g) is more easily absorbed than iron in plants and this is another major quality of meat. In addition,

meat contains varying amounts of fat, which is composed of non-essential saturated fat. The energy provided by meat depends upon its fat content. Besides iron, meat provides minerals such as zinc and B-vitamins. It is poor in calcium (10 to 25 mg per 100 g) but rich in phosphorus. Liver is extremely rich in many nutrients.

Table 22 shows the nutritive value of meat, fish and eggs.

TABLE 22
Nutritive value of Meat, Fish and Eggs (g/100 g)

	Proteins	Fat	Minerals
Meat, Goat	21.4	3.6	1.1
Fish	19.5	2.4	1.5
Egg. hen*	13.3	13.3	1.0
Liver goat	20.0	3.0	1.3

* Two large eggs without shell weigh about 100 g.

7. Fats and oils

Good cooking demands liberal use of oils and fats. Fats which are liquid at room temperature are called oils. Fats and oils are good sources of energy and fat-soluble vitamins. Fats of animal origin are poor sources of essential fatty acids. Those of vegetable origin are rich in poly-unsaturated fatty acids, excepting coconut and palm oils. The vegetable oils contain no vitamin A and D, except for red palm oil which is extremely rich in carotene. During the past 25 years, there has been a great increase in manufacture of vanaspati (hydrogenated fat) under various trade names. Margarine is made from vegetable oils and is fortified with vitamin A and D.

8. Sugar and jaggery

These are carbohydrate foods. Sugar is produced from sugarcane in India, and from sugar beet elsewhere. Refined sugar is pure sucrose and contains no other nutrients. Jaggery is prepared from sugarcane in India and is consumed in place of sugar. It contains useful amounts of carotene and iron derived from cooking pans. Honey consists of about 75 per cent sugars, mostly fructose and glucose.

9. Condiments and spices

These include asafoetida, cardamom, chillies, garlic, cloves, ginger, mustard, pepper, tamarind, turmeric, etc. They are mainly used to enhance the palatability of foods and stimulate appetite. The essential oils present in them have carminative properties and may aid in digestion. Excessive consumption of condiments is associated with peptic ulcer.

10. Miscellaneous

Beverages : Diet includes beverages, and especially water which is essential to life. Beverages include drinks which are appreciated for their flavour or their stimulating properties. They may be classified as follows :

(i) Coffee, tea, cocoa.
(ii) Soft drinks : aerated water, lemonade, pepsi cola, fruit juices, etc.
(iii) Alcoholic beverages : wine, beer, whisky and traditional preparations. Alcoholic beverages are rich in calories.

Coffee, tea and cocoa

(a) *Coffee :* Coffee contains caffeine (0.6 to 2.0 per cent), volatile oils (caffeol) and tannic acid. Caffeine is a stimulant of the nervous system. When coffee seeds are roasted, tannin is destroyed, proteins are coagulated and the pleasant aroma is liberated.

(b) *Tea :* There are two main varieties of tea – the green and the black varieties. Green tea which is more astringent than the black variety is popular in China, Japan and Assam. The chemical composition of tea is as follows : (i) *caffeine :* 2 to 6 per cent (ii) *tannic acid :* 6 to 12 per cent (iii) *theophylline :* traces (iv) *essential volatile oils:* 5 per cent. Tea is prepared by adding leaves to boiling water. When milk is added; the casein of milk combines with tannin and forms a harmless complex.

(c) *Cocoa :* Cocoa is obtained from cocoa beans. It is rich in fat, and contains theobromine which has stimulating properties. The composition of a cup of tea, coffee and cocoa containing the usual amount of sugar is given in Table 23. The nutritive value of a cup of tea or coffee is really due to its milk and sugar content.

TABLE 23
The chemical composition of coffee, tea and cocoa (values per cup of 150 ml)

		Coffee	Tea	Cocoa
Protein	(g)	1.8	0.9	7.2
Fat	(g)	2.2	1.1	8.8
Carbohydrate	(g)	17.8	16.4	26.2
kcal		98.0	79.0	213.0

Soft drinks

Some are carbonated (e.g., soda water incorporating carbon dioxide under high pressure) and others non-carbonated such as fruit juices. The principal ingredients of soft drinks are carbon dioxide, sugars, acids such as citric acid or tartaric acid, colouring and flavouring agents. Fruit beverages comprise fruit juices, squashes and cordials. Fruit squashes and cordials are diluted with water before consumption.

Alcoholic beverages

These are beer, whisky, rum, gin, arrack, etc. The alcoholic content of these beverages varies widely from 5 to 6 per cent in beers to 40 to 45 per cent in whisky, rum, gin and brandy. Alcohol supplies about 7 kcal per gram.

b. Vinegar

Natural vinegar is made from fermentation of fruits, malt and molasses. It contains a minimum of 3.7 per cent acetic acid. Synthetic vinegar should not be harmful if it is free from lead, copper, arsenic or mineral acids. Synthetic vinegar should be distinctly labelled "SYNTHETIC" according to Prevention of Food Adulteration Act rules.

NUTRITIONAL REQUIREMENTS

Basic concepts

The science of human nutrition is mainly concerned with defining the nutritional requirements for the promotion, protection and maintenance of health in all groups of the population. Such knowledge is necessary in order to assess the nutritional adequacy of diets for growth of infants,

children and adolescents, and for maintenance of health in adults of both sexes and during pregnancy and lactation in women *(83)*. In this context, a variety of terms have been used to define the amount of nutrients needed by the body such as : *optimum requirements, minimum requirements, recommended intakes* or *allowances,* and *safe level of intake.* Of these, the term "recommended dietary intake or allowance" (RDA) has been widely accepted *(1)*.

Recommended dietary allowance (RDA) : The average daily dietary nutrient intake level sufficient to meet the nutrient requirement of nearly all (97–98 per cent) healthy individuals in a particular life stage and gender group *(9)*.

Adequate intake : A recommended average daily intake level based on observed or experimentally determined approximations or estimates of nutrient intake by a group (or groups) of apparently healthy people, that are assumed to be adequate – used when an RDA cannot be determined. In the Indian context, this is referred to as "acceptable intake" *(9)*.

Tolerable upper intake level (UL) : The highest average daily nutrient intake level that is likely to pose no risk of adverse health effects for almost all individuals in the general population. As intake increases above the UL, the potential risk of adverse effect increases *(9)*.

Estimated average requirement (EAR) : The average daily nutrient intake level estimated to meet the requirement of half of the healthy individuals in a particular life stage and gender group *(9)*.

The RDA is derived from (a) the individual variability; and (b) the nutrient bioavailability from the habitual diet.

Individual variability : Definition of RDA takes into account the variability that exist in the requirement of a given nutrient between individuals in a given population group. The distribution of nutrient requirement in a population group is considered normal when the RDA corresponds to a requirement, which covers most of the individuals (97.5 per cent) in a given population. This corresponds to mean + 2 SD. This is termed as a safe level of nutrient; the chances of individual having requirements above the RDA is only 2.5 per cent. This principle is used in case of all nutrients except energy. In case of energy, intakes either in excess or below the actual requirement of energy are not safe. In respect to other nutrients, the RDA is 25 per cent (+ 2 SD) higher than the mean requirement, 12.5 per cent being considered as the extent of individual variability in the requirement of all those nutrients *(9)*.

Bioavailability : Bioavailability of a given nutrient from a diet, i.e., the release of the nutrient from the food, its absorption in the intestine and bioresponse have to be taken into account. It is the level of the nutrient that should be present in the diet to meet the requirement. The bio-availability factor is quite important in calcium, protein and trace elements like iron and zinc. In case of iron, the amount present in the diet is to be 20–30 times higher than the actual iron requirement to account for the low bioavailability of iron from a given diet, particularly a cereal–based diet.

RDA persents the level of the nutrient to be consumed daily to meet all the requirements of most of the individuals in a given population. However, it must be recognized that the RDA is not meant to be used as a standard to determine whether or not a given individual requirement has been met, since it is a level above the requirement of most individuals in a given population. RDA value of a nutrient is valid only when all other dietary nutrient intakes are satisfactory.

REFERENCE BODY WEIGHTS *(9)*

Age, gender and body weight largely determine the nutritional requirement of an individual. Body weights and heights of children reflect their state of health, nutrition and growth rate, while weight and heights of adults represent what can be attained by an individual with normal growth. Anthropometric measurements of infants and children of well-to-do families having access to good health care and no nutritional constraints are usually treated as reference values. The purpose of recommending nutrient requirements is to help attaining these anthropometric reference standards.

WHO standard weights and heights of infants and pre-school children

World Health Organization has recently published multi-centre growth reference standards for 0–60 month boys and girls, based on studies carried out among predominantly exclusively breast-fed children in six countries viz., USA, Brazil, Ghana, Norway, Oman and India. The median weights of infants and pre-school children (1–3 years) can be taken as reference values for Indian children.

Reference Indian adult man and woman

"Reference man" is aged between 18–29 years and weighs 60 kg with a height of 1.73 metre and a BMI of 20.3; is free from disease and physically fit for active work. On each working day, he is engaged in 8 hours of occupation which usually involves moderate activity; while when not at work he spends 8 hours in bed, 4-6 hours in sitting and moving about, 2 hours in walking and in active recreation or household duties.

"Reference woman" is aged between 18–29 years, non-pregnant non-lactating (NPNL) and weighs 55 kg with a height of 1.61 metre and a BMI of 21.2, is free from disease and physically fit for active work. On each working day she is engaged in 8 hours of occupation, which usually involves moderate activity, while when not at work she spends 8 hours in bed, 4–6 hours in sitting and moving about, 2 hours in walking and in active recreation or household duties.

Infants

The average of birth weight and body weight at 6 months is used for computing the reference body weight for infants 0–6 months of age. For 6–12 months, an average of body weight at 6 months and at 12 months is taken for computation.

Children

For children 1–3 years of age, an average of body weight at 18 months, 30 months, 42 months of WHO median weight is taken (as mentioned above).

The reference body weight for children of 4–6 years are obtained by averaging the body weight of 4+, 5+ and 6+ years. Similarly for other age groups also the reference body weights were obtained from the 95th centile value of body weights of rural India.

Adults

The average of values for age category of 18–19, 20–24, and 25–29 years was used for computing the reference weights for adult man and woman.

ENERGY

Energy is a prime requisite for body function and growth. When a child's intake of food falls below a standard reference, growth slows, and if low levels of intake persist, adult stature will be reduced. Similarly, if adults fail to meet their food requirements they lose weight. This may lead to reduced ability to work, to resist infection, and weakened will to enjoy the normal satisfaction of life. This underlines the need for an adequate intake of food which is the source of all energy.

Measurement of energy

The energy value of foods has long been expressed in terms of the kilocalorie (kcal). The kilocalorie is generally expressed as "Calorie"– written with a capital "C" *(74)*. This has been replaced by the "joule" expressed as J, which has been accepted internationally. These units are defined as follows :

Joule, a physical unit of energy, is defined as the energy required to move 1 kg of mass by 1 metre by a force of 1 Newton acting on it (One Newton is the force needed to accelerate one kg mass by 1 metre per sec^2).

Kilocalorie (kcal) is defined as the heat required to raise the temperature of one kg of water by 1°C from 14.5°C to 15.5°C. The unit kcal is still popularly used.

The relationship between the two units of energy is as follows :

1 kcal	=	4.184 KJ (Kilo Joule)
1 KJ	=	0.239 kcal
1000 kcal	=	4184 KJ = 4.18 MJ (Mega Joule)
1 MJ	=	239 kcal

Reference man and woman

Energy intake recommendations are formulated for a "reference man" and a "reference woman" whose profiles are described, and then necessary adjustments are made for subjects who deviate from the standard reference. This procedure was first devised by the FAO Committee on calorie requirements in 1950 *(75)* and has been in use ever since.

Energy requirements

The energy requirement of an individual is defined as that level of energy intake from food that balances energy expenditure, when the individual has a body size and composition and level of physical activity, consistent with long-term good health, also allowing for maintenance of economically essential and socially desirable activity. In children and pregnant and lactating women, it includes the energy needs associated with the deposition of tissues or secretion of milk at rates consistent with good health *(9)*. The two standard deviation value is not added to the average requirement. This is because the energy intake and expenditure of an individual are finely balanced, and any surplus energy consumption will be stored as fat and a continuous excess of intake will lead to obesity *(9)*. Adults and even growing children are known to adapt either intake to suit their output, or output to suit intake over a very wide range. We do not have a proper understanding of the lower limit of adaption.

Broadly, the total energy requirement of an individual is made up of three components :

(a) energy required for basal metabolism. This is about 1 kcal/hour for every kg of body weight for an adult;
(b) energy required for daily activities such as walking, sitting, standing, dressing, climbing stairs, etc; and
(c) energy expenditure for occupational work. This is further classified as light work (an office clerk), moderate work and heavy work (manual physical labour).

The first component is nearly the same for all individuals. It is the latter two components that vary depending upon the type of activities. Procedures for calculating total energy expenditure are given in the WHO Expert Committee Report on Energy and Protein Requirements *(6)*.

Factors affecting energy requirements

Energy requirements vary from one person to another depending upon inter-related variables acting in a complex way, such as age, sex, working condition, body composition, physical activity, physiological state etc. All these factors lead to differences in food intake.

Energy requirements have been laid down by various expert groups of FAO and. WHO *(6, 38, 76)*. It has become customary for countries to lay down their own standards. Thus there are British standards, American standards, Canadian standards, etc. The standards in India are those recommended by the Indian Council of Medical Research which are set out in Table 24. These standards are revised from time to time in the light of newer knowledge.

Vulnerable groups

(a) *Pregnant and lactating mothers :* The energy requirements of women are increased by pregnancy (+350 kcal daily throughout pregnancy) and lactation (+600 kcal daily during the first 6 months, and +520 kcals daily during the next 6 months) over and above their normal requirements. This is to provide for the extra energy needs associated with the deposition of tissues or the secretion of milk at rates consistent with good health *(6)*.

(b) *Children :* Because of their rapid growth rate, young children require proportionately more energy for each kilogram of body weight than adults (see Table 29).

A problem that arises is in recommending intakes in communities where a large number of children are underweight because of malnutrition. In order to provide for "catch-up growth" during childhood, intakes should be based on age rather than weight where practical *(77)*. The ICMR standards are based on age, and not on body weight (except during the first year of life).

Children above the age of 13 years need as much energy as adults. This is because they show a good deal of physical activity, almost equal to hard work by adults. This is also the age when puberty sets in and there is a spurt in growth and an increase in metabolic rate. This fact should be borne in mind when planning dietaries for children.

(c) *Adults :* The energy requirements decrease with age because of a fall in BMR and a decrease in physical activity in most persons. In general, there is a 2 per cent decline of resting metabolism for each decade for adults *(31)*. The FAO/WHO committee suggested that after the age of 40 years, requirements should be reduced by 5 per cent per each decade until the age of 60, and by 10 per cent for each decade thereafter *(76)*.

TABLE 24

Energy requirements of Indians at different ages (2010)

Age group	Category	Body weights	Requirement (kcal/d)[a]	Requirement (kcal/kg/day)
Man	Sedentary work	60	2,320	39
	Moderate work	60	2,730	46
	Heavy work	60	3,490	58
Woman	Sedentary work	55	1,900	35
	Moderate work	55	2,230	41
	Heavy work	55	2,850	52
	Pregnant woman	55 + GWG[b]	+ 350	
	Lactation	55 + WG[c]	+600	
			+520	
Infants	0-6 months	5.4	500	92
	6-12 months	8.4	670	80
Children	1-3 years	12.9	1,060	82
	4-6 years	18.1	1,350	75
	7-9 years	25.1	1,690	67
Boys	10-12 years	34.3	2,190	64
Girls	10-12 years	35.0	2,010	57
Boys	13-15 years	47.6	2,750	58
Girls	13-15 years	46.6	2,330	50
Boys	16-17 years	55.4	3,020	55
Girls	16-17 years	52.1	2,440	47

a Rounded off to the nearest 10 kcal/d.

b GWG – Gestational weight gain. Energy need in pregnancy should be adjusted for actual body weight, observed weight gain, and activity pattern for the population.

c WG – Gestational weight gain remaining after delivery.

Note : The current estimate of energy requirement of infants is 11–20 per cent lower than the 1988 estimates.

Source : *(9)*

Source of energy

The main source of energy in Indian diets, which are predominantly plant food based, are carbohydrate, fat, protein and dietary fibre. They supply energy at the following rates :

Protein	–	4 kcal/g
Fat	–	9 kcal/g
Carbohydrate	–	4 kcal/g
Dietary fibre	–	2 kcal/g

Dietary fibre forms an indigestible and important component of plant food and was never earlier considered as source of energy. These dietary fibres (soluble and insoluble) undergo fermentation in the colon and yield short chain fatty acids, such as butyric, propionic and acetic acids which are utilized as a source of energy by the colon cells and by the liver. Hence they are known to yield energy from fermentable fibre and no energy from non-fermentable fibre. In conventional foods, 70 per cent of fibre is fermentable. In general, energy conversion factor for fibre is taken as 2.0 kcal/g. Hitherto, dietary fibre was not determined directly as a source of energy and there is a need to recalculate energy yield of various foods on the basis of their revised content of carbohydrates, proteins, fat and dietary fibre *(9)*.

The main source of energy in diets is carbohydrates derived largely from cereals. These cereals constitute about 80 per cent of our diet and provide 50–80 per cent of daily energy intake. However, energy contribution from diets varies very widely. Those belonging to low income group have only 5 per cent fat in their diet, whereas affluent families derive as high as 30 per cent of their dietary energy from fat. Most families derive 10–12 per cent of energy from proteins *(9)*.

Nutritional individuality

In normal individuals at all ages and of both sexes, there is a large variation in energy intake but the reasons for this wide range of nutritional requirements are not known. The concept of nutritional individuality needs to be stressed, and its neglect may result in the over-feeding of some whose needs happen to be less than the "average standard requirement" *(78)*.

PROTEIN

Protein requirements vary from individual to individual. Apart from age, sex and other physiological variables, factors like infection, worm infestation, emotional disturbances and stress situations can affect a person's protein requirement.

Assessment of protein

(a) *PROTEIN QUALITY*

The quality of a protein is assessed by comparison to the "reference protein" which is usually egg protein. Two methods of assessment of protein quality needs mention :

(i) Amino acid score : It is a measure of the concentration of each essential amino acid in the test protein expressed as a percentage of that amino acid in the reference protein.

$$\text{Amino acid score} = \frac{\text{mg of amino acid per g of test protein}}{\text{mg of the same amino acid per g of reference protein.}} \times 100$$

The amino acid (or chemical) score is somewhere between 50 and 60 for starches, and 70 and 80 for animal foods *(69)*.

(ii) Net protein utilization (NPU) : It is a product of digestibility coefficient and biological value divided by 100 *(8)*. The NPU gives a more complete expression of protein quality than the amino acid score. It is a biological method that requires special laboratory facilities.

$$\text{NPU} = \frac{\text{Nitrogen retained by the body}}{\text{Nitrogen intake}} \times 100$$

In calculating protein quality, 1 gram of protein is assumed to be equivalent to 6.25 g of N.

The protein requirement varies with the NPU of dietary protein. If the NPU is low, the protein requirement is high and vice versa. The NPU of the protein of Indian diets varies between 50 and 80.

(b) *PROTEIN QUANTITY*

The protein content of many Indian foods has been determined and published in food composition tables. One way of evaluating foods as source of protein is to determine what per cent of their energy value is supplied by their protein content. This is known as **Protein–Energy Ratio** (PE ratio or percentage).

$$\text{PE per cent} = \frac{\text{Energy from protein}}{\text{Total energy in diet}} \times 100$$

This concept is useful because in many population groups adequate diet is not consumed to meet energy needs, resulting in energy deficits. The ratio of protein requirement,

expressed as the ratio of protein calories to the energy requirement is as given in Table 25.

TABLE 25

Protein-energy ratio for different age groups (2010)

Group	Protein requirement g/kg/d	Energy requirement kcal/kg/d	PE ratio of requirement
Pre-school children 1-5 years	0.94	81	4.6
School children 6-10 years	0.91	71	5.1
Adolescents			
11-18 years (Boys)	0.88	60	5.8
11-18 years (Girls)	0.86	55	6.3
Adults			
Men (Sedentary)	0.83	39	8.5
Women (Sedentary)	0.83	36	9.2
Men (Moderate active)	0.83	46	7.2
Women (Moderate active)	0.83	42	7.9

Source : *(9)*

The protein-energy percentage value of some commonly used foods is as shown in Table 26.

TABLE 26

Relative protein value of some foods : per cent of total energy supplied by protein

Food	Nutrients per 100 g		Energy from proteins	
	kcal	Protein (g)	Actual (kcal)	PE%
Fish	100	20.0	80	80
Milk (cow)	67	3.2	13	20
Dhal	350	21.0	84	24
Rice	350	7.0	28	8
Potato	100	1.6	6	6
Banana	100	1.0	4	4
Tapioca	160	0.7	3	2

If the PE is less than 4 per cent, the subject will be unable to eat enough to satisfy protein requirements. It is recommended that protein should account for approximately 10–12 per cent of the total daily energy intake.

Dietary intakes

It is customary to express requirement in terms of grams per kg of body weight. This principle applies to all age groups, although absolute additions in units of grams of protein per day are made for pregnancy and lactation.

The ICMR Expert Group *(9)* suggested an intake of one gram of protein per kg of body weight for adult males and females, assuming a NPU of 65 for the dietary protein. Table 29 gives the protein intakes for individuals of different ages and physiological states.

Vulnerable groups

The protein requirements of women are increased during pregnancy. For 10 kg gestational weight gain the requirement increases by 1, 7 and 23 g/day in 1st, 2nd and 3rd trimesters respectively; and during lactation by about 13 g per day (during 0 to 6 months), over and above their normal requirements.

Young children (0 to 6 years) require proportionately more protein for each kilogram of body weight than adults. They are more vulnerable to malnutrition.

The ICMR Expert Group *(9)* has not made any recommendations for the elderly. It seems reasonable to assume that the requirement of the aged are not less than that for young adults, because it is an accepted fact that protein utilization is less efficient in the elderly *(6)*.

All estimates of protein requirement are valid only when the energy requirements are fully met. If the total energy intake is inadequate some dietary protein will be diverted to provide energy. It is now accepted that there are no body protein stores which can be filled up by a high protein intake.

At present there is no evidence that higher intakes of protein confer greater benefit, although the possibility cannot be ruled out. Most people, if they can, apparently choose to eat more protein than the physiological requirement. The question remains whether high protein intakes, far from being beneficial, may actually be harmful *(7)*.

Amino acid requirements

The protein intake must also satisfy the need for essential amino acids. The 2007 WHO Expert Committee Report on Energy and Protein Requirements gives current estimates of amino acid requirements (in mg/kg per day) for adults. These are reproduced in Table 27.

TABLE 27

Essential amino acid (EAA) requirements : Adult

Amino acid	FAO/WHO/UNU 2007	
	mg/kg/d	mg/g protein
Histidine	10	15
Isoleucine	20	30
Leucine	39	59
Lysine	30	45
Methionine	10	16
Cysteine	4	6
Methionine + Cysteine	15	22
Threonine	15	23
Phenylalanine + Tyrosine	25	38
Tryptophan	4	6
Valine	26	39
Total EAA	184	277
Total protein	0.66 g/kg/d	
Safe level of protein (Mean + 1.96 × SD)	0.83 g/kg/d	

Source : *(9)*

New tissues cannot be formed unless all the essential amino acids are present in the diet. The requirement of EAA decreases sharply as one advances in age. The quality of the diet is far more critical for the infant than for the adult.

FAT

The daily requirement of fat is not known with certainty. During infancy, fats contribute to a little over 50 per cent of the total energy intake. This scales down to about 20 per cent in adulthood. The ICMR Expert Group (2010) has recommended an intake of 20 per cent of the total energy intake as fat, of which at least 50 per cent of fat intake should consist of

vegetable oils rich in essential fatty acids. The requirement of essential fatty acids ranges from 3 per cent energy intake to 5.7 per cent of energy intake in young children.

Suggested levels of fat intake are as given in Table 28.

TABLE 28

Recommendations for dietary fat intake for Indians (2010)

Age/Gender/ Physiological groups	Physical activity	Minimum level of Total fat (% E)	Fat from foods other than visible fats, % E	Visible fat %E	Visible fat g/p/d
Adult Man	Sedentary				25
	Moderate	20	10	10	30
	Heavy				40
	Sedentary				20
	Moderate	20	10	10	25
	Heavy				30
Adult Woman	Pregnant women	20	10	10	30
	Lactating women				30
Infants	0 - 6 months	40-60		Human milk	
	7-24 months	35	10	25	25
Children	3-6 years				25
	7-9 years				30
Boys	10-12 years				35
	13-15 years	25	10	15	45
	16-17 years				50
Girls	10-12 years				35
	13-15 years				40
	16-17 years				35

CARBOHYDRATE

The recommended intake of carbohydrate in balanced diets is placed so as to contribute between 50 to 80 per cent of total energy intake. Most Indian diets contain amounts more than this, providing as much as 90 per cent of total energy intake in some cases, which makes the diet imbalanced. This needs to be corrected through nutrition education.

The recommended dietary allowances for energy, protein, fat and minerals is summarized in Table 29.

OTHER RECOMMENDED INTAKES

(a) *Fat soluble vitamins*

The daily requirement of vitamins A is given in Table 30. The recommended dietary allowance of vitamin E is placed at 10 mg of alpha tocopherol equivalents for adult males and 8 mg for adult females.

(b) *Water soluble vitamins*

The recommended intakes are given in Table 30. The requirements of thiamine, riboflavin and niacin are closely related to energy intake and utilization, and are stated in terms of 1000 kcal intake of energy as below :

Thiamine ..... 0.5 mg/1000 kcal
Riboflavin ..... 0.6 mg/1000 kcal
Niacin ..... 6.0 mg/1000 kcal

(c) Minerals

The recommended intakes of important minerals are as given in Table 29.

TABLE 29

Summary of Recommended Dietary Allowances (RDA) for energy, protein, fat and minerals for Indians – 2010

Group	Category/Age	Body weight (kg)	Net energy (kcal/d)	Protein (g/d)	Visible fat (g/d)	Calcium (mg/d)	Iron (mg/d)	Zinc (mg/d)	Magnesium (mg/d)

Source : *(9)*

All nutritional requirements are interrelated. For example, there is a close interrelationship between the energy and protein requirements, between requirements for phosphorus, calcium and vitamin D, between fats and vitamins, and between carbohydrates and vitamins.

It has been said that food is not only a collection of nutrients open to statistical or dietary study, but also simultaneously a system of communication, a protocol for customs, situations and behaviour.

BALANCED DIET

A diet may be defined as the kinds of food on which a person or group lives. A balanced diet is defined as one which contains a variety of foods in such quantities and proportions that the need for energy, amino acids, vitamins, minerals, fats, carbohydrate and other nutrients is adequately met for maintaining health, vitality and general well-being and also makes a small provision for extra nutrients to withstand short duration of leanness *(69)*. A balanced diet has become an accepted means to safeguard a population from nutritional deficiencies *(79)*.

In constructing balanced diet, the following principles should be borne in mind : (a) First and foremost, the daily requirement of protein should be met. This amounts to 10–15 per cent of the daily energy intake. (b) Next comes the fat requirement, which should be limited to 15–30 per cent of the daily energy intake (c) Carbohydrates rich in natural fibre should constitute the remaining food energy. The requirements of micronutrients (Table 29 and 30) should be met.

The dietary pattern varies widely in different parts of the world. It is generally developed around the kinds of food produced (or imported) depending upon the climatic conditions of the region, economic capacity, religion, customs, taboos, tastes and habits of the people. Balanced diets formulated by the Indian Council of Medical Research are given in Annexure II at the end of this chapter.

A nutritional education guide "The Food Guide Pyramid" emphasizes foods from the five major food groups shown in the three lower sections of the Pyramid (Fig. 1). Each of these food groups provides some, but not all, of the nutrients required. Foods in one group can't replace those in another. No one of these major food groups is more important than another – for good health, one needs them all.

DIETARY GOALS

All countries should develop a national nutrition and food policy setting out "dietary goals" for achievement *(72)*. The dietary goals **("prudent diet")** recommended by the various Expert Committees of WHO *(15,79)* are as below :

(a) dietary fat should be limited to approximately 15–30 per cent of total daily intake;

(b) saturated fats should contribute no more than 10 per cent of the total energy intake; unsaturated vegetable oils should be substituted for the remaining fat requirement;

(c) excessive consumption of refined carbohydrate should be avoided; some amount of carbohydrate rich in natural fibre should be taken;

(d) sources rich in energy such as fats and alcohol should be restricted;

(e) salt intake should be reduced to an average of not more than 5 g. per day; (salt intake is more in tropical countries. In India it averages 15 g. per day);

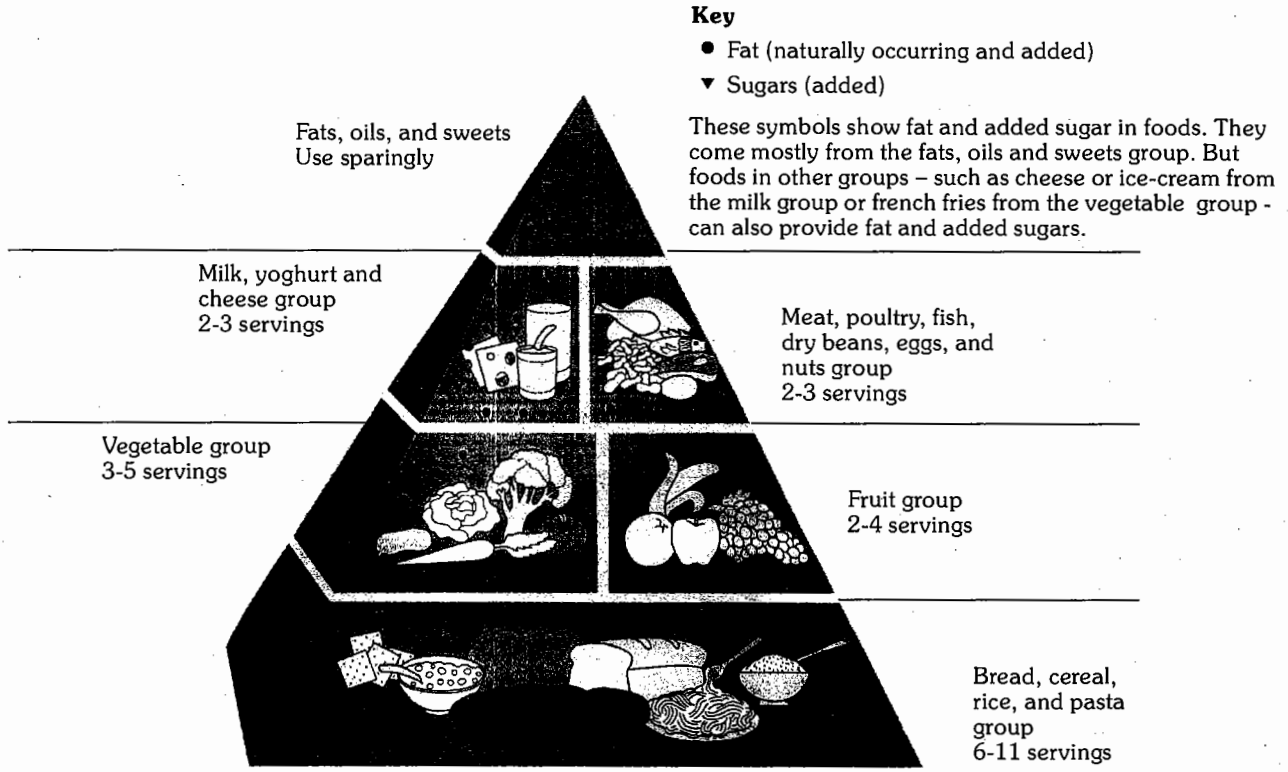

FIG. 1
The food guide pyramid

Source : *(80)*

(f) protein should account for approximately 10–15 per cent of the daily intake;
(g) junk foods such as colas, ketchups and other foods that supply empty calories should be reduced.

There may be conditions under which the above recommendations for daily food intake do not apply. For example, diet should be adapted to the special needs of growth, pregnancy, lactation, physical activity, and medical disorders (e.g., diabetes).

NUTRITIONAL PROBLEMS IN PUBLIC HEALTH

There are many nutritional problems which affect vast segments of our population. The major ones which deserve special mention are highlighted :

1. Low birth weight

Low birth weight (i.e., birth weight less than 2500 g) is a major public health problem in many developing countries. About 28 per cent of babies born in India are LBW *(81)* as compared to 4 per cent in some developed countries. In countries where the proportion of LBW is high, the majority are suffering from foetal growth retardation. In countries where the proportion of LBW infants is low, most of them are preterm *(82)*. Although we do not know all the causes of LBW, maternal malnutrition and anaemia appear to be significant risk factors in its occurrence. Among the other causes of LBW are hard physical labour during pregnancy, and illnesses especially infections. Short maternal stature, very young age, high parity, smoking, close birth intervals are all associated factors. All these factors are interrelated.

Since the problem is multifactorial, there is no universal solution. Interventions have to be cause-specific. This matter has already been discussed in Chapter 9.

The proportion of infants born with LBW was selected as one of the nutritional indicators for monitoring progress towards Health for All by the year 2000.

2. Protein energy malnutrition

Protein energy malnutrition (PEM) is identified as a major health and nutrition problem in India. It occurs particularly in weaklings and children in the first years of life. It is not only an important cause of childhood morbidity and mortality, but leads also to permanent impairment of physical and possibly, of mental growth of those who survive *(9)*. The current concept of PEM is that its clinical forms – kwashiorkor and marasmus – are two different clinical pictures at opposite poles of a single continuum.

The incidence of PEM in India in pre-school age children is 1–2 per cent *(83)*. The great majority of cases of PEM, nearly 80 per cent, are the "intermediate" ones, that is the mild and moderate cases which frequently go unrecognized. The problem exists in all the States and that nutritional marasmus is more frequent than kwashiorkor.

In the 1970s, it was widely held that PEM was due to protein deficiency. Over the years, the concept of "protein gap" has given place to the concept of "food gap". That is, PEM is primarily due to (a) an inadequate intake of food (food gap) both in quantity and quality, and (b) infections, notably diarrhoea, respiratory infections, measles and intestinal worms which increase requirements for calories, protein and other nutrients, while decreasing their absorption and utilization. It is a vicious circle – infection contributing to malnutrition and malnutrition contributing to infection, both acting synergistically (Fig. 2).

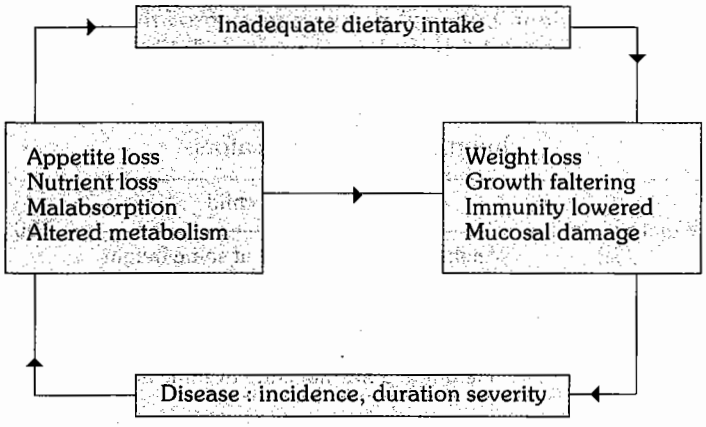

FIG. 2
Malnutrition/Infection cycle

Source : *(68)*

There are numerous other contributory factors in the web of causation, viz. poor environmental conditions, large family size, poor maternal health, failure of lactation, premature termination of breast-feeding, and adverse cultural practices relating to child rearing and weaning such as the use of over–diluted cow's milk and discarding cooking water from cereals and delayed supplementary feeding *(84)*.

Malnutrition is self-perpetuating. A child's nutritional status at any point of time depends on his or her past nutritional history, which may particularly account for the present status. To some extent, this nutritional history is linked to the mother's health and nutritional status. This in turn has been influenced by her living conditions and nutritional history during her own childhood (Fig. 3).

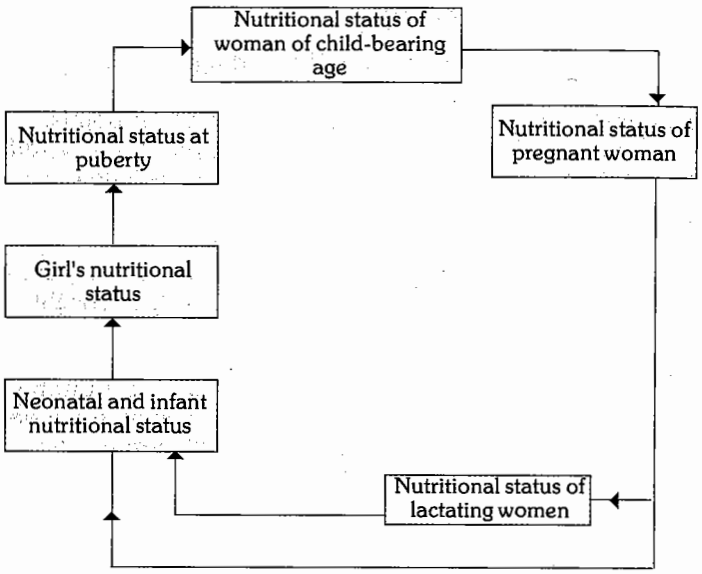

FIG. 3
Influence of each generation's nutritional status on the following generation.

Source : *(68)*

Early detection of PEM

The first indicator of PEM is under-weight for age. The most practical method to detect this, which can be employed even by field health workers, is to maintain growth charts. These charts indicate at a glance whether the child is gaining or losing weight.

The principal features of kwashiorkor and marasmus are shown in Table 31.

TABLE 31

Principal features of severe PEM

FEATURES	MARASMUS	KWASHIORKOR
CLINICAL	*ALWAYS PRESENT*	
Muscle wasting	Obvious	Sometimes hidden by oedema and fat
Fat wasting	Severe loss of subcutaneous fat	Fat often retained but not firm
Oedema	None	Present in lower legs, and usually in face and fore arms
Weight for height	Very low	Low but may be masked by oedema
Mental changes	Sometimes quiet and apathetic	Irritable, moaning, apathetic
CLINICAL	*SOMETIMES PRESENT*	
Appetite	Usually good	Poor
Diarrhoea	Often (current and past)	Often (current and past)
Skin changes	Usually none	Diffuse pigmentation, sometimes 'flaky paint dermatosis'
Hair changes	Seldom	Sparse, silky, easily pulled out
Hepatic enlargement	None	Sometimes, due to accumulation of fat
BIOCHEMICAL		
Serum albumin	Normal or slightly decreased	Low (<3 g/100 ml blood)
Urinary urea per g creatinine	Normal or decreased	Low
Hydroxyproline/creatinine ratio	Low	Low
Plasma/amino acid ratio	Normal	Elevated

CLASSIFICATION OF PEM

PEM is a spectrum of conditions ranging from growth failure to overt marasmus or kwashiorkor, hence classification has to be based on arbitrary cut-off-points. It is to identify children requiring nutritional or health interventions. Some of the classifications are as follows :

Gomez' classification *(68)*

Gomez' classification is based on weight retardation. It locates the child on the basis of his or her weight in comparison with a normal child of the same age. In this system, the "normal" reference child is in the 50th centile of the Boston standards. The cut-off values were set during a study of risk of death based on weight for age at admission to a hospital unit. This classification therefore, has a prognostic value for hospitalized children.

$$\text{Weight for age (\%)} = \frac{\text{weight of the child}}{\text{weight of a normal child of same age}} \times 100$$

Between 90 and 110%	:	normal nutritional status
Between 75 and 89%	:	1st degree, mild malnutrition
Between 60 and 74%	:	2nd degree, moderate malnutrition
Under 60%	:	3rd degree, severe malnutrition

Weight is widely recorded and the classification is easy to compute. The disadvantages are (a) A cut-off-point of 90 per cent of reference is high *(80* per cent being approximately equivalent to –2SD or the 3rd percentile), thus some normal children may be classified as 1st degree malnourished. (b) By measuring only weight for age it is difficult to know if the low weight is due to a sudden acute episode of malnutrition or to long-standing chronic undernutrition *(85)*.

Waterlow's classification *(68)*

When a child's age is known, measurement of weight enables almost instant monitoring of growth : measurements of height assess the effect of nutritional status on long-term growth. Table 32 shows the Waterlow's classification.

TABLE 32

Waterlow's classification

H/A \ W/H	> m – 2 SD	< m – 2 SD
> m – 2 SD	Normal	Wasted
< m – 2 SD	Stunted	Wasted and stunted

m = mean, SD = standard deviation

Source : *(68)*

Waterlow's classification defines two groups for protein energy malnutrition :

- malnutrition with retarded growth, in which a drop in the height/age ratio points to a chronic condition– shortness, or stunting :
- malnutrition with a low weight for a normal height, in which the weight for height ratio is indicative of an acute condition of rapid weight loss, or wasting.

This combination of indicators makes it possible to label and classify individuals with reference to two poles : children with insufficient but well-proportioned growth and those with a normal height, but who are wasted (Table 33)

TABLE 33

Interpretation of indicators

$$\text{Weight/Height (\%)} = \frac{\text{Weight of the child}}{\text{Weight of a normal child at same height}} \times 100$$

$$\text{Height/Age (\%)} = \frac{\text{Height of the child}}{\text{Height of a normal child at same age}} \times 100$$

Nutritional status	Stunting (% of height/age)	Wasting (% of weight/height)
Normal	> 95	> 90
Mildly impaired	87.5 – 95	80 – 90
Moderately impaired	80 – 87.5	70 – 80
Severely impaired	< 80	< 70

Source : *(68)*

Arm circumference : *(68)*

Arm circumference yields a relatively reliable estimation of the body's muscle mass, the reduction of which is one of the most striking mechanisms by which the body adjusts to inadequate energy intakes. Arm circumference cannot be used before the age of one year; between ages one and five years, it hardly varies.

An arm circumference exceeding 13.5 cm is a sign of a satisfactory nutritional status, between 12.5 and 13.5 cm it indicates mild–moderate malnutrition and below 12.5 cm, severe malnutrition.

For the purpose of comparison, growth charts are provided with reference curves. These curves show the limit of normal growth. The WHO reference curves are based on extensive cross-sectional data of well-nourished healthy children, assembled by the National Centre for Health Statistics (NCHS). Malnutrition is defined by WHO as a weight-for-age below the median minus two standard deviations of the NCHS reference population *(86)*.

Preventive measures

There is no simple solution to the problem of PEM. Many types of actions are necessary. The following is adapted from the 8th FAO/WHO Expert Committee on Nutrition *(1)* for the prevention of PEM in the community :

(a) *Health promotion*

1. Measures directed to pregnant and lactating women (education, distribution of supplements).
2. Promotion of breast-feeding.
3. Development of low cost weaning foods : the child should be made to eat more food at frequent intervals.
4. Measures to improve family diet.
5. Nutrition education – Promotion of correct feeding practices.
6. Home economics.
7. Family planning and spacing of births.
8. Family environment.

(b) *Specific protection*

1. The child's diet must contain protein and energyrich foods. Milk, eggs, fresh fruits should be given if possible.
2. Immunization.
3. Food fortification.

(c) *Early diagnosis and treatment*

1. Periodic surveillance.
2. Early diagnosis of any lag in growth.
3. Early diagnosis and treatment of infections and diarrhoea.
4. Development of programmes for early rehydration of children with diarrhoea.
5. Development of supplementary feeding programmes during epidemics.
6. Deworming of heavily infested children.

(d) *Rehabilitation*

1. Nutritional rehabilitation services.
2. Hospital treatment.
3. Follow-up care.

3. Xerophthalmia

Xerophthalmia (dry eye) refers to all the ocular manifestations of vitamin A deficiency in man. It is the most widespread and serious nutritional disorder leading to blindness *(87)* particularly in South-East Asia.

Xerophthalmia is most common in children aged 1–3 years, and is often related to weaning. The younger the child, the more severe the disease. It is often associated with PEM. Mortality is often high in this age group *(21)*. The victims belong to the poorest families. Associated risk factors include ignorance, faulty feeding practices and infections particularly diarrhoea and measles which often precipitate xerophthalmia. In some countries, "epidemics" of xerophthalmia have occurred in association with food donation programmes involving skimmed milk, which is totally devoid of vitamin A *(88)*.

The States badly affected are the southern and eastern States of India notably Andhra, Tamil Nadu, Karnataka, Bihar and West Bengal. These are predominantly rice-eating States and rice is devoid of carotene. The North Indian States have relatively few cases of xerophthalmia *(89)*.

Prevention and control

Prevention and control of xerophthalmia must be an integral part of primary health care. An overall strategy can be defined, according to WHO, in terms of short-term, medium-term and long-term action *(24)*.

(a) *Short-term action :* A short-term preventive approach that has already demonstrated its efficacy is the administration of large doses of vitamin A orally, in recommended doses to vulnerable groups, on a periodic basis. This can be organized quickly and with a minimum of infrastructure.

(b) *Medium-term action :* An approach widely used to promote regular and adequate intake of vitamin A is **fortification** of certain foods with vitamin A. Addition of vitamin A to *dalda* in India is a typical example. Many other foods have also been considered for vitamin A fortification, viz. sugar, salt, tea, margarine and dried skimmed milk. Fortifying an appropriate food with vitamin A is a complex process. The greatest challenge to successful fortification programmes is choosing a food that is likely to be consumed in sufficient quantities by groups at risk *(90)*.

(c) *Long-term action :* These are measures aimed at reduction or elimination of factors contributing to ocular disease, e.g., persuading people in general, and mothers in particular, to consume generously dark green leafy vegetables or other vitamin A rich foods; promotion of breast-feeding for as long as possible; improvements in environmental health such as ensuring safe and adequate water supply and construction and maintenance of sanitary latrines to safeguard against diarrhoea; immunization against infectious diseases such as measles, prompt treatment of diarrhoea and other associated infections; better feeding of infants and young children; improved health services for mothers and children; social and health education. All these are components of primary health care.

Vitamin A deficiency in India (VAD) *(91)*

VAD has been recognized as a major controllable public health and nutritional problem in India. An estimated 5.7 per cent children in India suffer from eye signs of VAD. Recent evidence suggests that even mild VAD probably increases morbidity and mortality in children, emphasizing the public health importance of this disorder. VAD is one of the major deficiencies among lower income strata population in India.

Though the prevalence of severe forms of VAD such as corneal ulcers/softening of cornea i.e. keratomalacia has in general become rare, Bitot spots were present in varying magnitudes in different parts of the country as reported by National Nutritional Monitoring Bureau in 2003. The prevalence was higher than WHO cut-off level of 0.5 per cent, indicating the public health significance of the problem of VAD. There is huge inter-state variation in the prevalence of VAD among children. It is also a matter of concern that only 21 per cent of children of age 12 to 35 months receive a vitamin A dose. Less than 10 per cent coverage was reported in Nagaland, Uttar Pradesh reported 7.3 per cent coverage. Only states such as Tamil Nadu (37.2 per cent), Goa (37.3 per cent), Kerala (38.2 per cent) and West Bengal (41.2 per cent) have better coverage, though it is still low.

In India, in 1970 a national programme for prevention of nutritional blindness was initiated to fight this deficiency. The beneficiaries of this programme were pre-school children (1–5 years). The programme was modified in 1992 to cover children in age group of nine months to three years only. Since Tenth Five Year Plan vitamin A supplementation exists as an integral component of RCH programme which is now a part of NRHM. The guidelines issued in November 2006 cover children upto 5 years of age.

The programme focusses on *(92)*: (a) Promoting consumption of vitamin A rich foods by pregnant and lactating women and by children under-five years of age and appropriate breast-feeding; (b) Administration of massive dose of vitamin A up to five years. First dose of 100,000 IU with measles vaccination at nine months and subsequent doses of 200,000 IU each, every six months up to the age 5 years; (c) For sick children – all children with xerophthalmia to be treated at health facilities; all children suffering from measles to be given one dose of vitamin A if they have not received it in the previous one month; all cases of severe malnutrition to be given one additional dose of vitamin A *(92)*.

4. Nutritional anaemia

Nutritional anaemia is a disease syndrome caused by malnutrition in its widest sense *(54)*. It has been defined by WHO as "a condition in which the haemoglobin content of blood is lower than normal as a result of a deficiency of one or more essential nutrients, regardless of the cause of such deficiency" *(52)*. Anaemia is established if the haemoglobin is below the cut-off points recommended by WHO (Table 13). By far the most frequent cause of nutritional anaemia is iron deficiency, and less frequently folate or vitamin B_{12} *(49)*.

The problem

WORLD

Nutritional anaemia is a worldwide problem with the highest prevalence in developing countries. It is found especially among women of child-bearing age, young children and during pregnancy and lactation. It is estimated to affect nearly two-thirds of pregnant and one-half of non-pregnant women in developing countries *(93)*. The populations of developed countries are not by any means completely free of anaemia, and a significant percentage of women of child-bearing age (estimated between 4 and 12 per cent) suffer from anaemia *(94)*.

INDIA

Iron deficiency anaemia is the most widespread micronutrient deficiency affecting all age groups irrespective of gender, cast, creed and religion. In India, this silent emergency is rampant among women belonging to reproductive age group (15–49 years), children (6–35 months) and low socio-economic strata of the population. Overall, 72.7 per cent of children up to the age 3 years in urban areas and 81.2 per cent in rural areas are anaemic.

While analyzing the data for states with anaemia level of 70% among children, it was found that, except for Punjab, all other states had more than 50% prevalence of anaemia among pregnant women. This again reiterates the strong relationship between anaemia levels of mothers and children. Also, the overall prevalence has increased from 74.2% (1998–99) to 79.2% (2005–06). Nagaland had the lowest prevalence (44.3%), Goa was next (49.3%) followed by Mizoram (51.7%). Bihar had the highest prevalence (87.6%) followed closely by Rajasthan (85.1%), and Karnataka (82.7%). Moderate and severe anaemia is seen even among the educated families both in urban and rural areas. There are inter-state differences in prevalence of anaemia that are perhaps attributable partly to differences in dietary intake and partly to access to health care *(91)*.

As per District Level Health Survey (DLHS) (2002–04), prevalence of anaemia in adolescent girls is very high (72.6%) in India, with prevalence of severe anaemia among them much higher (21.1%) than that in preschool children (2.1%). In adolscent girls, educational or economic status does not seem to make much of a difference in terms of prevalence of anaemia. Prevention, detection, or management of anaemia in adolescent girls has till now not received much attention. In view of the high prevalence of moderate and severe anaemia in this group and the fact that many of them get married early, conceive, and face the problems associated with anaemia in pregnancy, it is imperative to screen them for anaemia and treat them.

Iron deficiency can arise either due to inadequate intake or poor bioavailability of dietary iron or due to excessive losses of iron from the body. Although most habitual diets contain seemingly adequate amounts of iron, only a small amount (less than 5 per cent) is absorbed *(96)*. This poor bio-availability is considered to be a major reason for the widespread iron deficiency *(95)*. Women lose a considerable amount of iron especially during menstruation. Some of the other factors leading to anaemia are malaria and hookworm infestations. In addition mothers who have born children at close intervals become anaemic due to the additional demands of the rapid pregnancies and the loss of blood in each delivery.

Megaloblastic anaemia is not encounterd frequently in general population, but it occurs occasionally in pregnant women from poor income groups. It is possible that the widespread iron deficiency (microcytic anaemia) could mask megaloblastic anaemia. In a recent study, sub-clinical folate deficiency was found to be about 30 per cent in pregnant women from rural North India. A high level of sub-clinical folate deficiency was also reported in semi-urban school children. There are some sporadic reports indicating its prevalence in adults *(9)*.

Detrimental effects

The detrimental effects of anaemia can be seen in three important areas *(49)* : (a) *Pregnancy* : Anaemia increases the risk of maternal and foetal mortality and morbidity. In India, 19 per cent of maternal deaths were found to be due to anaemia *(54)*. Conditions such as abortions, premature births, postpartum haemorrhage and low birth weight were especially associated with low haemoglobin levels in pregnancy. (b) *Infection* : Anaemia can be caused or aggravated by parasitic diseases, e.g., malaria, intestinal parasites. Further, iron deficiency may impair cellular responses and immune functions and increase susceptibility to infection (c) *Work capacity* : Anaemia (even when mild) causes a significant impairment of maximal work capacity. The more severe the anaemia, the greater the reduction in work performance, and thereby productivity. This has great significance on the economy of the country.

Interventions

An estimation of haemoglobin should be done to assess the degree of anaemia. If the anaemia is "Severe", less than 10 g/dl high doses of iron or blood transfusion may be necessary. If haemoglobin is between 10–12 g/dl, the other interventions are :

(1) Iron and folic acid supplementation

In order to prevent nutritional anaemia among mothers and children, the Government of India sponsored a National Nutritional Anaemia Prophylaxis Programme during the Fourth Five Year Plan. The Programme is based on daily supplementation with iron and folic acid tablets to prevent mild and moderate cases of anaemia. The beneficiaries are "at risk" groups viz pregnant women, lactating mothers and children under 12 years.

Eligibility criteria (97) : These are determined by the haemoglobin levels of the patients. If the haemoglobin is between 10 and 12, daily supplement with iron and folic acid tablets is advised; if it is less than 10 g, the patient is referred to the nearest primary health centre.

Dosage : (a) MOTHERS : One tablet of iron and folic acid containing 100 mg of elemental iron (300 mg of ferrous sulphate) and 0.5 mg of folic acid should be given daily. The daily administration should be continued until 2 to 3 months after haemoglobin level has returned to normal so that iron

stores are replenished. It is necessary that estimation of haemoglobin is repeated at 3–4 month intervals. The exact period of supplementation will depend upon the progress of the beneficiary. (b) CHILDREN : If anaemia is suspected, a screening test for anaemia may be done on infants at 6 months, and 1 and 2 years of age. One tablet of iron and folic acid containing 20 mg of elemental iron (60 mg of ferrous sulphate) and 0.1 mg of folic acid should be given daily for 100 days. For children 6–60 months, ferrous sulphate and folic acid is to be provided in a liquid formulation. For safety sake, the liquid formulation should be dispensesd in bottles so designed that only 1 ml can be dispensed each time. School children, 6 to 10 year old and adolescents are also to be included in the national programme. Children 6-10 years of age are to be provided 30 mg. elemental iron and 250 mcg. folic acid per day for 100 days. Adolescents are given the same dosage and duration as adults *(92)*.

(2) Iron fortification

The WHO experts *(49)* did not recommend iron fortification strategy for control of anaemia in regions where its prevalence is high. However, studies in India at the National Institute of Nutrition, Hyderabad showed that simple addition of ferric ortho-phosphate or ferrous sulphate with sodium bisulphate was enough to fortify salt with iron *(98)*. When consumed over a period of 12–18 months, iron fortified salt was found to reduce prevalence of anaemia significantly. Fortification of salt with iron has been accepted by the Government of India as a public health approach to reduce prevalence of anaemia. Commercial production of iron fortified salt was started in 1985 *(98)*.

Iron fortification has many advantages over iron supplementation. As salt is a universally consumed dietary item, all segments of the population stand to benefit. No special delivery systems are required *(53)*.

(3) Other strategies

There are other strategies such as changing dietary habits, control of parasites and nutrition education. These are longterm measures applicable to situations where the prevalence and severity of anaemia are lower. Cost and time involved to meet the desired goals through these strategies are disproportionately high *(53)*.

5. Iodine deficiency disorders (IDD)

Iodine deficiency is yet another major nutrition problem in India. Previously, iodine deficiency was equated with goitre. In recent years, it has become increasingly clear that iodine deficiency leads to a much wider spectrum of disorders commencing with the intrauterine life and extending through childhood to adult life with serious health and social implications. Table 16 presents the iodine deficiency disorders in approximate order of increasing severity. The social impact of iodine deficiency arises not so much from goitre as from the effect on the central nervous system *(56)*.

The problem

Whereas goitre has ceased to be a major problem in many developed countries (although not eradicated) it continues to be a serious health problem in many Third World Countries. For example iodine deficiency is a health problem of considerable magnitude in India and the neighbouring countries of Bangladesh, Bhutan, Myanmar, Indonesia, Nepal, Sri Lanka and Thailand. More people are affected and levels of severity are higher in South-East Asia than anywhere else in the world *(99)*.

It has always been thought in India that goitre and cretinism were only found to a significant extent in the "Himalaya goitre belt" which is the world's biggest goitre belt. It stretches from Kashmir to the Naga Hills in the east, extending about 2,400 km and affecting the northern States of Jammu and Kashmir, Himachal Pradesh, Punjab, Haryana, Delhi, Uttar Pradesh, Bihar, West Bengal, Sikkim, Assam, Arunachal Pradesh, Nagaland, Mizoram, Meghalaya, Tripura and Manipur. In recent years renewed surveys outside the conventional goitre belt have identified endemic foci of iodine deficiency and the associated IDD in parts of Madhya Pradesh, Gujarat, Maharashtra, Andhra Pradesh, Kerala, Karnataka and Tamil Nadu. More and more new areas are being identified. Even areas near the sea coast like Bharuch district in Gujarat and Ernakulam district in Kerala are found goitre-affected. In short, no State in India can be said to be entirely free from goitre (Fig. 4).

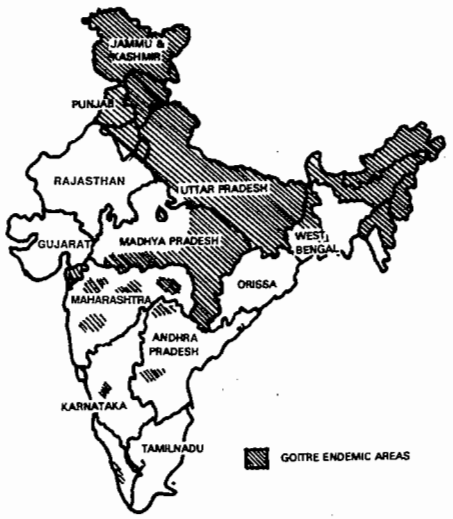

FIG. 4
Goitre endemic areas in India

The magnitude of the problem in India is far greater than what had been estimated in 1960s, when it was estimated that about 9 million persons were affected by goitre. Results of sample surveys conducted in 325 districts covering all the states/UTs have revealed that 263 districts are endemic where the prevalence of IDD is more than 10 per cent. It is estimated that more than 71 million persons are suffering from goitre and other iodine deficiency disorders in the country *(100)*.

Goitre control

There are four essential components of national goitre control programme. These are iodized salt or oil, monitoring and surveillance, manpower training and mass communication.

1. Iodized salt

The iodization of salt is now the most widely used prophylactic public health measure against endemic goitre. In India the level of iodization is fixed under the Prevention of Food Adulteration (PFA) Act and is not less than 30 ppm at the production point, and not less than 15 ppm of iodine at the consumer level *(98)*. Iodized salt is most economical, convenient and effective means of mass prophylaxis in

endemic areas. Under the national IDD control activities, the Government of India proposed to completely replace common salt with iodized salt in a phased manner *(98)*.

The National Institute of Nutrition at Hyderabad has come out with a new product, common salt fortified with iron and iodine. Community trials have been launched to examine the efficacy of the "two-in-one" salt *(98)*.

Iodized oil : Another method which has demonstrated its efficacy for controlling goitre is intramuscular injection of iodized oil (mostly poppy-seed oil). Scientists at the National Institute of Nutrition, Hyderabad have now successfully developed a process to produce iodized oil in safflower or safola oil *(101)*.

The advantage of the injection procedure is that an average dose of 1 ml will provide protection for about 4 years. Although more expensive than iodated salt, this method has the advantage that it can be applied rapidly and in places where iodization of salt is not feasible or iodated salt is in short supply. However, the difficulty with this procedure is one of logistics, i.e., in reaching every victim or potential victim of IDD for the injection, which means that this approach is less practicable.

Iodized oil, oral : The oral administration of iodine as iodized oil or as sodium iodate tablets, is technically simpler than the injection method. Limited research has found that these procedures are effective against goitre but more costly than intramuscular injections.

2. Iodine monitoring

Countries implementing control programmes require a network of laboratories for iodine monitoring and surveillance. These laboratories are essential for a) iodine excretion determination b) determination of iodine in water, soil and food as part of epidemiological studies, and c) determination of iodine in salt for quality control.

Neonatal hypothyroidism is a sensitive pointer to environmental iodine deficiency and can thus be an effective indicator for monitoring the impact of a programme *(99)*.

3. Manpower training

It is vital for the success of control that health workers and others engaged in the programme be fully trained in all aspects of goitre control including legal enforcement and public education.

4. Mass communication

Mass communication is a powerful tool for nutrition education. It should be fully used in goitre control work. Creation of public awareness is central issue of a successful public health programme.

5. Hazards of iodization

A mild increase in incidence of thyrotoxicosis has now been described following iodized salt programmes. An increase in lymphocytic thyroiditis (Hashimoto's disease) has also been claimed. The risk of iodism or iodide goitre however seems to be very small *(58)*.

6. Endemic fluorosis

In many parts of the world where drinking water contains excessive amounts of fluorine (3–5 mg/L), endemic fluorosis has been observed. Endemic fluorosis has been reported to be an important health problem in certain parts of the country, e.g., Andhra Pradesh (Nellore, Nalgonda and Prakasam districts), Punjab, Haryana, Karnataka, Kerala and Tamil Nadu *(60)*. The toxic manifestation of fluorosis comprise the following :

(a) *Dental fluorosis :* Fluorosis of dental enamel occurs when excess fluoride is ingested during the years of tooth calcification – essentially during the first 7 years of life *(101)*. It is characterized by "mottling" of dental enamel, which has been reported at levels above 1.5 mg/L intake *(102)*. The teeth lose their shiny appearance and chalk-white patches develop on them. This is the early sign of dental fluorosis. Later the white patches become yellow and sometimes brown or black. In severe cases, loss of enamel gives the teeth a corroded appearance. Mottling is best seen on the incisors of the upper jaw. It is almost entirely confined to the permanent teeth and develops only during the period of formation *(61)*.

(b) *Skeletal fluorosis :* This is associated with lifetime daily intake of 3.0 to 6.0 mg/L or more *(102)*. There is heavy fluoride deposition in the skeleton. When a concentration of 10 mg/L is exceeded, crippling fluorosis can ensue *(103)*. It leads to permanent disability.

(c) *Genu valgum :* A new form of fluorosis characterized by genu valgum and osteoporosis of the lower limbs has been reported in some districts of Andhra Pradesh and Tamil Nadu *(104)*. The syndrome was observed among people whose staple was sorghum *(jowar)*. Further studies showed that diets based on sorghum promoted a higher retention of ingested fluoride than do diets based on rice *(14)*.

Intervention

(a) *Changing the water source :* One solution to the problem is to find a new source of drinking water with a lower fluoride content (0.5 to 0.8 mg/L) if that is possible. Running surface water contains lower quantities of fluorides than ground water sources such as wells. (b) *Chemical treatment :* If the above is not possible, the water can be chemically defluoridated in a water treatment plant, even though such treatment is moderately expensive *(101)*. The National Environmental Engineering Research Institute, Nagpur developed a technique for removing fluoride by chemical treatment. It is called **Nalgonda technique** for defluoridation of water *(105)*. It involves the addition of two chemicals (viz. lime and alum) in sequence followed by flocculation, sedimentation and filtration. (c) *Other measures :* Fluoride supplements should not be prescribed for children who drink fluoridated water. The use of fluoride toothpaste in areas of endemic fluorosis is not recommended for children upto 6 years of age *(101)*.

7. Lathyrism

Lathyrism is a paralyzing disease of humans and animals. In the humans it is referred to as **neurolathyrism** because it affects the nervous system, and in animals as **osteolathyrism** (odoratism) because the pathological changes occur in the bones resulting in skeletal deformities *(8)*. Neurolathyrism is a crippling disease of the nervous system characterized by gradually developing spastic paralysis of lower limbs, occurring mostly in adults consuming the pulse, Lathyrus sativus in large quantities.

The problem

Neurolathyrism is prevalent in parts of Madhya Pradesh, Uttar Pradesh, Bihar and Orissa. It has also been reported in Maharashtra, West Bengal, Rajasthan, Assam and Gujarat where the pulse is grown. The magnitude of the problem can

be assessed from the fact that at one time in Rewa and Satna districts of Madhya Pradesh alone, there were 25,000 and 32,000 cases respectively. According to reports, there are no fresh outbreaks of the disease in endemic areas. This is attributed to the shifting trends in agronomical practices in the region *(106)*. Lathyrism has also been reported to occur in Spain and Algeria where *Lathyrus* is eaten *(8)*.

The pulse

Lathyrus sativus is commonly known as "Khesari dhal". It is known by local names such as Teora dhal, Lak dhal, Batra, Gharas, Matra etc. *(106)*. The seeds of lathyrus have a characteristic triangular shape and grey colour. When dehusked the pulse looks similar to red gram dhal or bengal gram dhal. Like other pulses, lathyrus is a good source of protein, but for its toxin which affects the nerves. It is eaten mostly by the poor agricultural labourer because it is relatively cheap. Studies have shown that diets containing over 30% of this dhal if taken over a period of 2–6 months will result in neurolathyrism.

The toxin

The toxin present in lathyrus seeds has been identified as Beta oxalyl amino alanine (BOAA). It has been isolated in crystalline form and is water soluble; this property has been made use of in removing the toxin from the pulse by soaking it in hot water and rejecting the soak water. Studies indicate that there is a blood-brain barrier to this toxin. In order to overcome this barrier, the pulse must be eaten in large amounts over a period of time for 2 months or more. Besides BOAA several other toxins have also been reported *(107)*.

The disease

The disease affects mainly young men between the age of 15 to 45 years and manifests itself in stages : (a) *Latent stage* : The individual is apparently healthy, but when subjected to physical stress exhibits ungainly gait. Neurological examination shows characteristic physical signs. This stage is considered important from the preventive aspect, since at this stage, if the pulse is withdrawn from the diet, it will result in complete remission of the disease. (b) *No-stick stage* : the patient walks with short jerky steps without the aid of a stick. A large number of patients are found in this stage. (c) *One-stick stage* : The patient walks with a crossed gait with a tendency to walk on toes. Muscular stiffness makes it necessary to use a stick to maintain balance. (d) *Two-stick stage* : the symptoms are more severe. Due to excessive bending of knees and crossed legs, the patient needs two crutches for support. The gait is slow and clumsy and the patient gets tired easily after walking a short distance. (e) *Crawler stage* : Finally the erect posture becomes impossible as the knee joints cannot support the weight of the body. There is atrophy of the thigh and leg muscles. The patient is reduced to crawling by throwing his weight on his hands *(106)*.

Interventions

The possible interventions for the prevention and/or control of lathyrism are :

(a) *Vitamin C prophylaxis* : Although this condition is believed to be irreversible, in certain instances the damages could be repaired by the daily administration of 500–1000 mg of ascorbic acid for a week or so. The damage could also be prevented by generous provision of ascorbic acid in the lathyrogenic diet, as demonstrated in guinea pigs and monkeys.

(b) *Banning the crop* : This is an extreme step not feasible for immediate implementation. The Prevention of Food Adulteration Act in India has banned *lathyrus* in all forms – whole, split or flour. But the ban is not operative where it is needed, viz. Madhya Pradesh, Bihar, Orissa and Gujarat where the pulse is widely grown.

If however, it is not possible to avoid consuming khesari dhal, it is desirable that the proportion of the *dhal* should never form more than a quarter of the total amount of cereals and pulses eaten per day.

(c) Removal of toxin

(1) *Steeping method* : Since the toxins are water soluble, they can be removed by soaking the pulse in hot water. This method can be practised at home. A large quantity of water is boiled and the pulse is soaked in hot water for 2 hours; after which the soaked water is drained off completely. The pulse is washed again with clean water, then drained off and dried in the sun. The pulse is then used for consumption. The drawback with this method is that it entails loss of vitamins and minerals.

(2) *Parboiling* : An improved method of detoxicating the pulse is "parboiling" as is done in the case of parboiled rice. This technique is suitable for large scale operation. Simple soaking in lime water overnight followed by boiling is credited to destroy the toxin. This treatment also destroys trypsin inhibitiors. Lime is easily available as it is used with betel leaves.

(c) *Education* : The public must be educated on the dangers of consuming this pulse and the need for removing its toxin before consumption.

(d) *Genetic approach* : Certain strains of *lathyrus* contain very low levels of toxin (0.1%). The selective propagation and cultivation of such strains may be the most effective way to eradicate lathyrism without any drastic change in the food habits of the people. Low toxin varieties can be obtained from the Indian Agricultural Research Institute, New Delhi.

(e) *Socio-economic changes* : In the final analysis, it is only socio-economic changes or overall development that can root out lathyrism.

NUTRITIONAL FACTORS IN SELECTED DISEASES

1. Cardiovascular disease

It is now generally agreed that diet governs many situations favouring the onset of "heart disease", particularly coronary heart disease. Of all the factors associated with CHD (e.g., plasma cholesterol, high blood pressure, cigarette smoking, lack of physical activity) plasma cholesterol has a very high statistical significance with the incidence of CHD. The risk of CHD appears to increase as the plasma cholesterol concentration rises *(108)*. Various studies have supported the role of elevated blood levels of cholesterol and low density lipoproteins (LDL) in the development of atherosclerosis. Geographical studies have shown that there is no population in whom CHD is common that does not have a relatively high mean level of plasma total cholesterol (TC) in adults *(15)*. These observations have been reinforced by metabolic studies. In addition trials of the effect of dietary changes on CHD have suggested that altering the fatty acid composition of the diet in favour of greater intake of polyunsaturated fatty acids (PUFA) and less intake of saturated fats, while restricting the intake of fat

calories to less than 30 per cent of the total calories, may lower the risk that CHD will subsequently develop *(109)*. The evidence of association is now so strong for cholesterol and CHD that the WHO Expert committee (1982) considered its effect to be "causal" in populations although this cannot be claimed yet for individuals *(15)*. The WHO Expert Committee *(15)* concludes that there is a well established triangular relationship between habitual diet, blood cholesterol levels and CHD. The current report of the expert group of the ICMR (2010) on Nutrient Requirement and Recommended Dietary Allowances for Indians endorses the views.

Cholesterol

Cholesterol occurs in all foods of animal origin. Part of it is synthesized in the body. The plasma cholesterol is determined by (a) the amount absorbed from food (b) the amount synthesized in the body (c) the rate of catabolism and excretion in the bile (d) intestinal reabsorption of bile acids, and (e) the equilibrium between plasma and tissues. The extent to which cholesterol intake influences total cholesterol levels is highly variable.

Lipoproteins

Cholesterol is carried in plasma lipoproteins. Lipoproteins are divided into four major classes – chylomicrons, very low-density lipoproteins (VLDLs), low-density lipoproteins (LDLs) and high-density lipoproteins (HDLs). The total serum cholesterol is the sum of the cholesterol in 3 lipoprotein fractions, viz. VLDL, LDL, and HDL cholesterol. Most of the serum cholesterol (close to 50 per cent) is in LDL. Whereas LDL is dominated by its cholesterol content, VLDL is dominated by its triglyceride content.

LDL has been shown to function in the delivery of cholesterol to body cells. Excessive level of LDL thus leads to the accumulation of cholesterol in tissue cells particularly the smooth muscle cells of the vascular system. It is thus involved in the arteriosclerotic process. In contrast, HDL functions in the removal of cholesterol from cells. This mechanism underlines its protective effect in CHD. From long-term observations it became quite clear that HDL levels, the higher they are, the more protective they seem to be against CHD.

Fatty acids

In populations where the plasma cholesterol is high, there is also generally a high consumption of saturated fats. Clinical studies on selected volunteers under well-defined conditions have clearly demonstrated that a high intake of saturated fatty acids over several weeks or months causes an increase in plasma cholesterol. The cholesterol-raising effect is mainly produced by C_{12}, C_{14} and C_{16} acids; stearic acid and fatty acids with less than 12 carbon atoms have a smaller effect on plasma cholesterol. The mechanisms by which these saturated fatty acids act (possibly on cholesterol synthesis) is not fully known.

Dietary unsaturated fatty acids with two or more double bonds have been shown to lower plasma cholesterol. The mechanism of reduction of serum cholesterol by polyunsaturated fatty acids is not clear but includes reduced synthesis of VLDL. The proposition has often been made that a low HDL/LDL ratio favours the development of atheroma, thus favouring the onset of CHD *(110)*.

Polyunsaturated fatty acids (e.g., linoleic and arachidonic acids) have an additional role, that is, to inhibit platelet aggregation and thus prevent thrombus formation. Recent research indicates that arachidonic acid metabolizes in the vascular endothelium to form two important metabolites, namely prostacyclin and thromboxane (Fig. 5). These two compounds have opposing effects on the cardiovascular system. Whereas thromboxane induces platelet aggregation, prostacyclin inhibits the same and prevents intravascular thrombus formation. Prostacyclin was found also to relax coronary blood vessels, thus opposing the action of thromboxane. It has been suggested that generation of prostacyclin is the biochemical mechanism underlying the well-known ability of blood vessels to resist platelet aggregation. Linoleic acid which is the main precursor of arachidonic acid is therefore regarded as the body's best bulwark against CHD. In short, essential fatty acids have in the last decade come to be regarded as of major importance in clinical nutrition.

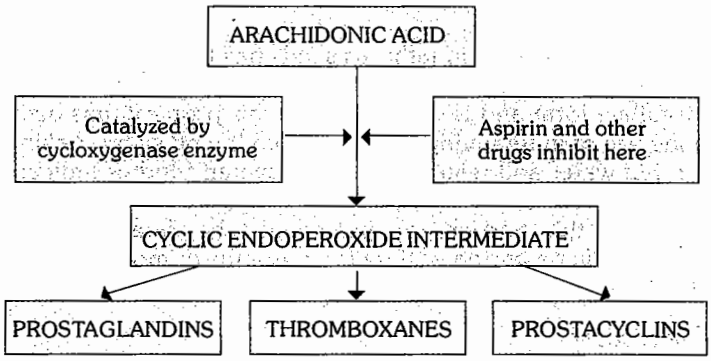

FIG. 5

Steps in the conversion of arachidonic acid to prostaglandins, etc.

It has been shown that cholesterol in blood can be reduced by controlling the amount and type of fat in the diet. However, several populations, particularly in Africa and in the South Pacific have intakes of fat similar to those observed in Western countries, but the average plasma cholesterol level remains below 200 mg/dl, and coronary heart disease is rare. It has been argued that this discrepancy may be due to a "favourable" intrinsic (possibly genetic) mechanism for lipid handling, when receiving a diet shown experimentally to raise total cholesterol. This illustrates an important interplay between dietary and genetic determinants of individual blood cholesterol levels *(15)*.

Evidence is emerging that ischaemic myocardium may not metabolise all fatty acids equally, and that the accumulation of some of these in the myocardium may be more closely associated with sudden cardiac death *(110)*.

Triglycerides

In a very large proportion of individuals with a raised cholesterol level, the blood concentration of triglycerides (TG) is also markedly increased. Some workers have indeed claimed that correlation between TG and CHD is as good as that between total serum cholesterol and CHD. Recently it has been shown that TG levels act as a significant independent risk factor for CHD *(102)*. Both cholesterol and TG are associated with specific proteins in the plasma to form lipoproteins.

The most important determinant of TG level is the activity of the enzyme, lipoprotein lipase in the endothelial lining of the capillaries and in a variety of tissues. This enzyme removes TG particularly from the very low density lipoproteins (VLDL) and converts these to the lipoproteins of higher density. In certain genetically determined diseases, this enzyme may be absent. A reduction in its activity or a reduced capacity to deal with increased levels of TG may be important in more common diseases such as diabetes where high concentrations of TG are often observed.

Carbohydrate

Coronary heart disease rates are lowest in populations eating high carbohydrate diets. Support for the hypothesis that consumption of complex carbohydrates may decrease the risk of CHD comes from historical trends of food consumption patterns and mortality rates in US. It is generally recognized that such mortality rates were quite low until about 1920. After 1920 there was a steady increase in the mortality rate until 1968 when a decline began *(109)*. The principal nutritional change that has occurred since the early 1920 has been a decrease in the consumption of dietary carbohydrate. Further support comes from feeding studies. A decrease in serum cholesterol was observed during the vegetable feeding period. Neither high carbohydrates nor high sucrose feeding has induced atherosclerosis in animals, An inverse association of fibre intake with the risk of CHD has also been observed *(111)*.

Salt

There are good and consistent correlations between dietary sodium intake and the incidence of hypertension. Thus the highest incidence of hypertension is found in north Japan where the sodium intake is above 400 mmol/day, while primitive societies ingesting less than 60 mmol/day have virtually no hypertension. Susceptible individuals in primitive populations who change from low to high intake of sodium have been found to develop hypertension. Hypertension can be successfully treated with a drastically low sodium diet (less than 10 mmol/day *(110)*.

2. Diabetes

In a diabetic, there is impaired metabolism of glucose in the body, which leads to excess of glucose in blood and urine. Insulin helps in checking and maintaining the level of glucose in blood. Insulin deficiency leads to accelerated utilization of energy reserves from fat stores. The fatty acids are oxidized by liver to ketone bodies. Excess of ketone bodies leads to their accumulation in urine. This condition is known as ketoacidosis and can result in diabetic coma. Due to insulin deficiency excess of fatty acids are converted to triglycerides. In diabetes these accumulate in the blood. Insulin is also important for synthesis of proteins and deficiency of insulin leads to muscle wasting.

Studies in England showed that diabetics ate an average 1000 kcal per day more than non-diabetics. It was also found that most diabetics were in non-manual occupations than non-diabetics. And the diet of diabetics did not appear to differ in any marked way from that of non-diabetics, except in quantity. There is no sound evidence that any specific dietary factor is diabetogenic.

It has been suggested that deficiencies of trace elements such as chromium, copper and zinc may play a role in the pathogenesis of diabetes mellitus, but clinical evidence is lacking *(112)*.

Malnutrition-related diabetes mellitus has recently attracted attention. Protein deficiency may be involved in the pathogenesis of some forms of diabetes. Excessive consumption of alcohol can increase the risk of diabetes by damaging the pancreas and liver and by promoting obesity.

3. Obesity

In richer countries and in some developing countries, obesity is a health problem. The connection between severe obesity and premature death from diabetes, hypertension and CHD is well established *(113)*. The basic cause of obesity is overnutrition. A diet containing more energy than needed may lead to prolonged postprandial hyperlipidaemia and to deposition of triglycerides in adipose tissue resulting in obesity *(110)*.

It is known that a relative insulin resistance takes place in obesity in peripheral tissues, mainly adipose tissues, while the insulin secretion is normal or increased. The demonstrated reduction in the sensitivity to insulin of the large adipocyte can be attributed to the decreased affinity of the insulin receptors or to a reduction in their number in the cell membrane. Through a feedback mechanism the insulin secretion is stepped up, thus leading to a state of hyperinsulinism.

From a practical point of view all hypotheses concerning the genesis of obesity could be put down to over-nutrition, to a hyper-energy food intake. This is a sound basis for preventive and therapeutic recommendations *(114)*.

4. Cancer

It is postulated that 80 per cent of cancers may be due to environmental factors, and it is possible that some dietetic factors may be involved. Existing knowledge is reviewed briefly as below:

(a) *Dietary fat*

Population surveys have shown a strong positive correlation between cancer colon and dietary intake of fat *(115)*. It has been suggested that the high fat intake accounts for the high incidence of colon cancer in Western communities. In Japan, recent increases in fat consumption have been associated with striking increase in rates of colon cancer *(116)*. Dietary fat is believed to increase the secretion of bile acids in the bowl which are then metabolized by bacterial flora into carcinogen or co-carcinogens *(117)*. However, no known carcinogen has yet been identified from faeces and the evidence is thus incomplete.

A positive correlation between per capita consumption of dietary fat and breast cancer rates has also been noted. A reduction in dietary fat may alter the risk of breast cancer *(118)*, perhaps by increasing oestrogen production or prolactin release *(119)*.

(b) *Dietary fibre*

Several studies indicate that the risk of colon cancer is inversely related to the consumption of dietary fibre, which may protect against intestinal carcinogens or precursors by dilutional or other effects *(120)*. Although the available epidemiological data are not entirely consistent, the weight of evidence generally supports the hypothesis that fibre protects against colon cancer *(116)*.

(c) *Micronutrients*

Micronutrients may also have a protective influence, since cancers of the lung and several other sites have been associated with a low intake of vitamin A *(117)*. The risk of stomach cancer has been related to a deficiency of vitamin C, which may act by inhibiting the formation of carcinogenic nitrosamines in the stomach *(121)*. Trace elements (e.g., selenium) have also been implicated in the aetiology of cancer *(116)*.

(d) *Food additives and contaminants*

Food additives and contaminants (e.g., preservatives, artificial colours, artificial sweeteners, pesticides, flavours, anti-oxidants) have always been under suspicion as possible carcinogens in their long-term effects. Food processing involves exposure to high temperature, oxidation, polymerization, production of nitrosamines, polycyclic aromatic hydrocarbons, etc which are injurious to health. It is thought in some quarters that nitrosamines are responsible for certain types of gastric carcinoma. Saccharin and cyclamate are weak bladder carcinogens or co-carcinogens in laboratory animals, but the risk in man is very small if present at all *(122)*. Aflatoxin is a carcinogenic metabolite. Coffee intake has been associated with bladder cancer and recently with pancreatic cancer *(123)* but causal relationships have not been established. The mutagenic properties of food additives are under constant surveillance.

(e) Alcohol

Heavy drinking increases the risk of liver cancer. It is estimated that alcohol contributes to about 3 per cent of all cancer deaths *(124)*. Some recent studies have suggested that beer consumption may be related to cancer rectum, but the association has not been confirmed *(117)*.

The above review indicates that much evidence has accumulated to indicate that nutrition has an influence on cancer incidence and mortality. There is in this field a remarkable dearth of facts and an abundance of speculation.

ASSESSMENT OF NUTRITIONAL STATUS

The nutritional status of an individual is often the result of many interrelated factors. It is influenced by the adequacy of food intake both in terms of quantity and quality and also by the physical health of the individual *(125)*. The nutritional status of a community is the sum of the nutritional status of the individuals who form that community. The main objective of a "comprehensive" nutritional survey is to obtain precise information on the prevalence and geographic distribution of nutritional problems of a given community, and identification of individuals or population groups "at risk" or in greatest need of assistance. In the absence of this information, problems cannot be defined and policies formulated. The purpose of nutritional assessment is to develop a health care programme that meets the needs defined by that assessment, including evaluation of the effectiveness of such programmes *(58)*.

In nutritional surveys, it is not necessary to examine all the persons in a given community. Examination of a random and representative sample of the population covering all ages and both sexes in different socio-economic groups is sufficient to be able to draw valid conclusions. All surveys should be planned with the aid of expert statistical advice. Decisions of many kinds have to be made in advance : duration of survey; type of survey whether cross-sectional or longitudinal; standardization of measurement techniques and survey instruments, etc. Opportunity might be taken of conducting, perhaps on a sub-sample, an intensive investigation of nutritional status.

Assessment methods

The assessment of the nutritional status involves various techniques. Proper evaluation demands a many-angled approach, covering all the different stages in the natural history of nutritional diseases, including prepathogenesis stage as shown in Fig. 6 *(126)*.

The assessment methods include the following :

1. Clinical examination
2. Anthropometry

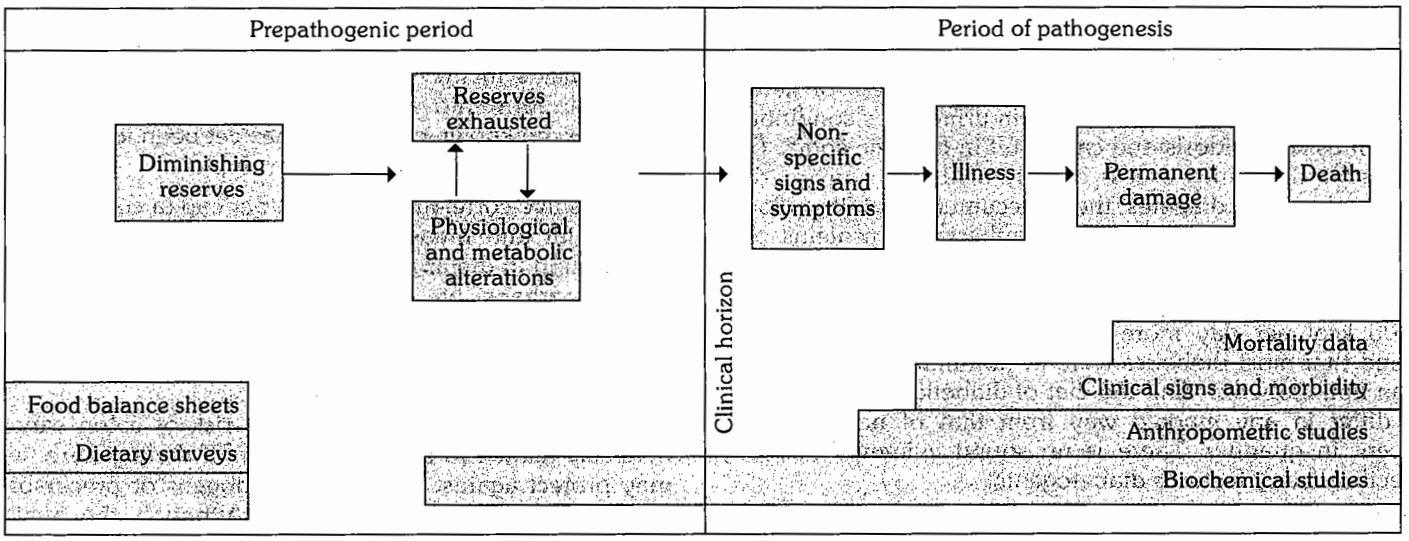

FIG. 6

Methods of nutritional assessment and their relationship to the natural history of disease

3. Biochemical evaluation
4. Functional assessment
5. Assessment of dietary intake
6. Vital and health statistics
7. Ecological studies.

The different methods used for the appraisal of nutritional status are not mutually exclusive; on the contrary, they are complimentary.

1. Clinical examination

Clinical examination is an essential feature of all nutritional surveys since their ultimate objective is to assess levels of health of individuals or of population groups in relation to the food they consume. It is also the simplest and the most practical method of ascertaining the nutritional status of a group of individuals. There are a number of physical signs, some specific and many non-specific, known to be associated with states of malnutrition. When two or more clinical signs characteristic of a deficiency disease are present simultaneously, their diagnostic significance is greatly enhanced. A WHO Expert Committee *(127)* classified signs used in nutritional surveys into three categories as those :

(a) *not related to nutrition,* e.g., alopecia, pyorrhoea, pterygium

(b) *that need further investigation,* e.g., malar pigmentation, corneal vascularization, geographic tongue

(c) *known to be of value,* e.g., angular stomatitis, Bitot's spots, calf tenderness, absence of knee or ankle jerks (beri-beri), enlargement of the thyroid gland (endemic goitre), etc.

However, clinical signs have the following drawbacks : (a) malnutrition cannot be quantified on the basis of clinical signs (b) many deficiencies are unaccompanied by physical signs and (c) lack of specificity and subjective nature of most of the physical signs. To minimize subjective and objective errors in clinical examination, standard survey forms or schedules have been devised covering all areas of the body. A specimen nutrition assessment schedule is given at the end of this chapter (Annexure I).

2. Anthropometry

Anthropometric measurements such as height, weight, skinfold thickness and arm circumference are valuable indicators of nutritional status. In young children, additional measurements such as head and chest circumference are made. If anthropometric measurements are recorded over a period of time, they reflect the patterns of growth and development, and how individuals deviate from the average at various ages in body size, build and nutritional status. Anthropometric data can be collected by non-medical personnel, given sufficient training. This subject is discussed in detail in Chapter 9.

3. Laboratory and biochemical assessment

(a) LABORATORY TESTS : (i) *Haemoglobin estimation :* It is the most important laboratory test that is carried out in nutrition surveys. Haemoglobin level is a useful index of the overall state of nutrition irrespective of its significance in anaemia. An RBC count and a haematocrit determination are also valuable. (ii) *Stools and urine :* Stools should be examined for intestinal parasites. History of parasitic infestation, chronic dysentery and diarrhoea provides useful background information about the nutritional status of persons. Urine should also be examined for albumin and sugar.

(b) BIOCHEMICAL TESTS : With increasing knowledge of the metabolic functions of vitamins and minerals, assessment of nutritional status by clinical signs has given way to more precise biochemical tests which may be applied to measure individual **nutrient** concentration in body fluids (e.g., serum retinol, serum iron) or detection of abnormal amounts of **metabolites** in urine (e.g., urinary iodine) frequently after a loading dose, or measurement of **enzymes** in which the vitamin is a known co-factor (for example in riboflavin deficiency) to help establish malnutrition in its preclinical stages.

Biochemical tests are time–consuming and expensive. They cannot be applied on a large scale, as for example in the nutritional assessment of a whole community. They are often carried out on a subsample of the population. Most biochemical tests reveal only current nutritional status; they are useful to quantify mild deficiencies. If the clinical examination has raised a question, then the biochemical tests may be invoked to prove or disprove the question raised. A short list of currently advocated biochemical tests applicable in nutritional surveys is given in Table 34.

TABLE 34

Some biochemical tests used in nutrition surveys

Nutrient	Method	Normal value
Vitamin A	Serum retinol	20 mcg/dl
Thiamine	Thiamine pyrophosphate (TPP) stimulation of RBC transketolase activity	1.00–1.23 (ratio)
Riboflavin	RBC glutathione reductase activity stimulated by flavine adenine dinucleotide	1.0–1.2 (ratio)
Niacin	Urine N-methyl nicotinamide	(not very reliable)
Folate	Serum folate	6.0 mcg/ml
	Red cell folate	160 mcg/ml
Vitamin B_{12}	Serum vitamin B_{12} concentration	160 mg/L
Vitamin C	Leucocyte ascorbic acid	15 mcg/10^8 cells
Vitamin K	Prothrombin time	11–16 seconds
Protein	Serum albumin (g/L)	35
	Transferrin (g/L)	20
	Thyroid-binding pre-albumin (mg/L)	250

Source : *(128)*

4. Functional indicators

Static indices of nutritional status (biochemical indicators) will continue to play an important role as they are well–established and familiar to practitioners and public health workers. Functional indices of nutritional status are emerging as an important class of diagnostic tools. Some of these are given in Table 35.

TABLE 35
Functional indices of nutritional status

System	Nutrients
1. *Structural integrity*	
Erythrocyte fragility	Vit.E,Se
Capillary fragility	Vit.C
Tensile strength	Cu
2. *Host defence*	
Leucocyte chemotaxis	P/E, Zn
Leucocyte phagocytic capacity	P/E, Fe
Leucocyte bactericidal capacity	P/E, Fe, Se
T cell blastogenesis	P/E, Zn
Delayed cutaneous hypersensitivity	P/E, Zn
3. *Haemostasis*	
Prothrombin time	Vit.K
4. *Reproduction*	
Sperm count	Energy, Zn
5. *Nerve function*	
Nerve conduction	P/E, Vit B_1, B_{12}
Dark adaptation	Vit.A, Zn
EEG	P/E
6. *Work capacity*	
Heart rate	P/E, Fe
Vasopressor response	Vit.C

Source : *(129)*

5. Assessment of dietary intake

The value of nutritional assessment is greatly enhanced when it is supplemented by an assessment of food consumption. Direct assessment of food consumption involves dietary surveys which may be household inquiries or individual food consumption surveys. Well organized survey methods for this purpose are available *(130,131)*.

A diet survey may be carried out by one of the following methods : (i) WEIGHMENT OF RAW FOODS : This is the method widely employed in India as it is practicable and if properly carried out is considered fairly accurate. The survey team visits the households, and weighs all food that is going to be cooked and eaten as well as that which is wasted or discarded. The duration of the survey may vary from 1 to 21 days, but commonly 7 days which is called "one dietary cycle". (ii) WEIGHMENT OF COOKED FOODS : Foods should preferably be analyzed in the state in which they are normally consumed, but this method is not easily acceptable among people. (iii) ORAL QUESTIONNAIRE METHOD : This is useful in carrying out a diet survey of a large number of people in a short time. Inquiries are made retrospectively about the nature and quantity of foods eaten during the previous 24 or 48 hours. If properly carried out, oral questionnaire method can give reliable results. A diet survey may also include collection of data relating to dietary habits and practices.

The data that is collected have to be translated into (a) mean intake (grams) of food in terms of cereals, pulses, vegetables, fruits, milk, meat, fish and eggs, and (b) the mean intake of nutrients per adult man value or "consumption unit". This exercise requires the use of suitable tables of food composition. An excellent guide for carrying out this analysis is the Indian Council of Medical Research (ICMR) publication : "Nutritive Value of Indian Foods" *(43)*.

A diet survey provides information about dietary intake patterns, specific foods consumed and estimated nutrient intakes. It indicates relative dietary inadequacies as judged by present standards. Not only will such information be valuable for planning health education activities, but it will also allow an assessment to be made of the extent and nature of changes needed in the agriculture and food production industries.

6. Vital statistics

An analysis of vital statistics – mortality and morbidity data – will identify groups at high risk and indicate the extent of risk to the community. Mortality in the age group 1 to 4 years is particularly related to malnutrition. In developing countries, it may be as much as 20 times that in countries such as Australia, Denmark or France. The other rates commonly used for this purpose are : infant mortality rate, second-year mortality rate, rate of low birth-weight babies and life expectancy. These rates are influenced by nutritional status and may thus be indices of nutritional status. Mortality data, however, do not provide a satisfactory picture of the nutritional status of a population *(132)*.

Data on morbidity (e.g., hospital data or data from community health and morbidity surveys) particularly in relation to protein energy malnutrition, anaemia, xerophthalmia and other vitamin deficiencies, endemic goitre, diarrhoea, measles and parasitic infestations can be of value in providing additional information contributing to the nutritional status of the community.

7. Assessment of ecological factors

Malnutrition is the end result of many interacting ecological factors. In any nutrition survey it is necessary to collect ecological information of the given community in order to make the nutrition assessment complete. A study of the ecological factors comprise the following : (a) FOOD BALANCE SHEET : This is an indirect method of assessing food consumption, in which supplies are related to census population to derive levels of food consumption in terms of per capita supply availability. The estimate refers to the country as a whole, and so conceals differences which may exist between regions, and among economic, age and sex groups. The great advantage of this method is that it is cheaper and probably simpler than any method of direct assessment. Used intelligently, this method does give an indication of the general pattern of food consumption in the country. (b) SOCIO-ECONOMIC FACTORS : Food consumption patterns are likely to vary among various socio-economic groups. Family size, occupation, income, education, customs, cultural patterns in relation to feeding practices of children and mothers, all influence food consumption patterns. (c) HEALTH AND EDUCATIONAL SERVICES : Primary health care services, feeding and immunization programmes should also be taken into consideration. (d) CONDITIONING INFLUENCES : These include parasitic, bacterial and viral infections which precipitate malnutrition. It is necessary to make an "ecological diagnosis" of the various factors influencing nutrition in the community before it is possible to put into effect measures for the prevention and control of malnutrition.

NUTRITIONAL SURVEILLANCE

The concept of nutritional surveillance is derived from disease surveillance. Nutritional surveillance has been defined as "Keeping watch over nutrition, in order to make decisions that will lead to improvement in nutrition in population" *(133)*. Three distinct objectives have been defined for surveillance systems : (a) to aid long-term planning in health and development, (b) to provide input for programme management and evaluation, and (c) to give timely warning and intervention to prevent short-term food consumption crises *(133, 134)*.

Nutritional surveillance and growth monitoring

Nutritional surveillance should not be confused with growth monitoring. The differences are shown in Table 36.

Growth monitoring is oriented to the individual child, and is a dynamic measure of its health from month to month. It focuses on normal nutrition and the means to promote continued growth and good health. It requires enrolment of the infant at an early stage, preferably before 6 months. Regular monthly participation is crucial to detect early onset of growth faltering.

Nutritional surveillance, on the other hand, can be carried out on a representative sample of children in the community. It gives a reliable idea of the overall nutritional condition of village (or area) A – whether it is good or bad, is better or worse than that of village B or C (and so requires supplies and personnel), and whether it is improving or deteriorating with time. It can help to diagnose malnutrition and assess the impact of occurrence like drought or measures designed to alleviate malnutrition in the community at large.

TABLE 36

Comparison of growth monitoring and nutritional surveillance

Factor	Growth monitoring	Nutritional surveillance
Strategy	Preservation of normal growth	Detection of undernutrition
Approach	Educational–motivational	Diagnostic–interventional
Enrolment	All infants	Representative sample
Age	Start before 6 months and continue monthly	Representative ages at longer intervals
Number	Small groups, preferably between 10 and 20	Any size group; 50 to 100 most efficient
Weigher/Recorder	Mothers guided by worker	Trained worker
Weight card	Simple, emphasis growth	Precise, nutritional status
Nutritional emphasis	Maintaining good nutrition	Detect malnutrition
Response	Early home intervention based on local knowledge	Nutritional rehabilitation often with supplements
Response time	Brief, resumption of normal growth	Long, regain of good nutrition in community
Interventions	Primary health care; oral rehydration therapy; vaccines; vitamin A; deworming; contraceptives; chloroquine; other treatment	Food supplements of community–wide response, such as food subsidy
Referral	Health system for check-up and possible brief food supplements	Malnutrition rehabilitation, often in special centre

Nutritional status indicators

Indicators that are considered useful for the surveillance of nutritional status are given in Table 37. There is an increasing trend to use nutritional indicators to measure quality of life, specially as a means of evaluating both development programmes and health programmes. Many of the indicators used in nutritional surveillance are the same as the socio-economic and health status indicators recommended for monitoring progress in health.

TABLE 37

Concise list of indicators of nutritional status

Phenomenon	Indicator
Maternal Nutrition	birth weight
Infant and preschool child nutrition	proportion being breast fed and proportion on weaning foods, by age in months, mortality rates in children aged 1,2,3 and 4 years, with emphasis on 2–year–olds If age known : height for age weight for age If age unknown : weight for height arm circumference clinical signs and syndromes
School child nutrition	height for age, and weight for height at 7 years or school admission clinical signs

SOCIAL ASPECTS OF NUTRITION

Food means not only proteins, fats, minerals, vitamins and other nutrients – but much more; it is part of security and civilization. Nations and civilizations are linked together not only by *ideas*, but also by *bread*. Hunger and malnutrition are problems everywhere and have harassed mankind and threatened peace throughout history. It is no wonder that the growing incidence of hunger and malnutrition should have come to the forefront of international concern.

Problem of malnutrition

Malnutrition has been defined as "a pathological state resulting from a relative or absolute deficiency or excess of one or more essential nutrients". It comprises four forms – undernutrition, overnutrition, imbalance and the specific deficiency *(136)*. (1) *Undernutrition :* This is the condition which results when insufficient food is eaten over an extended period of time. In extreme cases, it is called starvation. (2) *Overnutrition :* This is the pathological state resulting from the consumption of excessive quantity of food over an extended period of time. The high incidence of obesity, atheroma and diabetes in western societies is attributed to overnutrition. (3) *Imbalance :* It is the pathological state resulting from a disproportion among essential nutrients with or without the absolute deficiency of any nutrient. (4) *Specific deficiency :* It is the pathological state resulting from a relative or absolute lack of an individual nutrient.

We do not know enough about the dimensions of the problem. According to FAO reports, there are about 460 million people – 15 per cent of the world's population, excluding China – who are malnourished, of which about 300 million live in South Asia where they constitute one-third of the population *(137)*. What makes the situation most serious is that malnutrition's main victims are children under the age of 15. But children under the age of 5 years are hit the hardest. On a global scale the five principal nutritional deficiency diseases that are being accorded the highest priority action are kwashiorkor, marasmus, xerophthalmia, nutritional anaemias and endemic goitre *(137)*. These diseases represent the tip of the "iceberg" of malnutrition; a much larger population are affected by "hidden" malnutrition which is not easy to diagnose.

The effects of malnutrition on the community are both direct and indirect. The direct effects are the occurrence of frank and subclinical nutrition deficiency diseases such as kwashiorkor, marasmus, vitamin and mineral deficiency diseases. The indirect effects are a high morbidity and mortality among young children (nearly 50 per cent of total deaths in the developing countries occur among children under-5 years of age as compared to less than 5 per cent in developed countries), retarded physical and mental growth and development (which may be permanent), lowered vitality of the people leading to lowered productivity and reduced life expectancy. Malnutrition predisposes to infection and infection to malnutrition; and the morbidity arising therefrom as a result of complications from such infectious diseases as tuberculosis and gastro-enteritis is not inconsiderable. The high rate of maternal mortality, stillbirth and low birth-weight are all associated with malnutrition.

In the more developed countries of the world nutritional problems are somewhat different. Overnutrition is encountered much more frequently than undernutrition. The health hazards from overnutrition are a high incidence of obesity, diabetes, hypertension, cardiovascular and renal diseases, disorders of liver and gall bladder. From this brief review, it is obvious that the consequences of malnutrition are ominous.

Ecology of malnutrition

Malnutrition is a man-made disease. It is a disease of human societies. It begins quite commonly in the womb and ends in the grave. The great advantage of looking at malnutrition as a problem in human ecology is that it allows for variety of approaches towards prevention. Jelliffe (1966) *(136)* listed the ecological factors related to malnutrition as follows : conditioning influences, cultural influences, socio-economic factors, food production and health and other services.

(1) CONDITIONING INFLUENCES : Infectious diseases are an important conditioning factor responsible for malnutrition, particularly in small children. Diarrhoea, intestinal parasites, measles, whooping cough, malaria, tuberculosis all contribute to malnutrition. In fact it is a vicious circle – infection contributing to malnutrition, and malnutrition causing an otherwise minor childhood ailments to become killers. It has been shown that where environmental conditions are poor, small children may suffer from some infection or the other for almost half of their first three years of life. The interrelationship between malnutrition and infection has been well documented.

(2) CULTURAL INFLUENCES : Lack of food is not the only cause of malnutrition. Too often there is starvation in the midst of plenty. People choose poor diets when good ones are available because of cultural influences which vary widely from country to country, and from region to region. These may be stated as follows : (a) *Food habits, customs, beliefs, traditions and attitudes :* Food habits are among the oldest and most deeply entrenched aspects of any culture. They have deep psychological roots and are associated with love, affection, warmth, self image and social prestige. The family plays an important role in shaping the food habits, and these habits are passed from one generation to another. Rice is the staple cereal in the eastern and southern States of India and wheat is the staple cereal in the northern States. During the second World War, when wheat was made available in place of rice in South India people refused to buy wheat because it was not their staple cereal. The story is told of a Philippine student who died of beriberi after writing an essay explaining how the disease could be prevented. The crux of the problem is that many customs and beliefs apply most often to vulnerable groups, i.e. infants, toddlers, expectant and lactating women. Papaya is avoided during pregnancy because it is believed to cause abortion. In Gujarat, valuable foods such as dhals, leaf greens, rice and fruits are avoided by the nursing mother. There is a widespread belief that if a pregnant woman eats more, her baby will be big and delivery difficult. Certain foods are "forbidden" as being harmful for the child. Then there are certain beliefs about hot and cold foods, light and heavy foods. (b) *Religion :* Religion has a powerful influence on the food habits of the people. Hindus do not eat beef, and Muslims pork. Some orthodox Hindus do not eat meat, fish, eggs and certain vegetables like onion. These are known as food taboos which prevent people from consuming nutritious foods even when these are easily available. (c) *Food fads :* In the selection of foods, personal likes and dislikes play an important part. These are called "food-fads". The food fads may stand in the way of correcting nutritional deficiencies. (d) *Cooking practices :* Draining away the rice water at the end of cooking, prolonged boiling in open pans, peeling of vegetables, all influence the nutritive value of foods. (e) *Child rearing practices :* These vary widely from region to region and influence the nutritional status of infants and children. Examples of this situation are premature curtailment of breast feeding, the adoption of bottle feeding and adoption of commercially produced refined foods. (f) *Miscellaneous :* In some communities, men eat first and women eat last and poorly. Consequently, the health of women in these societies may be adversely affected. Chronic alcoholism is another factor which may lead to serious malnutrition.

(3) SOCIO-ECONOMIC FACTORS : Malnutrition is largely the by-product of poverty, ignorance, insufficient education, lack of knowledge regarding the nutritive value of foods, inadequate sanitary environment, large family size, etc. These factors bear most directly on the quality of life and are the true determinants of malnutrition in society. The speed with which populations are growing in many developing countries is another important factor to reckon with. It has made the solution of the malnutrition problem more difficult. In short, the causes of malnutrition are built into the very nature of society, in the socio-economic and political structures, both nationally and internationally *(137)*.

(4) FOOD PRODUCTION : Increased food production should lead to increased food consumption. The average Indian has 0.6 hectare of land surface compared to 5.8 hectare per head in the developed countries. The per capita arable land for an average Indian is only 0.3 hectare *(138)*. Yields per hectare are only about one-fourth of those achieved in the industrialized countries. Given the best technology known at present, most developing countries could increase their food production several fold. But increased food production will not solve the basic problem of hunger and malnutrition in much of the developing world. Scarcity of food, as a factor responsible for malnutrition, may be true at the family level; but it is not true on a global basis, nor is it true for most of the countries where malnutrition is still a serious problem. It is a problem of uneven distribution between the countries and within the countries. It is said that there will be very little malnutrition in India today if all the food available can be equitably distributed in accordance with physiological needs *(139)*.

(5) HEALTH AND OTHER SERVICES : The health sector can, if properly organized and given adequate resources can combat malnutrition. Some of the remedial actions that can be taken up by the health sector are : (1) *Nutritional surveillance :* Nutritional surveillance implies the continuous monitoring in a community or area of factors or conditions which indicate, relate to, or impinge on the nutritional status of individuals or groups of people (WHO, 1976) *(140)*. The first task is to identify the groups and individuals affected – through clinical examination and simple body measurements of persons attending health centres and hospitals. A further step is to carry out surveys in the villages. The data will give a more realistic picture of the nutritional status of the community. (2) *Nutritional rehabilitation :* Immediate measures are required as soon as the malnourished subjects are located. Children suffering from severe PEM with complications need urgent care, may be in a hospital. Less severely affected children can be treated on a domiciliary basis or in special nutrition rehabilitation centres. These centres should be linked with health centres. (3) *Nutrition supplementation :* The target groups are mothers and children. Supplementary feeding is normally regarded as a stop-gap measure for the rehabilitation of malnourished children. (4) *Health education :* It is opined that by appropriate educational action, about 50 per cent of nutritional problems can be solved. Health education programmes in nutrition is often a weak component. Its reinforcement is a key element in all health services development.

Preventive and social measures

Since malnutrition is the outcome of several factors, the problem can be solved only by taking action simultaneously at various levels – family, community, national and international levels. It requires a coordinated approach of many disciplines – nutrition, food technology, health administration, health education, marketing, etc. In short, it calls for a comprehensive programme of social development of the entire country.

ACTION AT THE FAMILY LEVEL

The principal target of nutritional improvement in the community is the family, and the instrument for combating malnutrition at the family level is nutrition education. The housewife is the "manager" to the consumption of foods in the family. In some families, the husband determines what foods will reach the table. Both the husband and the wife need to be educated on the selection of right kinds of local foods and in the planning of nutritionally adequate diets within the limits of their purchasing power. Harmful food taboos and dietary prejudices can be identified and corrected. Since food expenditure often amounts to 50–70 per cent of family budgets, nutrition education programmes should be a good investment *(141)*. The promotion of breast-feeding and improvement in infant and child feeding practices are the two areas where nutrition education can have a considerable effect. Action is also needed to counter misleading commercial advertising with regard to baby foods. Attention should also be focused on the nutritional needs of expectant and nursing mothers and children in the family. The shortage of protective foods can be met to some extent by planning a kitchen garden or keeping poultry. Adequate nutrition can be obtained in most countries with a combination of locally available and acceptable foods. Other related activities at the family level are the "package" of mother and child health, family planning and immunization services. The community health workers and the multipurpose workers are the kind of people in key positions to impart nutrition education to the families in their respective areas.

ACTION AT THE COMMUNITY LEVEL

Action at the community level should commence with the analysis of the nutrition problem in terms of (a) the extent, distribution and types of nutritional deficiencies; (b) the population groups at risk, and (c) the dietary and non-dietary factors contributing to malnutrition. To obtain this information, diet and nutrition surveys in carefully chosen representative population samples will have to be carried out using standardized methodologies which will permit comparisons in time and space. Having obtained information about the magnitude of the nutrition problem in the community, the next important step will be to plan realistic and feasible approaches to the control of the problem based on local resources. In many developing countries such as India, it is usual to start with direct intervention measures such as supplementary feeding programmes, midday school meals, vitamin A prophylaxis programme, but these will only provide palliative, partial or temporary solutions. The real permanent solution can only come from fundamental measures that will correct the basic causes of malnutrition. This implies, first of all, increasing the availability of foods both in quantity and quality, but – much more important – making sure that the people suffering or at risk of malnutrition can obtain these foods. The Applied Nutrition Programme is an attempt at production of various types of protective foods by the community for the community. The Integrated Child Development Services (ICDS) Programme makes a concerted and coordinated effort to deliver a basic minimum package consisting of supplementary nutrition, immunization, health check-ups, health and nutrition education for the mothers and non-formal education for the preschool age children. The target groups are children up to six years, pregnant and lactating women, and other women in the age group 15 to 44 years. Significant improvements in the overall living conditions of the people is also called for at the community level. This includes such measures as health

education, improvement of water supply, control of infectious diseases. In brief, a broad socio-economic development of the entire community is called for.

ACTION AT THE NATIONAL LEVEL

The burden of improving the nutritional status of the people, by and large, is the responsibility of the State. The ninth Report of the Joint FAO/WHO Expert Committee on Nutrition (1976) *(140)* suggested several new approaches and strategies for action at the national level. Some of the strategies and approaches undertaken at the national level in India are : (1) *Rural development* : The nutritional uplift of people, especially in a country like India, can come about only as part and parcel of an overall socio-economic development of rural areas where 80 per cent of people live. Even an impressive increase in total food production will not solve the problem of undernutrition if the income levels of vast sections of the people continue to be so low that they cannot afford to buy the foods they need. It is therefore necessary to raise the living standards and purchasing power of the people. This implies a broad–based programme of rural development. (2) *Increasing agricultural production* : The food production potential is still greatly under-utilized. It must keep pace with population growth. This implies application of modern farming practices, the expansion of cultivated areas, the use of fertilisers, better seeds, and so on. Increased food production is meaningless if not accompanied by an effective food distribution system. This implies marketing, land tenure and food price policies. Irrigation projects undertaken to increase food production could be counter-productive if parallel measures aimed at prevention of mosquito–breeding and other vector control measures are not built into the programmes. (3) *Stabilization of population* : The population policy in India is related to food and nutrition policy. The accent now is on birth spacing and a small family norm. (4) *Nutrition intervention programmes* : Several nutritional problems of developing countries today can be mitigated, if not entirely solved by short-term programmes. The prevention and control of endemic goitre through iodized common salt; the control of anaemia through distribution of iron and folic acid tablets to pregnant and nursing mothers, or possibly through fortification of common foods with iron; the control of nutritional blindness through periodic administration of massive oral doses of vitamin A to children at risk; supplementary feeding programmes for preschool children are examples of such measures. These programmes have a direct impact on the health and nutritional status of particular segments of the population. These programmes alleviate the situation as a temporary measure : (5) *Nutrition related health activities* : Several programmes within the field of health, seemingly unrelated to nutrition, may have a profound impact on the nutritional status. The National Malaria Eradication Programme, by opening up vast tracts of land for cultivation, has made an outstanding contribution to health and nutrition. Since malnutrition is closely related to infection, all programmes of immunization and improvement of environmental sanitation will inevitably have a beneficial effect on nutrition. Programmes of family planning could make a major contribution to the improvement of nutritional status of mothers and children. All these programmes may be considered as alternative approaches to improving the nutritional status of the people. The FAO/WHO Expert Committee on Nutrition (1976) stressed that food and nutrition planning must be an integral part of the overall socio-economic development.

ACTION AT THE INTERNATIONAL LEVEL

Food and nutrition are global problems, just as health and sickness; and both are interrelated. There is considerable scope for international cooperation in solving the problems of malnutrition. International cooperation can play an important role in mitigating the effects of acute emergencies caused by floods and droughts. The establishment of the multilateral *World Food Programme* in 1963 to stimulate and promote economic and social development as a means of providing enough safe food to those in need and to come to the aid of victims of emergency is an example of international cooperation. Several international agencies such as the FAO, UNICEF, WHO, World Bank, UNDP, and CARE are working in close collaboration helping the national governments in different parts of the world in their battle against malnutrition.

FOOD SURVEILLANCE

Food surveillance is essential for the protection and maintenance of community health. Broadly it implies the monitoring of food safety/food hygiene. The WHO *(142)* has defined food safety/food hygiene as "all conditions and measures that are necessary during the production, processing, storage, distribution and preparation of food to ensure that it is safe, sound, wholesome and fit for human consumption." The Declaration of Alma-Ata considered food safety as an essential component of primary health care.

The importance of surveillance of foodborne diseases has been underlined in the WHO Sixth General Programme of Work for the period 1978–1983. The most important international programme carrying out activities in the field of food hygiene is the Joint FAO/WHO Food Standard Programme *(143)*.

FOOD HYGIENE

Food is a potential source of infection and is liable to contamination by microorganisms, at any point during its journey from the producer to the consumer. Food hygiene, in its widest sense, implies hygiene in the production, handling, distribution and serving of all types of food *(144)*. The primary aim of food hygiene is to prevent food poisoning and other food-borne illnesses. Food hygiene can be grouped under the following headings.

MILK HYGIENE

Source of Infection

Milk is an efficient vehicle for a great variety of disease agents. The sources of infection or contamination of milk may be (1) the dairy animal (2) human handler or (3) the environment, e.g., contaminated vessels, polluted water, flies, dust, etc. *(145)*.

Milkborne diseases

A Joint FAO/WHO Expert Committee (1970) on Milk Hygiene classified milkborne diseases as under *(146)*.

(1) Infections of animals that can be transmitted to man:

Primary importance :
- Tuberculosis
- Brucellosis
- Streptococcal infections
- Staphylococcal enterotoxin poisoning
- Salmonellosis
- Q fever.

Lesser importance :
- Cow-pox
- Foot and mouth disease
- Anthrax
- Leptospirosis
- Tick-borne encephalitis.

(2) Infections primary to man that can be transmitted through milk :
- Typhoid and paratyphoid fevers
- Shigellosis
- Cholera
- Enteropathogenic Escherichiacoli (EEC)
- Non-diarrhoeal diseases
  - (a) Streptococcal infections
  - (b) Staphylococcal food poisoning
  - (c) Diphtheria
  - (d) Tuberculosis
  - (e) Enteroviruses
  - (f) Viral hepatitis

Clean and safe milk

The safety and keeping quality of milk are related to its microbial content. The first essential in the production of clean and safe milk, therefore, is a healthy and clean animal. Milk from a healthy udder contains only a few organisms, and these are relatively unimportant. Secondly, the premises where the animal is housed and milked should be sanitary. The milk vessels must be sterile and kept covered. The water supply must be bacteriologically safe. Milk handler must be free from communicable diseases, and before milking they must wash their hands and arms. Where possible, milking machines must be used. Milk should be cooled immediately to below 10 deg.C after it is drawn to retard bacterial growth. In the production of good quality milk, cleanliness of all containers and equipment in which milk is handled is very important.

Methylene blue reduction test : It is an indirect method for detection of microorganisms in milk. The test is carried out on the milk accepted for pasteurization. It is based on the observation that bacteriae growing in milk bring about a decrease in the colour imparted to milk. In conducting the test, definite quantities of methylene blue are added to 10 ml of milk and the sample is held at a uniform temperature of 37 deg C until the blue colour has disappeared. The milk which remains blue the longest is considered to be of the best quality and a scale of grading different milk samples, on the basis of the time required to reduce a definite quantity of methylene blue has been worked out. The test thus serves as confirmation of heavy contamination and compared with direct counts of bacteriae, it saves time and money.

Pasteurization of milk

Pasteurization may be defined as the heating of milk to such temperatures and for such periods of time as are required to destroy any pathogens that may be present while causing minimal changes in the composition, flavour and nutritive value (WHO, 1970) *(146)*. There are several methods of pasteurization. Three are widely used : (1) *Holder (Vat) method :* In this process, milk is kept at 63–66 deg C for at least 30 minutes, and then quickly cooled to 5 deg C. Vat method is recommended for small and rural communities. In larger cities, it is going out of use. (2) *HTST method :* Also known as "High Temperature and Short Time Method". Milk is rapidly heated to a temperature of nearly 72 deg C, is held at that temperature for not less than 15 seconds, and is then rapidly cooled to 4 deg C. This is now the most widely used method. Very large quantities of milk per hour can be pasteurized by this method. (3) *UHT Method :* Also known as "ultra-high temperature method." Milk is rapidly heated usually in 2 stages (the second stage usually being under pressure) to 125 deg C for a few seconds only. It is then rapidly cooled and bottled as quickly as possible.

Pasteurization is a preventive measure of public health importance and corresponds in all respects to the modern principles of supplying safe milk. Pasteurization kills nearly 90 per cent of the bacteria in milk including the more heat-resistant tubercle bacillus and the Q fever organisms. But it will not kill thermoduric bacteria nor the bacterial spores. Therefore, despite pasteurization, with subsequent rise in temperature, the bacteria are bound to multiply. In order to check the growth of microorganisms, pasteurized milk is rapidly cooled to 4 deg C. It should be kept cold until it reaches the consumer. Hygienically produced pasteurized milk has a keeping quality of not more than 8 to 12 hours at 18 deg C.

Tests of pasteurized milk

(1) *Phosphatase test :* This test is widely used to check the efficiency of pasteurization. The test is based on the fact that raw milk contains an enzyme called phosphatase which is destroyed on heating at a temperature which corresponds closely with the standard time and temperature required for pasteurization. At 60 deg C for 30 minutes phosphatase is completely destroyed. Consequently, the test is used to detect inadequate pasteurization or the addition of raw milk. (2) *Standard plate count :* The bacteriological quality of pasteurized milk is determined by the standard plate count. Most countries in the West enforce a limit of 30,000 bacterial count per ml of pasteurized milk. (3) *Coliform count :* Coliform organisms are usually completely destroyed by pasteurization, and therefore, their presence in pasteurized milk is an indication either of improper pasteurization or post–pasteurization contamination. The standard in most countries is that coliforms be absent in 1 ml of milk.

MEAT HYGIENE

The term "meat" includes various tissues of animal origin. The diseases which may be transmitted by eating unwholesome meat are: (1) TAPEWORM INFESTATIONS : Taenia solium, T. saginata, *Trichinella spiralis and Fasciola hepatica.* (2) BACTERIAL INFECTIONS : anthrax, actinomycosis, tuberculosis and food poisoning.

Meat inspection

Animals intended for slaughter are subjected to proper ante mortem and post mortem inspection by qualified veterinary staff. The principal causes of antemortem rejection of animals are emaciation, exhaustion, pregnancy, sheep–pox, foot–rot, actinomycosis, brucellosis, febrile conditions, diarrhoea and other diseases of an infectious nature rendering meat unfit for human consumption. The main causes of the post mortem rejection are cysticercus bovis, liver fluke, abscesses, sarcocystis, hydatidosis, septicaemia, parasitic and nodular infections of liver and lungs, tuberculosis, cysticercus cellulosae, etc. *(147)*. The characteristics of good meat are that it should be neither pale pink nor a deep purple tint, firm and elastic to touch, should not be slimy and have an agreeable odour.

Slaughter houses

Slaughter houses are the places where animals, whose flesh is intended for human consumption, are killed. The hygiene of the slaughter house is of paramount importance to prevent the contamination of meat during the process of dressing. The following minimum standards for slaughter houses have been suggested under the Model Public Health Act (1955) in India *(148)*. (1) *Location* : Preferably away from residential areas. (2) *Structure* : Floors and walls upto 3 feet should be impervious and easy to clean. (3) *Disposal of wastes* : Blood, offal, etc. should not be discharged into public sewers but should be collected separately. (4) *Water supply* : should be independent, adequate and continuous. (5) *Examination of animals* : Ante mortem and post mortem examination to be arranged. Animals or meat found unfit for human consumption should be destroyed or denatured. (6) *Storage of meat* : Meat should be stored in fly-proof and rat-proof rooms; for overnight storage, the temperature of the room shall be maintained below 5 deg C. (7) *Transportation of meat* : Meat shall be transported in fly-proof covered vans. (8) *Miscellaneous* : Animals other than those to be slaughtered should not be allowed inside the shed.

FISH

Fish deteriorates or loses its freshness because of autolysis which sets in after death and because of the bacteria with which they become infected. Stale fish should be condemned. The signs of fresh fish are : (1) it is in a state of stiffness or rigor mortis, (2) the gills are bright red, and (3) the eyes are clear and prominent.

Fish is the intermediate host of the tape worm, *Dibothriocephalus latus*. This cestode is communicable to man, but is very rarely encountered. Sewage, bacteria and viruses (e.g., the virus of hepatitis type A) may be concentrated in shellfish such as oysters, and fish may carry *Vibrio parahaemolyticus, Salmonella spp., Clostridium botulinum* type E, and other organisms *(149)*. Consumption of certain fish may sometimes give rise to 'fish poisoning'.

TINNED FISH : When called upon to inspect tinned fish (or meat or any food), the following points should be noted : the tin must be new and clean without leakages or rusting; there should be no evidence of having been tampered with such as sealed openings; on opening the tin, the contents should not be blown out which indicates decomposition.

EGG

Although the majority of freshly laid eggs are sterile inside, the shells become contaminated by faecal matter from the hen. Microorganisms including pathogenic Salmonella can penetrate a cracked shell and enter the egg *(149)*.

FRUITS AND VEGETABLES

Fruits and vegetables constitute another important source for the spread of pathogenic organisms, protozoans and helminths. These infections are a serious menace to public health where sewage is used for growing vegetables. The vegetables which are consumed raw in the form of salads pose a problem in food sanitation. People should be educated to wash the vegetables before eating them raw. Vegetables which are cooked are free from this danger.

Sanitation of eating places

Sanitation of eating establishments is a challenging problem in food sanitation. The following minimum standards have been suggested for Restaurants and Eating Houses in India under the Model Public Health Act (1955) *(148)*. (1) *Location* : Shall not be near any accumulation of filth or open drain, stable, manure pit and other sources of nuisances. (2) *Floors* : To be higher than the adjoining land, made with impervious material and easy to keep clean. (3) *Rooms* : (a) Rooms where meals are served shall not be less than 100 sq. feet and shall provide accommodation for a maximum of 10 persons. (b) Walls up to 3 feet should be smooth, corners to be rounded; should be impervious and easily washable. (c) Lighting and ventilation – ample natural lighting facilities aided by artificial lighting with good circulation of air are necessary. (4) *Kitchen* : (a) Floor space minimum 60 sq. ft. (b) Window opening to be 25 per cent of floor area. (c) Floor to be impervious, smooth, easy to keep clean and non–slippery. (d) Doors and windows to be rat–proof, fly–proof, and of the self–closing type. (e) Ventilators 2 per cent of the floor area in addition to smoke pipes. (5) *Storage of cooked food* : Separate room to be provided. For long storage, control of temperature is necessary. (6) *Storage of uncooked foodstuffs* : Perishable and non-perishable articles to be kept separately, in rat–proof and vermin–proof space; for storage of perishable articles temperature control should be adopted. (7) *Furniture* : Should be reasonably strong and easy to keep clean and dry. (8) *Disposal of refuse* : To be collected in covered, impervious bins and disposed off twice a day. (9) *Water supply* : To be an independent source, adequate, continuous and safe. (10) *Washing facilities* : To be provided. Cleaning of utensils and crockery to be done in hot water and followed by disinfection.

Food handlers

Food sanitation rests directly upon the state of personal hygiene and habits of the personnel working in the food establishments. Proper handling of foods, utensils and dishes together with emphasis upon the necessity for good personal hygiene are of great importance. The infections which are likely to be transmitted by the food handlers are diarrhoeas, dysenteries, typhoid and paratyphoid fevers, enteroviruses, viral hepatitis, protozoal cysts, eggs of helminths, strepto and staphylococcal infections, and salmonellosis.

The first essential is to have complete medical examination carried out of all food handlers at the time of employment. Any person with a history of typhoid fever, diphtheria, chronic dysentery, tuberculosis or any other communicable disease should not be employed. Persons with wounds, otitis media or skin infections should not be permitted to handle food or utensils. The day to day health appraisal of the food handlers is also equally important; those who are ill should be excluded from food handling. It is also important that any illness which occurs in a food handler's family should at once be notified.

Education of food handlers in matters of personal hygiene, food handling, utensils, dish washing, and insect and rodent control is the best means of promoting food hygiene. Many of the food handlers have little educational background. Certain aspects of personal hygiene are therefore required to be continually impressed upon them: (a) *Hands :* The hands should be clean at all times. Hands should be scrubbed and washed with soap immediately after visiting a lavatory and as often as necessary at other times. Finger nails should be kept trimmed and free from dirt. (b) *Hair :* Head coverings should be provided, particularly in the case of females to prevent loose hair entering the food-stuffs. (c) *Overalls :* Clean white overalls should be worn by all food handlers. (d) *Habits :* Coughing and sneezing in the vicinity of food, licking the fingers before picking up an article of food, smoking on food premises are to be avoided.

FOOD-BORNE DISEASES

The term "food-borne disease" is defined as : "A disease, usually either infectious or toxic in nature, caused by agents that enter the body through the ingestion of food." With the increase in urbanization, industrialization, tourism and mass catering systems, food-borne diseases are on the increase throughout the world. Food-borne diseases may be classified as :

A. Food-borne intoxications

1. Due to naturally occurring toxins in some foods *(150)*
   a. Lathyrism (beta oxalyl amino-alanine)
   b. Endemic ascitis (Pyrrolizidine alkaloids).
2. Due to toxins produced by certain bacteria *(130, 151)*
   a. Botulism
   b. Staphyloccus poisons
3. Due to toxins produced by some fungi *(149, 152)*
   a. Aflatoxin
   b. Ergot
   c. Fusarium toxins
4. Food-borne chemical poisoning *(153, 154)*
   a. Heavy metals, e.g., mercury (usually in fish), cadmium (in certain shellfish) and lead (in canned food)
   b. Oils, petroleum derivatives and solvents (e.g., Trycresyn phosphate or TCP)
   c. Migrant chemicals from package materials
   d. Asbestos
   e. Pesticide residues (DDT, BHC)

B. Food-borne infections

Group	Examples of illness in each group
(1) Bacterial diseases	Typhoid fever, Paratyphoid fever, Salmonellosis, Staphylococcal intoxication, *Cl.perfringens* illness, Botulism, B.cereus Food Poisoning, *E.coli* diarrhoea, Non-cholera vibrio illness,V.parahaemolyticus infection, Streptococcal infection, Shigellosis Brucellosis
(2) Viral diseases	Viral hepatitis, Gastroenteritis
(3) Parasites	Taeniasis Hydatidosis, Trichinosis, Ascariasis, Amoebiasis, Oxyuriasis

FOOD TOXICANTS

1. Neurolathyrism

The cause of neurolathyrism is a toxin, Beta oxalyl amino alanine (BOAA) which is found in the seeds of the pulse, *L.sativus* (Khesari dhal). Neurolathyrism is a public health problem in certain parts of the country where this pulse is eaten (see page 644).

2. Aflatoxins *(155, 156)*

Aflatoxins are a group of mycotoxins produced by certain fungi, *Aspergillus flavus* and *A parasiticus*. These fungi infest foodgrains such as groundnut, maize, parboiled rice, sorghum, wheat, rice, cotton seed and tapioca under conditions of improper storage, and produce aflatoxins of which B_1 and G_1 are the most potent hepatotoxins, in addition to being carcinogenic. The most important factors affecting the formation of the toxin are moisture and temperature. Moisture levels above 16 per cent and temperatures ranging from 11 to 37°C favour toxin formation. Aflatoxicosis is quite a public health problem in India. The latest report (1975) of 400 cases of aflatoxin poisoning including 100 deaths from Banswada and Panchmahal districts of Rajasthan and Gujarat respectively highlight the problem in India. Aflatoxin B_1 has also been detected in samples of breast milk and urine collected from children suffering from infantile cirrhosis, Attempts are also being made to relate aflatoxin with human liver cirrhosis.

Control and preventive measures : A crucial factor in the prevention of fungal contamination of foodgrains is to ensure their proper storage after drying, Moisture content should be kept below 10 per cent. If the food is contaminated, it must not be consumed. It is also essential to educate the local population on the health hazards of consuming contaminated foodgrains.

3. Ergot *(157, 158)*

Unlike Aspergillus, ergot is not a storage fungus, but a field fungus. Foodgrains such as bajra, rye, sorghum, and wheat have a tendency to get infested during the flowering stages by the ergot fungus *(Claviceps purpurea)*. Fungus grows as a blackish mass and the seeds become black and irregular and are harvested along with food grains. Consumption of ergot infested grain leads to ergotism. Sporadic outbreaks of ergot poisoning in human population have been reported from time to time in areas where bajra is consumed as a staple. The symptoms are acute but rarely

fatal and include nausea, repeated vomiting, giddiness and drowsiness extending sometimes for periods upto 24 to 48 hours after the ingestion of ergoty grain. In chronic cases, painful cramps in limbs and peripheral gangrene due to vasoconstriction of capillaries have been reported. However, the long-term effects of consuming small amounts of the toxin are not known. A disquieting feature is that the recently introduced high-yielding varieties of bajra are more susceptible to infestation. Ergot-infested grains can be easily removed by floating them in 20 per cent salt water. They can also be removed by hand-picking or air floatation. The upper safe limit for the ergot alkaloids has been estimated to be 0.05 mg per 100 grams of the food material.

4. Epidemic dropsy *(159, 144)*

From time to time, outbreaks of "epidemic dropsy" are reported in India. The cause of epidemic dropsy was not known until 1926, when Sarkar ascribed it to the contamination of mustard oil with argemone oil. Lal and Roy (1937) and Chopra et.al., (1939) gave experimental proof of the cause of epidemic dropsy. Mukherji *et.al.*, (1941) isolated a toxic alkaloid, *sanguinarine* from argemone oil and found out its chemical formula. This toxic substance interferes with the oxidation of pyruvic acid which accumulates in the blood.

The symptoms of epidemic dropsy consist of sudden, non-inflammatory, bilateral swelling of legs, often associated with diarrhoea. Dyspnea, cardiac failure and death may follow. Some patients may develop glaucoma. The disease may occur at all ages except breast-fed infants. The mortality varies from 5–50 per cent.

The contamination of mustard or other oils with argemone oil may be accidental or deliberate. Seeds of *Argemone mexicana* (prickly poppy) closely resemble mustard seeds. The plant grows wild in India. It has prickly leaves and bright yellow flowers. Crops of mustard are gathered during March, and during this period, the seeds of argemone also mature and are likely to be harvested along with mustard seeds. Sometimes unscrupulous dealers mix argemone oil with mustard or other oils.

Argemone oil is orange in colour with an acrid odour. The following tests may be applied for the detection of argemone oil : (1) *Nitric acid test :* A simple test is to add nitric acid to the sample of oil in a test tube. The tube is shaken and the development of a brown to orange–red colour shows the presence of argemone oil. The nitric acid test is positive only when the level of argemone oil is about 0.25 per cent *(160)*. (2) *Paper chromatography test :* This is the most sensitive test yet devised. It can detect argemone oil up to 0.0001 per cent in all edible oils and fats.

The accidental contamination of mustard seeds can be prevented at the source by removing the argemone weeds growing among oil-seed crops. Unscrupulous dealers may be dealt with by the strict enforcement of the Prevention of Food Adulteration Act.

5. Endemic ascites *(161, 162)*

In Kusmi Block of Sarguja district in Madhya Pradesh, during 1973 and again during 1976, an outbreak of rapidly developing ascites and jaundice was reported among the Nagesia tribals. Both the sexes and all the age groups, except infants, were affected. The overall mortality was 40 per cent.

Studies conducted by the National Institute of Nutrition, Hyderabad showed that the local population subsist on the millet *Panicum miliare* (known locally as Gondhli) which gets contaminated with weed seeds of Crotalaria (locally known as *Jhunjhunia*). On chemical analysis. *Jhunjhunia seeds* were found to contain *pyrrolizidine alkaloids* which are *hepatotoxins*.

The preventive measures comprise educating the people in the affected areas about the disease, deweeding of the Jhunjhunia plants which grow along with the staple, and simple sieving of the millet at the household level to remove the seeds of *Jhunjhunia* which are considerably smaller than those of the millet.

6. Fusarium toxins *(163)*

Fusarium species of field fungi are known to contaminate food crops and pose health hazards to livestock and man. The problem of fusarium contamination of sorghum is believed to be on the increase. Rice is also known to be a good substrate for fusarium. Work is now in progress at the National Institute of Nutrition to isolate, and identify the toxic metabolites produced by *fusarium incamatum*.

Food additives

The concept of adding "non-food" substances to food products is not new. Pickling is an ancient culinary practice aimed at preserving food articles such as mango, lime, etc for fairly long periods by the addition of salt and spices. Modern science of food technology has revolutionized food processing with the introduction of chemical additives to increase the shelf-life of food, improve its taste, and to change its texture or colour. Majority of the processed foods such as bread, biscuits, cakes, sweets, confectionary, jams, jellies, soft drinks, ice creams, ketchup and refined oils contain food additives.

Food additives are defined as non–nutritious substances which are added intentionally to food, generally in small quantity, to improve its appearance, flavour, texture or storage properties *(164)*. This definition also includes animal food adjuncts which may result in residues in human food and components of packing materials which may find their way into food *(165)*.

Food additives may be classified into two categories : Additives of the **first category** include colouring agents (e.g., saffron, turmeric), flavouring agents (e.g., vanilla essence), sweeteners (e.g., saccharin), preservatives (e.g., sorbic acid, sodium benzoate), acidity imparting agents (e.g., citric acid, acetic acid), etc *(166)*. These agents are generally considered safe for human consumption. Additives of the **second category** are, strictly speaking, contaminants incidental through packing, processing steps, farming practices (insecticides) or other environmental conditions *(167)*. Uncontrolled or indiscriminate use of food additives may pose health hazards among consumers. For example, certain preservatives such as nitrites and nitrates can lead to the production of toxic substances, e.g., nitrosamines that have been implicated in cancer aetiology.

The use of food additives is subjected to government regulations throughout the world. In India two regulations (viz. the Prevention of Food Adulteration Act and the Fruit Products Order) govern the rules and regulations of food additives *(167)*. Any food that contains food additives that

are not permitted is considered to be adulterated; if the permissible limit exceeds then also the food is considered adulterated. The nature and quantity of the additive shall be clearly printed on the label to be affixed to the container. Whenever, any extraneous colouring matter has been added to any article of food, the words "Artificially Coloured" shall be written on the label. At the international level, in 1963, a joint FAO/WHO programme on food standards was established, with the FAO/WHO Codex Alimentarius Commission as its principal organ. Protection of the health of consumers is the primary aim of the Commission. The ultimate effects of food additives on man is an important problem of public health and is therefore of great concern to the public and the health administrators.

Food fortification

Fortification of food is a public health measure aimed at reinforcing the usual dietary intake of nutrients with additional supplies to prevent/control some nutritional disorders. WHO *(1)* has defined "food fortification" as "the process whereby nutrients are added to foods (in relatively small quantities) to maintain or improve the quality of the diet of a group, a community, or a population."

Programmes of demonstrated effectiveness of fortification of food or water are : fluoridation of water as a preventive of dental caries; iodization of salt for combating the problem of endemic goitre, and food fortification (e.g., vanaspati, milk) with vitamins A and D. Technology has also been developed for the twin fortification of salt with iodine and iron.

In order to qualify as suitable for fortification, the vehicle and the nutrient must fulfil certain criteria *(25)* :

(a) the vehicle fortified must be consumed consistently as part of the regular daily diet by the relevant sections of the population or total population;

(b) the amount of nutrient added must provide an effective supplement for low consumers of the vehicle, without contributing a hazardous excess to high consumers;

(c) the addition of the nutrient should not cause it to undergo any noticeable change in taste, smell, appearance, or consistency; and

(d) the cost of fortification must not raise the price of the food beyond the reach of the population in greatest need.

Finally, an adequate system of surveillance and control is indispensable for the effectiveness of food fortification. Food fortification is a long-term measure for mitigating specific problems of malnutrition in the community.

Adulteration of foods

Adulteration of foods is an age-old problem. It consists of a large number of practices, e.g., mixing, substitution, concealing the quality, putting up decomposed foods for sale, misbranding or giving false labels and addition of toxicants. Adulteration results in two disadvantages for the consumer : first, he is paying more money for a foodstuff of lower quality; secondly, some forms of adulteration are injurious to health, even resulting in death, as for example, adulteration of mustard oil with argemone oil causing epidemic dropsy or adulteration of edible oils with trycresyn phosphate (TCP) resulting in paralysis and death.

Food adulteration practices vary from one part of the country to another, and from time to time. Our knowledge about the current practices of food adulteration is by no means complete. Table 38 shows the types of adulteration seen in India *(168)*.

TABLE 38

Adulteration of foods

Food material	Common adulterants
Cereals such as wheat, rice	Mud, grits, soapstone bits
Dals	Coal-tar dyes, khesari dal
Haldi (Turmeric) powder	Lead chromate powder
Dhania powder	Starch, cow dung or horse dung powder
Black pepper	Dried seeds of papaya
Chilli powder	Saw dust, brick powder
Tea dust/leaves	Blackgram husk, tamarind seeds powder, saw dust, used tea dust
Coffee powder	Date husk, tamarind husk, Chicory,
Asafoetida (Hing)	Sand, grit, resins, gums
Mustard seeds	Seeds of prickly poppy-Argemone
Edible oils	Mineral oils, argemone oil
Butter	Starch, animal fat.
Ice-cream	Cellulose, starch, non-permitted colours
Sweetmeats	Non-permitted colours.
Fresh green peas in packing	Green dye
Milk	Extraction of fat, addition of starch and water
Ghee	Vanaspati

Prevention of Food Adulteration Act, 1954

Enacted by the Indian Parliament in 1954, with the objective of ensuring pure and wholesome food to the consumers and to protect them from fraudulent and deceptive trade practices, the Prevention of Food Adulteration (PFA) Act was amended in 1964, 1976 and lately in 1986 to make the Act more stringent. A minimum imprisonment of 6 months with a minimum fine of Rs.1,000 is envisaged under the Act for cases of proven adulteration, whereas for the cases of adulteration which may render the food injurious to cause death or such harm which may amount to grievous hurt (within the meaning of section 320 of I.P.C.) the punishment may go upto life imprisonment and a fine which shall not be less than Rs.5,000. With the amendment in 1986, the consumer and the voluntary organizations have been empowered under the Act to take samples of food.

Rules are framed which are revised from time to time by an expert body called the "Central Committee for Food standards" which is constituted by the Central Government under the provisions of the Act. Any food that does not conform to the minimum standards is said to be adulterated. Although it is a Central Act, its implementation is largely carried out by the State Governments and local bodies in their respective areas. However, the Centre plays a vital role in proper coordination, monitoring and surveillance of the programme throughout the country. A chain of food laboratories and four regional appellate Central Food Laboratories (Kolkata, Mysore, Ghaziabad and Pune) whose report is considered to be final have been established.

Training being an important component of the programme for prevention of food adulteration, the Directorate General of Health Services organizes in-service training programme for different functionaries responsible for implementation of the PFA Act. Food inspectors, analysts and the senior officers concerned with the implementation of the Act in States are provided training.

Food adulteration is a social evil. The general public, traders, and Food Inspectors are all responsible for perpetuating this evil – the public, because of lack of awareness of the dangers of adulteration and their general disinterest; the traders, for their greed for money, and Food Inspectors who find food adulteration a fertile ground to make easy money. Unless the public rises up against the traders and unscrupulous food inspectors, this evil cannot be curbed. It is here the voluntary agencies and consumer guidance societies can play a vital role.

Food standards

(a) CODEX ALIMENTARIUS : The Codex Alimentarius Commission, which is the principal organ of the joint FAO/WHO Food Standards Programme formulates food standards for international market. The food standards in India are based on the standards of the codex alimentarius. (b) PFA STANDARDS : Under the Prevention of Food Adulteration Act (1954) standards have been established which are revised from time to time by the "Central Committee for Food Standards". The purpose of the PFA standards is to obtain a minimum level of quality of foodstuffs attainable under Indian conditions. (c) THE AGMARK STANDARDS : These standards are set by the Directorate of Marketing and Inspection of the Government of India. The Agmark gives the consumer an assurance of quality in accordance with the standards laid down. (d) BUREAU OF INDIAN STANDARDS : The ISI mark on any article of food is a guarantee of good quality in accordance with the standards prescribed by the Bureau of Indian Standards for that commodity. The Agmark and ISI standards are not mandatory; they are purely voluntary. They express degrees of excellence above PFA standards.

National Nutrition Policy 1993 *(169)*

Inspite of the significant improvement in food production and advancement in science since independence, under–nutrition continues to be a widespread problem in India. In the year 1993, Govt. of India announced National Nutrition Policy 1993. As nutrition is a multi-sectoral issue, it needs to be tackled at various levels through direct nutrition interventions for specifically vulnerable groups as well as through various development policy instruments which will create conditions for improved nutrition. The strategy consists of the following :

A. Direct intervention – Short-term

1. Nutrition interventions for specially vulnerable groups.
   a. Expanding the Safety Net – The universal immunization programme, oral rehydration therapy and the integrated child development services have a considerable impact on child survival and extreme forms of malnutrition.
   b. Improving growth monitoring between age group 0 to 3 years, with closer involvement of the mothers.
   c. Reaching the adolescent girls through ICDS so as to make them ready for safe motherhood.
   d. Ensuring better coverage of expectant women in order to reduce the incidence of low birth weight babies.
2. Fortification of essential foods.
3. Popularization of low cost nutritious food.
4. Control of micro-nutrient deficiencies among vulnerable groups.

B. Indirect Policy Instruments : Long-term institutional and structural changes

1. Food security – In order to ensure aggregate food security, a per capita availability of 215/kg/person/year of food grain needs to be attained.
2. Improvement of dietary pattern through production and demonstration.
3. Improving the purchasing power of the urban and rural poor and improving the public food distribution system.
4. Land reforms.
5. Health and family welfare.
6. Basic health and nutrition knowledge.
7. Prevention of food adulteration.
8. Nutrition surveillance.
9. Monitoring of nutrition programmes.
10. Research into various aspects of nutrition, both on the consumption side and the supply side.
11. Equal remuneration for women.
12. Communication through established media for the implementation of nutrition policy.
13. Minimum wage administration.
14. Community participation.
15. Education and literacy particularly that of women.
16. Improvement of the status of women.

COMMUNITY NUTRITION PROGRAMMES

The Government of India have initiated several large-scale supplementary feeding programmes, and programmes aimed at overcoming specific deficiency diseases through various Ministries to combat malnutrition. They are as shown in Table 39.

TABLE 39

Nutrition programmes in India

Programme	Ministry
1. Vitamin A prophylaxis programme	Ministry of Health and Family Welfare
2. Prophylaxis against nutritional anaemia	Ministry of Health and Family Welfare
3. Iodine deficiency disorders control programme	Ministry of Health and Family Welfare
4. Special nutrition programme	Ministry of Social Welfare
5. Balwadi nutrition programme	Ministry of Social Welfare
6. ICDS programme	Ministry of Social Welfare
7. Mid-day meal programme	Ministry of Education
8. Mid-day meal scheme	Ministry of Human Resources Development

1. Vitamin A prophylaxis programme

One of the components of the National Programme for Control of Blindness is to administer a single massive dose of an oily preparation of vitamin A containing 200,000 IU (110 mg of retinol palmitate) orally to all pre-school children in the community every 6 months through peripheral health workers. This programme was launched by the Ministry of Health and Family Welfare in 1970 on the basis of technology developed at the National Institute of Nutrition at Hyderabad. An evaluation of the programme has revealed a significant reduction in vitamin A deficiency in children (see page 615, 616 for details).

2. Prophylaxis against nutritional anaemia

In view of its public health importance, a national programme for the prevention of nutritional anaemia was launched by the Govt. of India during the fourth Five Year Plan. The programme consists of distribution of iron and folic acid (folifar) tablets to pregnant women and young children (1–12 years). Mother and Child Health (MCH) Centres in urban areas, primary health centres in rural areas and ICDS projects are engaged in the implementation of this programme. The technology for the control of anaemia through iron fortification of common salt has also been developed at the National Institute of Nutrition at Hyderabad (see page 642 for more details).

3. Control of iodine deficiency disorders

The National Goitre Control Programme was launched by the Government of India in 1962 in the conventional goitre belt in the Himalayan region with the objective of identification of the goitre endemic areas to supply iodized salt in place of common salt and to assess the impact of goitre control measures over a period of time.

Surveys, however, indicated that the problem of goitre and iodine deficiency disorders was more widespread than it was thought earlier, with nearly 145 million people estimated to be living in known goitre endemic areas of the country. As a result, a major national programme – the IDD Control Programme – was mounted in 1986 with the objective to replace the entire edible salt by iodide salt, in a phased manner by 1992 (see page 643 for more details).

4. Special nutrition programme

This programme was started in 1970 for the nutritional benefit of children below 6 years of age, pregnant and nursing mothers and is in operation in urban slums, tribal areas and backward rural areas. The supplementary food supplies about 300 kcal and 10–12 grams of protein per child per day. The beneficiary mothers receive daily 500 kcal and 25 grams of protein. This supplement is provided to them for about 300 days in a year. This programme was originally launched as a Central programme and was transferred to the State sector in the fifth Five Year Plan as part of the Minimum Needs Programme *(170)*. The main aim of the Special Nutrition Programme is to improve the nutritional status of the target groups. This programme is gradually being merged into the ICDS programme.

5. Balwadi nutrition programme

This programme was started in 1970 for the benefit of children in the age group 3–6 years in rural areas. It is under the overall charge of the Department of Social Welfare. Four national level organizations including the Indian Council of Child Welfare are given grants to implement the programme. Voluntary organizations which receive the funds are actively involved in the day-to-day management. The programme is implemented through ***Balwadis*** which also provide pre–primary education to these children. The food supplement provides 300 kcal and 10 grams of protein per child per day. Balwadis are being phased out because of universalization of ICDS.

6. ICDS programme

Integrated Child Development Services (ICDS) programme was started in 1975 in pursuance of the National Policy for Children. There is a strong nutrition component in this programme in the form of supplementary nutrition, vitamin A prophylaxis and iron and folic acid distribution. The beneficiaries are preschool children below 6 years, and adolescent girls 11 to 18 years, pregnant and lactating mothers. The States and Union Territories are encouraged to undertake additional ICDS projects on the Central pattern to cover more beneficiaries *(170)*.

The workers at the village level who deliver the services are called ***Anganwadi workers.*** Each Anganwadi unit covers a population of about 1000. A network of Mahila Mandals has been built up in ICDS Project areas to help Anganwadi workers in providing health and nutrition services. The work of Anganwadis is supervised by *Mukhyasevikas.* Field supervision is done by the Child Development Project Officer (CDPO).

7. Mid-day meal programme

The mid-day meal programme (MDMP) is also known as School Lunch Programme. This programme has been in operation since 1961 throughout the country. The major objective of the programme is to attract more children for admission to schools and retain them so that literacy improvement of children could be brought about *(169)*.

In formulating mid-day meals for school children, the following broad principles should be kept in mind *(171)*.

(a) the meal should be a *supplement* and not a substitute to the home diet

(b) the meal should supply at least one-third of the total energy requirement, and half of the protein need

(c) the cost of the meal should be reasonably low

(d) the meal should be such that it can be prepared easily in schools; no complicated cooking process should be involved

(e) as far as possible, locally available foods should be used; this will reduce the cost of the meal, and

(f) the menu should be frequently changed to avoid monotony.

MODEL MENU

A model menu for a mid-day school meal is given in Table 40.

TABLE 40

A mid-day school meal

Foodstuffs	g/day/child
Cereals and millets	75
Pulses	30
Oils and fats	8
Leafy vegetables	30
Non-leafy vegetables	30

The National Institute of Nutrition, Hyderabad has prepared model recipes for the preparation of school meals suitable for North and South Indians. Copies of these publications can be had gratis on request. The National Institute of Nutrition is of the view that the minimum number of feeding days in a year should be 250 to have the desired impact on the children *(172)*.

School feeding should not be considered as an end in itself. The important goals to be accomplished are : reorientation of eating habits; incorporating nutrition education into the curriculum; encouraging the use of local commodities; improving school attendance as well as educational performance of the pupils. Since the number to be fed are in millions, the problem is one of balance between the resources and the number to be fed.

The mid-day meal programme became part of the Minimum Needs Programme in the Fifth Five Year Plan *(170)*.

8. Mid-day meal scheme *(173)*

Mid-day meal scheme is also known as National Programme of Nutritional Support to Primary Education. It was launched as a centrally sponsored scheme on 15th August 1995 and revised in 2004. Its objective being universalization of primary education by increasing enrolment, retention and attendance and simultaneously impacting on nutrition of students in primary classes. It was implemented in 2,408 blocks in the first year and covered the whole country in a phased manner by 1997–98. The programme originally covered children of primary stage (classes I to V) in government, local body and government aided schools and was extended in Oct. 2002, to cover children studying in Education Guarantee Scheme and Alternative and Innovative Education Centres also.

The central assistance provided to states under the programme is by way of free supply of food grain from nearest Food Corporation of India godown at the rate of 100 g. per student per day and subsidy for transport of food grain. To achieve the objective, a cooked mid-day meal with minimum 300 Calories and 8 to 12 grammes of protein content will be provided to all the children in class I to V.

Some suggesstions for preparation of nutritious and economical mid-day meals are as under :

- Foodgrains must be stored in a place away from moisture, in air tight containers/bins to avoid infestation.
- Use whole wheat or broken wheat (dalia) for preparing mid-day meals.
- Rice should preferably be parboiled or unpolished.
- 'Single Dish Meals' using broken wheat or rice and incorporating some amount of a pulse or soyabeans, a seasonal vegetable/green leafy vegetable, and some amount of edible oil will save both time and fuel besides being nutritious. Broken wheat pulao, leafy khicheri, upma, dal-vegetable bhaat are some examples of single dish meals.
- Cereal pulse combination is necessary to have good quality protein. The cereal pulse ratio could range from 3:1 to 5:1.
- Sprouted pulses have more nutrients and should be incorporated in single dish meals.
- Leafy vegetables when added to any preparation should be thoroughly washed before cutting and should not be subjected to washing after cutting.
- Soaking of rice, dal, bengal gram etc. reduces cooking time. Wash the grains thoroughly and soak in just sufficient amount of water required for cooking.
- Rice water if left after cooking should be mixed with dal if these are cooked separately and should never be thrown away.
- Fermentation improves nutritive value. Preparation of idli, dosa, dhokla etc. may be encouraged.
- Cooking must be done with the lid on to avoid loss of nutrients.
- Over cooking should be avoided.
- Reheating of oil used for frying is harmful and should be avoided.
- Leafy tops of carrots, radish, turnips etc. should not be thrown but utilized in preparing mid-day meals.
- Only 'iodized salt" should be used for cooking mid-day meals.

Monitoring and evaluation of nutrition programmes

Good preventive medicine demands effective planning, monitoring and evaluation of health programmes. An important advance in this field is the development of the **randomized controlled trial** for the evaluation of the effectiveness and efficiency of health care programmes.

Criticism is often voiced that nutrition programmes are not based on good intentions. It is considered unethical to launch a major nutritional programme (or for that matter any other health programme) without a built-in-provision for monitoring, evaluation and feed-back.

Since health and nutrition of the young child is indivisible from the health and nutrition of the family as a whole, there is now increasing recognition that it is only through an improvement of the family diet as a whole, that the diet of the young child in the poor family can be improved *(174)*. Secondly, a question is raised : How long will a country be able to feed its children who may number 100 million or more without any socio-economic improvements? An eminent nutrition scientist in India has said : "In the long run, we can hope to improve the nutritional status of our children only through improvement in the economic conditions of the community to a level at which families can afford balanced diets. Organized State-sponsored feeding programmes cannot be the permanent answer to the problem" *(85)*.

ANNEXURE–1

Nutrition Assessment Schedule

Serial No. Date :

Name : Age :

Address : Sex :

District : Village :

CLINICAL :

(1) *General appearance* : Normal built/Thin built/Sickly

(2) *Hair* : Normal/lack of lustre/dyspigmented/thin and sparse/easily pluckable/flag sign

(3) *Face* : Diffuse depigmentation/naso-labial dyssebacea/moon face

(4) *Eyes* : Conjunctiva - normal/dry on exposure for 1/2 min/dry and wrinkled/bitot's spots/ brown pigmentation/angular conjunctivitis/pale conjunctiva
Cornea - normal/dryness/hazy or opaque

(5) *Lips* : Normal/angular stomatitis/cheilosis

(6) *Tongue* : Normal/pale and flabby/red and raw/fissured/geographic

(7) *Teeth* : Mottled enamel/caries/attrition

(8) *Gums* : Normal/spongy/ bleeding

(9) *Glands* : Thyroid enlargement/parotid enlargement

(10) *Skin* : Normal/dry and scaly/follicular hyperkeratosis/petechiae/peliagrous dermatosis/flanky paint dermatosis/scrotal and vulval dermatosis

(11) *Nails* : Koilonychia

(12) *Oedema* : Independent parts

(13) *Rachitic changes* : Knock-knees or bow legs/epiphyseal enlargement/beading of the ribs/pigeon chest

(14) *Internal systems* : Hepatomegaly/psychomotor change/mental confusion/sensory loss/muscle wasting/ motor weakness/loss of position sense/loss of vibration sense/loss of ankle and knee jerks/calf tenderness/cardiac enlargement/tachycardia.

ANTHROPOMETRIC :

Weight (kg) : Head circumference (cm) :

Height (cm) : Chest circumference (cm) :

Mid-upper-arm circumference (cm) : Skinfold :

LABORATORY

ANNEXURE–3

Suggested substitution for non-vegetarians

Food item which can be deleted from non-vegetarian diets	Substitution that can be suggested for deleted item or items
50% of pulses (20-30 g)	1. One egg or 30 g of meat or fish 2. Additional 5 g of fat or oil
100% of pulses (40-60 g)	1. Two eggs or 50 g of meat or fish 2. One egg plus 30 g meat 10 g of fat or oil

Source : *(140)*

ANNEXURE–4

Additional allowances during pregnancy and lactation

Food items	During pregnancy	Calories (kcal)	During lactation	Calories (kcal)
Cereals	35 g.	118	60 g.	203
Pulses	15 g.	52	30 g.	105
Milk	100 g.	83	100 g.	83
Fat	-	-	10 g.	90
Sugar	10 g.	40	10 g.	40
Total		293		521

Source : *(140)*

ANNEXURE–5

Exercise and physical activity

Individuals over the age of 20 years should undertake a minimum of 30 minutes of physical activity of moderate intensity (such as walking 5–6 km/hr) on most, if not all days of the week. Greater health benefits can be obtained by engaging in physical activity of longer duration or more vigorous intensity (such as jogging, running, cycling and swimming).

Sedentary people embarking on a physical activity programme should undertake a moderate intensity activity of short duration to start with and gradually increase the duration or intensity. Other day-to-day activities like walking, housework, gardening, will be beneficial not only in weight reduction but also for lowering of blood pressure and serum triglycerides. This also elevates HDL (good) cholesterol in blood. Simple modification in lifestyle like deliberately climbing up the stairs instead of using the lift and walking for short distance instead of using a vehicle could also immensely help in increasing our physical activity.

Exercise programme should include 'warm up' and 'cool down' periods each lasting for 5 minutes. During exercise, the intensity of exercise should ensure 60–70% increase in heart rate.

Previously inactive men over the age of 40 years, women over the age of 50 years and people at high risk for chronic diseases like heart disease and diabetes should first consult a physician before engaging in a programme of vigorous physical activity such as running and swimming.

*Energy expenditure on various physical activities (kcal/hr)

Activity			kcal/hr	Activity		kcal/hr
Cleaning/Mopping		....	210	Shuttle	....	348
Gardening		....	300	Table Tennis	....	245
Watching TV		....	86	Tennis	....	392
Cycling				Volley Ball	....	180
	15 (Km/hr)	....	360	Dancing	....	372
Running				Fishing	....	222
	12 (Km/hr)	....	750	Shopping	....	204
	10 (Km/hr)	....	655	Typing	....	108
	8 (Km/hr)	....	522	Sleeping	....	57
	6 (Km/hr)	....	353	Standing	....	132
Walking	4 (Km/hr)	....	160	Sitting	....	86

* Approx. energy expenditure for 60 Kg reference man. Individuals with higher body weight will be spending more calories than those with lower body weight. Reference woman (50 kg) will be spending 5% less calories.

ANNEXURE–6

Approximate calorific value of some cooked preparations

Preparation	Quantity for one serving	Calories (kcal)
1. Cereal		
Rice	1 cup	170
Phulka	1 No.	80
Paratha	1 No.	150
Puri	1 No.	100
Bread	2 slices	170
Poha	1 cup	270
Upma	1 cup	270
Idli	2 Nos.	150
Dosa	1 No.	125
Khichidi	1 cup	200
Wheat porridge	1 cup	220
Semolina porridge	1 cup	220
Cereal flakes with milk (corn/wheat/rice)	1 cup	220
2. Pulse		
Plain dhal	1/2 cup	100
Sambar	1 cup	110
3. Vegetable		
With gravy	1 cup	170
Dry	1 cup	150
4. Non-Vegetarian		
Boiled egg	1 No.	90
Omelette	1 No.	160
Fried egg	1 No.	160
Mutton curry	3/4 cup	260
Chicken curry	3/4 cup	240
Fish fried	2 big pieces	220
Fish cutlet	2 Nos.	190
Prawn curry	3/4 cup	220
Keema kofta curry	3/4 cup (6 small koftas)	240
5. Savoury snacks		
Bajji or pakora	8 Nos.	280
Besan ka pura	1 No.	220
Chat (Dahi-pakori)	5 pieces	220
Cheese balls	2 Nos.	250
Dahi vada	2 Nos.	180
Vada	2 Nos.	140
Masala vada	2 Nos.	150
Masala dosa	1 No.	200
Pea-kachori	2 Nos.	380
Potato bonda	2 Nos.	200
Sago vada	2 Nos.	210
Samosa	1 No.	200
Sandwich (butter - 2 tsp)	2 Nos.	200
Vegetable puff	1 No.	170
Pizza (Cheese and tomato)	1 slice	200
6. Chutneys		
Coconut/ground/til	2 tbsp	120
Tomato	1 tbsp	10
Tamarind (with jaggery)	1 tbsp	60
7. Sweets and desserts		
Besan barfi	2 pieces	400
Chikki	2 pieces	290
Fruit cake	1 piece	270
Rice puttu	1/2 cup	280
Sandesh	2 Nos.	140
Double ka meetha	1/2 cup	280
Halwa (kesari)	1/2 cup	320
Jelly/Jam	1 tsp	20
Custard (caramel)	1/2 cup	160
Srikhand	1/2 cup	380
Milk chocolate	25 g	140
Ice-cream	1/2 cup	200
8. Beverages		
Tea	(2 tsp sugar+ 50 ml. toned milk)	1 cup	75
Coffee	(2 tsp sugar+ 10 ml toned milk)	1 cup	110
Cow's milk	(2 tsp sugar)	1 cup	180
Buffalo's milk	(2 tsp sugar)	1 cup	320
Lassi	(2 tsp sugar)	1 glass (200 ml)	110
Squash		1 glass (200 ml)	75
Syrups (Sherbat)		1 glass (200 ml)	200
Cold drinks		1 bottle (200 ml)	150
Fresh lime juice		1 glass (200 ml)	60

	Serving	Calories
Nuts		
Almonds	10 Nos.	85
Cashewnuts	10 Nos.	95
Coconut (fresh)	1/4	130
Coconut (dry)	1/4	140
Peanuts	50 Nos.	90
Fresh fruits		
Apple	1 medium	65
Banana	1 medium	90
Grapes	30 Nos.	70
Guava	1 medium	50
Jackfruit	4 pieces	90
Mango	1 medium	180
Mosambi/orange	1 medium	40
Papaya	1 piece	80
Pineapple	1 piece	50
Sapota	1 medium	80
Custard apple	1 medium	130
Watermelon/muskmelon	1 slice	15
Salads		
Beetroot	1 medium	30
Carrot	1 medium	20
Cucumber	1 medium	15
Onion	1 medium	25
Radish	1 medium	10
Tomato	1 medium	10

ANNEXURE–7

Ranges of population nutrient intake goals

Dietary factor	Goal (% of total energy, unless otherwise stated)
Total fat	15-30%
Saturated fatty acids	<10%
Polyunsaturated fatty acids (PUFAs)	6-10%
n-6 Polyunsaturated fatty acids (PUFAs)	5-8%
n-3 Polyunsaturated fatty acids (PUFAs)	1-2%
Trans fatty acids	<1%
Monounsaturated fatty acids (MUFAs)	By difference[a]
Total carbohydrate	55-75%[b]
Free sugars[c]	<10%
Protein	10-15%[d]
Cholesterol	<300 mg per day
Sodium chloride (sodium)[e]	<5 g per day (<2 g per day)
Fruits and vegetables	≥ 400 g per day
Total dietary fibre	From foods
Non-starch polysaccharides (NSP)	From foods

a This is calculated as : total fat – (saturated fatty acids + polyunsaturated fatty acids + trans-fatty acids).

b The percentage of total energy available after taking into account that counsumed as protein and fat, hence the wide range.

c The term "free sugars" refers to all monosaccharides and disaccharides added to foods by the manufacturer, cook or consumer, plus sugars naturally present in honey, syrups and fruit juices.

d The suggested range should be seen in the light of the Joint WHO/FAO/UNU Expert Consultation on Protein and Amino Acid Requirements in Human Nutrition, held in Geneva from 9 to 16 April 2002.

e Salt should be iodized appropriately. The need to adjust salt iodization, depending on observed sodium intake and surveillance of iodine status of the population, should be recognized.

Medicine and Social Sciences

"The secret of national health lies in the homes of the people"

The term "social sciences" refers to a composite of several disciplines. These disciplines are anthropology, economics, political science, psychology, sociology etc. In general, these disciplines contribute to our understanding of society and human behaviour. The social sciences relevant to medicine are psychology and sociology. They should be considered like anatomy and physiology, the basic sciences of medicine.

Social context of medicine

Health cannot be isolated from its social context. The last few decades have shown that social and economic factors have as much influence on health as medical interventions. All these factors have a direct bearing on the incidence, course and outcome of a wide variety of communicable and non-communicable diseases as well as on many other health problems besetting the world today. They also have an important effect on the provision of health care to all strata of society *(1)*. Poverty, malnutrition, poor sanitation, lack of education, inadequate housing, unemployment, poor working conditions, cultural and behavioural factors all predispose to ill-health. Today more than ever before, there has been an increasing recognition that successful application of medicine to individuals and groups involves more than mere scientific or biological knowledge; it involves an understanding of the behaviour of individuals and groups who live together and also share certain values of life. Man is a social animal. The patient is no longer considered as one who is under strict laboratory control, but an individual with personal idiosyncrasies, erratic habits, customs and beliefs reacting on his body and mind. It has been aptly said that even a person with a broken leg may present complex social and personal factors which may influence his recovery. Thus there has been a shift from the earlier concept of visualizing disease in terms of a specific germ to the involvement of "multiple factors" in the causation of disease. Good doctors are being identified as those who treat people, and bad ones as those who treat cases. As a result of this new outlook, concepts of sociology are increasingly being used in the study of disease in human societies.

How much effect social changes might have on health of the people is shown in Fig. 1.

It suggests that health is influenced by four sets of variables– individual predispositions, ecological predispositions, current circumstances, and opportunities. These variables are in turn influenced by the major sources of social changes : economic, political, educational and other systems. The health status of the people can feed back into and influence factors relating to social structure which may in turn influence the predisposing variables, and therefore health *(2)*.

Medicine and the social sciences are concerned, in their own special way, with human behaviour. Specialists in community health, clinical medicine, epidemiology are all seeking the cooperation and help of social scientists in understanding problems such as the social component of health and disease, "illness behaviour" of people, efficient use of medical care and the study of medical institutions. A brief sketch of the current interest of these disciplines in social science is given below :

1. COMMUNITY HEALTH

Community health workers are often faced with the problem of why people who need a particular service are least likely to use it or fail to secure the total benefit which is expected. A case in point is immunization against communicable diseases. Although, there is a wide range of prophylactic vaccines, immunization has not gained universal acceptance. The family planning programme in India is a recent example of a health service of which people are not making use to the extent desired. Similarly, health programmes relating to mother and child health care services, improvement of water supplies, installation of sanitary latrines, improvement of dietary patterns and infant rearing practices have all proved abortive or only partially successful. The resistance of the people is felt not only in the field of community health, but in fact even in fields designed to improve their general standard of living. The central question in community health is : Why do people behave as they do ? This is the basic problem which the social scientists are studying in India, and are often asked to explain this failure of health measures. In the western countries, social scientists are working on problems of mental health, hospital organization, social class difference in disease, rehabilitation, and professional roles and relationships. In industries, the social scientists are invited to look into the relationships between members of a team who are concerned with doing a job in order to improve the overall performance of the work team. In short, the social scientists are stepping in increasing numbers into the field of community health. The theme common to community health and social sciences is human behaviour. Many community health problems in essence are social problems, and vice versa.

2. CLINICAL MEDICINE

During the past half century, the scientific content of medicine has increased enormously. The acute

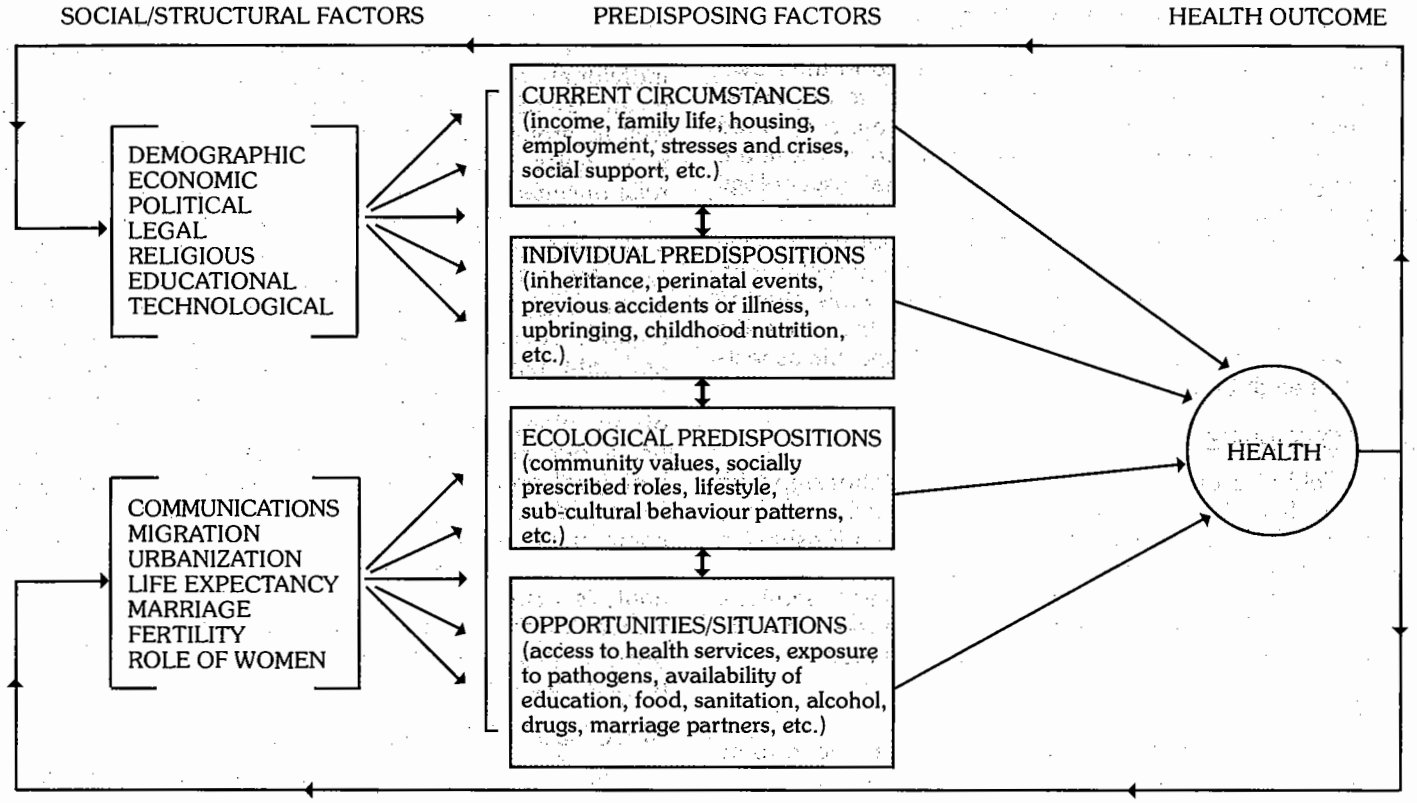

FIG. 1
Social factors influencing the health of people

Source : *(2)*

communicable diseases have been brought under control, and good medical care is available to more people than ever before. This has brought to a sharp focus, the so-called "modern diseases" such as cardiovascular disease, cancer, diabetes and mental illness. These diseases have defied "cure" and prevention, and are currently the major causes of morbidity and mortality in developed societies. The clinicians also tend to believe that "psychophysiological stress reactions" are involved in cases of rheumatoid arthritis, obesity, ulceration of intestine, skin diseases, constipation, diarrhoea and epilepsy. It has become apparent that control of these diseases involves not merely medical care but basic changes in the behaviour and habits of the patients, which is a field of specialization of social scientists. The social scientists are asked to investigate the life situations of the patients with a view to discover linkages between specific life situations and specific types and cases of illness.

The clinicians have also shown interest in what is known as "illness behaviour" of patients, i.e., why different people react in different ways to the same disease process or regimen of treatment. It is not known why some people (whether by reason of education, religion, social class difference or occupational status) make light of symptoms and some respond in an exaggerated manner, to the slightest pain or discomfort. This is an important area of medical sociology. The doctor-patient relationship, patient care management, hospital organization, collusion of medical treatment and cultural practices are all current interests of medical sociology.

Criticism is often voiced that the present medical sciences (e.g., anatomy, physiology, microbiology, pathology) are insufficient to train the physician to cope with the sociocultural aspects of medicine. It is recognized that the physician needs two kinds of knowledge – medical knowledge and social knowledge, so that he could more effectively serve the patient and the community. Hence is the current interest of medical men in social sciences.

3. EPIDEMIOLOGY

Epidemiologists have also forged a close alliance with social scientists in studying the distribution of health and disease in human population, and of factors that cause the distribution. Disease is studied in relationship to factors such as social status, income, occupation, housing, overcrowding, social customs, habits and behaviour. Examples can be found in researches into the ecology of coronary heart disease, duodenal ulcer, schizophrenia, mental subnormality, suicide, accidents, and several other conditions.

To sum up, social scientists are studying a great many things of considerable interest to medicine and public health. They have "given fruitful attention to the growing place of medicine and medical practice in the social system, and to different attitudes and values which various segments of the population have towards health, illness and medical care. They have made noteworthy advances in mapping out the social organization of health personnel; the social structure and functioning of hospitals have been studied to advantage, as have the social roles played by patients and health personnel as they interact in different settings. They have paid particular attention to the situation of health personnel who are professionals, and to the social processes through which these persons acquire the outlook, standards and competence considered necessary for providing satisfactory professional services. They have also undertaken investigations which relate various social and psychological factors to different kinds of diseases in patients as well as to the course of certain diseases" *(3)*.

SOCIAL AND BEHAVIOURAL SCIENCES

Medicine and social sciences are concerned in their own special way with human behaviour. The term 'social sciences' is applied to those disciplines which are committed to the scientific examination of human behaviour. These are economics, political science, sociology, social psychology and social anthropology. The term 'behavioural sciences' is applied to the last three, i.e., sociology, social psychology and social anthropology, because they deal directly with human behaviour. Each of these disciplines, while sharing the major goals of social sciences, i.e., the scientific examination of human behaviour deals with specific aspects of public health in the study of man.

(a) ECONOMICS

The field of economics has a very close relationship with sociology. It is the parent discipline from which sociology has emerged. Economics deals with human relationships in the specific context of production, distribution, consumption and ownership of scarce resources, goods and services. Sociology and economics overlap in many senses; both are concerned with interdependence in human relations.

(b) POLITICAL SCIENCE

Historically economics and political science tended to be a single discipline. As a separate discipline, political science is concerned with the study of the system of laws and institutions which constitute government of whole societies.

(c) SOCIOLOGY

Sociology deals with the study of human relationships and of human behaviour for a better understanding of the pattern of human life. It is also concerned with the effects on the individual of the ways in which other individuals think and act.

(d) SOCIAL PSYCHOLOGY

This discipline sprang from psychology. It is concerned with the psychology of individuals living in human society or groups. The emphasis is on understanding the basis of perception, thought, opinion, attitudes, general motivation and learning in individuals and how these vary in human societies and groups. In other words, it deals with the effect of social environment on persons, their attitudes and motivations.

(e) ANTHROPOLOGY

The word anthropology is derived from the root words, anthropos meaning man and *logos* meaning science. It is the study of the physical, social and cultural history of man. The study of human evolution, racial differences, inheritance of bodily traits, growth and decay of the human organism is called *physical anthropology*. The study of the development and various types of social life is called *social anthropology*. The study of the total way of life of contemporary primitive man, his ways of thinking, feeling and action is called *cultural anthropology (4)*. Of all the sciences, which study various aspects of man, anthropology is one which comes nearest to being a total study of man. *Medical anthropology*, deals with the cultural component in the ecology of health and disease.

SOCIOLOGY

Sociology is derived from the Latin socio, meaning society and the Greek *logos*, meaning science. The word *society* is derived from the root words *socius*, meaning individual and *societa*, meaning group. Society is a group of individuals who have organized themselves and follow a given way of life, and sociology is the study of individuals as well as groups in a society. Sociology can be viewed from two angles : (a) First, it can be seen as the *study of relationships between human beings*, and how these relationships change or vary in different parts of the world and at different times. The unit of study can be a small group (e.g., family) consisting of parents and children, or the study can extend beyond the family or small groups into the complex society where a greater number of people interact and interdepend in terms of economics, political power, general organization and ways of living. (b) The other part of sociology is concerned with the *study of human behaviour*. Human behaviour is determined not merely by biological and physical environmental factors but also by social factors. Every form of human behaviour has a social component. Sociologists are interested in the study of the social determinants of human behaviour. In the final analysis it may be stated that the aim of sociology is to search for the pattern of relationships between people in order to pave the way for the betterment of individuals in relation to society *(5)*.

SPECIALIZATION WITHIN SOCIOLOGY

Sociology has grown rapidly since World War II resulting in an increase in specialization within the general field of sociology. Some of the major fields of specialization are : medical sociology, urban sociology, rural sociology, industrial sociology, sociology of religion, sociology of education, criminology, hospital sociology, and demography.

MEDICAL SOCIOLOGY

Medical sociology is a specialization within the field of sociology. Its main interest is in the study of health, health behaviour and medical institutions. As a specialized field, it was first proposed by Charles McIntire in 1894 *(6)*. It is defined as "professional endeavour devoted to social epidemiology, the study of cultural factors and social relations in connection with illness, and the social principles in medical organization and treatment" *(6)*.

Broadly speaking medical sociology includes studies of the medical profession, of the relationship of medicine to public, and of the social factors in the aetiology, prevalence, incidence and interpretation of disease.

CONCEPTS IN SOCIOLOGY

Such terms as society, social structure, social institutions, role, socialization, social control mechanisms, customs, culture, acculturation, social problems, social pathology and social survey are frequently used by all sociologists and form part of the necessary equipment by means of which they organize their thinking, do research and communicate the results of research *(7)*. Some of these concepts have also crept into medical terminology and are being increasingly used in epidemiological studies. A brief account of these concepts is given below.

SOCIETY

Human beings everywhere are members of a group or groups. A man who can live without society, said Aristotle, is either a beast or God. A group of people may or may not form a society. For example, a group of people coming together

temporarily for a while to witness a hockey match do not constitute society; they are merely a crowd. But if the same group of people settle down and organize themselves, then they form a society. Thus, society may be defined in simple terms as an organization of member agents. The outstanding feature of society is a *system* – a system of social relationships between individuals. The importance of society lies in the fact that it controls and regulates the behaviour of the individual both by law and customs. It can exert pressure on the individual to conform to its norms. In short, society is a vast network of relationships and compulsions that propel, direct and constrain man's individual efforts. The character of society is dynamic; it changes over time and place. Public health is an integral part of the social system. It is influenced by society, and society by public health. In many places it is the social organization that has made it possible to translate into practice the scientific concepts and achievements. As a result, the mortality rates have been brought to low levels and the life expectancy at birth has soared to very high levels.

COMMUNITY

Various definitions of community are given in dictionaries and other publications. Some imply homogenity, e.g., "The people living in a particular place or region and usually linked by common interests" *(8)*; or "A group of individuals and families living together in a defined geographic area, usually comprising a village, town or city" *(8)*.

The definition accepted by WHO Expert Committee is "A community is a social group determined by geographical boundaries and/or common values and interests. Its members know and interact with each other. It functions within a particular social structure and exhibits and creates certain norms, values, and social institutions. The individual belongs to the broader society through his family and community *(8)*.

SOCIAL STRUCTURE

Social structure refers to the pattern of inter-relations between persons. Every society has a social structure – a complex of major institutions, groups, power structure and status hierarchy. The study of social structure is comparable to the study of anatomy and that of social organization to that of physiology.

SOCIAL INSTITUTIONS

A social institution is an organized complex pattern of behaviour in which a number of persons participate in order to further group interest. The family, the school, the church, the club, the hospital, political parties, professional associations and the panchayats are all social institutions. Within each institution, the rights and duties of the members are defined.

ROLE

In a society, individuals are allocated roles as people in a drama. Sociologists have classified roles into ascribed and achieved, according to whether a particular role is "given" by virtue of sex, age, and birth status or "acquired" by virtue of education or otherwise. In a single day, a man may play a role of husband, father, employee, friend, son, brother, committee chairman, guest, neighbour. The playing of these roles enables him to cooperate with others in many situations according to well-defined roles *(9)*. When a person falls ill, he assumes what is known as a "Sick role". In this role he is expected to decrease or relinquish his normal duties, seek medical aid, and carry out the orders given by the physician.

SOCIALISM

Socialism, to put it briefly, is the general term for any economic doctrine that favours the use of property and resources of the country for the public welfare. It is a system of production and distribution based on *social ownership* for raising the living standard of the working class, as opposed to capitalism which is based on *private ownership* of the means of production and aims at maximum private profit at the expense of the working masses. While the motto of capitalism is 'all for each' and 'each for each', that of socialism is 'all for all' and 'each for all'. These are two extremes. Ever since Louis Blanc set forth the socialist principle "from each according to his abilities, to each according to his needs", socialism has undergone many changes and taken varied shades.

SOCIALIZATION

Every society has its beliefs, customs, traditions and prejudices. A man acquires these in his everyday social interaction with the people of the society. This is called "socialization" or the process by which an individual gradually acquires culture and becomes a member of a social group. Children going to school is an instance of socialization. The internship training programme of doctors is another instance; it gives them an opportunity to learn how to become acceptable to the public at large as doctors.

SOCIAL CONTROL MECHANISMS

In every society there are rules, formal and informal, for the maintenance of relationships of authority and subordination. The laws and enactments of Parliament are social control mechanisms. In the field of health, there are various Acts, some central and others state or local which help to maintain the standards of health. Even in small organizations, there are sets of formal rules and regulations which control the behaviour of individuals to perform different roles. Besides formal rules, sometimes, informal social pressures are brought to bear upon individuals to help construct "norms" of behaviour. The informal social pressure may be exerted by powerful groups, individuals or friends. These mechanisms work largely through reward and punishment. For example, in India, the government is offering a small financial reward to those who undergo sterilization operation. It is a sort of informal social pressure to further the programme of family planning in India. The social control mechanisms vary from group to group. A study of these mechanisms may be helpful to the community health worker in carrying out the health programmes.

CUSTOMS

The mere existence of a society, the mere plurality of individuals gives rise to customs from which no single member of the community can escape. The 'highly developed' societies of the modern world are just as replete with social customs as the 'primitive societies' of the past. These customs are quite numerous and quite as powerful. Customs are technically divided into "folkways" and 'mores'. The folkways are the right ways of doing things in what is regarded as the less vital areas of human conduct. The more stringent customs are called "mores". The public takes an active part in their enforcement. Laws are generally customs-inspired. The starting point of all customs is

convention. Convention is the practice promoted by convenience of the society or the individual.

CULTURE

The word "culture" is widely used in sociology. It is the central concept around which cultural anthropology has grown. Culture is defined as "learned behaviour which has been socially acquired". Culture is the product of human societies, and man is largely a product of his cultural environment. Culture is transmitted from one generation to another through learning processes, formal and informal. Culture plays an important part in human societies. It lays down norms of behaviour and provides mechanisms which secure for an individual his personal and social survival *(4)*. In general, it is widely held, that culture stands for the customs, beliefs, laws, religion and moral precepts, arts and other capabilities and skills acquired by man as a member of the society.

Cultural factors in health and disease have engaged the attention of medical scientists and sociologists. Every culture has its own customs, some of which have a profound influence on the incidence of disease. In developed countries, for example, cancer of the lung from smoking and cirrhosis of liver from drinking are the result of the abuse of widely proclaimed social habits. In India, chewing pan is associated with oral cancer. It is now fairly established that cultural factors are deeply involved in matters of personal hygiene, nutrition, immunization, seeking early medical care, family planning, child rearing, disposal of refuse and excreta, outlook on health and disease – in short, the whole way of life.

ACCULTURATION

Acculturation means "culture contact." When there is contact between two people with different types of culture, there is diffusion of culture both ways. There are various ways by which culture contact takes place *(10)*. (1) trade and commerce, (2) industrialization, (3) propagation of religion, (4) education, and (5) conquest. The British brought their culture into India through conquest. An Indian is said to be the next best Englishman. It is because of culture contact, which has both good and bad aspects. The introduction of scientific medicine is through culture contact. The changes in food habits of people is brought about through culture contact; many orthodox brahmins in India today eat meat. The widespread use of tobacco all over the world is because of culture contact. The radio, the television, the cinema have been important factors in shaping the cultural-behaviour patterns of people.

STANDARD OF LIVING

The term "standard of living" refers to the usual scale of our expenditure, the goods we consume and the services we enjoy. It includes food, dress, house, amusements and in short the mode of living.

The standard of living in a country depends upon : (1) the level of national income (2) the total amount of goods and services a country is able to produce (3) the size of the population (4) the level of education (5) general price level and (6) the distribution of national income.

There are vast inequalities in the standards of living of the people in different countries of the world. The extent of differences in the level of living can be known through the comparison of *per capita income* on which the standard of living of people primarily depends.

DYNAMICS OF SOCIAL CHANGE

The interaction between social factors and health issues is complex and sometimes unpredictable. For example, in Western Europe during the nineteenth century, increase in income and wealth, resulting from the Industrial Revolution, was accompanied by decrease in both birth and death rates. Many authors have in fact argued that increased income was the main cause of these changes *(2)*. The situation in the developing world has varied and differs from the so-called "demographic transition" in Europe. In many parts of Asia, and to a certain extent in Latin America, death rates, particularly among infants, have declined steadily in the past decade and birth rates have declined rather dramatically. Yet the increase in income has been very modest. In Africa, on the whole, death rates, particularly of infants, remain high, birth rates are not declining, the benefits of increased income are not yet apparent, and concern over population growth is just emerging. The relationship between wealth, birth, and death rates observed in the development of West European countries, is thus obviously not universal *(2)*.

A typical feature of traditional societies is a sense of continuity and immutability in patterns of social life. Transitional societies may be better able to cope with change, and modern societies are perhaps best adapted to assimilate rapid changes. A major difference between traditional and modern societies is that, in the former, young people can be fairly sure that their lives will be substantially similar to their parent's, while, in the latter, young people can be fairly sure that their lives will be substantially different from their parent's, and that their children's lives will be different from their own. In transitional societies, young people may simultaneously be involved in two cultures : the traditional one in which their parents grew up and which they still value, and the modern one which may be portrayed in the mass media. A similar clash of cultures may occur in the lives of young people whose families have migrated to another country or from a rural to an urban area *(2)*.

SOCIAL STRESS

A major source of stress, particularly in transitional societies, is the conflict generated by new opportunities and frustrations arising from societal changes. These stress-inducing conditions include : the wave of migration from rural to urban areas and the consequent diminution in the traditional family support system; a greater exposure through mass media to ideas that had been previously culturally alien; tourism; changes in the technological needs of society requiring skills that are different from those of the previous generation and for which the training or education available may be inadequate and the encouragement by commercial interests of economic aspirations that are often unrealistic *(2)*. The pressure is mostly felt where young people have little control over their own destinies, where rapid population expansion means greater competition in the younger age groups, and where resources are inadequate to meet their needs.

It is well understood that the causation of physical and psychological disorders is multifactorial. The experience of stress, particularly in the absence of a social support system or when there is a discrepancy between the actual and perceived demands of a stressful situation, may contribute to further disorders *(2)*. Psychological stress and inadequate coping ability has been implicated as a contributory factor in virtually all diseases *(2)*. In particular, there are direct links between stress and hypertension and coronary heart disease.

SOCIAL PROBLEMS

In a community, there are both individual and social problems. Individual problems become social problems when they affect a large number of people amounting to a threat to the welfare or safety of the whole group. But all individual problems are not social problems. Poverty, crime and disease are the common social problems. Many public health problems are social problems and vice versa. Alcoholism, venereal diseases, mental illness and narcotic addiction are both, public health and social problems. Such social problems as housing, divorce, population growth, increased number of old people have public health implications calling for a combined sociological and public health action.

SOCIAL PATHOLOGY

The term "social pathology" is given a restricted interpretation linking it to poverty, crime, delinquency and vagrancy. In the modern context, the term is also used to describe the relation between disease and social conditions. The social pathology of accidents, diabetes, cardiovascular disease, cancer, chronic bronchitis have all been subject of recent investigations in medical literature. Social pathology is uncovered by "social surveys".

SOCIAL SURVEYS

Social surveys disclose social pathology. Social surveys have played an important part, in the development of public health. It was such a survey by Chadwick that led to the foundation of the General Board of Health in 1848 in Great Britain. There is a strong kinship between epidemiological survey and social survey. When the objective of the research is to study the role of social factors in the aetiology of disease, the two merge into what is known as "social epidemiology". Large scale social epidemiological studies have investigated the relationship of social factors to heart disease, cancer and arthritis *(11)*.

CASE STUDY

Case study is a method of exploring and analyzing the life of a social unit – be that unit a person, a family, an institution, culture group, or even an entire community. Its aim is to determine the factors that account for the complex behaviour patterns of the unit and the relationships of the unit to its surrounding milieu. The case study differs from the survey in the respect that it attempts to collect a large amount of information from a small number of units whereas a survey collects a relatively small amount of information from a large number of units. Thus the case study can yield valuable data about the unit studied than is possible from survey data. A combination of survey and case study could, for example, provide more information about a population of interest than either method could do alone. A case study also has its limitations, i.e., a single instance may or may not be representative of a larger population.

FIELD STUDY

Whereas surveys are concerned with the breadth of knowledge (systematic collection of data from population or samples of population through personal interviews or other data-gathering devices), field studies are concerned with depth of knowledge; they involve observation of people *in situ*.

COMMUNICATION

The term "communication" refers to a social process – the flow of information, the circulation of knowledge and ideas, and the propagation of thoughts. The role of communication in community health is to help motivate people to accept ideas; the ultimate aim of communication is to bring about changes in behaviour. The *mass media* (e.g., song and drama, radio talks, posters) are extensively used as vehicles of dissemination of information.

SOCIAL DEFENCE

A new concept has come into vogue in recent times – the concept of social defence. It covers the entire gamut of preventive, therapeutic and rehabilitative services for the protection of society from antisocial, criminal or deviant conduct of man. Included in this are measures relating to the prevention and control of juvenile delinquency, eradication of beggary, social and moral hygiene programmes, welfare of prisoners, prison reforms, elimination of prostitution, control of alcoholism, drug addiction, gambling and suicides *(12)*. Many States in India have enacted the Children Act for the prevention and control of juvenile delinquency. Under the Suppression of Immoral Traffic in Women and Girls Act, services are being provided for the elimination of prostitution in society. Social defence is a system developed to defend society against criminality not merely by treating and defending the offended, but also by creating such conditions in the community which are conducive for a healthy and wholesome growth of human life. The Government of India renamed the Central Bureau of Correctional Services as National Institute of Social Defence in 1975. This Institute is under the Department of Social Welfare.

PSYCHOLOGY

Psychology is defined as "the study of human behaviour – of how people behave and why they behave in just the way they do". It is concerned with the individual, his personality and behaviour. A knowledge of psychology is essential to know others better; to differentiate between the normal and abnormal, to understand attitudes, beliefs, learning and memory processes; and to help promote mental health in individuals and families.

Scope of psychology

Psychology is vast in its scope, as indicated by the numerous branches of psychology, e.g., normal psychology, abnormal psychology, educational psychology, social psychology, child psychology, applied psychology, psychoanalysis, etc. Medical psychology deals with patients suffering from disorders of the mind. Persons trained in medicine and psychology are called psychiatrists. Thus psychology includes every aspect of human life and every type of human relation.

DYNAMICS OF BEHAVIOUR

The theme common to community medicine and psychology is human behaviour i.e., manner of acting or of conducting one self. The main concern of psychology is to study human behaviour. Human behaviour is the result of physical and mental factors (body and mind) interacting in complicated ways. Behaviour is "the total reactions (of an individual) accessible to external observation. Thought and understanding are implicit behaviour which are observable not directly. but solely by inference from other observable behaviours."

The broad categories of factors that may influence individual and community health behaviour include :

knowledge, beliefs, values, attitudes, skills, finance, materials, time, and the influence of family members, friends, co-workers, opinion leaders, and even health workers themselves. Serious consideration must also be given to the community or social context in which a given type of behaviour occurs. Pervasive issues such as norms, male/female roles, ethnic discrimination, poverty, unemployment, and educational opportunities may limit the ability of some of the sections of the community to behave in a healthy manner *(13)*.

Cultural and social factors provide a setting for individuals. However, behavioural decisions may also be made that are other than those predicted on the basis of these factors. Psychological factors relating to public health programmes may be considered under the heading of health, illness and treatment behaviours.

Health behaviour

Health behaviour refers to those activities people undertake to avoid disease and to detect asymptomatic infections through appropriate screening tests. For instance, sexually transmitted diseases can be prevented by avoiding sexual exposure with infectious sexual partners. Other health behaviours that might reduce the risks of infection include the use of condoms, of bactericidal products immediately before and after sexual exposure, and the appropriate use of antimicrobial agents with proper supervision *(13)*. In addition the risks of transmission can be reduced by assisting in the detection of infection in sexual partners before they have further unprotected sexual exposure with other susceptible partners. People with good health habits (e.g., daily brushing of teeth, non-smoking) are less likely to develop venereal infection than persons with poor health habits *(13)*.

Illness behaviour

Illness behaviour refers to how people react to symptoms. Generally, people who detect symptoms will wait to see if the symptoms persist or worsen. If the symptoms continue, the affected person may ask a friend or acquaintance for advice, before seeking medical help.

Treatment behaviour

Treatment behaviour refers to those activities used to cure diseases and restore health. It is important for patients to take medication as directed, return for tests for cure, and cooperate in efforts to identify untreated cases. Research has not shown that any particular group or personality type is more compliant than any other.

All forms of behaviour are responses to stimuli. For example, a child sees a dog rushing towards him, and starts running away. The sight of a dog rushing towards him is the stimulus and running away is the response. To understand behaviour, we must find out the cause for stimulus. The goal of psychology is to find relations that exist between stimuli and responses.

RESPONSES

The various responses may be classified as follows :

i) *Physical responses :* habits, skills

ii) *Organic responses :* emotions, feelings, tension

iii) *Intellectual responses :* perceptions, thinking, reasoning.

CAUSES

All behaviour is caused, and the causes are very complex. They include :

i) *Environmental stimuli*

The environmental stimuli (e.g., sight, smell, touch, etc.) reach the cerebral cortex through nerve impulses. The information received is assembled and evaluated. By another set of impulses, the cerebral cortex "orders" the behaviour of the individual. This is known as **conscious behaviour.** It is the behaviour determined by the standards or expectations of the society, e.g., professional behaviour of doctors with patients. This accounts for the variation in a person's behaviour in different situations.

ii) *Emotions and feelings*

Behaviour is also dependant on our feelings and emotions. These stimuli arise from within the body. When we say a person is blind with rage or paralysed with fear, we mean that he is a victim or captive to his own emotions. Emotions thus affect our behaviour. The seat of primary emotions (e.g., anger, joy, hunger) is the thalamus in the brain. It is under the control of cerebral cortex. When the influence of cerebral cortex is removed, as for example, when an injury to cerebral cortex occurs, the person's behaviour may be affected.

iii) *Needs*

An individual's behaviour is also influenced by his needs. The terms – needs, wants, desires and urges are used synonymously.

iv) *Motivation*

Motivation is an inner force which drives an individual to a certain action. It also determines human behaviour. Without motivation, behavioural changes cannot take place.

v) *Intellectual perception*

A person's intellectual perception, thinking and reasoning can influence his behaviour in a given situation. That is why each individual behaves in ways which make sense to him.

Making adjustments

Behaviour is also described as an **adjustment** to meet the needs of a given situation. For example, when a person does not succeed in something there are several ways he or she can react:

- losing temper and complaining to every one
- isolating oneself or simply avoiding facing others
- making excuses for the failure
- accepting failure with good grace and making amends by changing his behaviour or otherwise.

This adjustment is both active and passive. That is why some people blow hot and cold to suit their physical and social environment.

Unconscious behaviour

There is also behaviour of which the individual is not conscious. For example, if ten people witness an accident, we get ten conflicting reports of the accident. This is because of certain forces (e.g., perceptions, prejudices, and notions) which colour the incident, over which the individual has no

control. Another example is that some people forget important things because they are unpleasant and remain happily unconscious about them.

EMOTIONS

An emotion is a strong feeling of the whole organism. Emotions motivate human behaviour. An emotional experience is characterized by both external and internal changes in the human being. The "external" changes are those which are apparent and easily seen by others such as changes in facial expression, changes in posture. By studying the facial expression we can find out if a person is angry, happy, depressed or elevated. The "internal" changes brought about by emotions are psychological such as rapid pulse, respiration, increased blood pressure, tension and pain. Usually these changes are temporary, and subside when the individual returns to the "normal".

Some of the major emotions are :

Fear	Jealousy	Sympathy
Anger	Moodiness	Pity
Love	Joy	Lust
Hate	Sorrow	Grief

Scientists have proved that emotions can be a major barrier to communication. Man is indeed a slave to his emotions. The doctor should be able to understand the emotions of the patient. Once the emotional barriers are broken down, a mutual trust between the patient and the doctor develops, and the patient will begin to talk more freely about himself. This is the basis of doctor–patient relationship. The desirable qualities in a doctor are cheerfulness and an even temperament. Moodiness, emotional instability and getting easily upset are undesirable qualities.

Some specific emotions

(1) FEAR : Fear is the most common emotion of man. It may produce excitement or depression; flight or fight. Some of the common fears of man are – fear of the dark, fear of dogs, fear of snakes, fear of ghosts, fear of sickness, fear of death, etc. When the fear becomes exaggerated or unnecessary, it is called **phobia**. Such fears are common in patients with mental disorders. (2) ANGER : Anger or rage is another basic emotion of man. It is a reaction of the offensive type. Anger is a destructive force. If it is not controlled, it may impel a person even to commit murder. (3) ANXIETY : Anxiety may manifest in such symptoms as rapid pulse and breathing, flushing, tremors, sweating, dry mouth, nausea, diarrhoea, raised blood pressure, etc. Patients admitted to hospitals are anxious. Anxiety leads to tension, and tension to pain. The doctor must understand the patient's anxiety and give him reassurance. A kind word from the doctor or nurse works like a magic and gives the patient considerable relief from mental anxiety. (4) LOVE : Love is a feeling of attachment to some person. It is a basic emotion of man.

Role of emotions in health and disease

Emotional states determine human behaviour. Anger can cause a person to be rude and sarcastic. Disorders of emotion interfere with human efficiency – lack of concentration, lack of appetite, increased risk of accidents, lack of sleep, palpitation, etc. Emotional disorders in children may appear in the form of temper tantrums, abdominal pain, spasms, tics, and anti–social behaviour such as aggressiveness.

Psychosocial illness : There are a group of diseases known as "psychosocial diseases" (mind acting on body), e.g., essential hypertension, peptic ulcer, asthma, ulcerative colitis which are attributed to disturbed emotional states.

Control of emotions

A well-adjusted and mentally healthy person is one who is able to keep his emotions under control. One should not be carried away by one's emotions. Children should be shown love and appreciation so that they may grow into emotional maturity. For adults, a happy family life is basic for emotional adjustment. Patients who are anxious need reassurance and their fears must be allayed. The following tips may be useful in controlling one's emotions : (i) cultivate hobbies, good habits of reading and recreation (ii) adopt a philosophy of life to enable you to avoid mental conflicts (iii) try to understand your own limitations, and (iv) develop a sense of humour. A study of psychology helps us to understand the basis of emotions and the need to keep emotions under control.

MOTIVATION

Motivation is a key word in psychology. It is an inner force which drives an individual to a certain action. It also determines human behaviour. Motivation may be positive (the carrot) or negative (the stick). Without motivation, behavioural changes cannot be expected to take place. Positive motivation is often more successful than negative motivation. Motivation is not manipulation. A motivated person acts willingly and knowingly. The terms motives, needs, wants, desires and urges are all used synonymously; these terms are interrelated and interdependent.

Kinds of needs and urges

It is difficult to define human needs. There are many kinds of needs and urges : (a) *Biologic needs :* These are survival needs. A hungry man needs food, a thirsty man water, a sick man medicine. There are other needs such as sleep, rest, recreation and fresh air. The doctor should be aware of these needs in the day-to-day care of the patients. (b) *Social needs :* The need for company, the need for love and affection, the need for recognition, the need for education are all social needs. Some of these needs are met by the family, and some by the community. (c) *Economic needs :* Economic security, that is security from want, is one which everyone desires. (d) *Ego-integrative needs :* The desire for prestige, power and self-respect come in this category.

Motivation is contagious; it spreads from one motivated person to another. We make use of motives and incentives in community health work. Motivation of eligible couples for a small family norm is an important activity in the National Family Welfare Programme. Motivation is required to enlist people's participation in community health work.

INCENTIVES

Incentives are among the factors that stimulate motivation and encourage specific behaviours. Incentives can be either intrinsic or extrinsic, material or psychological, self determined or selected by others. An intrinsic incentive is the benefit that comes from solving one's own problems. Extrinsic incentives are rewards that do not relate directly to the goal towards which the desired behaviour is aimed, for example, financial compensation of individuals undergoing sterilization operation for family planning. Material

incentives are tangible goods or services; psychological incentives include the satisfaction, self-esteem, or enhanced capabilities gained through a proposed course of action *(13)*.

LEGISLATION

Legislation can serve as an important tool to support, promote and sustain activities at the community level. Laws should satisfy requirements and, at the same time be compatible with the political, cultural, social, and economic situation of the country. This is essential because laws may antagonize the population and make the community uncooperative.

OBSERVATION

Treatment involves lot of correct observation of the patient's condition. Observation involves two mental activities – perception and attention. Hippocrates, the Father of Medicine, laid the foundation of modern medicine by accurate observation of signs and symptoms. By observing an apple fall, Newton formulated the theory of gravitation. By observation penicillin was discovered. Observation is a psychological skill. It consists of the noting of the phenomena of life as they occur. It requires correct use of the senses of seeing, hearing, touch, smell, movements etc. A doctor should cultivate the habit of correct observation. Correct observation leads to correct thinking, reasoning and learning.

Observation promotes attention. To observe more carefully is called attention. A moving object attracts more attention than a static object, a large object attracts more attention than a small object, an uncommon object attracts more attention than, a common one, a bright colour attracts more attention than a dull colour. In attention, certain adjustments of sense organs are involved such as turning the head, converging the eyes, In other words, attention means closer observation. Attention is not a fixed state or power of the mind. We constantly change our attention from one object to another according to the demands of the situation. Concentration, i.e., the focusing of consciousness on a particular object to the exclusion of all other objects has been defined as sustained attention.

Errors in perception

The word perception implies observation, recognition and discrimination. Perception takes place with the help of sensory organs. Thus we have visual perception, auditory perception, olfactory perception, and muscular perception. The disorders of perception are : (1) *Imperception :* That is, inability to recognize. This may be due to damage to the sense organs, e.g., anaesthesia. (2) *Illusion :* An illusion is a false perception. Mistaking a rope for a snake, a tree for an animal are called illusions. Illusions occur in mental diseases. Illusions may be auditory or visual. (3) *Hallucination :* Hallucination is an imaginary perception. It is a gross error of perception. Seeing objects that do not exist, hearing sounds that are false, seeing objects moving in a room are called hallucinations. Hallucinations occur in mental disorders.

ATTITUDES

Attitudes are acquired characteristics of an individual. They are more or less permanent ways of behaving. An attitude includes three components : (a) a cognitive or knowledge element (b) an affective or feeling element, and (c) a tendency to action. An attitude has been defined as a relatively enduring organization of beliefs around an object, subject or concept which pre-disposes one to respond in some preferential manner.

Attitudes are not learnt from textbooks, they are acquired by social interaction, e.g., attitude towards persons, things, situations and issues (e.g., government policies, programmes and administrative measures). It has been truly said that attitudes are caught, and not taught. Once formed, attitudes are difficult to change. The responsibility to develop healthy attitudes devolves upon parents, teachers, religious leaders and elders. Our success or failure in life depends upon our attitudes. Social psychology is largely a study of attitudes. In recent years, attitude surveys and attitude measurements have been widely used by psychologists and health professionals.

OPINIONS AND BELIEFS

Opinions are views held by people on a point of dispute. They are based on evidence available at the time. Opinions by definition are temporary, provisional. They can be looked on as beliefs for the time being. Beliefs, on the other hand are permanent, stable, almost unchanging. These are usually derived from our parents, grand-parents, and other people we respect. We accept beliefs, without trying to prove that they are true. Every community has its own beliefs. As beliefs are held strongly, they are often difficult to change. They can be harmful, helpful or neutral. It is thus easier to give up one's opinions when faced with the facts; attitudes and beliefs do not succumb so easily.

INTERESTS

Numerous interests come into play in a communication situation. Most significant are our own interests – of security, pleasure, and self-esteem. Then come the interests of the various groups we are associated with : primary and secondary, as well as the reference groups whose values and norms we aspire to promote. Our communities, castes, language groups, peer groups, and other religious, social, political and professional groups so dear to us are vital to our interests. One must not overlook the social, regional and national interests that shape our selection of communications, and also the way we perceive them *(14)*.

LEARNING

Learning is any relative permanent change in behaviour that occurs as a result of practice or experience. It means acquiring something new – new knowledge, new techniques, new skills, new fears and new experiences.

Learning is necessary for man's survival and for human progress. It includes not only acquiring knowledge but also skills and formation of habits, and development of perception. Learning depends largely upon intelligence. Learning also depends upon motivation, and motivation depends on the need students feel to learn. Learning is a continuous process. It is both conscious and unconscious.

Conditions affecting learning

(1) *Intelligence :* Learning depends upon the intelligence or mental faculty of an individual. It involves the activity of sensory adjustment and motor mechanisms of the body. The mental faculty is related to heredity, nutrition and IQ. Children with low IQ are poor learners; they may not learn at all. (2) *Age :* The curve of learning reaches its peak between 22 and 25 years of age. After the age of 30, there is a sharp decline. It has been appropriately said : You cannot teach

"an old dog a new trick". (3) *Learning situation :* Physical facilities for learning, viz, institutions, teachers, textbooks, audio-visual aids promote learning. (4) *Motivation :* In order to learn effectively, there must be adequate motivation. The powerful motives are encouragement, praise, reward and success. These stimulate learning. (5) *Physical health :* A Physically handicapped person, e.g. deaf, dumb, chronically sick cannot learn. (6) *Mental health :* Worries, anxieties, and fears interfere with learning.

Types of learning

There are 3 types of learning :

(1) **Cognitive** learning (knowledge)

(2) **Affective** learning (attitudes)

(3) **Psychomotor** learning (skills)

Psychologists have experimented a good deal with animals and man to find out how learning takes place. They have proposed a number of theories : (1) *Learning by conditioned reflex :* It is well known that when dogs see food, they begin to salivate; this is an inborn reflex. Pavlov, the Russian physiologist discovered that if a bell was rung when the dogs were fed, eventually, salivation could be induced by the ringing of the bell alone. This is called conditioned reflex. The psychologists proposed that learning takes place partly by the mechanism. (2) *Trial and error :* The lower animals such as apes and cats learn by trial and error method. We also learn a good deal by this method. A child tries and tries again using a number of approaches until accidentally the ideal approaches, becomes obvious. This method of learning is very slow, laborious and primitive. (3) *Learning by observation and imitation :* We learn a good deal by observation and imitation. A child copies or imitates gestures, facial expressions and movements such as walking. He learns language by observation and imitation. Observation is an important element in medical examination. Observation promotes attention, discrimination and recognition. It was by observation, Hippocrates, Father of Medicine, separated medicine from magic. Part of the doctor's and nurse's education has always been to observe the patient's condition, and to make decisions based on these observations. (4) *Learning by doing* : In this type of learning there is coordination of muscular responses with sensory impulses. Nursing skills (e.g., bed making, applying bandages, giving bath) are learnt by doing. Learning to type-write or learning a new game or a musical instrument are all examples of learning by doing. (5) *Learning by remembering :* We also learn by memorizing – remembering dates, events, memorising a poem, remembering faces, etc. (6) *Learning by insight :* When we are faced with a problem, we solve it by insight or mental exploration. When the doctor makes a diagnosis, some amount of insight is involved. It appears that human beings learn by a combination of methods. (7) *Demonstration :* Here a procedure is carried out step by step, slowly and accurately before an audience, the demonstrator ascertaining that the audience understands how to perform it. The demonstration involves the audience in discussion, when possible. (8) *Field experience :* It involves a series of activities for diagnosing problems, planning procedures to solve them and implementing and evaluating these programmes. It provides opportunities to acquire with number of skills. (9) *Problem solving :* It is closely related to field experience in that the problems are identified and plans to solve them are made, but if the time is short, the plans may be executed by another group of trainees or by the service staff.

Learning is measured by student's performance. There are many ways of measuring student's learning viz., multiple choice questions, essay writing, project work, practical examination, oral examination, etc. Usually a combination of different methods is used.

HABITS

Habit is an accustomed way of doing things, example in the field of health is washing one's hands before handling food. It is usual way of action or an act performed without thinking. Habits are said to have 3 characteristics : (a) they are acquired through repetition (b) they are automatic, and (c) they can be performed only under similar circumstances. Habits accumulated through generations emerge as customs; and customs in turn create habits. Habits once formed persist and influence human behaviour.

Habit formation

Habits are formed. They are of many kinds, e.g., habits relating to food, sleep, work, smoking, intake of drugs and alcohol, etc. There are both good and bad habits. Good habits promote health; bad habits (e.g., drug dependance) may ruin health. Therefore, cultivation of good habits is desirable. The principles involved in habit formation are :

(1) Habit formation should begin early in childhood, when the child has not yet formed any habits, and is receptive to all influences;

(2) Habits are formed by frequent repetition;

(3) It takes time to form habits; they cannot be formed overnight;

(4) There should be a strong emotional stimulus to form habits (e.g., taking a vow, reward, recognition, etc.);

(5) Good habits kill bad habits. The best way to break bad habits is to cultivate good habits.

Habits build up human personality. Man should not become a slave to his habits, he should remain a master. It is the job of the psychologist to find out how good habits can be developed, and bad ones eliminated.

FRUSTRATIONS AND CONFLICTS

Frustrations

All people have needs – biological, social, economic, which they try to satisfy. When they are unable to meet their needs and desires, they feel frustrated.

The sources of frustration may be external – e.g., unemployment, failures and defeats, or, internal – e.g., lack of health, lack of intellectual ability, etc.

Sometimes, frustration may rouse the individual to higher and bigger effort to overcome failures. The individual may bypass the frustration conditions by changing his goals in life. Frustration, if it is allowed to continue, may damage one's personality. It may generate feelings of anger, dejection, hostility, withdrawal or even attempts at suicide. That is why some people take to drugs and alcohol to escape frustration.

Conflicts

A conflict is like a tug of war between two or more courses of action or between opposing ideas. The person is required to act one way or the other, often generating painful emotions as for example in choosing a life partner or

a job. He has to weigh the pros and cons of the situation to be able to make a correct decision. It is essential for a person's mental health that conflicts should be resolved as quickly as possible, within a reasonable period of time, before emotional disturbances occur.

DEFENCE MECHANISMS

When an individual is faced with problems, difficulties or failures, he employs certain ways or devices to achieve health, happiness or success. These are called **defence mechanisms**. Psychologists have identified a number of such defence mechanisms, which include the following :

1. Rationalization

Instead of accepting failure and correcting himself, the individual tries to make excuses and justifies his behaviour. It is like the proverbial fox declaring that the grapes were sour, when it could not reach them. This is called rationalization. It is a face-saving device.

2. Projection

Sometimes the individual blames others for his mistakes or failures. It is just like the student saying that he could not score good marks in the examination because, his teacher did not like him.

3. Compensation

Many people make use of compensation to enhance their self-esteem and prestige. The familiar example is that the student who is not good in his studies may distinguish himself in sports or dramatics, music or other activities.

4. Escape mechanism

Some individuals adopt what is known as an "escape mechanism" to overcome failure or defeat. Some students pretend illness and do not appear for examinations. This is an escape phenomenon. Then there are others who take to alcohol or drugs trying to solve their problems. This is also an escape phenomenon.

5. Displacement

An office clerk badly snubbed by his superior takes it out on his wife and children on reaching home. This is like a rebound phenomenon. It is trying to escape from one situation and fixing blame on another situation.

6. Regression

Some people resort to childhood practices (e.g., weeping when something goes wrong) as a mode of adjustment.

The above list of "defence mechanisms" serves to illustrate the various modes of adjustments the individual adopts to escape from realities. He is either too keen to hide his faults, or run away from his troubles and problems. A mentally healthy person will not use defence mechanisms for achieving success or happiness.

PERSONALITY

The term "personality" is a key word in psychology. It implies certain *physical* and *mental* traits which are characteristic of a given individual; these traits determine to some extent, the individual's behaviour or adjustments to his surroundings. The terms personality and human behaviour are inter-related. Psychology, in its broader concept, implies study of human personality. It is important to bear in mind that the personality of the doctor affects very much the well-being of the patient.

Components of personality

There are at least 4 components of human personality :

(1) PHYSICAL : These are the physical traits or features of an individual namely height, weight, colour, facial expression, physical health, etc. To the layman, a good personality means an impressive, symmetrical and healthy body. (2) EMOTIONAL : A person's emotions also go into the make-up of his personality. Emotions are the feelings we have – fear, anger, love, jealousy, guilt, worries. These feelings affect an individual's personality. (3) INTELLIGENCE : Personality also implies intellectual ability. An intelligent person will have a forceful personality. A person with sub-normal intelligence is described as a "dull" person. (4) BEHAVIOUR : Behaviour is a reflection of one's personality. It is partly dependent upon our feelings and partly on the expectations of the society. Behaviour is described in such terms as gentle, kind, affectionate, balanced, submissive and aggressive. When we assess human personality, all these components must be taken into consideration.

Personality traits

A trait is described as tendency to behave in a consistent manner in variable situations. Human personality is a bundle of traits. The basic personality traits are established by the age of 6 years. Some traits, we cultivate (e.g., good manners); some, we may conceal (e.g., kindliness); and some, we modify depending upon the society in which we are placed (e.g., sense of humour). The following are some of the personality traits :

- Cheerfulness
- Good manners
- Sportsmanship
- Honesty
- Kindliness
- Loyalty
- Reliability
- Sense of humour
- Tactfulness
- Willing to help others.

The personality traits we look for in a doctor are kindliness, honesty, patience, tolerance, perseverance, consciousness, thoroughness and initiative. It is possible to cultivate these traits.

The Swiss Psychiatrist, Carl Jung (1875–1961) divided personalities into 2 types – **extrovert** and **introvert**. The extrovert is a person who is thought to be dashing, practical, active, showing-off and easily mixes with people. An introvert is a person who is reserved, shy and generally keeps to himself. Most people exhibit characteristics of both.

Development of personality

Human life consists of definite stages of growth, and each stage is marked by distinctive psychology. (1) INFANCY : The first one year of life is called infancy. The infant is hardly a social creature. There is rapid physical and mental growth. The infant is totally dependent on the mother. By the end of first year, the infant is able to stand up for a short while and tries to walk with a little support. He enjoys simple tricks and games. (2) PRE-SCHOOL CHILD: This stage is marked by considerable growth of brain. The child feeds himself, speaks, loves his home, fears dark, loves stories and wants to assume responsibility. He begins to mix with other small children. (3) SCHOOL-AGE : The school-age period ranges from 5 to 15 years. The school going child is active all the time. By the age of 8, the mental powers are fully developed. The brain of the child at the age of 8 years is almost of the same size as an adult. The child begins to

reason. There is a gradual detachment from the family, and greater attachment to his playmates and friends. He begins to form groups. The period of childhood terminates with the onset of puberty, which is about 11 years in the case of girls and 13 in the case of boys. (4) ADOLESCENCE : Adolescence or "teenage" is a turbulent period in one's life. This is a period of rosy dreams, adventure, love and romance. The teenager strives for independence. He dislikes parental authority. He becomes fully aware of social values and norms. There is rapid physical growth. (5) ADULTS : The person is mature and more balanced. The physical and mental characteristics are fully developed. It is difficult to draw a line when adolescence ceases, and adulthood begins. (6) OLD AGE : It is difficult to say when old age begins. It is a gradual process marked by decline in physical powers and acuity of sense organs. Old age is marked by certain psychological changes such as impaired memory, rigidity of outlook, irritability, bitterness, inner withdrawal and social maladjustment.

Character and will

The concept of personality also involves assumptions about character and will of the person. Will indicates determination and character implies moral worth. Personality and character are not identical; both are different. Man's character may be good at one time and bad at another time, though his personality remains the same. There is no acceptable definition of character.

THINKING

Man is called a thinking animal. Thinking includes perception, memory, imagination and reasoning. It is an active mental process. Imaginative thinking is a mental process, it involves thinking in the absence of original sensory stimuli. Day-dreaming and thinking about our future plans are examples of imaginative thinking. The highest form of thinking is said to be creative thinking , e.g., an artist painting a picture. Creative thinking is said to be responsible for new inventions, new views of life and new discoveries. The anatomical basis of thinking is cerebral cortex. In fact, the purpose of education is to teach people to think, and not merely to memorize facts and figures.

Problem solving

An aspect of thinking is problem solving. It is regarded as the highest stage in human learning. Some problems in life are relatively simple; there are others which are more difficult and complex calling for thinking and reasoning. REASONING requires intelligence. There are several steps in the reasoning process – collection of information on the subject, the arrangement of data carefully, observation of the implications, drawing conclusions and testing the conclusions. An intelligent person reasons well. Reasoning is not always fool-proof. Fallacies may also occur.

INTELLIGENCE

Intelligence is an important aspect of personality. It has not been satisfactorily defined as yet. The widely accepted definition is that it is the ability to see meaningful relationships between things. It includes perceiving, knowing, reasoning and remembering. Psychologists believe that intelligence results from an interplay between hereditary and environmental factors. Some psychologists emphasize genetic factors as having major significance while others emphasize environmental factors.

There is considerable relationship between a person's degree of intelligence and range of activities, the level of achievement and the depth of understanding possible to him. As psychologists observed the differences between animals and human beings, and the differences between organisms of the same species, they were impressed by the fact that there are variations in the case and adequacy with which adjustments to new situations occur. It was out of such observations that the concept of intelligence arose.

Mental age

The first tests of intelligence were devised by Binet and Simon (1896). They developed the concept of *mental age*. That is, a child who could do the five-year tests but who could not go on to the six-year level, was credited with mental age of five years. The concept of mental age indicated the level of intelligence achieved, but it gave no indication of the brightness or dullness of the individual concerned. Terman revised these tests, defining intelligence as the capacity to use abstract ideas for solving problems. Gessel indicated four sectors of intellectual development for consideration : (a) motor ability (b) adoptive behaviour (c) language development and (d) personal-social behaviour.

Intelligence Quotient

This is an improvement over the concept of mental age. It is obtained by dividing the mental age by chronological age, and multiplying by 100.

$$IQ = \frac{\text{Mental age}}{\text{Chronological age}} \times 100$$

When the mental age is the same as chronological age, the IQ is 100. The higher the IQ, the more brilliant the child. 80 per cent of people have an IQ of or near 100. On the other hand, say for example, if a child is 10 years of age and his mental age level is that of 5 years, the IQ is 50.

Levels of Intelligence		IQ Range
Idiot	.....	0–24
Imbecile	.....	25–49
Moron	.....	50–69
Borderline	.....	70–79
Low normal	.....	80–89
Normal	.....	90–109
Superior	.....	110–119
Very superior	.....	120–139
Near genius	.....	140 and over

The current interpretation is that the IQ is the measurement of the quality and potential of intelligence. The higher the IQ the more *"brilliant"* the child is and is more capable of higher performance at school age.

ADULT INTELLIGENCE

The components of adult intelligence have been analyzed by many specialists. Thurstone *(15)*, for instance, defines them as :

(1) space : the ability to perceive objects
(2) number : familiarity with elementary arithmetic
(3) verbal comprehension : the ability to reason from verbal concepts
(4) facility of expression : the ability to employ the appropriate words
(5) memory : the ability to retain words and ideas

(6) induction : the ability to discover principles
(7) deduction : the ability to use those principles to solve concrete problems
(8) flexibility and quickness of thought.

Intelligence tests

Intelligence tests can be classified under the categories of group tests and individual tests. These two kinds of tests have been constructed mostly to meet practical necessities. Naturally, if large numbers of subjects are to be tested, it would be more convenient to test them in large group to save time and trouble. But under particular situations, such as in a guidance clinic, each individual could be tested separately and would need to be tested separately. To suit these different requirements, we now have both group tests and individual tests. In a group test, all the subjects must start at one time and finish at the same time just as in an examination. Here, the time factor is constant. One's intelligence is measured in terms of the amount of work successfully completed within the given time. Individual tests on the other hand need not necessarily depend on a constant time factor. Time tests can also be used for individuals. Strictly speaking, all tests of intelligence are measures of *performance*. However, the term *performance* is customarily applied to tests which call for a minimal understanding and use of language. These tests provide a measure of fundamental psychological process, such as reasoning and seeing relationship, without at the same time depending upon particular cultural or educational opportunities. They enable us to measure the intelligence of individuals : – (1) who are too young to have learned a language, (2) who are illiterate through lack of educational opportunity or feeble-mindedness, and (3) who speak only a foreign tongue.

As the child grows older, his intelligence undergoes a gradual increase. There is an improvement with age in his versatility of adjustment – in the readiness with which he gathers information and acquires new skills which enable him to adjust to the changing circumstances of his environment. When a normally healthy school child, whose educational opportunities have been average, is tested year after year, his IQ remains fairly constant. Changes in educational opportunities lead to fluctuations in IQ. There are cases on record, too, where the IQ rose considerably after glandular therapy.

The chief values of discovering a child's IQ are that : (1) those of low IQ can be taken aside for special education in line with their capacity to acquire intelligent behaviour; (2) those of very high capacity can be selected for education in keeping with their capacity; (3) intelligence tests as an aid in the determination of the right time to enter school; (4) the use of intelligence test in maintaining the adjustment of a pupil to his work; (5) the selection of applicants for college and professional school; (6) the use of intelligence test in educational guidance; and (7) the use of intelligence test to the therapist *(16)*.

Measurement of disability

There have been many attempts to measure or record in standardized form the aspects of behaviour, psychological functions and social performance. One of the most important is Wing's Comprehensive Handicaps, Behaviour and Skills Schedule (HBS) which has been used in epidemiological studies to assess the total child population in terms of detailed scales of specific abilities and disabilities. Results from these surveys have raised important questions about ethnic differences in disability profiles, individual programme planning, defining new syndromes of disability and the possibilities of new parameters for classification. The HBS is essentially a research tool, but Wing has developed from it a small practical schedule for use in service contexts using what had emerged as the most important aspect of mobility, communication and social interaction. The resulting Disability Assessment Schedule (DAS) is being used in several communities as a source of high quality routine data for total population *(17)*.

SOCIAL PSYCHOLOGY

Social psychology is an important branch of psychology. It is defined *as the science of behaviour of the individual in society.* That is, it studies the behaviour of the individual in group, crowd, mob, audience and other social situations. It also studies the *attitudes* of the individuals towards cultural and social values.

Group behaviour

Man is a social being. From birth till death, he is associated with people. He is born in particular culture which is made up of customs, laws, ideals, art, literature, crafts, science, technology and institutions. All these act on the individual and influence his social behaviour. Group behaviour is also known as social behaviour.

Social interaction

(a) *Inter-personal relationships :* The individual learns many things from his parents, teachers and friends. This is known as person–to–person interaction.

(b) *Inter-group relationships :* The individual is a member of a group, of a family and of a community. He has to follow the traditions of the group. For example, in many communities in India the person is not permitted to marry outside his caste. This is the result of person-to-group interaction.

The individual, through social interaction and social learning acquires patterns of behaviour prevalent in his society, and is accepted as a member of that community. This process of adaptation is known as socialization. Social interaction converts the biological organism into human, social and moral.

As a result of social interaction, the individual acquires attitudes towards persons, things, situations and issues. Social attitudes are shared by others in the community, e.g., attitude to prohibition, family planning, child marriage, etc. In any democratic society, people's attitudes are a matter of vital importance to the State.

Group morale

Every group has leaders. They are responsible for the solidarity of the group behaviour and the morale of the people in the group.

Groups work together. They have definite programmes and objectives. Often their members think, feel and act together. Many community problems can be solved by group effort. We can approach the group through group discussions. The problem is one of how to make these group activities happy and satisfying experiences for those who participate in them.

SOCIOLOGY

Sociology is the science of society. It deals with the study of relationship between human beings, it also deals directly with the study of human behaviour. Whereas the unit of study of psychology is the *individual,* the unit of study of sociology is the *group.* Sociology studies man in the context of society and as a part of it.

Medical sociology is a specialization within the field of sociology. Its main interest is in the study of health, health behaviour and medical institutions. Illness is viewed not only as a medical problem but also as a psychological and social problem. The problems presented by patients are not always purely medical but also psycho-social. Diseases such as tuberculosis, leprosy, sexually transmitted diseases have a big social component in their aetiology. Medical scientists are increasingly turning their attention to the study of social, behavioural and cultural factors of illness. A social approach to disease treatment is also emphasized. The doctor needs to have a fuller appreciation of biological, behavioural and social sciences. A successful doctor must possess a knowledge of the community and the factors which affect the health of the community.

THE INDIVIDUAL

Rights of the Individual

During the 19th Century, the rights of man received some small recognition. In 1946 the subject of human rights again received attention. In 1948, the General Assembly of the United Nations adopted the Universal Declaration of Human Rights. The declaration consists of 30 Articles, and recognizes that all human beings are born free and equal in dignity and rights. The Right to better living conditions, and the Right to Health and Medical Service are vital articles. In 1959, the General Assembly of the United Nations also adopted. "The Declaration of the Rights of the Child". The Universal Declaration of Human rights speaks of the right to health in the following terms :

> Everyone has the right to a standard of living adequate for the health and well-being of himself and of his family, including food, clothing, housing, and medical care and necessary social services, and the right to security in the event of unemployment, sickness, disability, widow-hood, old age or other lack of livelihood in circumstances beyond his control.
>
> Motherhood and childhood are entitled to special care and assistance. All children, whether born in or out of wedlock, shall enjoy the same social protection.

The Constitution of the World Health Organization expressed itself as follows :

> The enjoyment of the highest attainable standard of health is one of the fundamental rights of every human being without distinction of race, religion, political belief, economic or social condition.

Most countries of the world have accepted the idea of the right to health.

The Constitution of India guarantees 7 broad categories of fundamental rights :

(1) the right to equality
(2) the right to freedom of speech and expression
(3) the right against exploitation
(4) the right to freedom of practice and propagation of religion
(5) the right of minorities to conserve their culture
(6) the right to property; and
(7) the right to constitutional remedies for the enforcement of fundamental rights.

Responsibility for health

Although health is now recognized as a fundamental right of every human being, it has to be earned by individual effort. It cannot be given by one person to another.

The responsibility for health rests not only on the individual but also upon the community or State. There are certain responsibilities which the individual must accept or exercise in order to achieve optimum health. These are responsibilities regarding personal health, e.g., diet, care of teeth, skin, recreation, exercise, cultivation of healthful habits, immunization, reporting early when falling sick, optimum utilization of available health services, etc.

In all civilized societies, the Government or State assumes responsibility to safeguard or promote the health and welfare of its citizens. Russia was the first country to give its citizens a constitutional right to all health services. There is provision for health in the Constitution of India. The Directive principles of State policy of the Constitution of India states :

The State shall, in particular, direct the policy towards securing –

> That the health and strength of workers, men and women and the tender age of children are not abused and that citizens are not forced by economic necessity to enter a vocation unsuited to their age or strength.
>
> That children and youth are protected against exploitation and against moral and material abandonment.
>
> The State shall, within the limits of its economic capacity and development, make effective provision for securing the right to work, to education and to public assistance in case of unemployment, old age, sickness and disablement, and in other cases of undeserved want.
>
> The State shall, make provision for securing just and humane conditions of work and maternity relief.
>
> The State shall regard the raising of the level of nutrition and standard of living of its people and the improvement of public health as among its primary duties.

SOCIAL ORGANIZATION

Society is a group of individuals drawn together by a common bond of nearness and who act together in general for the achievement of certain common goals. The individual needs the group – not necessarily a particular group or always the same group or the same group for all needs. Different groups are needed for different purposes; these groups comprise social organization.

The social groups to which people belong are the family, the kinship and caste, religion, village, town or city and the state. Besides these, there are certain functional groups such as the panchayat, the club and various associations. Cutting across these groups, there are groups based on social status.

1. THE FAMILY

The family is the basic unit in all societies. It is the most powerful example of social cohesion. A detailed discussion of the nature and functions of the family is given in the following pages.

2. RELIGION AND CASTE

The caste system in India is an example of a "closed class", i.e., there is no mobility or shifting from one class to another, and the members remain throughout life time wherein they are born. Each caste is governed by certain rules and sanctions relating to endogamy, food taboos, ritual purity, etc. Each caste group within a village is expected to give certain standardized services to the families of other castes. For example, a carpenter repairs tools, a barber (nai) cuts hair, a potter supplies earthenware vessels. In the towns and cities and industrial areas, the caste system, although existing, is not rigid : there is considerable inter-communication and interpersonal relationships not strictly based on caste hierarchy.

3. TEMPORARY SOCIAL GROUPS

(1) *The Crowd :* When a group of people come together temporarily, for a short period, motivated by a common interest or curiosity (e.g., to witness a football match), it is known as a crowd. The crowd lacks internal organization and leadership. When the interest is over, the crowd disperses. (2) *The Mob :* The mob is essentially a crowd, but has a leader who forces the members into action. There may be a symbol in the shape of a flag or slogan. The mob is more emotional than a crowd. Like the crowd, it is unstable and without internal organization. When the purpose of the mob is achieved, the group disperses. (3) *The Herd :* This is also a crowd with a leader. Here the members of the group have to follow the orders of the leader without question, e.g., the tourist group under a guide.

4. PERMANENT SPATIAL GROUPS

(1) *The Band :* It is the most elementary community of a few families living together. Here the group has organized itself and follows a pattern of life e.g., gypsies in India. (2) *The Village :* The village is a small collection of people permanently settled down in a locality with their homes and cultural equipments. From time immemorial, the village has constituted a basic unit in India. According to the 2011 census, there were 6,40,867 villages in India. The average population of a village is estimated to be 550. This is the general picture, although there are variations. In Kerala for example, houses are not in clusters. It has been stated that the villages in India are like "little republics having nearly everything they want within themselves; and almost independent of foreign relations; they seem to last where nothing else lasts". The survival of the villages and in fact Indian culture, during periods of foreign dependence, has been due to the continuity of village organization. Castes, religion, rituals, kinship, marriages and economy are some of the important aspects of the Indian villages. (3) *The Towns and Cities :* From a sociological point of view, a city or town may be defined as a relatively large, dense and permanent settlement of socially heterogeneous individuals. The community is subdivided into smaller groups on the basis of wealth and social class. Because of their size, primary contact among all its inhabitants is difficult. The 2011 census enumerated 7,935 towns and cities in India. When the population exceeds 100,000 it is called a city; on this basis, there were only 107 cities in India at the time of 1961 census. (4) *The State :* The state is an ecological social group based on territory. It is more stabilized and formalized. It is heterogeneous in nature. The Indian Union is a large State.

5. GOVERNMENT AND POLITICAL ORGANIZATION

Some form of government is detectable even among primitive societies. Government is an association of which law is the institutional activity. There is no society which lacks government. It is the supreme agent authorized to regulate the balanced social life in the interests of the public. To understand the organization of medical services in any country, it is essential to know its social and administrative organization.

The various types of government in different countries of the modern world are as follows : (1) *Democracy :* This is government of the people, by the people and for the people. India and USA have this form of government. (2) *Autocracy :* The ruler is absolute in his power, as in Jordan and Ethiopia (3) *Monarchy :* The head of the State is a monarch as found in UK, and Nepal, (4) *Socialistic :* The production and wealth are owned and controlled by the State. Examples are China and Poland. (5) *Oligarchy :* The country is ruled by a family group e.g., Thailand, Cambodia, Saudi Arabia.

In Capitalist countries, medical service is given to the population by various agencies in various ways. State medicine, insurance medicine, charity medicine and private medicine exist side by side. Medicine has developed into a trade – a service that is purchased by the patient and sold by the physician under a competitive system. In socialist countries, medicine, like education, is not a trade; it is a public function of society. All health activities are directed and controlled by central bodies, medical service is free and therefore available to all. It is, in other words, socialized medicine.

THE FAMILY

The family is a primary unit in all societies. It is a group of biologically related individuals living together and eating from a common kitchen. The term family differs from household in that all the members of a *household* may not be blood relations, e.g., servants. As a biological unit, the family members share a pool of genes : as a social unit, they share a common physical and social environment. As a cultural unit, the family reflects the culture of the wider society of which it forms a part and determines the behaviour and attitudes of its members. The family is also an epidemiological unit, and a unit for providing social services as well as comprehensive medical care. The family therefore has engaged the attention of sociologists, anthropologists, demographers, epidemiologists, medical scientists, and in fact all those who are concerned with family welfare.

The word, family, which is used in popular term, has made a good deal of confusion among the professionals. It is used in very many different senses. To avoid confusion, social scientists have used the term : (1) *Family of origin* or the family into which one is born, and (2) *Family of procreation* or the family which one sets up after marriage.

Family life cycle

Families are not constant; they are ever changing. A normal family-cycle is generally conceived as having six phases (Table 1).

TABLE 1

Basic model of nuclear family life cycle

Phases of family life cycle		Events characterizing	
No.	Description	Beginning of phase	End of phase
I.	Formation	Marriage	Birth of 1st child
II.	Extension	Birth of 1st child	Birth of last child
III.	Complete extension	Birth of last child	1st child leaves home
IV.	Contraction	1st child leaves home	Last child leaves home of parents
V.	Completed contraction	Last child has left home of parents	1st spouse dies
VI.	Dissolution	1st spouse dies	Death of survivor (extinction)

Source : *(18)*

Such a model, however, tends to apply only to areas of low mortality and requires amendment in high mortality situations to reflect the early death of children and even the death of the mother before any of the children are old enough to leave home. Moreover, "leaving home" is essentially an American and European phenomenon that has little relevance in many developing countries in Africa and Asia. A number of variations and exceptions, then, to the typical life-cycle such as the early death of children or one spouse, divorce, childlessness, etc., need to be taken into account.

Family cycle and stress

Structure

Each family experiences its own dynamics of formation, growth, maturation, and dissolution. Crises confronted may be divided into those that are transitional in the family life cycle (e.g., birth of first child or loss of spouse) or nontransitional (e.g., acts of war, uprooting, mental disorders, etc.). Family sociologists have studied effects of sudden shifts in economic status, migration, uprooting, disasters, physical change or incapacity of a family member, and impact of crises at various stages of the family life-cycle. It has been suggested that stress and health hazards are likely to increase when environmental changes occur at critical developmental periods such as, adolescence, first pregnancy, menopause, and retirement. The ability to cope in given situation depends, in part, on perception of threat, motivation and readiness to respond creatively, available emotional and social supports, and cultural provisions. Compared with other social organizations, the average family has distinct disadvantages. Its age composition is heavily weighted by dependents and is of uncertain sex distribution. No other institution is so exposed to crises and stress yet so potentially capable of resolving frustration and releasing tension *(19)*.

Childhood

As noted by number of observers, the literature on delinquency, psychiatric conditions, mental disorders, and other childhood disorders has produced considerable knowledge on insecurity, and incompetence, and on the damage done by marital discord, prenatal rejection, and institutional rearing. Much less is known about conditions facilitating normal development or why some children with a variety of unfortunate disadvantages still manage to develop a healthy personality, emotional security and social competence. Concern with childhood mental disorders is especially appropriate in developing countries, where children under 15 years of age account for about 40 per cent of the population compared to about 25 per cent in developed countries. Poverty and low socio-economic status appear to be associated with a greater incidence of mental disorder *(19)*.

Adolescence

While the age of puberty and physical maturation does not vary greatly throughout the world, adolescence as a stage of physiological growth is more closely associated with economic development, social and cultural values, and historical traditions. The age at which this development phase occurs may differ between countries within the same geographic region. Few nations really have adequate information on drug abuse, the sequelae of inappropriate sex behaviour, alcoholism, and related difficulties.

Parenthood

In modern society, preparation for parenthood is a complex and changing task. Parental skills do not necessarily come easily and naturally. In part, parents behave the way they do because of their own childhood experiences. Persons reared in unhappy, discordant, or disrupted homes are more likely to marry in their teens, to have out–of–wedlock children and to experience unhappy marriages and difficulties in child rearing *(19)*. Such links between childhood experiences and subsequent parental behaviour are not inevitable. There appears to be considerable capacity for modification of parental behaviour, as shown most frequently in the differential treatment of the second child. The stereotype roles of parenthood are losing their validity amidst cultural changes. There appears to be greater social sensitivity too, for example, parent–child communication when one parent dies, the death of an infant in the family, early childhood intervention, single parent families headed by women, and the relationship of family circumstances to wider social environment.

Ageing

India's population ages 60 and older is projected to increase dramatically from 8 per cent in 2010 to 19 per cent in 2050. By mid-century, this age group is expected to encompass 323 million people, a number greater than the total U.S. population in 2012. This profound shift in the share of older Indians–taking place in the context of changing family relationships and severely limited old-age income support–brings with it a variety of social, economic, and health care policy challenges. The ageing of India's population will lead to increases in the prevalence of chronic conditions such as diabetes and hypertension. By one measure, nearly one-half (45 per cent) of India's disease burden is projected to be borne by older adults in 2030, when the population age groups with high levels of chronic conditions will represent a much greater share of the total population *(19A)*. Similar increase in the population of older persons can be anticipated in other regions of the world.

Types of families

Family units throughout the world are not the same. Industrialization, urbanization, democratization and acculturation have affected the family structure and life. Social scientists have described three main types of families.

1. NUCLEAR FAMILY

The *nuclear* or *elementary* family is universal in all human societies. It consists of the married couple and their children while they are still regarded as dependents. They tend to occupy the same dwelling space. In the nuclear family, the

husband usually plays a dominant role in the household. The absence of grandparents, uncles, aunts and near relatives places a greater burden on the nuclear family in terms of responsibilities for child rearing. The husband-wife relationship is likely to be more intimate in the nuclear family than in the joint family. The term "new families" has come recently into vogue; it is applied to those under 10 years duration and consists of parents and children. The concept is important in view of studies relating to family planning *(20)*.

2. JOINT FAMILY

The *joint* or *extended* family is a kind of family grouping which is common in India, Africa, the Far East and the Middle East. It is more common in agricultural areas than in urban areas. The orthodox Hindu family in India is a joint family. As a price for education, urbanization and industrialization, we are losing the joint family system.

The main characteristics of a typical joint family are *(21)* : (1) It consists of a number of married couples and their children who live together in the same household. All the men are related by blood and the women of the household are their wives, unmarried girls and widows of the family kinsmen. (2) All the property is held in common. There is a common family purse to which all the family income goes and from which all the expenditures are met. (3) All the authority is vested in the senior male member of the family. He is the most dominant member and controls the internal and external affairs of the family. The senior female member by virtue of her being the wife of the male head shares his power so far as the women of the family are concerned. (4) The familial relations enjoy primacy over marital relations. Early and arranged marriage is advocated to ward off any threat from marital relationship.

The merit of the joint family system is that it is based on the motto : "union is strength". There is a sharing of responsibilities practically in all matters which gives the family a greater economic and social security. It provides economic and social security to the old, the helpless and the unemployed. It pools its income to help the young through school, to pay for a marriage or begin a commercial venture. It offers many of the services and advantages which an industrial society offers through more impersonal governmental, educational and financial agencies.

3 THREE GENERATION FAMILY

The three generation family is confused with the joint family. It is fairly common in the west. This tends to be a household where there are representatives of three generations. It occurs usually when young couples are unable to find separate housing accommodation and continue to live with their parents and have their own children. Thus, representatives of three generations related to each other by direct descent live together.

Functions of the family

The functions of the family have been stated as follows : (1) *Residence :* One of the major social functions of the family is to provide a clean and decent home to its members. In the west when a man marries he separates from his parents and sets up his own home. In India, it is the prevalent custom among the Hindus that the married couple should reside in the house of the parent. There are two types of residence – patrilocal and matrilocal. In the case of patrilocal residence, the wife goes to the house of the husband; in the matrilocal residence, the husband goes to live in the house of the wife. (2) *Division of labour :* In primitive societies, the roles and functions performed by people in family groups were rather well defined. The male had the sole duty to earn a living and support the family. The female had the total responsibility for the day to day care of children and running of the household. In industrialized and urbanized communities, there is less marked distinction between the functions of men and women. On the other hand, there has been an increasing coming together and sharing of responsibilities by men and women. The young wife in India now-a-days brings to marriage not only a dowry but a professional or semi-professional education and she seeks a professional career. This is another new feature of the modern family. The steady enlargement of the freedom of wives, and even children in the family, is leading towards a "communal family" where all its members play a part in its management. (3) *Reproduction and bringing up of children :* This is a very important function of a family. The mother takes absolute care of the infant and children up to a certain age. The father provides for education and teaches the child the social traditions and customs. (4) *Socialization :* The family is a bridge between generations and between father and sons. It is the transfer point of civilization. The cultural patterns relating to eating, cleanliness, dress, speech, language, behaviour, and attitudes are all transmitted through the family. (5) *Economic functions :* The family implies economic partnership for the family and the progeny. The inheritance of the property and the ownership and/or control of certain kinds of property like the farm, shop or dwelling are controlled by the family. Eventually the property is handed down to the children. (6) *Social care :* The family provides social care by (a) giving status in a society to its members, i.e., use of family names where it occurs. Some have a strong feeling of kinship that they belong to a particular family – it denotes some kind of association with someone distinguished in history in that particular society, (b) protecting its members from insult, defamation, etc., (c) regulating marital activities of its members, (d) regulating to a certain extent political, religious and general social activities, (e) regulating sex relations through incest-taboos.

FAMILY IN HEALTH AND DISEASE

Anyone who is concerned with medical practice or community health activities will come to know that family is ultimately the unit with which one has to deal. The family is a group of biologically related individuals. It is a pretty universal picture in all societies. Family performs many functions. There are certain functions which are relevant to health and health behaviour, and are important from the medical-sociology point of view.

1. CHILD REARING

One of the important functions of the family with which medical and community health workers are concerned, is the physical care of the dependent young in order that they may survive to adulthood and perpetuate the family. The way in which child rearing is undertaken differs enormously from society to society, and from time to time, depending upon factors such as capital resources, level of knowledge, state of technology and system of values. It is important to note that patterns of child care (e.g., feeding, nutrition, hygiene, sleep, clothing, discipline, habit training) are passed on from one generation to another. In many societies, child care is socially determined by tradition. The

ideas people have about nutrition, exercise, sleep and clothing have a large social component which varies from society to society and from time to time. For instance child care is more permissive in the East starting with the "on demand" schedule at mother's breast : in the West, child care is more rigid and confined to a set of rules. When the community health worker seeks to improve the health of the child, he meets several obstacles. These obstacles are the traditional ways which are supported by appeals to religion and other sanctions. For example, the problem of overcrowding is not merely a question of room space, but in many instances a question of sleeping habits, a part of a pattern of social customs which foster better relations between groups. Once again, variations between societies may be complex and difficult to change.

2. *SOCIALIZATION*

The second responsibility of the family is to socialize the "stream of new-born barbarians." It refers to the process whereby individuals develop qualities essential for functioning effectively in the society in which they live. It is a latent function. By socialization is meant teaching the young the values of society and transmitting information, culture, beliefs, general codes of conduct, by example and precept, in order to make them fit for membership in the wider society of which the family is a part. Organizations such as schools and religious places perform cultural functions for the introduction of the young into adult society. The young are persuaded, given punishments, rewards for good behaviour – all these vary from time to time. In some societies, the young are given freedom to develop into individuals who are freely able to take initiatives.

3. *PERSONALITY FORMATION*

This is even a more latent function. It is an area in which sociology comes closest to psychology. The capacity of an individual to withstand stress and strain and the way in which he interacts with other people is to a large extent determined by his early experience in the family, mainly with the father, mother and siblings who provide the earliest and most immediate component of the child's external environment. The family acts as a "placenta" excluding various influences, modifying others that pass through it and contributes some of its own in laying the foundation of physical, mental and social health of the child.

4. *CARE OF DEPENDANT ADULTS*

(a) *Care of the sick and injured :* In all forms of society, adults may become dependant either through injury, illness or because of basic biological limitation for performing functions normally expected by adults. The attitude of the society in regard to individuals who need care and attention varies considerably. In some societies, there is a great deal of harshness in respect of those who are sufferers. Such individuals are excluded from the full range of benefits. The kind of illness is also of great importance in determining the attitudes of society where the illness arouses fear (e.g., leprosy). However, the family is charged with the responsibility of care of such individuals. The family is expected to provide the front-line care, particularly the mother. Much depends upon her understanding of illness and the extent she believes herself capable of providing nursing care. Studies have shown that the family does more nursing than the hospital, even in highly developed countries *(20)*.

(b) *Care of women during pregnancy and child birth :* From the public health point of view, care of women during periods of recognized dependency, i.e., pregnancy and childbirth is an important function of the family. The attitude of society to pregnancy and child-bearing may have an important bearing on the infant deaths, premature and stillbirths, maternal morbidity and mortality. In many societies today, women are given financial help, maternity leave facilities, diet and nutritional supplements and decreased responsibilities during pregnancy and puerperium.

(c) *Care of the aged and handicapped :* An area of increasing importance, particularly in the western societies, is the care of the aged and infirm. The increased number of such people have created new problems in terms of long term care and specialist facilities. Without the support of the family, no amount of medical care can succeed. In India, the joint family provides for such support.

5. *STABILIZATION OF ADULT PERSONALITY*

The family is like a "shock absorber" to the stress and strains of life. The stress could be injury, illness, births, deaths, tension, emotional upsets, worry, anxiety, economic insecurity and the like. In such situations, the family provides an opportunity, both for adults and children, for release of tension so that the individual can attain mental equilibrium and strive to maintain a stable relationship with other people. The stress of modern living has increased the importance of mental illness as a public health problem. Alcoholism and narcotic addiction are also a reflection of this trend. Certain chronic illnesses such as peptic ulcer, colitis, high blood pressure, rheumatism, skin diseases are accepted as "stress diseases" having a prominent emotional element in their development. Thus the family has an important function in the stabilization of the personality of both adults and children, and in meeting their emotional needs.

6. *FAMILIAL SUSCEPTIBILITY TO DISEASE*

The members of a family share a pool of genes and a common environment and together, these decide their susceptibility to disease *(22)*. Certain diseases such as haemophilia, colour blindness, diabetes and mental illness are known to run through families. Schizophrenia, psychoneurosis and some forms of mental deficiency are also known to have a familial incidence. The family is often the playground also for such communicable diseases as tuberculosis, common cold, scabies, diphtheria, measles, mumps, rubella, chickenpox, dysentery, diarrhoea, and enteric fever. These diseases are known to spread rapidly in families because of the common environment which the family members share.

It is generally agreed that the incidence of congenital malformation is higher among offsprings of consanguineous as compared with non-consanguineous marriages.

7. *BROKEN FAMILY*

A broken family is one where the parents have separated, or where death has occurred of one or both the parents. Dr. John Bowlby brought out clearly the concept of "mental deprivation" as one of the most dangerous pathogenic factors in child development *(23)*. Separation of the child from its father (paternal separation) and separation of the child from both of its parents (dual–parental separation) are

important factors in child development. Children who are victims of broken families early in their childhood have been found sometimes to display in later years psychopathic behaviour, immature personality and even retardation of growth, speech and intellect *(22)*. Children from these families may drift away to prostitution, crime and vagrancy.

8. *PROBLEM FAMILIES*

Problem families are those which lag behind the rest of the community. In these families, the standards of life are generally far below the accepted minimum and parents are unable to meet the physical and emotional needs of their children. The home life is utterly unsatisfactory. The underlying factors in most problem families are usually those of personality and of relationship, backwardness, poverty, illness, mental and emotional instability, character defects and marital disharmony. These families are recognized as problems in social pathology *(24)*. Children who are reared in such an environment are victims of prostitution, crime and vagrancy. Problem families may be found in all social classes but are more common in the lower social classes. The health visitor, the health inspector, the midwife, the social worker, the medical officer of health, all can render useful service in rehabilitating such families in a community.

The family therefore plays an important part both in health and disease – in the prevention and treatment of individual illness, in the care of children and dependent adults, and in the stabilization of the personality of both adults and children. In most societies the family is the fulcrum of health services *(25)*. Medical schools are developing teaching programmes in family medicine, because, as Florence Nightingale had said : "the secret of national health lies in the homes of the people".

CULTURAL FACTORS IN HEALTH AND DISEASE

All people, whether rural or urban, have their own beliefs and practices concerning health and disease. It is now widely recognized that cultural factors are deeply involved in all the affairs of man, including health and sickness. Not all customs and beliefs are bad. Some are based on centuries of trial and error and have positive values, while others may be useless or positively harmful. Some of these cultural factors, hallowed by centuries of practice, have stood in the way of implementing health programmes. Where a change of behaviour was involved, the resistance of the people was maximum in accepting new programmes. Information about these factors, i.e., customs, cultural mores, habits, beliefs and superstitions is still woefully lacking. A brief account of the cultural factors relating to health and sickness, as observed in India, is given below :

1. Concept of aetiology and cure

Broadly, the causes of disease, as understood by the majority of rural people, fall into two groups : (a) supernatural and (b) physical.

(a) SUPERNATURAL CAUSES : (1) *Wrath of gods and goddesses :* There are good many people (even among the educated) who believe that certain diseases are due to the wrath of some god or goddess. Chickenpox is an outstanding example, it is known as *Chhoti Mata*. Where the disease is considered to be due to the wrath of gods and goddesses, administration of drugs is considered harmful. Cases are not notified and *pujas* are made to appease the gods (2) *Breach of taboo :* Breach of taboos is believed by some people to be responsible for certain diseases. Venereal diseases are believed by some to be due to illicit sexual intercourse with a woman of low caste, or a woman during menstruation. (3) *Past sins :* Diseases such as leprosy and tuberculosis are believed by some to be due to their past sins. (4) *Evil eye :* A widely held belief throughout the country is the effect of "evil eyes". Children are considered to be most susceptible to the effect of evil eyes. In order to ward off the effects of the evil eye, charms and amulets are prescribed and incantations recited by the exorcist. (5) *Spirit or ghost intrusion :* Some diseases such as hysteria and epilepsy are regarded as due to a spirit or ghost intrusion into the body. The services of an exorcist are sought to drive away the evil spirit or ghost.

(b) PHYSICAL CAUSES : Physical causes are also considered to be responsible for certain diseases. Among these are : (1) *The effects of weather :* Exposure to heat during summer is responsible for an attack of *loo* (heat stroke). The folk remedies consist of application of oil and ghee on the soles of feet and administration of *mango-phool* (prepared by keeping unripe mangoes under hot ashes for a few minutes, and extracting the pulp in cold water) with a pinch of salt. (2) *Water :* Impure water is associated with disease. (3) *Impure blood :* Skin diseases, viz. boils and scabies are considered to be due to impure blood. Eating neem leaves and flowers is considered to purify blood.

2. Environmental sanitation

(a) DISPOSAL OF HUMAN EXCRETA : Large percentage of people in rural areas use open fields for defecation. This practice is time-honoured and is considered harmless. The average Indian villager is averse to the idea of latrines. He considers that latrines are meant for city dwellers, where there are no fields for defecation. He is ignorant that faeces is infectious and pollutes water and soil and promotes fly breeding. Thus the problem of excreta disposal is bound up with numerous beliefs and habits based on ignorance. (b) DISPOSAL OF WASTES : The average villager is not aware that mosquitoes breed in collections of waste water. It is permitted to flow into the streets. The solid waste (refuse) is invariably thrown in front of the houses where it is permitted to accumulate and decompose. Periodically it is removed to the fields and used as manure. The animal dung (cow dung) is allowed to accumulate. It is used sometimes as manure and often times pressed into cakes, sun-dried and used as fuel. (c) WATER SUPPLY : The well occupies a pivotal place in the cultural environment of villages. It is also a common meeting place of men and women of the village, when they go to draw their supply of water. It is a place where people bathe and wash their clothes. It is a place where animals are washed and given a drink. These cultural practices lead to the pollution of well water. Tanks and ponds are used for washing, bathing, ablution and sometimes even as a source of drinking water. Some rivers are considered "holy". People go on pilgrimage to these rivers to have a dip. They not only have a dip but drink the raw water which they consider sacred. Samples of 'holy water' are bottled and carried over long distances for distribution among friends and relatives. Epidemics of cholera and gastroenteritis have been due to these cultural practices. Step–wells are associated with guineaworm disease. (d) HOUSING : Rural houses are practically the same all over the country. They are usually *katcha* and

damp, ill-lighted and ill-ventilated. For reasons of security, no windows are provided, and if at all one is provided, it is merely a small hole. Absence of a separate kitchen, latrine, bathroom and drainage are characteristic features of an average rural house. Animal keeping is very common in villages. Infrequently, human beings and animals live under one roof. Houses are generally kept clean inside, regularly white-washed or plastered with mud and cowdung.

3. Food habits

Food habits have deep psychological roots and are associated with love, affection, warmth, self-image and social prestige. The diet of the people is influenced by local conditions (e.g., soil, climate) religious customs and beliefs. Vegetarianism is given a place of honour in Hindu society. Even among vegetarians, the pattern of eating is not the same; some do not take onions and garlic on religious grounds. Muslims abhor pork, and Hindus beef – these food habits have a religious sanction from early days. The concept of hot and cold food is widely prevalent in the country. Foods such as meat, fish, eggs, and jaggery are considered to generate heat in the body; foods such as curd, milk, vegetables and lemon are considered to cool the body. These concepts are encountered by the modern physician when treating disease. Adulteration of milk is a common practice. Although the motive is economic gain, a deep-rooted belief is also responsible for this practice, i.e., if pure milk is boiled, the milk secretion of the donor animal may dry up. Muslims observe fasts during Ramzan and Hindus on several occasions. These fasts are considered important adjuncts to religion. Drinks and drugs are among the food habits of the people. Alcoholic drinks are tabooed by Muslims and high-caste *Hindus. Ganja, bhang* and *charas* are frequently consumed by *sadhus;* these habits are now spreading into the general population, especially the younger generation. Eating and drinking from common utensils is considered as a sign of brotherhood among Muslims. Hindu women often take food left over by their husband. In some societies, men eat first and women last and poorly. Some people do not eat unless they have taken a bath. Thus food is a subject of widespread customs, habits and beliefs, which vary from country to country, and from one region to another.

4. Mother and child health

Mother and child health is surrounded by a wide range of customs and beliefs all over the world. Marriage is universal in Indian society, and the family is incomplete without the birth of a male child. This has obvious implications in the context of the country's population problem and male : female ratio. The various customs in the field of MCH have been classified as good, bad, unimportant and uncertain. (1) *Good :* Customs such as prolonged breast-feeding, oilbath, massage and exposure to sun are good customs. (2) *Bad :* These vary from society to society. For example, some foods (e.g., eggs, meat, fish, milk, leafy vegetables) are forbidden during pregnancy in some parts of the country. In rural areas, most deliveries are conducted by the traditional untrained dai or birth attendant whose methods of conducting delivery are far from safe. The villagers have great faith in her. In some parts of the country, the child is not put to the breast during the first 3 days of birth because of the belief that colostrum might be harmful; instead the child is put on water, and sugar solution. Branding of the skin, administration of opium and drastic purgatives are all bad customs. The net result of these customs is high infant mortality and morbidity. (3) *Unimportant :* There are certain customs which are unimportant, viz, punching the ear and nose, application of oil or a paste of turmeric on the anterior fontanelle. (4) *Uncertain :* Sometimes, it may be difficult to say whether certain customs are good or bad. The practice of applying *kajal* or black soot mixed with oil to the eye-lids partly for beautification and partly for warding off the effects of "evil eye". Often-times, this custom has been blamed for transmitting trachoma and other eye infections. A knowledge of the local customs and beliefs is therefore very important for improving the health status of mothers and children. This is part of social paediatrics.

5. Personal hygiene

Indians have an immense sense of personal cleanliness, much of which is closely interwoven with ideas of ritual purification. Rituals are "a set or series of acts, usually involving religion or magic, with the sequence established by tradition." (1) *Oral hygiene :* Indians are very particular about oral hygiene. Many people in the countryside use twigs of neem tree as a toothbrush; some use ashes; and some charcoal. The educated and those who have come in contact with urban life use toothbrushes. Eating pan leaves smeared with lime with or without tobacco is a common social custom. (2) *Bathing :* Bathing naked is a taboo. Apart from regular baths of which Indians are very fond, there are baths fixed on special occasions. The women after menstruation must have a purifying bath; after childbirth, there may be two or three ceremonial baths, the time for which is fixed upon the advice of the priest. The practice of an oil bath is a good Indian custom. Womenfolk in the countryside use a paste consisting of gram, mustard oil and turmeric powder and rub it on the body before a bath. Thus, bathing is a ritual in India. (3) *Shaving :* This is done by the traditional barber (nai) in the countryside. He does not sterilize the instruments used, as he does not have any idea of micro-organisms. (4) *Smoking :* Smoking hubble-bubble is a social custom in some parts of the country. It can spread tuberculosis. Smoking with the burning end of the cigar in the mouth, which is a common custom among villagers in Andhra Pradesh, is associated with oral cancer. The 1971 Report of the Royal College of Physicians of London *(26)* on the effects of smoking and health provides useful summary of information on the diseases now known to be associated with smoking – cancer of the lung, chronic bronchitis and emphysema, coronary artery occlusion, angina pectoris, cancers of the mouth, pharynx, larynx, and oesophagus, cancer of the bladder and pulmonary tuberculosis. Among patients with peptic ulcer those who smoke have a higher death rate than those who do not. A mother's smoking during pregnancy may retard the growth of the foetus. (5) *Purdah :* Muslims and some high caste Hindu women observe *purdah*. The incidence of tuberculosis is reported to be high amongst those who observe *purdah,* which also deprives them of the beneficial effect of the sunrays. (6) *Sleep :* Many people in the villages sleep on the ground for reasons of poverty, and they are exposed to insect bites. (7) *Wearing shoes :* The transmission of hook-worm disease is associated with bare feet. Many villagers in South India do not wear shoes. (8) *Circumcision :* This is a prevalent custom among Muslims, which has a religious sanction.

6 Sex and marriage

Sexual customs vary among different social, religious and ethnic groups. For certain religious groups menstruation is a

time of uncleanness when women are forbidden to pray or have intercourse; orthodox Jews are forbidden to have intercourse for seven days after the menstruation ceases *(27)*. These customs have an important bearing in family planning.

Marriage is a sacred institution. It is the usual social custom in India to perform marriages early. It is considered a sound and desirable practice, because late marriages may create problems in adjustment, especially in joint family systems. Because of the universality of marriage in India problems of unmarried mothers and of illegitimate births are less than in the western countries. The mean age at marriage in India is 24 years in the case of boys and 21 years in the case of girls. There are differences in marriage–age by caste, females of the depressed classes have lower mean age at marriage. Child marriages are fortunately disappearing. Monogamy is the most universal form of marriage. Polygamy (marriage of one man with several woman) prevails in certain communities. Polyandry (marriage of several men with one women) is found among the Todas of Nilgiri hills, the inhabitants of Jaunsar Bawar in Uttar Pradesh and the Nayars in Malabar coast. The high rate of venereal diseases in Himachal Pradesh is attributed to the local marriage customs.

THE COMMUNITY

"No man is an island". From the time of birth until death, all normal human beings are part of a group, the family or community. The characteristics of a community are :

(1) the community is a contiguous geographic area

(2) it is composed of people living together

(3) people cooperate to satisfy their basic needs

(4) there are common organizations, e.g., markets, schools, stores, banks, hospitals.

In other words, a community is a network of human relationships. It is a major functioning unit of **society.** It is the place where our home is located; children are educated; sick people are treated and individual basic needs and desires are met.

Structure of society

(1) *Caste:* Indian society is mostly based on caste system. There are further sub-divisions into sub-castes. Each caste is governed by certain rules and regulations relating to food, drink, marriage, social contact and rituals. Castes follow a definite occupation. In urban areas, the caste system is less rigid. The Indian caste system is supported by religion.

(2) *Income :* On the basis of income, people have been grouped into classes – upper, middle and lower classes. People in the upper class enjoy better standards of life.

(3) *Occupation :* Occupation has also been adopted for classifying people. In India, there is no satisfactory occupational class system.

Rural societies

India is a land of villages. There are 6,40,867 villages. Out of every 1,000 population, 690 live in villages (as per 2011 census). The average population of an Indian village is about 550 or 100 families. The villages are self sufficient units for most of the routine requirements of its people. The rural people depend primarily upon agriculture. Caste, religion, ritual, kinship, marriage, and economy are some of the important aspects of Indian village society.

Urban societies

Towns and cities comprise the urban society. They are relatively large, dense and permanent settlements of people. According to the 2011 Census, there were 7,935 towns and cities in India. It has been said that civilization means the city and the city means civilization. The city represents the way of living of man in modern age. The occupational pattern of the urban people is different. They depend less on agriculture. There is an occupational diversity. The social life is impersonal and less intimate. Cities are the melting pots of races, people and cultures. Traditional patterns of belief and behaviour tend to be broken down. New ideas and patterns of behaviour emerge which further spread to villages.

Social mobility

Indian society is rigidly based on caste system. There is little social mobility, i.e., people do not change their caste or religion. In other words, Indian society is a "closed-class" system. There are societies known as the "open class societies" where movement of the social ladder is unrestricted, on the basis of achievement or gaining wealth. Open class societies are therefore more progressive where people according to their ability can go up the social ladder. In closed-class systems, it is difficult to make reforms without meeting resistance of the people.

SOCIAL CLASS

People in a community are differentiated by certain characteristics which they bear. These may be personal characteristics such as age, sex, marital status, place of birth and citizenship; *economic* characteristics such as occupation, type of activity; *cultural* characteristics such as language, religion and caste; and *educational* characteristics such as literacy and level of education. In Indian communities, especially in rural areas, caste is an important basis of social differentiation. The caste groups are hierarchial and carry different degrees of social prestige, which is correlated with a host of other socio-cultural factors.

Although defined differently in different societies and by different investigators, social class is closely bound up with economic status, level of education, way of life, attitudes and expectations, and exposure to different types and degree of stress. More important, it seems to have a direct bearing on the external resources and internal mechanisms available to individuals in attempting to deal with health problems *(1)*.

Social scientists have used *occupation* widely as a means of determining the level of social standing of an individual in a community, because occupation has an enormous importance in all societies for understanding human behaviour. In urbanized and industrialized communities, where there is a substantial division of labour, occupation is a major determinant of : (1) *Economic rewards :* That is income and wealth which can promote or achieve health easier. (2) *Extent of authority :* That is, occupation is an important determinant of authority which the individual has over other people; it spills over into his life itself, his pleasures and other activities, through control of purchasing power. Those who receive higher economic rewards tend to be vested with greater authority. For example, a person who is a judge exercises authority not only in the courts but commands respect from other people. His position enables him to acquire authority. (3) *Extent of obligations :* The

extent of obligations demanded of individuals by the rest of the community will be determined by the occupation he holds. One who holds a high place occupationally has greater obligations. (4) *Degree of status :* Closely allied with the occupational role is the degree of status and standing of the individual in the community. For example, medical practitioners in India enjoy a higher status in society than others. The occupation itself will give the person status irrespective of personal characters, age, and experience. (5) *Values and life styles :* The occupation of an individual very largely will determine many of the values the individual has, the things he feels worth pursuing, his life goals, his life style; his pleasures, friendships and relationships with others. Therefore, occupation is widely used as a measure of social differentiation. In technically advanced countries, occupation tends to range in a hierarchy – those who have high economic rewards have a higher level of prestige than those who are placed low in the social hierarchy.

Occupational classification

There are several occupational classifications, but none is satisfactory. Some sociologists have graded occupations in a hierarchy and then divided them into broader "prestige" categories. They have found a high degree of similarity between social grading of occupations in India and England. The oldest such classification that is epidemiologically useful is the Registrar General's occupational classification in England and Wales. All occupations are classified into five groups. Social class III is further subdivided into non-manual and manual groups :

I	Professional occupation
II	Intermediate occupation
III N	Non-manual skilled occupation
III M	Manual skilled occupation
IV	Partly skilled occupation
V	Unskilled occupation.

Limitations of occupational classification

Occupation is a useful measure of social differentiation particularly in communities highly industrialised and urbanized. We all tend to compare, for example, different social classes in relation to mortality and morbidity. But, there are certain limitations in using social classification based on occupations alone. These may be stated as follows : (1) *Heterogeneous grouping :* Each social class is a heterogeneous grouping of a wide variety of occupations. There is an assumption that these occupations are related to each other, which in fact, is not so. The people in each social class differ not only occupationally, but also in respect of educational status and family background. We have to recognize that categorization into social classes is merely one of convenience. (2) *Occupational mobility :* People sometimes change their occupations. This occupational mobility can lead to discrepancies in using social classes correctly over a period of time. Social classes themselves are subject to change. Certain occupations are promoted in social hierarchy and some demoted. For example, the Registrar General of England promoted university teachers from class II to class I and demoted company directors from class I to class II during the decade 1951–1961. Such changes in social classification may invalidate their comparative use over time. (3) *Women :* There are differences in classifying women alongside men. Some occupations are exclusively occupied by males and some by females. There is also sometimes ambiguity in the nomenclature of occupations occupied by men and women. If a man describes himself as a secretary, it is a highly paid occupation; if a woman describes herself as a secretary, it is usually a position in an office in a low capacity. Inspite of these limitations, social classification by occupation is an effective tool for examining various kinds of data related to people. Much research in social medicine in recent years has centred round social class and disease prevalence.

Other measures of social differentiation

There are other measures of social differentiation which may be of greater use or significance than occupation. These are : (1) *Education* : It measures the inculcation of values, knowledge and achievements of the individual. (2) *Income :* Another important way of distinguishing people is by the amount of income or wealth. Here again, there are difficulties because people have great reluctance to talk about their income truthfully. (3) *Purchasing power :* This may be of more important value than occupation in classifying people. (4) *Religion :* This is another important attribute of the individual which may have tremendous bearing on the health of the people. An examination of infant mortality among Christians, Hindus and Muslims in India revealed a low rate for Christians, a high rate for Hindus and highest for Muslims. These differences are attributed to religion which has a bearing on the socio-cultural patterns of living involving age-old habits, customs, and traditions affecting cleanliness, eating, clothing, child care and almost every detail of daily living. (5) *Rural and urban :* There are differences in the health and sickness status of people living in rural and urban areas. Rural and urban people differ in their life-style, opinions and values, which have a bearing on the health and sickness status. To sum up, it may be stated that each of these measures which may be employed for social differentiation have a "snag" too and therefore each must be examined critically and used with discrimination depending upon the subject matter of the enquiry.

Socio-economic status scale

Socio-economic status has been defined as the position that an individual or family occupies with reference to the prevailing average standards of cultural and material possessions, income, and participation in group activity of the community. The social status may be inherited, but in modern society, it is achieved on the basis of occupation, income, type of housing and neighbourhood, membership of certain associations and organizations, material possessions, etc.

There have been many attempts at developing scales for measuring socio-economic status. Hollingshed in USA employed three variables, viz education, occupation and residential address for measuring socio-economic status. Kuppuswamy *(28)* – in India prepared a scale based on education, occupation and income which are the three major variables contributing to socio-economic status in urban areas. Similar scales have also been prepared by Pareek and Kulshrestha *(29)* for use in rural and urban areas. Kuppuswamy's scale is fairly widely known. The modified version of the Kuppuswamy's socio-eonomic status scale for the year 2007 is given in Table 2.The income scale has been recalculated using All India Average Consumer Price Index for the industrial workers for the year 2001 as the new base year *(30, 31)*.

TABLE 2

Kuppuswamy's socio-economic status scale

(A) Education	Score
1. Profession or Honours	7
2. Graduate or postgraduate	6
3. Intermediate or post high school diploma	5
4. High school certificate	4
5. Middle school certificate	3
6. Primary school certificate	2
7. Illiterate	1

(B) Occupation	Score
1. Profession	10
2. Semi-profession	6
3. Clerical, shop-owner, farmer	5
4. Skilled worker	4
5. Semi-skilled worker	3
6. Unskilled worker	2
7. Unemployed	1

(C) Family income per month (in Rs.) original	Score	Modified for 1998	Modified for 2007
1. = 2000	12	= 13,500	= 19,575
2. 1000–1999	10	6750–13499	9788-19,574
3. 750–999	6	5050–6749	7323–9,787
4. 500–749	4	3375–5049	4894–7,322
5. 300–499	3	2025–3374	2936–4,893
6. 101–299	2	676–2024	980–2,935
7. < 100	1	< 675	< 979

Total score	Socio-economic class
26–29	Upper (I)
16–25	Upper-middle (II)
11–15 middle	Lower-middle (III)
5–10 lower	Upper-lower (IV)
<5	Lower (V)

Wealth Index *(32)*

One of the background characteristics used in the National Family Health Survey-III was an index of the economic status of households called the wealth index. The wealth index has been developed and tested in a large number of countries in relation to inequalities in household income, use of health services, and health outcomes. It is an indicator of the level of wealth that is consistent with expenditure and income measures. The economic index was constructed using the following household asset data and housing characteristics : household electrification; type of windows; drinking water source; type of toilet facility; type of flooring; material of exterior walls; type of roofing; cooking fuel; house ownership; number of household members per sleeping room; ownership of a bank or post-office account; and ownership of a mattress, a pressure cooker, a chair, a cot/bed, a table, an electric fan, a radio/transistor, a black and white television, a colour television, a sewing machine, a mobile telephone, any other telephone, a computer, a refrigerator, a watch or clock, a bicycle, a motorcycle or scooter, an animal-drawn cart, a car, a water pump, a thresher, and a tractor.

Each household asset is assigned a weight (factor score) generated through principal components analysis, and the resulting asset scores are standardized in relation to a normal distribution with a mean of zero and standard deviation of one. Each household is then assigned a score for each asset, and the scores were summed for each household; individuals are ranked according to the score of the household in which they reside. The sample is then divided into quintiles i.e., five groups with an equal number of individuals in each. In National Family Health Survey-III, one wealth index has been developed for the whole sample and for the country as a whole. Thus, at the national level, 20 per cent of the household population is in each wealth quintile although this is not necessarily true at the state level. Table 3 shows the wealth quintiles in India according to residence as urban and rural areas and in major states *(32)*.

As shown in Table 3 forty-eight per cent of the population in urban areas is in the highest wealth quintile; in contrast only 7 per cent of the rural population is in the highest wealth quintile. The distribution of the population across wealth quintiles shows large variations across states, with Delhi (70 per cent) and Goa (55 per cent) having over one-half of their populations in the highest quintile and Chhattisgarh, Orissa, Bihar, and Tripura, having only about one-tenth or less of their populations in the highest quintile. In Jharkhand, half of the population falls into the lowest wealth quintile. By contrast, in about half of the states, less than 10 per cent of households are in the lowest wealth quintile.

TABLE 3

Per cent distribution of the population by wealth quintiles, according to residence and state, India, 2005–06.

	Wealth quintile					
Residence/state	Lowest	Second	Middle	Fourth	Highest	Total
India	20.0	20.0	20.0	20.0	20.0	100.0
Urban	3.0	6.4	13.8	28.9	47.9	100.0

Social class and health

There are a large number of studies linking social class to incidence of disease. Income, occupation and education which are the major components of most measures of social class are also each generally positively correlated with health status. It adds to the conviction that social class affects health. Individuals in the upper social classes have a longer life expectancy, less mortality and a better health and nutritional status than those in the lower classes. Diseases also have been shown to affect people at various social levels differently. For example, coronary heart disease, hypertension, diabetes all have been shown to have a high incidence in social class I and a gradual decline in incidence in the other social classes. Diseases of skin, eye and ears, diarrhoea and dysentery have also shown a higher incidence in the lower classes, which can be ascribed to the poor state of physical environment in which they live. Social class differences in mental illness have also been reported. Infant mortality, general mortality, maternal mortality are all related to social class. To serve as an illustration (Table 4), the National Family Health Survey-III (2005–06) conducted in India shows the glaring differences in infant mortality rate among the households belonging to various wealth index brackets. Infant mortality rate is high (about 70.4 among the lowest wealth index households and is lowest (about 29.2) among the highest wealth index households.

TABLE 4

Infant mortality rate by wealth index in India (2005–06)

Wealth Index	Infant mortality rate per 1000 live births
Lowest	70.4
Second	68.5
Middle	58.3
Fourth	44.0
Highest	29.2

Source : *(32)*

Social class differences have also been observed in the family structure, and utilization of medical and health services. Families in the lower classes are bigger in size, women marry early and bear more children. The upper social classes are characterized by small sized families and fewer children. Individuals in the lower social classes have been found to make less use of the hospital facilities, consult the doctors less often and are less likely to utilize preventive health services such as prenatal and postnatal care, general check-ups and immunization services. Social classification therefore provides an important means of studying health and disease phenomena in communities, and has proved an effective tool.

Factors involved in social class differences in health and disease

It is the first concern of those in preventive medicine and those who provide medical care service to know why there are differences in mortality and morbidity from particular diseases in certain social classes. Many factors may be involved, the following are some : (1) *Physical environment :* Differences in mortality and morbidity may be due to differences in physical environment, e.g., housing, safe water, access to clean air, etc. People in the upper social hierarchy enjoy better physical facilities than those in the lower rungs of society. (2) *Differences in services provided :* There are differences in the availability of services for different social groups. So far as general practitioners are concerned, some areas are relatively undoctored as compared to others. On the whole, it seems the undoctored areas are the areas where a substantial proportion of individuals live. (3) *Material resources :* Differences in material resources, e.g., income, wealth and possession of tools which can promote or help achieve better health also intervene in the occurrence of disease or in the maintenance of health status in different social groups. (4) *Genetic endowment :* People in one social class tend to marry in the same social class. The differences in genetic endowment may also influence one's liability to disease. (5) *Educational status :* The educational level varies in different social classes. The ignorant and the illiterate are likely to have much difficulty in pursuing measures which may conduce to good health. (6) *Attitude to disease :* The attitude of people to health and sickness may vary in different social classes, which may account for differences in distribution of disease in the social classes. There are people who regard that illness is a punishment and there are others who regard that illness is due to natural causes. There are people who diagnose illness themselves and there are others who seek early medical aid. The attitudes of people therefore vary in different social classes. The continued differences which show up in many studies of morbidity and mortality and use of medical services are due to the persistence of substantial differences in social class. There is a great field for exploration of value systems, the significance of illness to families in different classes. The aim of preventive medicine should be to reduce the social class differences in health and disease.

HOSPITAL SOCIOLOGY

Hospitals are among the most complex organizations in modern society. There has been in recent years an examination from a sociology point of view of hospitals, of medical personnel and of the utilization of medical services. The modern hospital is a social universe with a multiplicity of goals, profusion of personnel and an extremely fine division of labour. The care of the patient is a master value even for those whose work seldom brings them into direct contact with sick people. The patient is the hospital's client *(33)*. This complex character of the hospital has fascinated the social scientists as a compelling scene for the study of human behaviour.

Social structure of a hospital

A hospital is not a static organization. It is subject to change in structure and function depending upon the changes which occur in the community. The structure and functions of the hospital have changed considerably to what they were 100 years ago. Historically, the hospital was more nearly a place of refuge for the sick and homeless, than a place for medical treatment. It was a charitable institution where one went to die rather than to be cured *(33)*. In contrast, hospitals today are concerned with active medical treatment, mobilizing all that is latest in medical sciences to produce a cure. In the 19th century, hospitals were occupied by poor and old patients. Hospitals today are occupied by all classes of people. The shift in the type of patients occupying hospitals has led to a new doctor-patient relationship. There is an increasing demand for higher academic qualifications which was not typical of the earlier medical organization of the 19th century. This has led to an increasing complexity of specialization within the medical

profession and no doctor today can provide single-handedly all the skills and facilities needed for treatment.

The other functions performed by hospitals are *teaching* either medical or nursing personnel and *research* designed to increase medical knowledge in which the patient is of secondary importance. The rural and district hospitals concentrate mainly on patient care. Teaching should take precedence over research in teaching hospitals.

The hospital today is a system of increasing complexity – it is a hotel and a school, a laboratory and a stage set for treatment – employing a large number of medical and paramedical personnel unlike the earlier hospitals in which very few professional groups were involved. At heart the hospital is like a federal system with several departments each enjoying considerable autonomy and discretion in its management of work. The great challenge is one of coordination *(33)*. It requires an administrative machinery to run the hospital smoothly and to avoid conflicts between administrative and professional staff, and between professionals. If a sizable portion of a group is dissatisfied, the system will break down.

The democratic ideal has certainly not yet been achieved in medicine. The structure of the wards, semi–private rooms and private rooms in hospitals is an obvious reflection of class lines. The service of the doctor in his private chamber tends to differ from that given in a public clinic not only in the time spent for case examination but in interpersonal attitudes. The public has come to expect hospitals to give tender, loving care to every patient every day *(34)*.

It is said that each hospital has a "personality" of its own – a tempo of work and an emotional atmosphere peculiar to a given hospital, its traditions, its community of staff and patients. The nature of the staff relationships will influence the staff–patient relationships and consequently the outcome of therapy. It is for this reason there are different atmospheres in different hospitals. Some have a good name, others a bad name.

Medical profession

There has been an examination from a sociological point of view of the medical profession. The medical profession, like any other occupational group is distinguished by certain characteristics. There is a professional body which controls the right to practice. The licence to practice is embodied in the legislation, and is given to those who have reached a level of competence that is considered minimum. In India, the Indian Medical Council Act was passed in 1933 to establish uniform standards of medical education in the country. A revision of the Act was made in 1956, which provides, in addition, for the maintenance of the All India Medical Register. The State Medical Councils control the right to practice and certain standards of practice and personal conduct are imposed upon its members. There is great insistence of maintenance of confidentiality, and right to practise medicine is withdrawn if there is professional misconduct. In other words, the State is regulating the relationship between professional men and their clients. Some of the possible conflicts in the medical profession may stem from the rules and regulations to which they are bound. The abolition of private practice, by Government doctors is an example of recent conflict.

Medical care – an Industry ?

The traditional physician was a self-employed small businessmen, with many of the same problems, goals and attitudes as other small businessmen. His practice was "solo–practice" based on "fee-for-service." Significant changes have taken place in the practice of medicine. The development of new diagnostic and therapeutic techniques require not only large capital investment but also skilled team of personnel. A large number of non-medical personnel are also involved in producing medical care. Society is being increasingly asked to subsidize medical education and medical care. There is a rapid development of insurance and other types of pre-payment. Now it is a national policy in many countries to make the best of known medical care available to all who need it regardless of economic status. Medical profession with its knowledge, experience and dedication is leading the way to developing better systems of health care for all. In economics, an industry is defined simply as a collection of individuals and institutions engaged in the use of similar scarce resources to produce similar goods or services. Sociologically speaking, medical care has the features similar to, big industry *(35)*.

Specialization *(36)*

The vast increase of medical knowledge during the 20th century has contributed to specialization in medicine. There are at present no less than 20 recognized specialities and many more sub-specialities. A specialist is defined as one who learns more about less and less. He is concerned with a particular organ or part of the body as opposed to the traditional general practitioner or "family doctor" who is concerned with the "whole person" or even the family.

Specialization has created problems for the traditional doctor–patient relationships. The specialist does not establish close relationship with the patient. As a consultant, he is less likely to maintain a continuing relationship with the patient. It is difficult for him to give the patient the requisite emotional support and understanding that is needed and which is the essence of a good doctor–patient relationship. Besides, specialization has encouraged jurisdictional disputes between one speciality and another and between specialists and generalist.

In short, specialization divides both doctor and patient; places strain on the traditional doctor–patient relationship; contributes to depersonalization. The social role of medicine with the assistance of the humanities and social sciences is forgotten. Over-specialization can lead to a lopsided development of the health services. Sociologists are paying increasing attention to an examination of the medical value system, the forces behind specialization, and selective factors in medical career choices *(36)*.

Doctor–patient relationship

An important area of medical sociology is doctor–patient relationship in which complex social factors are implicated. The patient comes unbidden to a doctor and enters voluntarily into a contract in which he agrees to follow the doctor's advice. By virtue of his technical superiority, knowledge and skill, the doctor exercises an authoritative role and issues "orders" to his patient. Some individuals may not be prepared to invest the doctor with full authority, this may lead to conflict between the doctor and patient.

Besides technical competence, the doctor must know how to communicate with his patient. In fact, a successful doctor is one who knows how well to communicate with his patient. In this regard, three levels of communication have been described *(37)* : (1) *Communication on an emotional plane :* The doctor must give a sympathetic ear to the complaints

made by the patient and his relatives. This is necessary to establish a quick rapport. The reason why folk medicine is successful is because the patient and his relatives feel they can talk more freely to a folk medical practitioner than with the modern physician. The interpersonal relationships between villagers and folk practitioners on one hand, and the villagers and the practitioners of modern medicine on the other hand are considerably different. (2) *Communication on a cultural plane :* Secondly, the doctor should be aware of the general concepts of culture and social organization of the community with which he is dealing. This helps to acquire certain "flexibility" in his dealings with patients. The reason why the indigenous and folk systems of medicine are successful in the rural areas is because they are part of the total way of life of the people : treatment is based mostly on charity, and payment to the physician may be in kind, and the medicines are prepared from ordinary plants common to the region. All these are appealing to the common man. Against this background, the western system of medicine is alien to the cultural patterns of the rural folk. To be successful, the modern doctor should couch his scientific advice in terms which fit an already existing cultural pattern. Then there is a great chance that this advice will be followed. For example, in communities where diseases and medicine are classified as *hot* and *cold,* it might be helpful for the doctor not to challenge this belief openly. A mere statement to a patient that the medicine is "hot" and will help to cure a "cold" disease may make for increased confidence. Anthropologists have therefore stressed the importance of understanding the community as a whole, its general cultural patterns and its social and political structure, and the native concepts of health and disease. (3) *Communication on an intellectual plane :* Practitioners of modern medicine come from well-to-do-families. By their education and training, they tend to be sophisticated. This leaves a wide gap between the intellectual level of the practitioners of modern medicine and the illiterate masses. In other words, there is an enormous "social distance" between the two groups. A successful doctor is one who reduces this distance and is able to communicate with his patient freely and wins his confidence. A most important component of doctor-patient communication is *humour.* It is the best icebreaker for the patient frozen by fear and anxiety.

The doctor who is able to communicate with his patient on these three planes is bound to give maximum psychological satisfaction to his patients. The other qualities which mar the reputation of a doctor are his greed for money, differential treatment between the rich and poor and lack of a sympathetic and friendly attitude. The patient can challenge the doctor's professional adequacy if the doctor does not know how to communicate. Patients who do not behave according to the doctor's expectations are often labelled as "un-cooperative."

Doctor–nurse relationship *(38)*

Medicine and nursing have common goals – the preservation and restoration of health. Yet their roles in achieving these objectives are not identical. The primary role of medicine comprises diagnosis and treatment – the "cure" process. In contrast, the primary role of nursing lies in the "care" process – consisting of caring, helping, comforting and guiding.

In the medical–care team, the physician tends to be autocratic and looks upon the nurse primarily as his helper following his orders and carrying out whatever he chooses to delegate. Because of the authoritarian role of the physician, the role of the nurse in guiding, helping and comforting the patient go largely unrealized. This is more so as technology is advancing, the nurse is asked increasingly to take up tasks instrumental to diagnosis and treatment. In effect, many of the patient's psychosocial needs persist, unidentified and unmet.

Currently, leaders in both the professions are exploring new approaches and roles with a view to provide improved patient care *(36).*

The sick role

To be ill is more than a medical condition. The sick person has to behave in certain prescribed ways. He comes unbidden to a hospital. As he strips off his clothing, so he strips off his customary identity in the world. He becomes subject to a time schedule and a pattern of activity not of his own making. He becomes passive for most part. He may even become child–like *(33).* Four aspects of the sick role have been described : (1) the sick person is exempted from his normal social responsibilities depending upon the severity of his illness, (2) he needs to be cared for, (3) sick role is regarded as a misfortune. (4) the sick person is obliged to seek competent medical care, and to cooperate with the doctor in the process of getting well. A typical sick role is temporary, but some patients prefer a prolonged sick role in order to escape everyday responsibilities.

Medical social work

Medical social work had its beginning in England in 1895 when a social worker, known as "Almoner" was appointed at the Royal Free Hospital, London. Later on in the United States, the term was expanded into medical social work. Today, medical social work, has grown into an important field of social work, and an integral part of medicine. Medical social work uses "case work" as its main technique to find out the social background of illness; this information helps the doctor in arriving at a social diagnosis, treating illness and estimating the prognosis. The purpose of medical social work is to help sick people – individual by individual, both through the best use of the patient's capabilities and community resources in matters of personal and social adjustments in the community, including rehabilitation. The person who can best do this type of work is one who had special training in social case work, the medical social worker.

Medical social worker

The medical social worker is a paramedical worker who has been trained in social case work, and in the art of interviewing people. There are many situations, in medical and public health organisations, where medical social workers are being employed, e.g., hospitals, tuberculosis clinics, family planning clinics, cancer control centres, mental health, maternal and child welfare, school and university health services. The medical social worker forms a link between the institution where he is employed and the community. The principal work of the medical social worker is to visit the family and probe into the personal, economic and social causes of illness and collect social history of the patient with a view to supplement the medical history. The medical social worker also tries to secure help to the patient through the community resources. In chronic disabling illnesses like tuberculosis, leprosy and poliomyelitis, the medical social worker helps in the rehabilitation of the patient. The medical social worker is now recognized as an

essential professional colleague of the doctor in the analysis and correction of the social and emotional factors and is increasingly relied upon for supplying information that is of fundamental importance in formulating the complete diagnosis and in directing the treatment of many patients. A medical social worker bears the same relationship to the effectiveness of social medicine, as does the nurse to clinical medicine.

From medical ethics to social ethics *(39)*

Since antiquity, the doctor/patient relationship has been governed by systems of medical ethics drawn from the Hippocratic, Chinese, Indian and other traditions. All held that the patient's good transcended other considerations. The physician determined what was the patient's good. Modern codes have added a social dimension, a responsibility for the health – the good of society and humanity in general, and a concern for justice. "Health for all", with its emphasis on social justice, on the equitable allocation of resources and on the responsibility of communities and individuals for their own health, is an expression of this change, and thus represents an ethical as well as a social goal.

The transformation of medical ethics has been stimulated partly by the progress of medical biotechnology and partly by profound social changes, associated with a recognition of human rights and freedoms, and of individual autonomy. Many medical choices can no longer be made purely on the basis of medical science. The emphasis on the social good has confronted lay individuals, whether policy–makers or patients, with ethical decisions and choices, requiring them to share with or often replace the physician or the scientist in determining what is ethically acceptable and good, to balance the patient's interests with those of society.

The explosion of expensive medical technologies, often of limited value to the patient, and the rise in people's expectations, have accentuated the problem of making the best use of limited resources. Policy-makers must set priorities to guide the allocation of resources among health goals and between health and other social goals. They do so under many pressures – social, economic, political, technological and ethical. They are forced to make choices often with tragic consequences. In principle medicine can use the full potential of modern biotechnology – for transplanting organs, for assisting reproduction, for postponing death, for reducing hereditary diseases, even for manipulating the genetic make-up of human beings. In practice the policy-maker by controlling resources and trying to reflect the dominant values of society, determines how much medicine can do, and even which patients may benefit. Thus the good of society and individual good may come into conflict.

For their part, individual patients today exercise autonomy and informed consent in deciding whether or not to accept or continue with treatment, even to continue to live, to become a subject of research, to permit the use of personal health data for study purposes, to be told – or not told – the truth, to permit the use of embryos, to donate organs and to withdraw life-support systems.

Individuals, like communities, are often the subjects of research, such as trials of drugs or vaccines or epidemiological studies. Some living in deprivation or even oppression are liable to exploitation. Researchers have a particular ethical responsibility to safeguard the rights of such people and to observe scrupulously the ethical principles of beneficence, avoidance of harm, and justice.

Consumer Protection Act

Consumer rights have become an important issue. For the first time in India, the Consumer Protection Act 1986 provided consumers a forum for speedy redressal of their grievances against medical services. In the entire health care delivery system the most vital sector is the medical profession. The active participation and dedication of doctors is very important for its survival. Over the centuries the medical profession has been accorded respect by the society. Since last decade or so, increasing commercialization of the profession has eroded this faith.

As far as the professional services are concerned, the evolution of law has followed a set course. Under the general law, a member of a profession is required to show a standard of care which a person of that profession is expected to posses. In developed nations such as USA and UK, patients do not encounter many difficulties, as the courts have developed principles of law which give important rights to patients. In India, people were not going to Civil Courts freely because court fee is very heavy and there is long delay to get final verdict. It may take several years. Parliament has provided an alternative, a quick, efficacious and economic remedy. According to this Act, the decision should be taken within 3 to 6 months. There is no court fee payment and the person can plead his own case. More recently even ESI hospitals have been brought within the ambit of the Consumer Protection Act. COPRA is a piece of comprehensive legislation and recognizes six rights of the consumer, namely : right to safety; right to be informed; right to choose; right to be heard; right to seek redressal; and right to consumer education.

If a patient or the relations of a patient feel that the suffering or death of a patient is because of either negligence by the concerned doctor or the heatlh facility, they can complain to the Medical Council of India or to the Consumer Court. The Medical Council of India, which is a statutory body created to monitor the medical profession has only ethical jurisdiction. The council can only cancel the registration of the concerned doctor temporarily or permanently but cannot punish a doctor or give a compensation.

A complaint against the medical professional can be filed in the consumer court. It should contain all the details of the case, an expert certificate or opinion from the doctor of concerned speciality (stating the complaint is prima facie true and needs further investigation) and the compensation demanded. These courts can only give compensation. The monetary limits of the compensation that can be granted by the consumer courts are as follows : (a) District Consumer Court – up to Rs. 20 lacs; (b) State Commission – Rs. 20 lacs to Rs. 1 crore; and (c) National Commission – above Rs. 1 crore.

Rights of the patient

1. Right to information on healthcare services available to them, diagnosis and treatment;
2. Right to have information about professionals involved in the patient care;
3. Right to safety from errors and malpractice;
4. Right to confidentiality and privacy;
5. Right to have prompt treatment in an emergency;
6. Right to get copies of medical records;
7. Right to informed consent;
8. Right to refuse to participate in human experimentations, and research;

9. Right to be informed about the rules and regulations of the hospital that apply to the patient and the facilities obtainable by the patient;
10. Right to choose and to seek second opinion about the disease and treatment etc.; and
11. Right to complain and have compensation within reasonably short time.

THE ART OF INTERVIEWING *(40)*

Interview is a device for investigation. It is an instrument of research. The chemist carries out research in test tubes; the bacteriologist uses the microscope in his laboratory. In much the same way, the social scientist uses the interview technique in his investigations. Modern medicine has changed its character; it has emerged as a social science in recent years. Social and psychological factors have come to be recognized as dominant factors in the natural history of disease. In order to elicit these factors, it may be necessary to employ the interview technique. It may be said that the interview technique is one of the contributions of social science to modern medicine.

Aims of interview

The major aims of interview are : (1) to secure information through face-to-face association and thereby gain the portrait of the entire personality, broad enough to encompass the social and psychological background (2) to form a hypothesis (3) to collect personal data for quantitative purposes and (4) to collect data from persons who are secondary sources of information.

Kinds of interview

Social scientists have described four kinds of interview : (a) *Direct or structured interview :* A schedule containing a set of predetermined questions is prepared. The researcher gets answers to these questions only. Generally the researcher does not add anything to what has been stated by the subject. He does not even alter the language. (b) *Non-directive or Unstructured interview :* No predetermined questions are asked. The researcher collects information by free discussion. The subject is asked to narrate in his own words his experiences, opinions or reactions about the particular subject under investigation. (c) *Focussed interview :* This type of interview is generally used to study the social and psychological effects of mass communication, e.g., reaction of a film show or radio programme. The researcher tries to focus his attention on a particular aspect of the problem and tries to know the experience, attitude and emotional responses regarding the concrete situation under study. (d) *Repetitive interview :* It is used when it is desired to note the gradual influence of some social or psychological process. A record has also to be maintained to study the change in continued sequence.

Technique of interview

Conducting an interview is both an art and science. Sociologists have described the following steps for conducting an interview *(40)*.

1. ESTABLISHING CONTACT

The first requisite before conducting an interview is to establish contact with the interviewee. Prior appointment regarding the time and place of interview is always desirable. It gives the interviewee a sense of satisfaction and a feeling of importance that his time has been valued.

2. STARTING AN INTERVIEW

The beginning should always be made from a general discussion of the problem. The researcher should create an atmosphere in which the interviewee freely tells his story in his own way. The researcher should let the interviewee do most of the talking, while he should himself listen to it attentively guiding and directing the interviewee about the subject matter wherever necessary. All controversial matters must be carefully avoided.

3. SECURING RAPPORT

A state of rapport must be established between the interviewee and the researcher. In the beginning every interviewee proceeds very cautiously giving only formal information. He may not like to discuss personal matters with a stranger. It therefore requires tact on the part of the researcher to create a friendly atmosphere and gain the confidence of the interviewee. Once rapport is gained and hesitation and shyness are overcome, the interviewee may feel overzealous to tell everything that he knows, and all that he feels without any attempt at secrecy or formality. The research worker must utilize this situation to the fullest advantage, and use it as best as he can. The state of rapport, sometimes may not last long; once the interviewee has relapsed into his former state, it may be very difficult to bring him back to rapport.

4. RECALL

At times, during the course of an interview, the interviewee may be so full of emotion that he drifts away from the main subject, and may even go into silence at the end of the narration. At such times, the researcher should give enough time to the interviewee to recollect and start again. At times, it may be necessary to refresh his memory by pointing out what he had been saying last.

5. PROBE QUESTIONS

When the interviewee, during an interview knowingly or unknowingly side-tracks some important aspect of the problem, the researcher has to be very cautious in catching these slips. Great care should be taken in putting probe questions. They should appear to the interviewee to be born of mere curiosity. If the interviewee has deliberately side-tracked a particular point, a very shrewd effort is needed to make him discuss a point at length, the same should not be doggedly pursued, lest rapport should be lost.

6. ENCOURAGEMENT

During the course of an interview, it is necessary to encourage the interviewee from time to time, by interpolating such complimentary expressions as "what you have said is really very illuminating; I never had such an enlightening discussion; you really have a very unique approach to the problem; I myself had never thought of it from that angle, etc." Great care should be taken that complimentary remarks should sound true appreciations, and not flattery otherwise they will lose all their effect.

7. GUIDING THE INTERVIEW

Sometimes, the interviewee digresses in his narration to less important topics, which he is most eager to relate, and if stopped from continuing the conversation he may get offended. It is the duty of the researcher to guide the subject in the right path without offending him.

8. RECORDING

Recording the statements should be reduced to a minimum during the course of an interview. If recording is continued, the flow of the conversation will slow down and the interview may take the form of questions and answers. Further, the interviewee will be conscious that his statements are being recorded. The researcher should jot down only important points.

9. CLOSING THE INTERVIEW

An interview should not be ended abruptly. The interviewee should not feel, at the close of the interview, that he has divulged many of his secrets to a stranger. The researcher should bring the interview to a natural close, followed by the usual forms of greetings.

10. REPORT

Soon after the interview, the report should be compiled when the mind is still fresh about the narration.

OPERATIONAL RESEARCH

The term 'operational research' was coined during the World War II in connection with the best use of a new invention, the radar. Since the war, the term has spread rapidly in Britain and America and it has come to mean today more than the study of the use of new inventions – the study of the whole systems of services rendered in industry, administration, education and health services *(38)*.

Operational research is defined as the application of scientific methods of investigation to the study of complex human organizations and services. A mathematician working on atomic structure is pursuing pure research; an engineer designing a new plant for an industry is pursuing applied research. In operational research, one is concerned all the time with the activities of a group of people with the purpose of inducing beneficial changes. Thus, operational research is a sociological science, and has an immense social content which distinguishes it from pure or applied research. The main objective of operational research is "to develop new knowledge about institutions, programmes, use of facilities, the people working in these activities and the individuals and communities served by them" in order to secure optimal utilization of resources in men, material and money in the service of the community *(41)*. A new area of operational research is emerging, i.e., "health operational research" *(42)*.

Phases in operational research

The procedure to be adopted in operational research differs according to the nature of the study. The usual procedure adopted generally consists of the following phases.

1. Formulation of the problem.
2. Collection of relevant data, if necessary, by a suitable sample.
3. Analysis of data and formulation of hypothesis.
4. Deriving solutions from the hypothesis or "model."
5. Choosing the optimal solution and forecasting results.
6. Testing of solution, e.g., pilot projects.
7. Implementing the solution in the whole system.

Operational research team

Operational research is a team work job and involves several workers. The composition of the team varies with the type of research. The minimum composition in social medicine applications is probably a public health administrator, an epidemiologist, a statistician, and a social scientist. This is in addition to ancillary workers such as clerks, peons and field workers. The team is headed by a director who is responsible for the whole project.

Operational research in health services *(42)*

Practically everything within the broad field of public health and social medicine – either a whole system or part of it – could be the subject of operational research. Examples of part problems are : optimal size of area and population to be covered by a midwife, or basic health unit; ideal vehicle for local health workers; leaving maximum time for technical personnel to utilize their skills; architectural design of hospitals and health centres; queuing problems in out-patient departments and hospital waiting lists; solutions to integration problems where specialised services have developed on emergency basis outside the general health services; study of bed load and nursing services in teaching and non-teaching hospitals; length of stay in hospitals and length of sickness absence; effectiveness or the extent to which the stated objective of a programme, e.g., malaria eradication, family planning is achieved; quality of medical care services; investigation of outbreaks of epidemic diseases and many others. Whenever social medicine passes from the stage of observation and classification to that of discovering and recommending appropriate action, it is involved in operational research.

SOCIAL PROBLEMS

In a community, there are both individual and social problems. When individual problems affect a large number of people, they become social problems. Some of the present day social problems are alcoholism, drug dependence, STD, vagrancy, juvenile delinquency, prostitution etc. Some of the social problems have medical implication, e.g., venereal diseases. Social problems are solved by social and political action, that is by social welfare programmes, social assistance, social legislation in the community to curb the social evils (e.g., The Prevention of Food Adulteration Act; The Prevention of Immoral Traffic Act; The Medical Termination of Pregnancy Act).

Prostitution

Prostitution is an age-old social evil. It is a social problem in most urban areas, and to a lesser extent in rural areas. Sociologists who have studied prostitution have mentioned the following underlying causes of prostitution. (1) changes in environment (2) breakdown of family relations (3) parenteral quarrels (4) want of affection (5) illegitimate love (6) easy money (7) low I.Q. (8) low moral standards (9) poverty, etc. The Government of India passed an Act in 1956 known as "The Suppression of Immoral Traffic Act in women and girls" which bans prostitution in its commercialized form as an organized means of living. The Act was amended and retitled as "Immoral Traffic (Prevention) Act" in 1986. It covers all persons, whether male or female, who are exploited sexually for commercial purposes.

Delinquency

A delinquent is one who shows deviation from normal behaviour. In other words, he is one who has committed an offence, e.g., theft, sexual offence, murder, burglary, etc. Delinquency is a social problem in many communities. The causes responsible for delinquency are social maladjustment, poverty, disturbed home conditions, alcoholism, drug addiction, and modern ways of living.

The programmes for the prevention and control of juvenile delinquency centre round the implementation of **The Children Act, 1960** which provides a specialized approach towards the care, protection, maintenance, training and rehabilitation of delinquent children. The institutional infrastructure consists of Juvenile/Children's Courts, child welfare boards, remand homes, certified schools, children homes and after–care facilities.

Dowry system

Dowry started as an innocent custom, a symbol of love from parents to their daughter on the eve of her marriage. But it has, in recent years, grown into a social evil with many instances of bride–burning and suicides. These are symptoms of societal corruption.

Under the **Dowry Prohibition (Amendment) Act, 1986** the minimum punishment for taking or abetting the taking of dowry has been raised to 5 years imprisonment and a fine of Rs.15,000. What is required is a sustained effort to go into the root causes of these evils. Well-entrenched social customs cannot be easily erased by an Act of Parliament.

Drug addiction

Drug addiction is defined as a state of periodic or chronic intoxication detrimental to the individual and society produced by the repeated intake of habit-forming drugs.

Drug abuse has reached an alarming proportion in recent years. "Drug culture" is fast making inroads into the lives of young people from all walks of life. The reasons given for drug dependence include the following :

- curiosity and natural tendency to experiment with drugs
- disturbed home environment : children from broken homes, indifferent parents, lack of communication between parents and children
- an escape phenomenon from tensions and frustrations in life, e.g., unemployment, failure in examinations
- impact of disco culture, mobile, TV, internet etc.
- ignorance regarding the habit-forming nature of the drugs.

To call a person a drug addict, the following criteria must be satisfied :

(1) *Psychological dependance :* there is an overpowering desire (compulsion) to take the drug and obtain it by any means.

(2) *Physical dependance :* when the drug is withdrawn, the patient shows "withdrawal symptoms" such as irrational and violent behaviour, nausea, diarrhoea, watering of eyes and nose, etc.

(3) *Development of tolerance :* there is a tendency to increase the dose.

Management

Though drug addiction may be considered as a social problem, the first step in its management is medical care, which includes :

a. identification of drug addicts and their motivation for drug detoxification
b. detoxification (requires hospitalization)
c. Post-detoxification counselling and follow-up (based on clinic and home visits), and
d. rehabilitation.

Simultaneously with medical treatment, changes in environment (home, school, college, social circle) are important. The patient must effect a complete break with his group, otherwise the chances of relapse are 100 per cent. Psychotherapy has a valuable place in the management of the addict.

Preventive measures include **education** of target groups and the general public through TV, radio, leaflets, and posters to create awareness of the problem. The Government have promulgated an Act called the "Narcotic Drugs and Psychotropic Substances Act" which came into force in 1985 to combat this problem. Refer to Chapter 17 for further details.

Alcohol abuse

Alcoholism is world-wide social and medical problem. Over the past 30 to 40 years, alcohol consumption has increased in quantity and frequency. The age at which people start drinking has also declined. The population groups at great risk are those undergoing rapid socio-economic and cultural changes; they view alcohol as a symbol of prestige and social status.

Consequences : The consequences of alcohol abuse cover a wide spectrum : crime, murder, prostitution, neglect of families, malnutrition, disease (e.g., cirrhosis of liver, alcohol-dependant syndrome, alcoholic psychosis), unemployment, indebtedness, child delinquency, road accidents, loss of friends and self-esteem. In short excessive alcohol results in serious medical, psychological and sociological problems.

Drinking by adults serves as a role model for the young. The identification of risk factors is essential for prevention. As drinking patterns vary considerably, the prevention of alcoholism is not easy. A widespread public education and discussion, and investigation of public attitudes may result in measurable improvement. This should be combined with social welfare and health services. Refer to Chapter 17 for further details.

Unmarried mothers

We do not have accurate statistics regarding unmarried mothers in India. Because of social customs and traditions in India, the problem of unmarried mothers in India must be insignificant. Such mothers have a multiplicity of needs – not only for medical termination of pregnancy and health risks but for understanding, warmth and guidance. In Western societies, where this problem is acute, they have special schools and counselling programmes for teenage mothers.

Handicapped

The handicapped comprise 7 main categories as shown below, during 2011 *(43)*.

	Categories	*Estimated number in India*
(i)	The blind	5.03 million
(ii)	The hearing disability	5.07 million
(iii)	The orthopaedically handicapped	5.43 million
(iv)	Multiple disabilities	2.11 million
(v)	The mentally retarded	1.50 million
(vi)	The mental illness	0.72 million
(vii)	The speech disability	1.99 million
(vii)	Others	4.92 million

The above figures are not static, but ever growing. In all civilized countries, the State looks after the handicapped. The rehabilitation services available for the handicapped in India are as follows : (1) medical care facilities (2) education for the blind, deaf and the orthopaedically handicapped (3) vocational training (4) job placement and sheltered workshops (5) pensions, scholarships and allowances for the education and training of the handicapped.

SOCIAL AGENCIES

Social welfare services have always been an integral part of the socio-cultural tradition of India. Soon after Independence, on the basis of a survey made by the Planning Commission, it was estimated that there were 10,000 voluntary organizations in the field of social welfare. Today the number is much greater. The activities are coordinated and assisted by the Ministry of Social Welfare and Women's Affairs. An autonomous Central Social Welfare Board is the main agency of the Ministry for undertaking and implementing programmes for women through the voluntary sector. Activities include welfare, training, health care, provision of women's hostels, as well as legal aid and support to women being exploited by families or employers. A few of the principal agencies are listed below :

1. All India Women's Conference, 6 Bhagwandas Road, New Delhi–110 001
2. National Association of Rural Women, Room No. 9/104, Jamnagar Hutments Block 11, Mansingh Road, New Delhi–110 001
3. National Council of Women, 12 Circular Road, Patna–800 001
4. India Social Institute, Department of Women's Development, 24 Benson Road, Bangalore–560046
5. Centre of Science for Villages, Magan, Sangrahalaya, Wardha – 442 001
6. Eastern India Women's Association
   E Ahmed Building, Lakhtokia, Guwahati.

COMMUNITY SERVICES

Administrative pattern of the country

(1) CENTRE

India is a Union of 29 States and 7 Union territories. Last state Telangana was formed on 2nd June 2014. The Constitution of India came into force on 26 January, 1950. The Union Executive consists of the President, the Vice President, the Prime Minister and the Council of Ministers. Rules of business have been framed under the Constitution.

India is a sovereign Democratic Republic with a Parliamentary form of government. Sovereignty ultimately rests with the people. The Parliament consists of the President, and the two Houses of Parliament – The Rajya Sabha and the Lok Sabha. The Rajya Sabha consists of 250 indirectly elected members, and the Lok Sabha 544 directly elected members. The main functions of Parliament are to make laws for the country, and to make finances available to the Government. The Parliament is assisted by several committees. The term of the Lok Sabha is 5 years.

(2) STATE

The administrative pattern in the States closely resembles that of the Union. The States executive consists of a Governor, and a council of Ministers with a Chief Minister as its head. The Governor who is the head in each state is appointed by the President for a term of 5 years. The State Legislature consists of Vidhan Sabha (Legislative Assembly) and its members are chosen by direct election. In Some States, there is also an Upper House known as Vidhan Parishad or Legislative Council. The powers of the State Legislature have been defined in the Constitution.

The Union territories (e.g. Puducherry, Andaman and Nicobar are administered by the President through an Administrator).

(3) LOCAL GOVERNMENT

(a) *Urban areas* : In big cities, the local Government institution is known as Corporation, and in medium and small towns as Municipal Committee or Council. The Corporations are headed by elected Mayors. The executive power of the Corporation vests in the Commissioner. The Corporation deals with matters concerning public health and sanitation, maintenance of roads, bridges, markets, playgrounds, parks and education. Municipalities are headed by elected Presidents.

(b) *Rural areas* : The rural areas are governed by the system of Panchayati Raj or democratic decentralization.

Democratic decentralization

In democratic societies, the trend is to distribute power as much as possible to the people themselves so that they may be able to manage their own affairs. The Panchayati Raj in India is nothing but democratic decentralization. It is a 3–tier system of local self–government.

Village level	...	*Gram Panchayat*
Block level	...	*Panchayat Samiti*
District level	...	*Zilla Parishad*

Gram Panchayats are elected by Gram Sabhas consisting of the entire adult population of the village. The panchayat consists of 9 to 15 elected members. The Panchayats are responsible for agricultural production, rural industries, medical relief, mother and child health, maintenance of village roads and streets, tanks and sanitation. It is envisaged that the Panchayat institutions will control everything including primary health centres and local schools. The Panchayat Samiti or Janpad Panchayat federates at the Block level, and the Zilla Parishad at the District level. The Panchyat Raj institutions have their own powers of taxation. For the speedy dispensation of Justice, Nyaya (Judicial) Panchyats or village courts have also been established.

LAWS

Laws are rules of the State. They regulate the individual and community behaviour. Some laws come into existence out of the local customs and traditions, e.g., the Hindu marriage Act. There are laws which are enacted by Parliament and State Legislatures. The supreme law of the land is the Constitution which sets out the rights of Government and an individual. Some of the important laws in the field of community health in India are :

(1) The Prevention of Food Adulteration Act. 1954.
(2) The Medical Termination of Pregnancy Act, 1971.
(3) The Employees' State Insurance Act, 1948.
(4) The Indian Factories Act, 1948.

(5) The Central Maternity Benefit Act, 1961.
(6) The Children Act, 1960.
(7) The Central Birth and Death Registration Act, 1969.
(8) The Epidemic Diseases Act, 1897.
(9) Juvenile Justice Act 1986.

COOPERATIVES

Cooperatives are a form of conducting business in society. Profits are distributed after all the costs are paid. The Government has established a system of cooperative societies for helping the farmers to obtain loans for dairy, poultry, and irrigation purposes. There are also other cooperatives such as Consumer Societies in urban and rural areas. There are also District Cooperative Unions and State Cooperative Unions.

EDUCATIONAL SERVICES

Education is one of the fundamental rights of man. The purpose of education is to "socialize" children so that they may imbibe the social values and norms of society and to prepare them as useful citizens. Education in India is primarily a responsibility of the State. The Constitution provides for free and compulsory education up to the age of 14 years. The National Policy on Education aims at achieving this goal, and for an investment of 6 per cent of National Income on education. The literacy rate in India for the year 2011 was 74.04 per cent; male literacy rate 82.14 per cent, female literacy rate 65.46 per cent. Education is fundamental to health and health to education.

The Central Government is concerned with the determination of educational standards, scientific and technical education, and research. The Medical Council of India prescribes standards for medical education in the country. There is a Ministry of Education at the Central and State levels. Education is thus an important community service, and the school an important community institution.

RECREATION AND CULTURAL ACTIVITIES

India has a great cultural heritage of dance, drama, music and art. There are 3 National Academies for the promotion of art, music and dance. Besides these, there are State Academies for the promotion of art. The All India Radio with its network of stations and the Television are powerful mass media in the country. India also leads the world in the production of films. The documentary films depict the life, art and culture of people in different regions of the country.

ECONOMICS

The word "economics" literally means "house-keeping". It deals with the human relationships in the specific context of production, distribution, consumption, ownership of resources, goods and services. Economics and sociology overlap in many areas.

Natural resources of the country

India is rich in natural resources and man-power (1) *Agriculture :* Agriculture is the main plank of the Indian economy. It accounts for nearly 44 per cent of the National Income, and provides employment to nearly 70 per cent of India's population. (2) *Forestry :* Forests constitute another important basic natural resource of the country. Nearly 19.4 per cent of the total land area of the country is occupied by forests. Forests are a source of timber, bamboo, canes, tendu leaves, gum, resins, tanning materials, rubber, dyes, honey, etc. (3) *Fisheries :* India has a vast sea-coast. The marine products earn foreign exchange. (4) *Minerals :* India is richly endowed with minerals, e.g., bauxite, coal, copper, diamond, gold, iron ore, manganese, mica, nickel, etc. (5) *Man-power :* The greatest natural resource of the country is its man-power. The population of the country is 1,210.1 million (2011). The people of India account for about 16 per cent of the world's population, while occupying only 2.4 per cent of the world's land area.

OCCUPATIONS

One of the first questions we ask a stranger or new acquaintance is "What are you doing ? or "What is your job ?". Occupation is thus a basis of social differentiation. Some occupations are prestigious (e.g., doctors, judges); others (e.g., manual labour) are not. Occupation also reflects the income of the individual, and his standard of living. The occupational structure in India is as shown in Table 5.

TABLE 5

Main workers by industrial categories, 2007

Industry	Total numbers (000)
Primary sector	
Agricultural & allied activities	1,425
Mining & quarrying	1,237
Secondary sector	
Manufacturing	5,837
Electricity, gas & water supply	899
Construction	936
Tertiary sector	
Wholesale and retail Trade, Hotels & Restaurant etc.	588
Transport, storage & communications	2,737
Other services	13,289
Total main workers	27,242

Source : *(44)*

INDUSTRIALIZATION

During the early years of this century, the major industries in India were cotton mill industry, jute industry and coal mining. During recent years, there has been considerable industrial expansion. A number of new industries have come up such as steel, sugar, cement, glass, chemicals, soap, vanaspati, heavy electrical and machine tools, etc.

Industries create new conditions of life and new conditions for adaptation. There is shifting of the population from rural to urban areas. People are removed from the warm intimacy of village life to the isolated and impersonal life in towns and cities. The community health problems arising out of industrialization are water and air pollution, creation of slums; accidents; communicable disease problems such as tuberculosis and venereal diseases; mental health problems such as delinquency; psychoneurosis and social problems such as alcoholism, drug dependence, prostitution, gambling and crime.

Health problems in industrialized countries have passed through various evolutionary stages, each characterized by different challenges to public health and personal health care. In the initial stage, infectious diseases, malnutrition,

and poor housing were combated by socio-economic improvements in combination with public health measures such as the provision of pure water supply and sewage disposal facilities. As scientific advances were made, broader control of acute bacterial and viral diseases were achieved by means of immunization and chemotherapy as well as increased health care for individuals.

The second evolutionary stage has been dominated by chronic diseases, particularly cardiovascular and cerebrovascular diseases and cancer. Scientific and technological progress has produced a wide array of medical interventions for diagnosis and cure, higher levels of specialization in medical practice, and transfer of much of the care previously rendered in doctor's clinic to elaborate and expensive hospitals. The cost of health care has risen dramatically.

There is evidence in some industrialized countries of a third stage, which might be described as social and environmental pathology. Threats to health arise not from intrinsic disorders of bodily structure and function, but from environmental hazards related to urban development and exposure to toxic substances, as well as from changes in social behaviour associated with violence, alcohol, and drug abuse of epidemic proportion. Industrialized countries have passed through these three stages over the course of more than a century. Developing countries, on the other hand, face the challenge of coping with all the three stages simultaneously, with just a fraction of the human and material resources available to their industrialized counterparts. Policies must be closely related to overall socio-economic development if countries with limited resources are to achieve the greatest possible benefits in health *(46)*.

ECONOMIC LEVELS

National Income

An important background influence is the size and strength of a country's economy, which is usually expressed in terms of one of the national aggregates, such as gross national product (GNP) or gross domestic product (GDP). These aggregates measure the total volume of national economic activity at current or constant price. By dividing the GNP or GDP by the total population, one arrives at **per capita** GNP or GDP, which are common general purpose indicators of national wealth. Per capita GNP may thus serve as a general measure of human welfare – that is, of health in a very broad sense. In practice, many health variables are indeed correlated with per capita GNP or GDP. Countries with a high per capita GNP are predominantly industrially developed, while those with a low one are predominantly agricultural, or developing.

Gross National Income (GNI)

Formerly known as GNP or Gross National Product. It is gross income generated from within the country as also net income received from abroad. It is expressed either "at current prices" i.e., at prices prevailing during the period to which the figure refers, or "at constant prices"; i.e., at prices prevailing during a fixed base period in the past, irrespective of the period to which the figures refers. Thus figures 'at constant prices' discount the effect of inflation after the base period and measure the changes in real terms. Figures 'at current prices' are naturally influenced by inflation but are more useful for, say, international comparisons for the same period.

For GNI per capita US $, the national currency is converted to current US Dollars using the Work Bank Atlas Method. This involves using a 3 year average of exchange rates *(45)*.

PER CAPITA INCOME

An index of the standard of living of the people is "per capita income". Per capita income in India is among the lowest in the world. According to recent statistics, the per capita income in India (2012–13) was Rs. 68,748 at current prices.

Gross Domestic Product (GDP)

GDP is gross income generated within a country, i.e., it excludes net income received from abroad.

Net National Product (NNP)

It is the GNP minus the capital we consume (e.g., equipment, machinery, etc.,) in the production process. In other words, NNP is the market value of all final goods and services after providing for depreciation.

Net Domestic Product (NDP)

It is the gross domestic product minus the value of depreciation on fixed assets.

GDP at Market Price

It is GDP at factor cost plus indirect taxes minus subsidies.

NNP at Market Price

It is NNP at factor cost plus indirect taxes minus subsidies.

GNP at Market Price

It is GNP at factor cost plus indirect taxes minus subsidies.

Purchasing Power Parity (PPP)

It is defined as the number of units of a country's currency required to buy the same amount of goods and services in the domestic market as one dollar would buy in the USA. According to the latest calculation of per capita GNI and overall GNP of the World Bank, based on PPP, India's per capita GNP in 2010 has been estimated at $ 3560 (PPP). It is the fourth largest country in terms of GNP (PPP) with about $ 2.5 trillion, preceded by the USA ($ 9.98 trn.), China (about $ 5.4 trn.) and Japan ($ 3.5 trn.) *(44)*.

Gross domestic savings

It is excess of current income over current expenditure.

Poverty

The number of people living in extreme poverty in the world has increased, and was estimated that about 19 per cent of world's population was living below one dollar per day income during the year 2005 *(47)*. Poverty wields its destructive influence at every stage of human life from the moment of conception to the grave. Poverty is the main reason why babies are not vaccinated, clean water and sanitation are not provided, and curative drugs and other treatments are unavailable. It is the main cause of low life expectancy, low birth weight babies, higher maternal mortality, handicap and disability, mental illness, stress, suicide, family disintegration and substance abuse. Table 6 shows the influence of income on health in South-East Asia Region.

TABLE 6

Per capita GNI, life expectancy at birth and infant mortality rate in SEAR countries (2012)

Country	Per capita GNI US $	Life expectancy at birth	Infant mortality rate
India	1,530	66.0	44
Bangladesh	840	70.0	33
Bhutan	2,420	68.0	36
Indonesia	3,420	71.0	26
Maldives	5,750	78.0	9
Myanmar	220	65.0	41
Nepal	700	68.0	34
Sri Lanka	2,920	74.0	8
Thailand	5,210	74.0	11

Source : *(47)*

The health consequences of poverty are severe. The poor die younger and suffer more from disability. They are exposed to greater risk from unhealthy conditions at home and at work. Malnutrition and the legacy of past illness mean that they are more likely to fall ill and slower to recover, especially if they have little access to health care. When a family's breadwinner becomes ill, other members of the household may at first cope by working harder themselves and by reducing consumption, even of food. Both adjustments can harm health of the whole family *(48)*.

The poor are forced into occupations that harm their health, lack of access to health care and education, live shorter life and in general lack access to resources and means to improve their lives. These social and economic aspects of poverty are inextricably linked. Addressing these underlying social factors can enable people to escape poverty. Sound economic policies must go hand-in-hand with addressing the social needs of the poor.

Investments to reduce health risks among poor and provision of insurance against catastrophic health care costs are important elements in a strategy for reducing poverty.

Global Hunger Index (GHI) *(50)*

The Global Hunger Index (GHI) is a tool designed to comprehensively measure and track hunger globally, by region and country. It highlights successes and failures in hunger reduction. It is calculated each year by the International Food Policy Research Institute.

GHI combines three equally weighted indicators into one index :

1. *Undernourishment :* the proportion of undernourished people as a percentage of the population (reflecting the share of the population with insufficient calorie intake);
2. *Child underweight :* the proportion of children under the age of five who are underweight (that is, have low weight for their age, reflecting wasting, stunted growth, or both), which is one indicator of child undernutrition; and
3. *Child mortality :* the mortality rate of children under the age of five (partially reflecting the fatal synergy of inadequate food intake and unhealthy environments).

The global hunger index is calculated by the following formula :

$$GHI = \frac{\text{Proportion of undernourished population (PNU) + Children under weight (CUW) + Child mortality in per centage (CM)}}{3}$$

For India the GHI for the year 2014 is :

$$\frac{17.0 + 30.7 + 5.6}{3} = 17.8$$

The calculations result in a 100-point scale on which zero is the best score (no hunger) and 100 the worst, although neither of these extremes is reached in practice. A value of 100 would be reached only if the whole population was undernourished, all children younger than five were underweight, and all children died before their fifth birthday. A value of zero would mean that a country had no undernourished people in the population, no children younger than five who were underweight, and no children who died before their fifth birthday.

Some definitions

1. *Hunger :* distress related to lack of food.
2. *Malnutrition :* an abnormal physiological condition, typically due to eating the wrong amount and/or kinds of foods; encompasses undernutrition and overnutrition.
3. *Undernutrition :* deficiencies in energy, protein, and/or micronutrients.
4. *Micronutrient deficiency (also known as hidden hunger) :* a form of undernutrition that occurs when intake or absorption of vitamins and minerals is too low to sustain good health and development in children and normal physical and mental function in adults. Causes include poor diet, disease, or increased micronutrient needs not met during pregnancy and lactation.
5. *Undernourishment :* chronic calorie deficiency, with consumption of less than 1,800 kilocalories a day, the minimum most people need to live a healthy, productive life.
6. *Overnutrition :* excess intake of energy or micronutrients.

Hidden hunger

Hidden hunger (micronutrient deficiency) is a form of undernutrition that occurs when intake and absorption of vitamins and minerals (such as zinc, iodine, and iron) are too low to sustain good health and development. Factors that contribute to micronutrient deficiencies include poor diet, increased micronutrient needs during certain life stages, such as pregnancy and lactation, and health problems such as diseases, infections, or parasites.

While clinical signs of hidden hunger, such as night blindness due to vitamin A deficiency and goitre from inadequate iodine intake, become visible once deficiencies become severe, the health and development of a much larger share of the population is affected by less obvious "invisible" effects. That is why micronutrient deficiencies are often referred to as hidden hunger.

Hidden hunger afflicts more than 2 billion individuals, or one in three people, globally (FAO 2013). Its effects can be devastating, leading to mental impairment, poor health, low productivity, and even death. Its adverse effects on child health and survival are particularly acute, especially within the first 1,000 days of a child's life, from conception to the age of two, resulting in serious physical and cognitive consequences. Even mild to moderate deficiencies can affect a person's well-being and development. In addition to

affecting human health, hidden hunger can curtail socio-economic development, particularly in low and middle income countries.

The nature of the malnutrition burden facing the world is increasingly complex. Developing countries are moving from traditional diets based on minimally processed foods to highly processed, energy-dense, micronutrient-poor foods and drinks, which lead to obesity and diet-related chronic diseases. With this nutrition transition, many developing countries face a phenomenon known as the "triple burden" of malnutrition-undernourishment, micronutrient deficiencies, and obesity. In higher income, more urbanized countries, hidden hunger can co-exist with overweight/obesity when a person consumes too much dietary energy from macronutrients such as fats and carbohydrates. While it may seem paradoxical, an obese child can suffer from hidden hunger.

The consequences of hidden hunger on the different stages of lifecycle are shown in Fig. 2.

Reproductive health and poverty reduction

Reproductive health has a significant role in poverty reduction and it is expected that successful programmes to promote reproductive health will contribute to the reduction of healthy year of life lost and hence the poverty reduction in equal measure. In addition to reduction of mortality and morbidity, reproductive health programmes address to unmet needs for family planning, relieving the poor of the burden of unwanted pregnancies and large families; they provide much-needed information and services to promote sexual health and responsible behaviour among adolescents and young people; and they promote gender equality and women's empowerment which is necessary for the success of reproductive health interventions. In doing so, these programmes contribute directly to the Millennium Development Goals of United Nations *(49)*. Fig. 3 shows how reproductive health can be used as a tool to poverty reduction.

Poverty is the most obvious problem in India. According to 2011–12 estimate about 21.9 per cent (269.78 million) population of the country is living below the "poverty line". The *"poverty line"* is defined as expenditure required for a daily Calorie intake of 2,400 per person in rural areas and 2,100 in urban areas. This expenditure is officially estimated at Rs. 228.9 per capita per month in rural areas and Rs. 264.1 in urban areas at 1993–94 prices *(44)*.

STANDARD OF LIVING

Please see page 672 for details.

SOCIAL SECURITY

Social security is defined as "security that society furnishes through appropriate organization, against certain risks to which its members are exposed". The risks which social security covers in most countries are **sickness, invalidity, maternity, old age and death.** Social security also includes social insurance and social assistance.

Social security for Industrial workers

The social security measures for industrial workers in India are contained in the following legislations :

(1) Workmen's Compensation Act, 1923
(2) Central Maternity Benefit Act, 1961
(3) Employees State Insurance Act, 1948
(4) The Family Pension Scheme, 1971

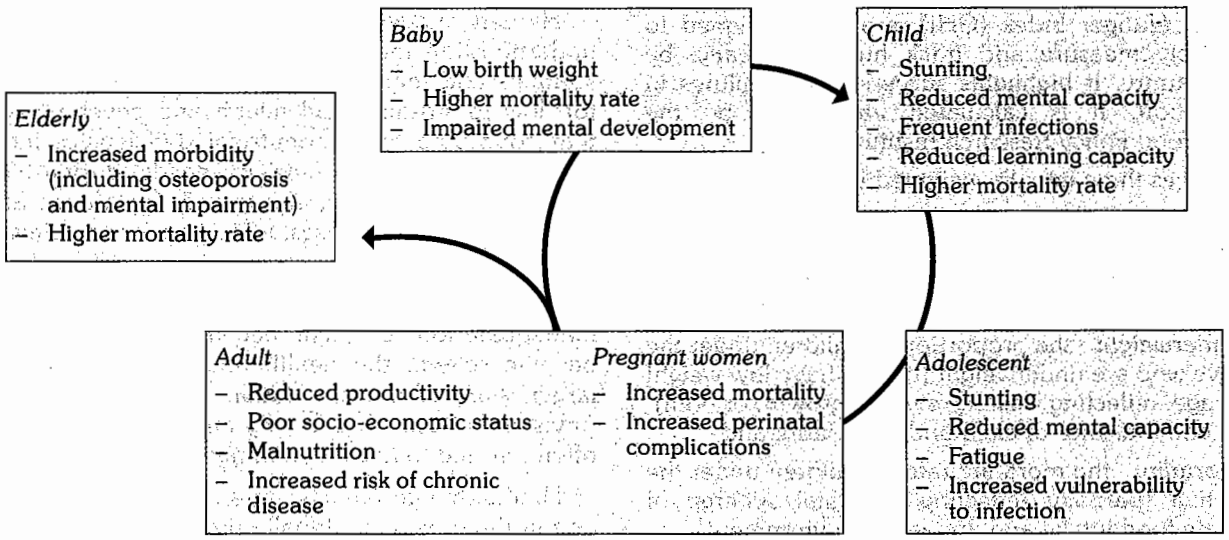

FIG. 2
Consequences of micronutrient deficiencies throughout the lifecycle

Source : *(50)*

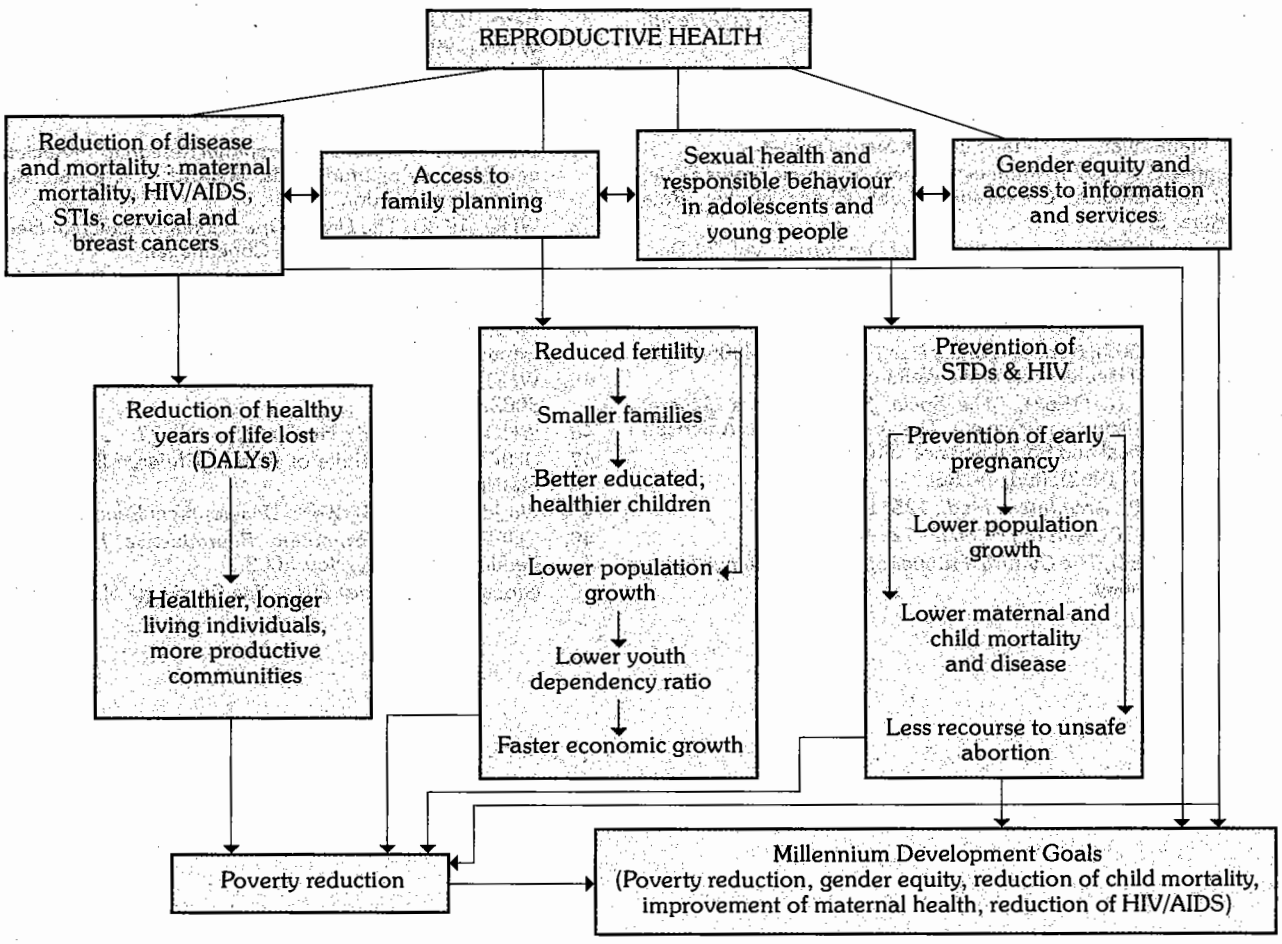

FIG. 3
Reproductive health as a poverty reduction strategy

Source : *(49)*

Some of these Acts have been described elsewhere in the text.

Social security for civil servants

The employees of the Central and State Government have pension, gratuity, provident fund and family pension schemes.

The Central Government Health Scheme in Delhi provides comprehensive medical care to all categories of Central Government Employees. The scheme has been extended to other cities also.

Social security for general public

The risks of death, accident, and fire etc. are covered by the Insurance schemes. The Life Insurance Corporation of India has many schemes for the general public. There are also public provident fund and ESI schemes.

Environment and Health

"The study of disease is really the study of man and his environment"

The term environment implies all the external factors – living and non-living, material and non-material – which surround man. In its modern concept, environment includes not only the water, air and soil that form our environment but also the social and economic conditions under which we live.

For descriptive purpose, environment has been divided into three components, all closely related :

(i) Physical : Water, air, soil, housing, wastes, radiation, etc.

(ii) Biologic : Plant and animal life including bacteria, viruses, insects, rodents and animals.

(iii) Social : Customs, culture, habits, income, occupation, religion etc.

The key to man's health lies largely in his environment. In fact, much of man's ill-health can be traced to adverse environmental factors such as water pollution, soil pollution, air pollution, poor housing conditions, presence of animal reservoirs and insect vectors of diseases which pose a constant threat to man's health. Often man is responsible for the pollution of his environment through urbanization, industrialization and other human activities. In 1972 the UN conference on the Human Environment focussed worldwide attention on the environmental hazards that threaten human beings. To facilitate work in this area, WHO has compiled a wide-ranging survey of environmental hazards to human health *(1)*.

The dictionary meaning of the word sanitation is "the science of safe-guarding health." One of the best definitions is that given by the National Sanitation Foundation of the USA, which is as follows : 'Sanitation is a way of life. It is the quality of living that is expressed in the clean home, the clean farm, the clean business, the clean neighbourhood and the clean community. Being a way of life it must come from within the people; it is nourished by knowledge and grows as an obligation and an ideal in human relations'. The term "environmental sanitation" has been defined by WHO as "the control of all those factors in man's physical environment which exercise or may exercise a deleterious effect on his physical development, health and survival".

In the past, sanitation was centred on the sanitary disposal of human excreta. Even now, to many people sanitation still means the construction of latrines. In actual fact, the term sanitation covers the whole field of controlling the environment with a view to prevent disease and promote health. Man has already controlled a number of factors in his environment, e.g., food, water, housing, clothing, sanitation. These controllable factors are those included in the "standard of living". It is the control of these factors that has been responsible for considerable improvement in the health of the people during the past century in the developed countries. However, man's mastery over his environment is not complete. As old problems are being solved, new problems are arising. Air pollution is of growing concern in many urban centres. Industrial growth has given rise to the problem of environmental pollution by industrial wastes. Advances in nuclear technology have produced the problem of radio-active pollution of the environment. The demographic growth and fast urbanization all over the world are bringing profound social and environmental changes. Therefore, the attainment of a healthy environment is becoming more and more complex. The term *environmental sanitation* is now being replaced by environmental health. Proper environmental health now requires the services of the public health qualified doctor, the epidemiologist, the public health engineer, the town planner, the sociologist, the economist, and the health inspector. A purely medical or engineering approach by itself is no longer sufficient; a combined multi-disciplinary programme of action is needed to achieve a healthy environment.

The purpose of environmental health is to create and maintain ecological conditions that will promote health and thus prevent disease. One of the essential public health care element is safe drinking water and sanitation. In 1990, more than 1 billion people in developing world lacked access to safe drinking water and nearly 2 billion people lacked an adequate system for disposing off their excreta *(2)*. Faeces deposited near homes, contaminated drinking water (sometimes caused by poorly designed or maintained sewerage systems), fish from polluted rivers and coastal waters, and agricultural produce, fertilized with human waste are all health hazards. Water quantity is as important as water quality. Washing hands after defecation and before preparing food is of particular importance in reducing disease transmission, but without abundant water in or near home, hygiene becomes difficult or impossible. The lack of water supply and sanitation is the primary reason why diseases transmitted via faeces are so common in developing countries. The most important of these diseases, diarrhoea and intestinal worm infestations, account for 10 per cent of the total burden of disease in developing countries. In addition, an inadequate water supply increases the risk of schistosomiasis, skin and eye infections, and guineaworm disease. Table 1 shows the percentage of population with access to safe water and adequate sanitation in South-East Asia countries.

Two of the changes needed to achieve "Health for All" are concerned with a healthy environment and healthy lifestyle and require initiatives by the individual, the family

TABLE 1

Population with access to safe water and adequate sanitation in South-East Asia countries 2012

Countries	Safe water (%)	Adequate sanitation (%)
India	93	36
Bhutan	98	47
Bangladesh	85	57
Indonesia	85	59
Maldives	99	99
Myanmar	86	77
Nepal	88	37
Sri Lanka	94	92
Thailand	96	93

Source : *(3)*

and the community. "Africa 2000" a new initiative aimed at providing universal coverage of water supply and sanitation services was launched. A broad programme for hygiene education and promotion of low-cost sanitation is being developed in cooperation with UNICEF and bilateral and multilateral organizations. Key hygiene behaviours and principles for promoting sanitation were identified. The global WHO/UNEP network for air and water quality monitoring are operational in more than 60 countries. Surface and ground water quality are monitored in 350 cities worldwide *(2)*.

Much of the ill-health in India is due to poor environmental sanitation, that is, unsafe water, polluted soil, unhygienic disposal of human excreta and refuse, poor housing, insects and rodents. Air pollution is also a growing concern in many cities. The high death rate, infant mortality rate, sickness rate and poor standards of health are in fact largely due to defective environmental sanitation. Improvement of environmental sanitation is therefore crucial for the prevention of disease and promotion of health of individuals and communities. Since more than 70 per cent of the population of India live in rural areas, the problem is one of rural sanitation. The first step in any health programme is the elimination through environmental control of those factors which are harmful to health. The environmental factors which are basic and fundamental to individual and community health are discussed in this chapter.

WATER

Much of the ill-health which affects humanity, especially in the developing countries can be traced to lack of safe and wholesome water supply. Water that is easily accessible, adequate in quantity, free from contamination, safe and readily available throughout the year. There can be no state of positive health and well-being without safe water. Water is not only a vital environmental factor to all forms of life, but it has also a great role to play in socio-economic development of human population. Each country should develop its own water resources agency which would collect all pertinent data on water resources, exploitation and hydrogeology. In 1981, the 34th World Health Assembly in a resolution emphasized that safe drinking water is a basic element of "primary health care" which is the key to the attainment of "Health for All by the year 2000 AD". More recently, Millennium Development Goals included safe water and sanitation in the attainable goals. Water is integrated with other PHC components because it is an essential part of health education, food and nutrition, and also MCH.

Safe and wholesome water

Water intended for human consumption should be both safe and wholesome. This has been defined as water that is

a. free from pathogenic agents
b. free from harmful chemical substances
c. pleasant to the taste, i.e., free from colour and odour; and
d. usable for domestic purposes.

Water is said to be *polluted* or *contaminated* when it does not fulfil the above criteria. Water pollution is a growing hazard in many developing countries owing to human activity. Without ample and safe drinking water, we cannot provide health care to the community.

Water requirement

The basic physiological requirements for drinking water have been estimated at about 2 litres per head per day. This is just for survival. But from the standpoint of public health and improvement of the quality of life, water should be provided in adequate volume. It will help to reduce the incidence of many water-related diseases among the people most at risk. The consumption of water, however, depends upon climate conditions, standard of living and habits of the people. A daily supply of 150–200 litres per capita is considered as an adequate supply to meet the needs for all urban domestic purposes. In India 40 litres of water supply per capita per day was the set target to be achieved in rural areas.It must be available close to the people, else they have to spend hours and a lot of energy, going back and forth to obtain it and the water is often polluted in the process.

Uses of water

The uses of water in a community are many, and the requirement in quantity and quality are varied. Conventionally, it has been convenient and economical to provide a single water supply sufficient in quantity to serve all uses and suitable in quality to meet drinking requirements, even though only a small fraction of the total water supply is actually used for drinking.

The uses of water include : (1) Domestic use : on domestic front, water is required for drinking, cooking, washing and bathing, flushing of toilets, gardening etc. (2) Public purposes : cleaning streets, recreational purposes like swimming pools, public fountains and ornamental ponds, fire protection and public parks. (3) Industrial purposes : for processing and cooling; (4) Agricultural purpose : irrigation (5) Power production from hydropower and steam power; (6) Carrying away waste from all manner of establishments and institutions. Water is therefore an essential factor in the economic, social and cultural development of a community. It can eliminate diseases, promote rural development and improve quality of life.

Sources of water supply

Water may be abstracted for use from any one of a number of points in its movement through the hydrological cycle. The safe yield of the source must be sufficient to serve the population expected at the end of the design period, which may be 10 to 50 years in future. The safe yield is generally defined as the yield that is adequate for 95 per cent of the year. The selection of a source requires professional advice. In general, water sources must conform to two criteria : (a) the quantity must be sufficient to meet present and future requirement (b) the quality of water must

be acceptable. There are three main sources of water :

1. RAIN
2. SURFACE WATER
   - Impounding reservoirs
   - Rivers and streams
   - Tanks, ponds and lakes.
3. GROUND WATER
   - Shallow wells
   - Deep wells
   - Springs.

1. Rain

Rain is the prime source of all water. A part of the rain water sinks into the ground to form ground water; part of it evaporates back into the atmosphere, and some runs off to form streams and rivers which flow ultimately into the sea. Some of the water in the soil is taken up by the plants and is evaporated in turn by the leaves. These events are spoken of as "water cycle". *CHARACTERISTICS* : Rain water is the purest water in nature. Physically, it is clear, bright and sparkling. Chemically, it is very soft water containing only traces of dissolved solids (0.0005 per cent). Being soft, it has a corrosive action on lead pipes. Bacteriologically, rain water from clean districts is free from pathogenic agents. *IMPURITIES* : Rain water tends to become impure as it passes through the atmosphere. It picks up suspended impurities from the atmosphere such as dust, soot and microorganisms and gases such as carbon dioxide, nitrogen, oxygen and ammonia. Gaseous sulphur and nitrogen oxides are emitted from power plants that use fossil fuels. These gases react with atmospheric water, forming dilute solution of sulphuric and nitric acid. The precipitation of these acids (acid rain) has begun to have serious impacts on surface water quality and on plants etc. There are very few places in the world like Gibralter which depend upon rain as a source of water supply.

2. Surface water

Surface water originates from rain water. It is the main source of water supply in many areas. Examples of surface water include rivers, tanks, lakes, wadis (water source which are dry, except in rainy season), man-made reservoirs and sea water. Surface water is prone to contamination from human and animal sources. As such it is never safe for human consumption unless subjected to sanitary protection and purification before use.

The vast majority of Indian cities and towns depend upon surface water sources, which are (1) Impounding Reservoirs. (2) Rivers and Streams, and (3) Tanks, Ponds and Lakes. In general, surface water supplies possess a high probability of organic, bacterial and viral contamination.

(1) IMPOUNDING RESERVOIRS

These are artificial lakes constructed usually of earthwork or masonry in which large quantities of surface water is stored. Dams built across rivers and mountain streams also provide large reserves of surface water. The area draining into the reservoir is called "Catchment area". Cities such as Mumbai, Chennai and Nagpur derive their water supply from impounding reservoirs. One disadvantage of storing water for long periods in reservoirs is the growth of algae and other microscopic organisms, which impart bad tastes and odours to water. *CHARACTERISTICS* : Impounding reservoirs usually furnish a fairly good quality of water. The water is usually clear, palatable and ranks next to rain water in purity. If the surrounding hills are covered with peat, the water may acquire a brownish coloration. The water is usually soft and considered to be free of pathogenic organisms. *IMPURITIES* : The upland surface water derives its impurities from the catchment area, the sources being human habitations and animal keeping or grazing. It is therefore very necessary to keep the catchment area free from human or animal intrusion. The general belief that mountain streams are very pure water is often untrue. Even if there is no human habitation or cattle near, there is still a possibility of contamination caused by wild animals.

(2) RIVERS

Many rivers furnish a dependable supply of water. Cities such as Delhi, Kolkata and Allahabad rely on river water for their needs. The chief drawback of river water is that it is always grossly polluted and is quite unfit for drinking without treatment. *CHARACTERISTICS* : River water is turbid during rainy season; it may be clear in other seasons. Clarity of water is no guarantee that the river water is safe for drinking. River water contains dissolved and suspended impurities of all kinds. The bacterial count, including the human intestinal organisms may be very high. *IMPURITIES* : Rivers are described as a direct connection between the alimentary canal of the people living upstream and the mouths of those below. The impurities of river water are derived from surface washings, sewage and sullage water, industrial and trade wastes, and drainage from agricultural areas. The customs and habits of the people like bathing, animal washing and disposal of the dead, all add to the pollution of water. *SELF–PURIFICATION* : Certain amount of self-purification does occur in river water by natural forces of purification such as dilution, sedimentation, aeration, oxidation, sunlight, plant and animal life but these agencies are not sufficient to render the water potable. River water needs purification before it can be used for drinking purposes.

(3) TANKS *(5,6)*

Tanks are large excavations in which surface water is stored. They are an important source of water supply in some Indian villages. Tanks are recipients of contamination of all sorts. They are full of silt and colloidal matter, especially immediately after the rains. The older tanks may be full of aquatic vegetation. Tanks are often used for washing of clothes, cattle, humans, cooking pots; children use it for swimming and there may be regular defecation around the edges which will be washed into the tank at the next rains. Tanks are thus subjected to unlimited possibilities of contamination and are highly dangerous, as a source of drinking water, even at the best of times. But unfortunately, the tank water is drunk without being boiled, disinfected or having undergone treatment of any kind which is responsible for an incalculable number of cases of sickness and death, particularly of children.

Improvement of tanks : A certain amount of natural purification does take place in tank water because of storage, oxidation and other agencies but these are not sufficient to render the water safe. The sanitary quality of tank water may be considerably improved by observing the following : (1) the edges of the tank should be elevated in order to prevent the entry of surface washings, (2) there should be a fence around the tank to prevent access to animals, (3) no one should be permitted to get into the tank directly (note the hazard of guineaworm infestation),

(4) there should be an elevated platform from where people can draw water, (5) the weeds should be periodically removed, (6) the tank should be cleaned at the end of the dry season. Inspite of these precautions, from a practical point of view, it is not possible to prevent pollution of tanks as the people who consume the tank water are often among the poorest in the country and do not have sanitary concepts. Considerable research is now in progress at national and international levels to ensure the village tank as a safe source of drinking water *(5)*. It is believed that the simplest solution consists of subjecting the tank water to some sort of sand filtration. Fig. 1 illustrates how this could be brought about. The addition of chlorine would undoubtedly add to the value of sand filtration.

Sea water

Though this source is plentiful, it has great many limitations. It contains 3.5 per cent of salts in solution. Off-shore waters of the oceans and seas have a salt concentration of 30,000 to 36,000 mg/litre (30–36 g/litre) of dissolved solids including 19,000 mg/litre of chloride, 10,600 mg/litre of sodium and 1,270 mg/litre of magnesium. Desalting and demineralization process involves heavy expenditure. It is adopted in places where sea water is the only source available *(4)*.

3. Ground water

Rain water percolating into ground constitutes ground water. Water used by humans comes mainly from land. It is now realized that there is a limit to ground water in the world. We should withdraw only quantities of water that can be renewed.

Ground water is the cheapest and most practical means of providing water to small communities. Ground water is superior to surface water, because the ground itself provides an effective filtering medium. The advantages of ground water are: (1) it is likely to be free from pathogenic agents, (2) it usually requires no treatment, (3) the supply is likely to be certain even during dry season. (4) It is less subject to contamination than surface water. The disadvantages are: (1) it is high in mineral content, e.g., salts of calcium and magnesium which render the water hard (2) it requires pumping or some arrangement to lift the water *(7)*. The usual ground water sources are wells and springs. Wells have been classified into shallow and deep wells, dug and tube wells.

WELLS

Traditionally wells are an important source of water supply. Even today, they are an important source of water supply in many communities. Technically, wells are of two kinds – shallow and deep. (1) *Shallow wells :* Shallow wells tap subsoil water i.e. the water from above the first impervious layer in the ground. They yield limited quantities of water, and the water is notoriously liable to pollution unless care is taken in well construction. (ii) *Deep wells :* A deep well is one which taps water from the water-bearing stratum below the first impervious layer in the ground (Fig. 2). Deep wells are usually machine-dug and may be several hundred metres deep. Deep wells furnish the safest water, and are often the most satisfactory sources of water supply.

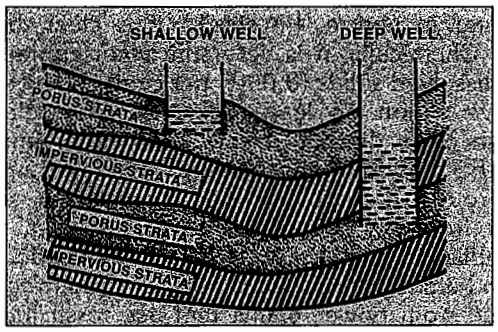

FIG.2
Shallow and deep wells

The points of difference between a shallow well and deep well are set out in Table 2.

Most of the wells in India are of the shallow type. Speaking generally, shallow wells are liable to pollution from neighbouring sources of contamination such as latrines, urinals, drains, cesspools, soakage pits and collections of

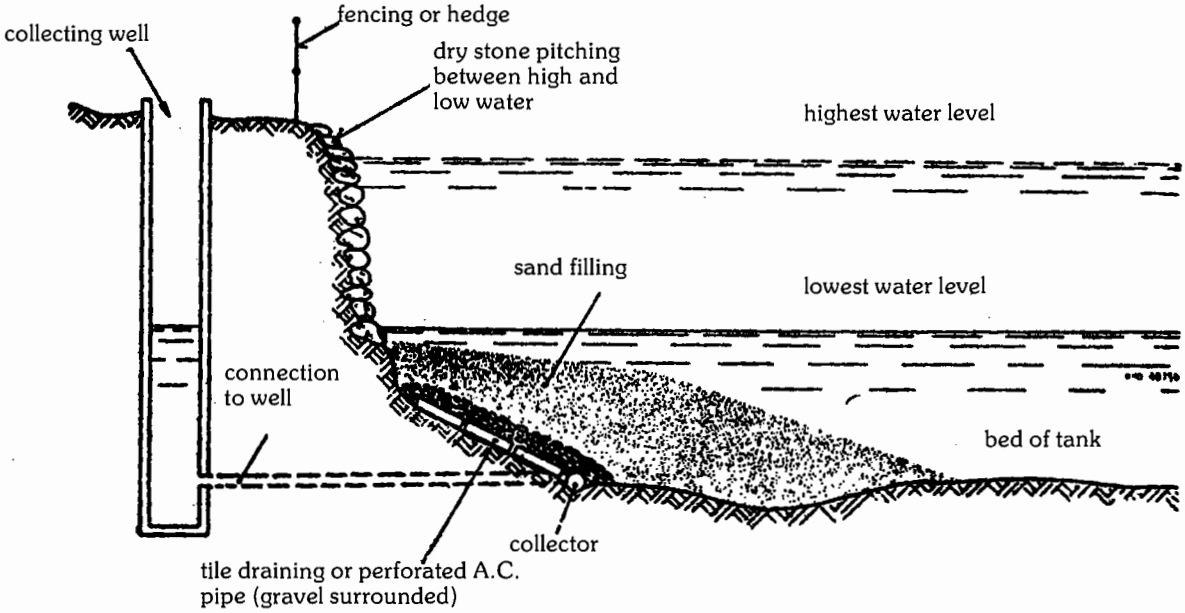

FIG. 1
Slow sand filtration of tank water

TABLE 2

Differences between a shallow well and deep well

	Shallow well	Deep well
1. *Definition*	Taps the water from above the first impervious layer	Taps the water from below the first impervious layer
2. *Chemical quality*	Moderately hard	Much hard
3. *Bacteriological quality*	Often grossly contaminated	Taps purer water
4. *Yield*	Usually goes dry in summer	Provides a source of constant supply

manure. Shallow wells are therefore a health hazard to the community if they are not made sanitary. A deep well can also become a health hazard if it is open, poorly constructed and not protected against contamination. ARTESIAN WELLS are a kind of deep wells in which the water rises above the level of ground water, because it is held under pressure between two impervious strata. Artesian wells are not common in India.

Saline intrusion : Near the sea, there is danger of infiltration of sea water in to deep wells. This gives a brackish taste to water and may make the water unfit for domestic use.

Wells may also be classified, according to the method of construction, into *dug wells* and *tube wells*. DUG WELLS are by far the commonest type in India. Two types of dug wells exist in our rural areas: (a) the unlined katcha well and (b) the masonry or pucca well. The katcha well is a hole dug into the water-bearing stratum. The pucca well is an open well, built of bricks or stones. STEP WELLS are a kind of pucca wells which are becoming obsolete, fortunately. Steps are constructed into these wells to enable people to descend into the well to fetch water or quench their thirst. In these wells, there is considerable personal contact between the user and the water. Some people may even wash their faces, hands and feet which is a common Indian custom. Guineaworm disease is quite a public health problem in areas where step wells are in use. The open dug wells and step wells are a health hazard to the community.

Improvement of dug wells

The unlined katcha wells may be made sanitary by deepening the bottom, installing a hand-pump with screen, and filling the well with coarse sand up to the water level, and with clay above that level. When the material used for filling is completely consolidated a platform and drainage may be constructed.

Masonry well improvement consists of making the upper 10 feet or more of the lining water-tight, raising the lining one foot above the ground, and providing a reinforced concrete slab cover at the top. One or more hand-pumps may be installed for lifting the water. Special attention should be paid to the foundation of the pump to prevent any possible leakage of waste water into the well.

SANITARY WELL

A sanitary well is one which is properly located, well–constructed and protected against contamination with a view to yield a supply of safe water (Fig. 3). The following points should be taken into consideration while constructing sanitary wells: (1) *LOCATION* : The first step in well construction is the choosing of a proper site. If bacterial contamination is to be avoided, the well should be located not less than 15 m (50 feet) from likely sources of contamination. The well should be located at a higher

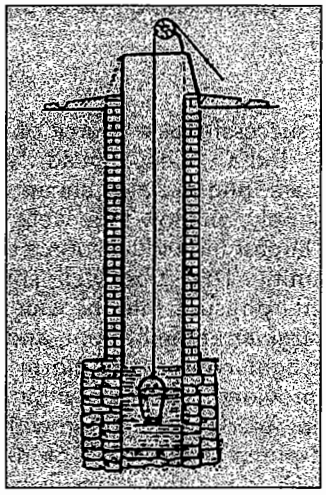

FIG. 3

Sanitary open well

elevation with respect to a possible source of contamination. The distance between the well and the houses of the users should also be considered. If the well is situated far away, people may not use it. It is therefore recommended that the well should be so located that no user will have to carry water for more than 100 m (100 yards) *(7)*. (2) *LINING* : The lining of the well should be built of bricks or stones set in cement up to a depth of at least 6 m (20 feet) so that water enters from the bottom and not from the sides of the well. The lining should be carried 60–90 cm (2–3 feet) above the ground level. (3) *PARAPET WALL* : There should be a parapet wall up to a height of at least 70–75 cms (28 inches) above the ground. (4) *PLATFORM* : There should be a cement-concrete platform round the well extending at least 1 m (3 feet) in all directions. The platform should have gentle slope outwards towards a drain built along its edges. (5) *DRAIN* : There should be a pucca drain to carry off spilled water to a public drain or a soakage pit constructed beyond the "cone of filtration" (area of drainage) of the well. (6) COVERING : The top of the well should be closed by a cement concrete cover because the bulk of the pollution is introduced into the well directly through the open top. Studies have shown that merely covering a well alone caused a marked improvement in the bacteriological quality of the water *(5)*. *Open* wells, therefore, cannot be considered sanitary, however well they might be constructed otherwise. (7) *HAND-PUMP* : The well should be equipped with a hand-pump for lifting the water in a sanitary manner. Studies have shown that when a pump is fitted there is marked improvement in the bacteriological quality of the water. The handpump should be of robust construction to withstand rough handling by the people. There should be an efficient maintenance service and arrangements for immediate repair if the pumps go out of order. (8) *CONSUMER RESPONSIBILITY* : The provision

of sanitary wells does not guarantee freedom from water-borne diseases unless the consumers observe certain basic precautions at the individual and family level. Strict cleanliness should be enforced in the vicinity of the well; personal ablutions, washing of clothes and animals, and the dumping of refuse and wastes should be prohibited. Ropes and buckets from individual homes should not be used for drawing a supply from the well. Water from the well should be carried in clean sanitary vessels to individual houses. All this requires health education. (9) *QUALITY* : The physical, chemical and bacteriological quality of water should conform to the acceptable standards of quality of safe and wholesome water.

TUBE WELLS
